# ⟨1⟩ INJECTIONS AND IMPLANTED DRUG PRODUCTS (PARENTERALS)—PRODUCT QUALITY TESTS

INTRODUCTION
PRODUCT QUALITY TESTS COMMON TO PARENTERAL DOSAGE FORMS
- Universal Tests
- Specific Tests

PRODUCT QUALITY TESTS FOR SPECIFIC PARENTERAL DOSAGE FORMS
- Solutions
- Sterile Powders for Solutions
- Suspensions
- Liposomes
- Sterile Powders for Suspensions
- Emulsions
- Implants
- Drug-Eluting Stents

## INTRODUCTION

Parenteral drug products include both injections and implanted drug products that are injected through the skin or other external boundary tissue, or implanted within the body to allow the direct administration of the active drug substance(s) into blood vessels, organs, tissues, or lesions. Injections may exist as either immediate- or extended-release dosage forms. Implanted parenteral drug products are long-acting dosage forms that provide continuous release of the active drug substance(s), often for periods of months to years. For systemic delivery, they may be placed subcutaneously; for local delivery, they may be placed in a specific region of the body. Routes of administration for parenteral drug products include intravenous, intraventricular, intra-arterial, intra-articular, subcutaneous, intramuscular, intrathecal, intracisternal, and intraocular.

Parenteral dosage forms include solutions, suspensions, emulsions, sterile powders for solutions and suspensions (including liposomes), implants (including microparticles), and products that consist of both a drug and a device such as drug-eluting stents. The definitions and descriptions of these dosage forms, and brief information about their composition and manufacturing processes, are found in *Pharmaceutical Dosage Forms* ⟨1151⟩. [NOTE—All references to chapters above 1000 are for informational purposes only, for use as a helpful resource. These chapters are not mandatory unless explicitly called out for application.]

This chapter is divided into three main sections: (1) universal product quality tests that are applicable to parenteral dosage forms; (2) specific product quality tests, which are tests that should be considered in addition to *Universal Tests*; and (3) product quality tests for specific dosage forms, which list applicable tests (universal and specific) for the specific dosage form.

This chapter applies, in whole or in part, when referenced in a drug product monograph (see *General Notices, 3.10 Applicability of Standards*).

The pharmacopeial definitions for sterile preparations for parenteral use may not apply to some biologics because of their special nature and licensing requirements (see *Biologics* ⟨1041⟩). However, some biological finished drug products containing "Injection" in the monograph title must meet the requirements of ⟨1⟩ or indicated chapter subparts, where it is specified in the monograph.

***Change to read:***

## PRODUCT QUALITY TESTS COMMON TO PARENTERAL DOSAGE FORMS

### Universal Tests

Universal tests are listed below and are applicable to parenteral dosage forms.

#### IDENTIFICATION

Identification tests are discussed in *General Notices, 5.40 Identification* should establish the identity of the drug or drugs present in the article and should discriminate between compounds of closely related structure that are likely to be present..

#### ASSAY

A specific and stability-indicating test should be used to determine the strength (content) of the drug product. In cases where the use of a nonspecific assay is justified, other supporting analytical procedures should be used to achieve overall specificity. A specific procedure should be used when there is evidence of excipient interference with the nonspecific assay.

@2024 USPC

### IMPURITIES

Tests for *Impurities* are discussed in *General Notices, 5.60 Impurities and Foreign Substances*. All articles should be tested to ensure that they meet the requirements.

### FOREIGN AND PARTICULATE MATTER

Articles intended for parenteral administration should be prepared in a manner designed to exclude particulate matter as defined in *Subvisible Particulate Matter in Therapeutic Protein Injections* ⟨787⟩, *Particulate Matter in Injections* ⟨788⟩, or *Particulate Matter in Ophthalmic Solutions* ⟨789⟩, as well as excluding other foreign matter as appropriate for the dosage form. Each final container of all parenteral preparations should be inspected to the extent possible for the presence of observable foreign and particulate matter (hereafter termed visible particulates) in its contents. The inspection process should be designed and qualified to ensure that every lot of all parenteral preparations is essentially free from visible particulates, as defined in *Visible Particulates in Injections* ⟨790⟩. Qualification of the inspection process should be performed with reference to particulates in the visible range and those particulates that might emanate from the manufacturing or filling process. Every container in which the contents show evidence of visible particulates must be rejected. The inspection for visible particulates may take place during examination for other defects such as cracked or defective containers or seals, or when characterizing the appearance of a lyophilized product.

When the nature of the contents or the container–closure system permits only limited inspection of the total contents, the 100% inspection of a lot should be supplemented with the inspection of constituted (e.g., dried) or withdrawn (e.g., from a dark amber container) contents of a sample of containers from the lot.

Large-volume injections for single-dose infusion, small-volume injections, and pharmacy bulk packages (PBPs) are subject to the light obscuration or microscopic procedures and limits for subvisible particulate matter set forth in ⟨788⟩, unless otherwise specified in the chapter or in the individual monograph. An article packaged as both a large-volume and a small-volume injection meets the requirements set forth for small-volume injections where the container is labeled as containing 100 mL or less. It meets the requirements set forth for large-volume injections for single-dose infusion where the container is labeled as containing more than 100 mL.

### STERILITY

The sterility of all drug products intended for parenteral administration should be confirmed by the use of methods described in *Sterility Tests* ⟨71⟩ or by an approved alternative method.

### BACTERIAL ENDOTOXINS

All articles intended for parenteral administration should be prepared in a manner designed to limit bacterial endotoxins as defined in *Bacterial Endotoxins Test* ⟨85⟩ or *Pyrogen Test* ⟨151⟩.

### CONTAINER CONTENT

Container contents should be determined when appropriate (see *Container Content for Injections* ⟨697⟩).

### PACKAGING SYSTEMS

The packaging system should not interact physically or chemically with the preparation to alter its strength, quality, or purity beyond the official or established requirements. The packaging system should meet the requirements in ▲*Elastomeric Components Used in Injectable Pharmaceutical Packaging/Delivery Systems* ⟨381⟩▲ (CN 1-Dec-2020), *Packaging and Storage Requirements* ⟨659⟩, *Containers—Glass* ⟨660⟩, *Plastic Packaging Systems and their Materials of Construction* ⟨661⟩, *Plastic Materials of Construction* ⟨661.1⟩, and *Plastic Packaging Systems for Pharmaceutical Use* ⟨661.2⟩. Further information regarding packaging systems testing may be found in *Assessment of Extractables Associated with Pharmaceutical Packaging/Delivery Systems* ⟨1663⟩ and *Assessment of Drug Product Leachables Associated with Pharmaceutical Packaging/Delivery Systems* ⟨1664⟩.

### CONTAINER–CLOSURE INTEGRITY

The packaging system should be closed or sealed in such a manner as to prevent contamination or loss of contents. Validation of container integrity must demonstrate no penetration of microbial contamination or gain or loss of any chemical or physical parameter deemed necessary to protect the product (see *Package Integrity Evaluation—Sterile Products* ⟨1207⟩, *Package Integrity Testing in the Product Life Cycle—Test Method Selection and Validation* ⟨1207.1⟩, *Package Integrity Leak Test Technologies* ⟨1207.2⟩, and *Package Seal Quality Test Technologies* ⟨1207.3⟩).

### LABELING

All articles intended for parenteral administration should meet the labeling requirements defined in *Labeling* ⟨7⟩.

## Specific Tests

In addition to the *Universal Tests* listed above, the following specific tests may be necessary depending on the dosage form.

@2024 USPC

### UNIFORMITY OF DOSAGE UNITS

This test is applicable for parenteral drug products and dosage forms packaged in single-unit containers. It includes both the mass of the dosage form and the content of the active substance in the dosage form (see *Uniformity of Dosage Units* ⟨905⟩).

### VEHICLES AND ADDED SUBSTANCES

There are other vehicles, both aqueous and nonaqueous, beyond those that are discussed below. All vehicles should be suitable for their intended use and not impact drug product quality.

**Aqueous vehicles:** Aqueous vehicles must meet the requirements of ⟨151⟩ or ⟨85⟩, whichever is specified in the monograph. Water for injection is generally used as the vehicle. Sodium chloride or dextrose may be added to render the resulting solution isotonic, and sodium chloride injection or Ringer's injection may be used in whole or in part instead of water for injection.

**Nonaqueous vehicles:** Fixed oils are classified under *Nonaqueous vehicles*. Fixed oils used as vehicles are of vegetable origin and are odorless. They meet the requirements in the test for *Solid Paraffin* in the *Mineral Oil* monograph with the cooling bath maintained at 10°.

Nonaqueous vehicles should also meet the requirements of the following tests:

- *Fats and Fixed Oils* ⟨401⟩, *Saponification Value*: Between 185 and 200
- *Fats and Fixed Oils* ⟨401⟩, *Iodine Value*: Between 79 and 141
- *Fats and Fixed Oils* ⟨401⟩, *Unsaponifiable Matter*: NMT 1.5%
- *Fats and Fixed Oils* ⟨401⟩, *Acid Value*: NMT 0.2
- *Fats and Fixed Oils* ⟨401⟩, *Peroxide Value*: NMT 5.0
- *Water Determination* ⟨921⟩, *Method Ic*: NMT 0.1%
- *Limit of Copper, Iron, Lead, and Nickel*: [NOTE—The test for nickel is not required if the oil has not been subjected to hydrogenation, or a nickel catalyst has not been used in processing.] Proceed as directed in *Fats and Fixed Oils* ⟨401⟩, *Trace Metals* or *Elemental Impurities—Procedures* ⟨233⟩. Meet the requirements in *Elemental Impurities—Limits* ⟨232⟩.

Synthetic mono- or diglycerides of fatty acids may be used provided they are liquid and remain clear when cooled to 10° and have a *Iodine Value* of NMT 140.

**Added substances:** Suitable substances may be added to preparations in order to increase stability or usefulness unless they are proscribed in the monograph. No coloring agent may be added to a preparation solely for the purpose of coloring the finished preparation (see *General Notices, 5.20 Added Substances* and *Antimicrobial Effectiveness Testing* ⟨51⟩).

Observe special care in the choice and use of added substances in preparations with volumes that exceed 5 mL. The following limits prevail unless otherwise directed:

- Mercury and cationic surface-active agents: NMT 0.01%
- Chlorobutanol, cresol, phenol, and similar substances: NMT 0.5%
- Sulfur dioxide or an equivalent amount of sulfite, bisulfite, or metabisulfite of potassium or sodium: NMT 0.2%

### ANTIMICROBIAL PRESERVATIVES

Antimicrobial agents must be added to preparations intended for injection that are packaged in multiple-dose containers unless one of the following conditions prevails: (1) there are different directions in the individual monograph; (2) the substance contains a radionuclide with a physical half-life of less than 24 h; or (3) the active ingredients are themselves antimicrobial. Substances must meet the requirements of ⟨51⟩ and *Antimicrobial Agents—Content* ⟨341⟩.

### WATER CONTENT

The water content of freeze-dried (lyophilized) products should be determined when appropriate (see ⟨921⟩).

### ALUMINUM CONTENT

See *Labeling* ⟨7⟩, *Aluminum in Large-Volume Injections (LVIs), Small-Volume Injections (SVIs), and Pharmacy Bulk Packages (PBPs) Used in Parenteral Nutrition (PN) Therapy* for information related to specific labeling requirements associated with aluminum content.

### COMPLETENESS AND CLARITY OF SOLUTIONS

The following tests are performed to demonstrate suitability of constituted solutions prepared before administration. Constitute the solution as directed in the labeling supplied by the manufacturer:

- The solid dissolves completely, leaving no undissolved matter.
- The constituted solution is not significantly less clear than an equal volume of the diluent or of purified water contained in a similar vessel and examined similarly. Protein solutions may exhibit an inherent opalescence.

The constituted solution is free from particulate matter that can be observed on visual inspection (see ⟨790⟩).

## PRODUCT QUALITY TESTS FOR SPECIFIC PARENTERAL DOSAGE FORMS

Product quality tests for the specific dosage forms are listed below. Specific chapter(s) referenced for the test can be found in the *Universal Tests* and *Specific Tests* sections.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M98730_03_01
@2024 USPC

## Solutions

A solution is a clear, homogeneous liquid dosage form that contains one or more chemical substances (e.g., drug substances or excipients) dissolved in a solvent (aqueous or nonaqueous) or a mixture of mutually miscible solvents. Solutions intended for parenteral administration (e.g., by injection or for irrigation) must be sterile and biocompatible with the intended administration site. This includes consideration of factors such as tonicity, pH, pyrogenicity, extraneous particulate matter, and physicochemical compatibility, among others.

Unless otherwise justified, the following tests are required for solutions for injection:

- *Universal Tests*
- *Specific Tests*
  - *Antimicrobial Preservatives*

## Sterile Powders for Solutions

Sterile powders for solutions (also referred to as sterile powders for injection) consist of drug substances and other components as dry-formulation ingredients to ensure the chemical and physical stability of the presentation within a final-use container. Companion sterile diluent or diluent compartments may be provided to facilitate constitution to the desired final volume.

The sterile article for injection may be presented in several forms: lyophilized powder intended for final solution, powdered solids intended for final solution, or dry solids that form viscous liquids upon constitution.

The description should include a section that deals with ease of dispersion and reconstitution. The dosage form is a homogeneous solid that is readily constituted to the final form with the specified diluent, and dispersion is completed with gentle agitation.

Unless otherwise justified, the following tests apply to sterile powders for injection:

- *Universal Tests*

The following applies to constituted solutions:

- Chapter ⟨905⟩: To ensure the consistency of dosage units, each unit in a batch should have a drug substance content within a narrow range around the label claim. Dosage units are defined as dosage forms that contain a single dose or a part of a dose of drug substance in each unit. For liquid dosage forms analysts should conduct the assay on an amount of well-mixed constituted material that is removed from an individual container under conditions of normal use, should express the results as delivered dose, and should calculate the acceptance value.

The following applies to dry cake:

- *Loss on Drying* ⟨731⟩: The procedure set forth in this chapter determines the amount of volatile matter of any kind that is driven off under the conditions specified.
- Chapter ⟨921⟩: Water or solvent content may have important effects on reconstitution and stability. For articles that require water or solvent content control, analysts should perform one of the methods described in ⟨921⟩ or a suitable replacement.
- *Appearance*: Analysts should assess the level of and the unit variation for the following parameters:
  - Color of Dry Cake: Varies within target parameters
  - Texture and Homogeneity of Dry Cake: Varies within target parameters
  - Presence of Foreign Material: All units with visible foreign material must be rejected

## Suspensions

Parenteral suspensions are liquid dosage forms that contain solid particles in a state of uniform dispersion. Suspensions for parenteral administration must be sterile and compatible with the administration site. Consideration should be given to pH and pyrogenicity, and appropriate limits should be identified. Physical stability evaluations of parenteral suspension preparations should include evaluations to confirm that the particle size range of suspended matter does not change with time and to confirm that the solids in the preparation can be readily resuspended to yield a uniform preparation.

The following tests are required for suspensions for injection unless otherwise justified:

- *Universal Tests*
- *Specific Tests*
  - *Uniformity of Dosage Units*
  - *Antimicrobial Preservatives*

## Liposomes

Liposomes are unique drug products with unique properties that can be either solutions or suspensions. Liposomes are aqueous dispersions of amphiphilic lipids and have low water solubility. They are organized as a bilayer sheet that encloses an internal aqueous compartment and are known as lipid bilayer vesicles. Liposomes can have a single lipid bilayer (unilamellar vesicle) or can have an onion-like multilayered structure (multilamellar vesicle). The amphiphilic lipids comprise a hydrated head group at the water interface of the bilayer attached to a hydrophobic group that forms the interior of the bilayer by association with the hydrophobic group of lipids from the opposite leaflet of the bilayer. The physical properties of the liposome and its bilayer can vary widely and depend on lipid composition, aqueous composition, and temperature relative to the acyl components' phase transition points. Because of the central aqueous compartment, a simple test for the presence of liposomes in a lipid dispersion is to determine the presence of an entrapped aqueous phase.

Official

https://pharmacopeia.com/

A liposome drug product consists of the drug substance, liposome components, and other inactive but critical ingredients such as an aqueous dispersion unless the contents are a lyophilized product.

Unless otherwise justified, the following tests are required for liposomes:

- *Universal Tests*
- *Specific Tests*
  - *Globule Size Distribution in Lipid Injectable Emulsions* ⟨729⟩

## Sterile Powders for Suspensions

Sterile powders for suspensions consist of drug substances and other components as dry-formulation ingredients to ensure the chemical and physical stability of the presentation within a final-use container. Companion sterile diluent or diluent compartments may be provided to facilitate constitution to the desired final volume.

The sterile article for injection may be presented in several forms: lyophilized powder intended for final suspension, powdered solids intended for final suspension, and microparticles that retain their integrity and are delivered as a sterile suspension. The description should include a section that deals with ease of dispersion and reconstitution. The dosage form is a homogeneous solid that is readily constituted to the final form with the specified diluent, and dispersion is completed with gentle agitation.

Unless otherwise justified, the following tests apply to sterile powders for injection:

- *Universal Tests*

**Microparticles:** Some microparticles are provided as a sterile powder to be reconstituted as a suspension before injection. The majority of microparticle preparations are for reconstitution as a suspension for injection. For quality test requirements, please refer to *Implants*.

## Emulsions

Emulsions for parenteral dosage forms are liquid preparations of drug substances dissolved or dispersed in a suitable emulsion medium. Oil-in-water or water-in-oil emulsions typically entrap the drug substance.

Emulsions typically are white, turbid, homogeneous liquid dosage forms that contain one or more chemical substances (e.g., drug substances and excipients) dissolved in a solvent (aqueous or nonaqueous) or mixture of mutually miscible solvents. Emulsions intended for intravenous administration must be sterile and must be compatible with the intended administration site.

Unless otherwise justified, the following tests are required for emulsions for injection:

- *Universal Tests*
- *Specific Tests*
  - Chapter ⟨729⟩

## Implants

Implants for extended release consist of a matrix of drug substance and polymeric excipient that may or may not have an outer rate-controlling membrane. The polymeric excipient must be biocompatible but may or may not be bioresorbable. Some implants are made from medical-grade metal with an osmotic pump inside that effects the extended release of the drug substance. Implants must be sterile and usually are formed in the shape of a cylinder, although other shapes are used. Solvents used to dissolve the formulation can lead to sterilization, and thus the internal sterility test method should demonstrate that the sample preparation does not lead to sterilization of the test sample.

Cylindrically shaped implants for systemic delivery usually are provided in an inserter for subcutaneous or local administration such as local ocular delivery. Implants also can be surgically implanted for local delivery, e.g., ocular delivery.

Unless otherwise justified, the following tests are required for implants:

- *Universal Tests*
- *Specific Tests*
  - *Uniformity of Dosage Units*

## In situ Gels

Sterile in situ gels are liquid preparations that are intended for injection into specific therapeutic targets. Typically they consist of polymers in organic solvents, and upon injection the solvents migrate away from the site, leaving a gelled mass. The preparations may be injected as-is, upon reconstitution, from in situ formation, or from chemically initiated catalysis that results in the final form.

Unless otherwise justified, the following tests are required for in situ gels:

- *Universal Tests*
- *Specific Tests*
  - *Antimicrobial Preservatives*

## Microparticles

Injectable, resorbable microparticles for extended release generally range from 20 to 100 µm in diameter. They consist of drug substances embedded within a biocompatible, bioresorbable polymeric excipient, e.g., polyester excipients. Microparticles are provided as a sterile powder in a vial or syringe.

Official

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M98730_03_01
@2024 USPC

Just before intramuscular or subcutaneous administration, the microparticle powder should be suspended in an aqueous injection vehicle (diluent). The injection vehicle usually consists of water for injection, surfactant, and a viscosity enhancer, and the vehicle may contain a compound that adjusts osmolality, e.g., a sugar with or without a compound that controls pH, e.g., an acid. The injection vehicle must be sterile and must be tested according to requirements for solutions that are intended for parenteral administration.

Unless otherwise justified, the following tests are required for microparticles for injection:

- *Universal Tests*
- *Specific Tests*
  - *Uniformity of Dosage Units*
  - *Water Content*

## Drug-Eluting Stents

Drug-eluting stents are tiny metal or polymer scaffolds used to keep arteries open following a medical intervention; the drug substance is incorporated into or onto the stent platform. Drug-eluting stents typically have two components of testing: (1) functional tests that generally are American Society for Testing and Materials (ASTM) International methods that fall outside the scope of this chapter and (2) analytical tests.

Unless otherwise justified, the following tests are required for drug-eluting stents:

- *Universal Tests*
- *Specific Tests*
  - *Uniformity of Dosage Units.* The content of the active substance in the dosage form is applicable for drug-eluting stents packaged in single-unit containers. The test can be performed by either content uniformity or weight variation (see ⟨905⟩). With appropriate justification, the number of stents needed for this test may be fewer than the recommended number of stents in ⟨905⟩.

# ⟨2⟩ ORAL DRUG PRODUCTS—PRODUCT QUALITY TESTS

## INTRODUCTION

Oral delivery is the most common route of administration for drug products. All oral drug products lead to systemic and/or local action in the oral cavity and/or gastrointestinal tract. Oral drug products fall primarily into two main categories: solids and liquids. Solid oral drug products include but are not restricted to capsules, tablets, granules, and powders. Similarly, liquid oral drug products include but are not restricted to solutions, suspensions, and emulsions. The definitions and descriptions of these dosage forms and brief information about their composition and manufacturing process are found in *Pharmaceutical Dosage Forms* ⟨1151⟩. [NOTE—All references to chapters above ⟨1000⟩ are for informational purposes only, for use as a helpful resource. These chapters are not mandatory unless explicitly called out for application.]

This chapter focuses on the product quality tests that are generally necessary for oral drug products for a single or combination of small molecules of active ingredients. Biologics in solid dosage forms are not considered. In this chapter, the terms "drug substance" and "active ingredient" are used interchangeably. The contents of this chapter do not necessarily apply to drug products that are intended for use other than by oral administration. For example, the chapter does not address oromucosal dosage forms. Some of the tests indicated in this chapter may be performed on an in-process basis or omitted as routine tests based on process validation. However, the product must meet USP compendial requirements when sampled and tested, once the product is on the market.

This chapter provides lists of consolidated common product quality test requirements in a concise and coherent fashion. This chapter applies, in part or whole, when referenced in a drug product monograph (see *General Notices, 3.10 Applicability of Standards*). This chapter includes the quality tests for the specific route of administration. The quality tests listed can be used as appropriate by manufacturers toward the development of new drug product monographs for submission to USP. If a validated performance test procedure is available for the specific drug product, it is identified in a general chapter below ⟨1000⟩. In cases where a validated procedure cannot be recommended, but if the information is available for a product quality and/or product performance test, it is described in an informational chapter above ⟨1000⟩.

### Drug Product Quality Tests and Performance Tests

Monograph tests, analytical procedures, and acceptance criteria for testing oral drug products are divided into two categories: 1) those that assess general product quality attributes, and 2) those that assess product performance, which is a specific quality attribute typically linked to bioavailability and bioequivalence studies (see *Assessment of Solid Oral Drug Product Performance and Interchangeability, Bioavailability, Bioequivalence, and Dissolution* ⟨1090⟩). Drug product quality tests are intended to assess attributes such as identification, strength (assay), impurities , dose content uniformity, pH, minimum fill, alcohol content, volatile content, and microbial content. Drug product performance tests are designed to assess in vitro drug release from dosage forms (e.g., *Dissolution* ⟨711⟩ and *Drug Release* ⟨724⟩). For liquid oral drug products in solution, performance is considered optimal, and a monograph performance test is not included.

Each of these attributes is important for a primary understanding of the quality and performance of a drug product. Thus, they form the basis for the monograph. A compendial product should meet all drug product quality tests and drug product performance tests contained in its monograph.

[NOTE—Dissolution tests, specifically dissolution profile similarity between higher strengths and lower strengths of a given manufacturer's product and dissolution profile similarity between the generic product and the reference product, are used for granting biowaivers. See ⟨1090⟩.]

***Change to read:***

## PRODUCT QUALITY TESTS FOR ORAL DRUG PRODUCTS

Drug product quality tests for oral drug products fall into two categories: 1) universal tests that are applicable to all oral drug products and should be included in the monograph, and 2) specific tests that should be considered for inclusion for specific types of oral products.

### Universal Tests for Oral Drug Products

Product quality attributes for oral dosage forms are important to ensure that commercialized products meet minimum quality requirements. Universal tests should be applied to all oral dosage forms and include *Description*, *Identification*, *Strength* (*Assay*), and *Impurities* (organic, inorganic, and residual solvents).

#### DESCRIPTION

Description is general in nature and is not a standard in itself. It communicates the appearance of an article that complies with monograph standards.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M3211_05_01
@2024 USPC

### IDENTIFICATION

The identification test is defined in *General Notices, 5.40 Identification*. It is included in a monograph as an aid to confirm that the article contains the labeled drug substance by providing a positive identification of the drug substance or substances in a drug product.

One method of confirming the identity is to compare the retention time of the sample with that obtained for the standard injections in a chromatographic assay procedure. Other methods often used to orthogonally confirm the identity of the active ingredient are: *Thin-Layer Chromatographic Identification Test* ⟨201⟩, *Spectroscopic Identification Tests* ⟨197⟩, *Nuclear Magnetic Resonance Spectroscopy* ⟨761⟩, *Near-Infrared Spectroscopy—Theory and Practice* ⟨1856⟩, and ▲*Raman Spectroscopy—Theory and Practice* ⟨1858⟩▲ (CN 1-Aug-2020), among others. The analytical procedure must be able to distinguish the active ingredient from all excipients that are present or from potential degradation products likely to be present. Care must also be taken to ensure that the chromatographic system separates the article from other closely related drug substances, impurities, and additives. Infrared and ultraviolet absorption also can be used for identification (see ⟨197⟩), if the procedure has been demonstrated to be selective for the drug substance via an appropriate validation or verification study. The results of the identification test must be compared to the results obtained from a similarly prepared, suitable Reference Standard.

### ASSAY

The assay is a specific and stability-indicating test to determine the potency (content) of the drug product. When a nonspecific assay (e.g., titration) is justified, other supporting analytical procedures should ensure that any interfering species can be detected. In general the *a priori* acceptance of ±10% variation in limits of a quality attribute (e.g., assay) from the target label claim (100%) in most cases is intended to account for manufacturing variability and shelf-life stability and is primarily based on the notion that such variation in a quality attribute is less likely to have any noticeable adverse impact on the desired clinical outcome. Acceptance criteria of 95.0%–105.0% are used with justification (e.g., for drug products with narrow therapeutic index). Activity assays and absolute content assays also are acceptable when justified.

### IMPURITIES

Process impurities, synthetic by-products, and other inorganic and organic impurities may be present in the drug substance and in the excipients used in the manufacture of the drug product. These impurities are limited by drug substance and excipient monographs. During product manufacture and over the shelf life of the product, degradation products can form. These can be a result of degradation of the drug substance or from interactions between the drug substance and excipient(s), among other factors. The procedures and acceptance criteria should specifically limit toxic materials. See specific requirements in the *General Notices 5.60, Impurities and Foreign Substances*. [NOTE—For additional information, see *Impurities in Drug Substances and Drug Products* ⟨1086⟩.]

## Specific Tests for Tablets

In addition to the *Universal Tests for Oral Drug Products* described above, the following specific tests for tablets should be considered, depending upon the nature of the drug substance and formulation.

### VOLATILE CONTENT

The test and the specific method depend on the nature of the article. Special consideration should be given to dosage forms for which water content has been shown to be a potential quality attribute and to products where solvent is used in the manufacture of the drug product.

When the presence of moisture or other volatile material may become critical, analysts must determine the amount of unbound volatile solvents or volatile matter of any kind that is driven off by *Loss on Drying* ⟨731⟩ or another suitable technique (e.g., water activity). For substances that appear to contain water as the only volatile constituent, the procedure given in *Water Determination* ⟨921⟩ may be appropriate. For drug products, analysts also should consult *Residual Solvents* ⟨467⟩.

### DISINTEGRATION

Disintegration is an essential attribute of oral solids, except for those intended to be chewed before being swallowed and for delayed- or extended-release products. This test measures the time it takes for the dosage unit to disintegrate in an aqueous medium and is described in detail in *Disintegration* ⟨701⟩. Certain dosage forms (e.g., effervescent tablets and others) may require special procedures and identity tests for bicarbonate when dissolved in water. The disintegration test for some of the dosage forms in this chapter is included for completeness. For detailed procedures, refer to ⟨701⟩. The disintegration test, if included, is used only as a quality control test and not as a product performance test and should conform with the specifications in the monograph. Only when disintegration has been correlated with dissolution of a dosage form can a disintegration test be used as a product performance test [International Council for Harmonisation (ICH) Guidance Q6A, available at www.ich.org]. In all other instances, a dissolution test should be considered as a product performance test.

### TABLET FRIABILITY

The test procedure is applicable to most compressed, uncoated tablets. Friability determines the ability of tablets to withstand mechanical stresses and their resistance to chipping and surface abrasion. [NOTE—For additional information, see *Tablet Friability* ⟨1216⟩.]

Official

https://pharmacopeia.com/

### TABLET BREAKING FORCE

Tablet breaking force measures the mechanical integrity of tablets, which is the force required to cause them to fail (i.e., break) in a specific plane. [NOTE—For additional information, see *Tablet Breaking Force* ⟨1217⟩.]

### UNIFORMITY OF DOSAGE UNITS

Uniformity of dosage units must be demonstrated by either content uniformity or weight variation. Content uniformity is based on the assay of the individual content of drug substance(s) in a number of dosage units to determine whether the individual contents are sufficiently close to label claim. Weight variation can be used as an alternative to estimate content uniformity under certain conditions (see *Uniformity of Dosage Units* ⟨905⟩).

## Specific Tests for Uncoated Tablets

Uncoated tablets include single-layer tablets that result from a single compression of particles and multilayer tablets that consist of concentric or parallel layers obtained by successive compression of particles of different composition. The excipients used generally are not specifically intended to modify the release of the active substance in the digestive fluids. Uncoated tablets include but are not limited to: effervescent tablets, buccal tablets, sublingual tablets, chewable tablets, orally disintegrating tablets, tablets for oral solution, and tablets for oral suspension. For uncoated tablets, disintegration should be tested as directed in ⟨701⟩.

### BUCCAL, SUBLINGUAL, AND ORALLY DISINTEGRATING TABLETS

These dosage forms are discussed in *Mucosal Drug Products—Product Quality Tests* ⟨4⟩. They are listed here for informational purposes and completeness.

### CHEWABLE TABLETS

Chewable tablets (intact) should undergo dissolution and disintegration testing, as a product performance test (if cited in the monograph), because they might be swallowed without proper chewing by a patient. In general, the dissolution and disintegration test conditions for chewable tablets should be the same as for nonchewable tablets of the same active ingredient or moiety.

### TABLETS FOR ORAL SOLUTION AND TABLETS FOR ORAL SUSPENSION

These are tablets intended to be dissolved or dispersed in water before administration, giving a homogeneous solution or dispersion. They are listed here for informational purposes and completeness.

## Specific Tests for Coated Tablets

Coated tablets are tablets covered with one or more layers of mixtures of various substances such as natural or synthetic resins, gums, gelatin, inactive and insoluble excipients, sugars, plasticizers, polyols, waxes, coloring matter authorized by the competent authority, and sometimes flavoring substances and active substances. Tablets coated by sugar or film include but are not limited to: plain coated tablets, extended-release tablets, and delayed-release tablets. A disintegration test, when applicable, should be performed as directed in ⟨701⟩.

There are no additional specific quality tests for extended-release tablets and delayed-release tablets. Universal quality tests should be applied to these products.

## Specific Tests for Capsules

In addition to the *Universal Tests for Oral Drug Products* described above, the specific tests included below should be considered, depending on the nature of the drug substance and formulation. Modified release capsules include delayed-release capsules and extended-release capsules.

Product quality tests that are considered specific to the type of capsule include those for volatile content (see ⟨731⟩ and ⟨921⟩). One-piece capsules typically are used to deliver a drug substance as a solution or suspension. Two-piece capsules consist of two telescoping cap-and-body pieces that are used to deliver solid material as powder, granules, or small tablets.

### UNIFORMITY OF DOSAGE UNITS

Uniformity of dosage units must be demonstrated by either content uniformity or weight variation. Content uniformity is based on the assay of the individual content of drug substance(s) in a number of dosage units to determine whether the individual contents are sufficiently close to label claim. Weight variation can be used as an alternative to estimate content uniformity under certain conditions (see ⟨905⟩).

### DISINTEGRATION

For capsules, proceed as directed in ⟨701⟩, if a disintegration test is required. Disintegration for modified release capsules may require special procedures.

@2024 USPC

There are no additional specific quality tests for modified release capsules. Universal quality tests should be applied to these products.

## Specific Tests for Granules

In addition to the *Universal Tests for Oral Drug Products* described above, the specific tests included below should be considered, depending on the nature of the drug substance and formulation.

Granules are solid dosage forms that are composed of agglomerations of smaller particles. Granules include but are not limited to: effervescent granules, coated granules, extended-release granules, and delayed-release granules.

Tests that are considered specific to the type of granules include volatile content (see ⟨731⟩ and ⟨921⟩). For disintegration for effervescent granules, refer to ⟨701⟩. On the basis of the nature of the article and scientific criteria, additional tests may apply, including powder fineness and content uniformity (see ⟨905⟩) if granules are packaged in single-unit containers.

## Specific Tests for Powders

Oral powders should indicate: "For Oral Use Only". Tests that are considered specific to the type of powders include: *Minimum Fill* ⟨755⟩ for products packaged in multiple-dose containers, content uniformity (see ⟨905⟩) for products packaged in single-unit containers, and volatile content (see ⟨731⟩ and ⟨921⟩).

On the basis of the nature of the article and scientific criteria, additional tests may apply, including pH in an aqueous solution, powder fineness, microbial limits, and others.

## Specific Tests for Liquids

The recommended product quality tests for a liquid drug product include the *Universal Tests for Oral Drug Products* described above and the specific tests included below. Most of the quality tests for liquids require the evaluation of single-dose products to estimate the quality attribute. Specific directions to perform the quality tests (including preservative content) for either single-dose or multiple-dose products are provided in the monograph or the general chapter. For example, weight variation may be used when adequacy of mix for the active substance(s) and excipients in the blend is well controlled to ensure their uniform distribution, as in solutions.

### DELIVERABLE VOLUME

When the liquid formulation is packaged in a multiple-dose container, compliance with *Deliverable Volume* ⟨698⟩ is required.

### ALCOHOL DETERMINATION

If the liquid formulation contains a quantity of alcohol, *Alcohol Determination* ⟨611⟩ should be included. The limits may be an absolute concentration, in percentage, or relative to a labeled content.

### pH

Liquid oral products typically are aqueous formulations that are susceptible to pH changes from exposure to atmospheric carbon dioxide ($CO_2$). The uptake of atmospheric carbon dioxide ($CO_2$) and consequent pH change of oral liquid products is only relevant to aqueous-based products. The pH of an oral liquid formulation can affect flavor and stability. The pH range as outlined in *pH* ⟨791⟩ is indicated in the monograph.

### MICROBIAL CONTENT

The presence of certain microorganisms in nonsterile preparations may have the potential to reduce or even inactivate the therapeutic activity of the product and has a potential to adversely affect the health of the patient. Some liquid oral products can be subject to extreme microbiological control, and others require none. The needed microbial specification for a given liquid oral product depends on its formulation and use and is indicated in the monograph.

[NOTE—For additional information, see *Microbiological Examination of Nonsterile Products: Acceptance Criteria for Pharmaceutical Preparations and Substances for Pharmaceutical Use* ⟨1111⟩.]

### ANTIOXIDANT

Release testing should be performed. Shelf-life testing may be unnecessary where justified by development and stability data (ICH Guidance Q6A).

### EXTRACTABLES

Where development and stability data show no significant evidence of extractables, elimination of this test may be proposed. Where data demonstrate the need and acceptance criteria for oral solutions—rubber stopper, cap liner, plastic bottle—data should be collected as early in the development process as possible (ICH Guidance Q6A).

Official

https://pharmacopeia.com/

TYPES OF LIQUID DOSAGE FORMS

Specific quality tests for these dosage forms are provided in their respective monographs.
**Solutions, powders, and granules for solution:** Tests of "for Solution" formulations are conducted on a well-mixed solution of the drug product constituted as described in the labeling.
**Emulsions, suspensions, and powders and granules for suspension:** Tests of "for Suspension" formulations are conducted on a well-mixed suspension of the drug product constituted as described in the labeling. Product quality tests for suspensions should include a test of suspendability.
**Powders and granules for solutions:** After dissolution or suspension, they comply with monograph requirements for the final dosage form. Volatile content (see ⟨731⟩ and ⟨921⟩) may be an additional quality test for powders and granules for reconstitution.

## Specific Tests for Miscellaneous Oral Dosage Forms

LYOPHILIZED ORAL PRODUCTS

***Water Determination*** ⟨921⟩**,** *Method I, Method Ia***:** Lyophilized oral products comply with the test. The limits are approved as indicated in the specific monograph.

# ⟨3⟩ TOPICAL AND TRANSDERMAL DRUG PRODUCTS—PRODUCT QUALITY TESTS

## INTRODUCTION

Topically applied drug products fall into two general categories: those applied to achieve local action and those applied to achieve systemic effects after absorption through the skin into the blood circulation. Local action can occur at or on the surface of the application site (e.g., stratum corneum); in the underlying tissues (e.g., epidermis and/or dermis); and in subcutaneous tissues (e.g., muscle or joint). Topically applied drug products include, but are not limited to, creams, gels, ointments, pastes, suspensions, lotions, foams, sprays, aerosols, solutions, and topical and transdermal delivery systems (TDS). The definitions and descriptions of these dosage forms, as well as brief information on their composition and/or manufacturing processes, can be found in *Pharmaceutical Dosage Forms* ⟨1151⟩.

Procedures and acceptable criteria for testing topically applied drug products can be divided into those that assess general product quality attributes and those that assess product performance. The product quality attributes include the following: description, identification, assay (strength), impurities, physicochemical and structural properties, uniformity of dosage units, water content, pH, apparent viscosity, microbial limits, antimicrobial preservative content, antioxidant content, sterility (if applicable), penetration enhancer content, and other tests that may be product specific. Product performance testing assesses drug release and other attributes that affect drug release from the finished dosage form.

This chapter provides lists of consolidated common product quality test requirements in a concise and coherent fashion. This chapter applies, in whole or in part, when referenced in a drug product monograph (see *General Notices, 3.10 Applicability of Standards*) and includes the quality tests for the specific route of administration. The quality tests listed can be used as appropriate by manufacturers toward the development of new drug product monographs for submission to *USP–NF*.

TDS release their active ingredients by different mechanisms. They can be passive or active. This chapter covers only the tests related to passive TDS.

## PRODUCT QUALITY TESTS FOR TOPICAL AND TRANSDERMAL DRUG PRODUCTS

### Additional Procedure for Products Packaged in Containers with a Non-Metered Pump

For some tests (e.g., viscosity, assay, etc.), with the exception of the uniformity in containers test, samples need to be collected from the pumped-out product. In these instances, the samples should be collected as follows:

1. Remove cap from container.
2. Fully depress and release the actuator, disposing of any material dispensed, and allowing the pump actuator to return to the initial position after each actuation. Repeat the sequence, as indicated in the patient instructions, until a full amount of material is dispensed.
3. Collect the next material dispensed as the sample. Generally, collect NMT the amount needed to perform a single analysis (for the assay test, typically NMT 2 actuations).

### Universal Tests

Universal tests [see International Council for Harmonisation (ICH) guidance *Q6A—Specifications: Test Procedures and Acceptance Criteria for New Drug Substances and New Drug Products: Chemical Substances*, available at www.ich.org] are listed as follows and are applicable to all topically applied drug products.

#### DESCRIPTION

A qualitative description of the drug product should be provided. The acceptance criteria should include the final acceptable appearance of the finished dosage form and packaging. A visual examination should identify changes in color, adhesive migration (i.e., cold flow; see *Cold Flow Test*) for TDS, separations, crystallization, and others that are specific to the drug product. The description should specify the content or the label claim of the article. For TDS, a visual examination should also be done to assess potential use issues with the product. The examination should include an assessment of the difficulty of removing the TDS from the pouch (e.g., due to adhesive migration adhering the system to the pouch); inability to remove the TDS from the pouch without damage to the system; and adhesive residue remaining on the pouch after removal of the TDS. This is not a compendial test but is part of the manufacturer's specification for the drug product.

#### IDENTIFICATION

Identification tests are discussed in *General Notices, 5.40 Identification*. Identification tests should establish the identity of the drug or drugs present in the article and should discriminate between compounds of closely related structures that are likely to be present. Identification tests should be specific for the drug substance(s) (e.g., infrared spectroscopy). Near-infrared (NIR) or Raman spectrophotometric methods also could be acceptable for the identification of the drug product (for additional information, see *Near-Infrared Spectroscopy—Theory and Practice* ⟨1856⟩ and *Raman Spectroscopy—Theory and Practice* ⟨1858⟩). Identification solely by a single chromatographic retention time is not specific.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M4033_08_01
@2024 USPC

### ASSAY

A specific and stability-indicating test should be used to determine the strength (active pharmaceutical ingredient content) of the drug product. This assay requirement can be satisfied for topical products containing antibiotics by a standard microbiological method (see *Antibiotics—Microbial Assays* ⟨81⟩). In cases when the use of a nonspecific assay (e.g., *Titrimetry* ⟨541⟩) is justified, other supporting analytical procedures should be used to achieve overall specificity.

### IMPURITIES

Process impurities, synthetic byproducts, impurities associated with the adhesive (e.g., residual monomers), residual solvents (see *Residual Solvents* ⟨467⟩), and other inorganic and organic impurities may be present in the drug substance and in the excipients used in the manufacture of the drug product and should be assessed and controlled. Impurities arising from the degradation of the drug substance and those arising during the manufacturing process of the drug product also should be assessed and controlled.

## Specific Tests

In addition to the *Universal Tests* listed previously, the following *Specific Tests* should be considered on a case-by-case basis.

### UNIFORMITY OF DOSAGE UNITS

This test is applicable for TDS and for topical dosage forms intended for systemic delivery, or where tight control of the dose is necessary to limit local irritation or undesired systemic exposure, packaged in single-unit containers, such as packets (see *Uniformity of Dosage Units* ⟨905⟩). The uniformity of dosage units specification is not intended to apply to solutions, suspensions, emulsions, ointments, or gels in single-unit containers intended for local action following external, cutaneous administration.

### WATER CONTENT

A test for water content should be included when appropriate (see *Water Determination* ⟨921⟩). This test is generally formulation dependent. Therefore, it is not included in the compendial drug product monograph but is part of the manufacturer's specification for the drug product.

### MICROBIOLOGICAL QUALITY

Microbiological examination of nonsterile drug products is performed according to the methods given in *Microbiological Examination of Nonsterile Products—Tests for Burkholderia cepacia Complex* ⟨60⟩ (as appropriate for aqueous formulations), *Microbial Enumeration Tests* ⟨61⟩, and *Tests for Specified Microorganisms* ⟨62⟩, as appropriate, unless the formulation itself is demonstrated to have antimicrobial properties. Recommended acceptance criteria for nonsterile pharmaceutical products based on total aerobic microbial count and total combined yeasts and molds count are given in *Microbiological Examination of Nonsterile Products: Acceptance Criteria for Pharmaceutical Preparations and Substances for Pharmaceutical Use* ⟨1111⟩.

### ANTIMICROBIAL PRESERVATIVE CONTENT

Acceptance criteria for antimicrobial preservative content in multiple-unit products should be established. They should be based on the levels of antimicrobial preservative necessary to maintain the product's microbiological quality at all stages throughout its proposed usage and shelf life (see *Antimicrobial Effectiveness Testing* ⟨51⟩).

### PENETRATION ENHANCER CONTENT

If an excipient is claimed to be a penetration enhancer, a test and acceptance criteria for its content should be established.

### ANTIOXIDANT CONTENT

If antioxidants are present in the drug product, tests of their content should be established unless oxidative degradation can be detected by another test method such as impurity testing. Acceptance criteria for antioxidant content should be established. They should be based on the levels of antioxidant necessary to ensure the product's stability at all stages throughout the product's proposed usage and shelf life.

### STERILITY

Depending on the use of the dosage form (e.g., products that will be applied to open wounds or burned areas), sterility of the product should be demonstrated as appropriate (see *Sterility Tests* ⟨71⟩).

### pH

When applicable, topically applied drug products should be tested for pH. Because some topically applied drug products contain very limited quantities of water or aqueous phase, pH measurements may not always be warranted. This test is generally formulation dependent. Therefore, it is not included in the compendial drug product monograph but is part of the manufacturer's specification for the drug product.

Official

https://pharmacopeia.cn/

### PARTICLE SIZE

When the finished product contains a suspended solid drug substance, the product should be examined for particle size. The particle size of the active drug substance(s) in topically applied drug products is usually established and controlled at the formulation development stage. However, topically applied drug products should be examined for evidence of particle alteration (i.e., change in drug polymorphic form, appearance of particles, size, shape, morphology, agglomeration, or aggregation) of the drug substance that may occur during the course of product processing and storage. These types of tests are generally formulation dependent. Therefore, such tests are not included in compendial drug product monographs but are part of the manufacturer's specification for the drug product.

### CRYSTAL FORMATION

When the drug substance is dissolved in the finished product, the product should be microscopically examined for evidence of crystal formation of the active drug substance. This test is generally formulation dependent. Therefore, it is not included in the compendial drug product monograph but is part of the manufacturer's specification for the drug product. It is recommended that the potential for the drug product to form crystals of drug substance be examined during product development.

### EMULSION GLOBULE SIZE

Because many semisolid dosage forms such as creams and lotions are multiphasic systems (e.g., emulsions) with co-existing oil and water/aqueous phases in the formulation, emulsion droplet size or globule size can be a critical quality attribute that characterizes the microstructure of these dosage forms. Therefore, control of the emulsion droplet and/or globule size should be considered a specific test for such products to ensure consistency, homogeneity, and physical stability in the drug product throughout the shelf life.

## IN VITRO DRUG RELEASE TEST

For TDS, the in vitro drug release test is required as a batch-to-batch quality control. See *Drug Release* ⟨724⟩ for apparatus and test conditions. The development and validation report of the in vitro drug release test needs to include sufficient detail and data to facilitate the assessment of whether the method is adequate as a quality control test for batch release and stability testing.

For semisolid dosage forms, an in vitro drug release test (IVRT) is currently not mandatory for batch release. See *Semisolid Drug Products—Performance Tests* ⟨1724⟩ for appropriate contexts of use for an IVRT, as well as discussions on method development, experimental design, data analysis, suitable equipment and their qualification, as well as other practical information.

## SPECIFIC TESTS FOR OPHTHALMIC DRUG PRODUCTS

See *Ophthalmic Products—Quality Tests* ⟨771⟩.

## SPECIFIC TESTS FOR TOPICAL AEROSOLS

See *Topical Aerosols* ⟨603⟩.

## SPECIFIC TESTS FOR TOPICALLY APPLIED SEMISOLID DRUG PRODUCTS

### Minimum Fill

Single- and multiple-unit containers must meet minimum fill requirements as established by testing described in *Minimum Fill* ⟨755⟩. For single-unit containers where the test for ⟨905⟩ is applied, the test for ⟨755⟩ is not required.

***Change to read:***

### Apparent Viscosity

Viscosity is a measure of a formulation's resistance to flow and is an assessment of a rheological property of a semisolid dosage form. The term "apparent viscosity" applies to non-Newtonian fluids, which comprise the majority of semisolid pharmaceutical dosage forms. For additional information, see *Rheometry* ⟨1911⟩ and *Measurement of* ▲*Yield Stress*▲ (CN 1-Dec-2023) *of Semisolids* ⟨1912⟩.

Measurement procedures should be developed as outlined in *Viscosity—Capillary Methods* ⟨911⟩, *Viscosity—Rotational Methods* ⟨912⟩, and *Viscosity—Rolling Ball Method* ⟨913⟩. For semisolids that show thixotropy and/or irreversible changes in viscosity after shearing, specific attention should be given to sample preparation procedures to minimize variability in the measurement of apparent viscosity caused by variable shear histories (e.g., mixing speed and temperature, filling operation, and sample handling). Furthermore, for some products it may be warranted to have apparent viscosity specifications at more

DOI: https://doi.org/10.31003/USPNF_M4033_08_01
@2024 USPC

than one stage of the manufacturing process (e.g., bulk in-process stage, final packaged product, etc.) or with more than one set of test conditions (e.g., high and low shear rates, different temperatures, etc.).

Apart from single-point viscosity measurements, more advanced rheological techniques (flow, oscillatory, creep, and stress relaxation testing) can be applied to develop a mechanistic understanding of a formulation and its structure. See ⟨1912⟩. These techniques may be useful for product development using the principles of quality by design or for comparative physicochemical and structural characterization of the test and reference products to support a demonstration of bioequivalence in an abbreviated new drug application. However, these techniques are not generally suitable for routine quality testing. Common parameters derived from rheological testing of semisolid pharmaceutical dosage forms that may be useful for characterization and comparison are the storage modulus, loss modulus, relaxation modulus, compliance, thixotropic index, and yield stress.

Acceptance criteria are product specific and defined to ensure that the apparent viscosity of each batch of semisolid drug product is within the the acceptable range determined during product development and is consistent between batches.

## Uniformity in Containers

Topically applied semisolid drug products may show physical separation during manufacturing processes and during their shelf life. To ensure the integrity of the drug product, it is essential to evaluate the uniformity of the finished product. This test applies only to multiple-unit containers, such as tubes and jars. This test does not apply to more fluid topical drug products in multiple-unit containers, such as emulsions, lotions, two-phase gels, or topical suspensions, in which the labeling directs the user to mix the product (e.g., shake well) before use.

### PRODUCTS PACKAGED IN TUBES

**Visual uniformity:** Carefully remove or cut off the bottom tube seal and make a vertical cut from the bottom to the top of the tube. Carefully cut the tube around the upper rim, open the two flaps, and lay the flaps open to expose the product.

Inspect the product visually for the presence of phase separation, change in physical appearance and texture (e.g., color change, crystallization, lumping), and other properties described in the product specification for *Description*. If there is no significant phase separation or change in physical appearance and texture, and if the product meets the *Description* criteria, the product passes the test. If the product exhibits significant phase separation or change in physical appearance or texture, the product fails the test.

**Uniformity of active ingredient(s):** The following procedures can be modified depending on the sensitivity of the quantitative procedure used to determine the amount of the drug substance(s) present in the formulation.

*For multiple-unit tubes that contain 5 g or more of product*

STAGE 1:

1. Using a single tube, after performing the test for *Visual uniformity*, remove an appropriate amount of the product from the top (i.e., cap end), middle, and bottom (i.e., seal end) portions of the tube. The sample size should be sufficient for at least one quantitative determination of the active ingredient(s) and should not exceed the maximum dose recommended by the product labeling for a single application.
2. Determine the amount of the active ingredient(s) in each portion of the product using any appropriate validated quantitative procedure, and evaluate the test results from the single tube using the *Stage 1* acceptance criteria outlined in number *3*.
3. *Stage 1* acceptance criteria are met if:
   - None of the 3 results are outside of the product assay range, and
   - The maximum difference in the amount of active ingredient(s) determined within the tube is NMT 10.0%. For example, if the 3 measurements within the tube are 97.0%, 95.2%, and 99.7%, the maximum difference would be 4.5% (i.e., 99.7% – 95.2% = 4.5%).
4. Proceed to *Stage 2* testing if *Stage 1* acceptance criteria are not met and none of the test results are outside the product assay range by more than 5.0% (e.g., if the product assay range is 90.0%–120.0%, the range will be 85.0%–125.0%), and the maximum difference in the amount of active ingredient(s) measured within the tube is NMT 10.0%. An example of a product that fails to meet *Stage 1* criteria: if the highest and lowest assay values were 106.0% and 94.7% of label claim, then the difference would be 106.0% – 94.7% = 11.3%.
5. Proceed to *Stage 3* testing if *Stage 1* acceptance criteria are not met, *Stage 2* acceptance criteria cannot be met, NMT 1 of the 3 test results is outside of the product assay range by more than ±5.0%, and the maximum difference of the amount of active ingredient(s) measured within the tube is NMT 15.0%.

STAGE 2:

1. Test an additional 2 tubes for *Visual uniformity* and *Uniformity of active ingredient(s)* for a total of 3 samples each from 3 tubes.
2. Determine the amount of the active ingredient(s) in each portion of the product using any appropriate validated quantitative procedure, and evaluate the test results from the 3 tubes using the *Stage 2* acceptance criteria.
3. *Stage 2* acceptance criteria are met if:
   - The *Visual uniformity* test is met for all tubes;
   - None of the 9 results (i.e., 3 each from 3 tubes) are outside of the product assay range by NMT 5.0%; and
   - The maximum difference of the amount of active ingredient(s) measured within each tube, for each of the samples tested, is NMT 10.0%.
4. Proceed to *Stage 3* testing if NMT 1 of the 9 test results is outside of the product assay range by ±5.0% and/or the maximum difference between the amount(s) of active ingredient(s) measured within each tube is more than 10% but NMT 15.0%.

DOI: https://doi.org/10.31003/USPNF_M4033_08_01

STAGE 3:

1. If *Stage 2* has been completed, test an additional 7 tubes for *Visual uniformity* and *Uniformity of active ingredient(s)* for a total of 3 samples each from 10 tubes. If *Stage 2* was skipped, test an additional 9 tubes for *Visual uniformity* and *Uniformity of active ingredient(s)* for a total of 3 samples each from 10 tubes.
2. Determine the amount of active ingredient(s) in each portion of the product using any appropriate validated quantitative procedure, and evaluate the test results from the 10 tubes using the *Stage 3* acceptance criteria as outlined in number *3*.
3. *Stage 3* acceptance criteria are met if:
    - The *Visual uniformity* test is met for all tubes;
    - NMT 1 of the 30 test results is outside of the product assay range by ±5.0%; and
    - The maximum difference of the amount of active ingredient(s) measured within each tube, for each of the 10 tubes tested, is NMT 15.0%.

*For multiple-unit tubes that contain less than 5 g of product*

STAGE 1:

1. Using a single tube, after performing the test for *Visual uniformity*, remove an appropriate amount of product from the top (i.e., cap end) and bottom (i.e., seal end) portions of the tube. The sample size should be sufficient for at least one quantitative determination of the active ingredient(s) and should not exceed the maximum dose recommended by the product labeling for a single application.
2. Determine the amount of the active ingredient(s) in each portion of the product using any appropriate validated quantitative procedure, and evaluate the test results from the tube using the *Stage 1* acceptance criteria outlined in number *3*.
3. *Stage 1* acceptance criteria are met if:
    - Neither result is outside of the product assay range; and
    - The difference between the amount of active ingredient(s) determined for the 2 samples within the tube tested is NMT 10.0%. For example, if the 2 measurements within a tube were 95.2% and 89.7%, the difference would be 5.5%.
4. Proceed to *Stage 2* testing if *Stage 1* acceptance criteria are not met and neither of the test results are outside the product assay range by more than ±5.0% (e.g., if the product assay range is 90.0%–120.0%, the range will be 85.0%–125.0%), and the difference between the amounts of active ingredient(s) measured within the tube is NMT 10.0%.
5. Proceed to *Stage 3* testing if *Stage 1* acceptance criteria are not met, *Stage 2* acceptance criteria cannot be met, NMT 1 of the test results is outside of the product assay range by more than ±5.0%, and the difference between the amounts of active ingredient(s) measured within the tube is NMT 15.0%.

STAGE 2:

1. Test an additional 2 tubes for *Visual uniformity* and *Uniformity of active ingredient(s)* for a total of 2 samples each from 3 tubes.
2. Determine the amount of the active ingredient(s) in each portion of the product using any appropriate validated quantitative procedure, and evaluate the test results from the 3 tubes using the *Stage 2* acceptance criteria as outlined in number *3*.
3. *Stage 2* acceptance criteria are met if:
    - The *Visual uniformity* test is met for all tubes;
    - None of the 6 test results (i.e., 2 each from 3 tubes) are outside of the product assay range by ±5.0%; and
    - The difference between the amount of active ingredient(s) determined for the 2 samples within each tube, for each of the 3 tubes tested is NMT 10.0%.
4. Proceed to *Stage 3* testing if NMT 1 of the 6 test results is outside of the product assay range by ±5.0%, and/or the maximum difference between the amount(s) of active ingredient(s) measured within each tube is more than 10% but NMT 15.0%.

STAGE 3:

1. If *Stage 2* has been completed, test an additional 7 tubes for *Visual uniformity* and *Uniformity of active ingredient(s)* for a total of 2 samples each from 10 tubes. If *Stage 2* was skipped, test an additional 9 tubes for *Visual uniformity* and *Uniformity of active ingredient(s)* for a total of 2 samples each from 10 tubes.
2. Determine the amount of active ingredient(s) in each portion of the product using any appropriate validated quantitative procedure, and evaluate the test results from the 10 tubes using the *Stage 3* acceptance criteria as outlined in number *3*.
3. *Stage 3* acceptance criteria are met if:
    - The *Visual uniformity* test is met for all tubes;
    - 19 of 20 test results are within ±5.0% of the product assay range; and
    - The difference between the amount of active ingredient(s) determined for the 2 samples within each tube, for each of the 10 tubes tested, is NMT 15.0%.

## PRODUCTS PACKAGED IN CONTAINERS OTHER THAN TUBES

For semisolid products packaged in a container other than a tube when the sampling method presented previously cannot be used, other sampling methods are acceptable, such as this method described for a jar:

1. Select a suitable syringe of sufficient length to extend to the bottom of the container.

DOI: https://doi.org/10.31003/USPNF_M4033_08_01
@2024 USPC

2. Remove and set aside the syringe plunger, and cut off the bottom of the syringe barrel. Sampling should take place from a location to the left or right of the mid-line of the jar surface to preserve an undisturbed region on the other side for any additional investigation (see *Figure 1*).

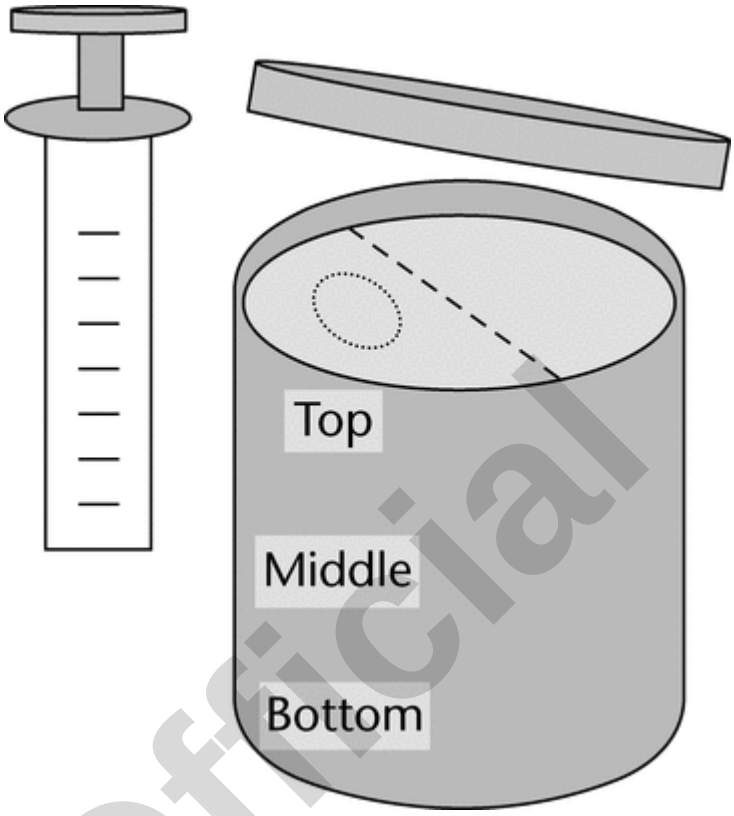

Figure 1. Sampling from a jar container.

3. Slowly push the syringe barrel into the container until it reaches the bottom. Then twist the syringe barrel containing the sample core, and remove the syringe from the container.
4. Insert the syringe plunger into the barrel, and carefully extrude the sample core onto a clean surface in three equal portions to represent the top, middle, and bottom portions of the container.
5. Remove an appropriate sample representative of the top, middle, and bottom portions of the container samples, and test according to the instructions outlined in *Products Packaged in Tubes*.

## Delivered-Dose Uniformity in Metered-Dose Containers

The test for delivered-dose uniformity is required for drug products contained either in metered-dose containers or in premetered-unit presentations. The test for delivered-dose uniformity includes dose uniformity over the entire unit shelf life. Select 1 container. Using separate collection vessels, quantitatively collect delivered doses representing the initial, middle, and the final dose from the container. Appropriately discard doses not collected for testing. Determine the drug substance content of each of the 3 collected samples using an appropriate and validated quantitative procedure or the procedure indicated in the individual monograph. A dose in this test is defined as the minimum recommended number of actuations specified in the product labeling or in the instructions for use but NMT 2 actuations. The target-delivered dose is specified by the product label claim, unless otherwise specified in the individual monograph.

## In-Process Testing

### PUMP FUNCTIONALITY TEST FOR METERED- AND NON-METERED-DOSE CONTAINER CLOSURES

This test is conducted during product development to establish that the airless pumps are performing as intended. This test is product dependent. Therefore, it is part of the manufacturer's controls for the drug product and it is not included in compendial drug product monographs.

During the filling process for semisolid or liquid products packaged in a non-metered-dose container closure requiring an actuator to dispense the product (for example, an airless pump container), in-process testing to verify pump functionality should be examined. Example tests include pumps to prime and total amount dispensed.

# SPECIFIC TESTS FOR TDS

TDS are formulated with an adhesive layer to ensure intimate contact with the skin and allow the delivery of the desired dose of the drug. Adhesives in TDS must permit easy removal of the release liner before use, adhere properly to human skin upon application, maintain adhesion to the skin during the prescribed period of use, and permit easy removal of the TDS at the end of use without leaving a residue or causing damage to the skin or other undesirable effect(s). Additionally, adhesives must be able to maintain the performance of the TDS throughout the shelf life of the drug product.

Testing of the physical properties of the TDS generally include peel adhesion, release liner peel, tack, cold flow, shear, and crystal formation (see *Crystal Formation*). The peel adhesion, release liner peel, and tack tests measure the adhesion properties of the TDS. Each of these tests measures the force required to separate the TDS from another surface. The cold flow and shear tests measure the cohesive properties of the TDS. These latter tests measure the resistance to flow of the adhesive matrix.

Acceptance criteria are product specific and defined to ensure that adhesion of each batch of TDS is within the range defined by the product design and is consistent between batches based on the product development specifications. Acceptance criteria should be established using in vitro testing results of representative batches, including clinical batches for which satisfactory in vivo adhesion performance has been demonstrated. Release and shelf life limits should be the same, unless justified.

In addition to physical testing, this section also discusses the *Leak Test* applicable to form-fill-seal-type (reservoir or pouched) TDS.

## Peel Adhesion Test

This test measures the force required to remove (peel away) a TDS attached to a standard substrate surface (e.g., polished stainless steel). The TDS is applied to the substrate using specified techniques for application and is conditioned at a specified temperature and time. Then the TDS is peeled away from the substrate with an instrument that allows for control of the peel angle (e.g., 90° or 180°) and peel rate (e.g., 300 mm/min), and the force profile is recorded. This procedure is repeated using a minimum of 5 independent samples yielding results from a suitable method. The product fails the test if the overall mean adhesion force is outside of the acceptable range determined during product development. During method development, suitable methods (including test panel surface) need to be identified. The method should allow the TDS to be removed entirely and cleanly, leaving no visually noticeable matrix residue on the substrate surface (i.e., an indication of adhesive failure).

Other failure modes (e.g., delamination at an interface, cohesive failure, etc.) are not indicative of true peel adhesion. The method should be developed to ensure an adhesive failure mode. Suitable methods do not result in undesired adhesion failures, including delamination at an interface (e.g., between a membrane and an adhesive layer or between two different adhesive layers of a bilayer product) or transfer of adhesive to the test panel (i.e., cohesive failure).

Release and shelf life limits should be the same, unless justified.

The geometry of a TDS (e.g., round or rectangular shaped) and its design (e.g., TDS with different surfaces such as an inner part and with a peripheral adhesive ring) should be considered in the method.

The substrate surface should be cleaned regularly and checked for scratches, as this may influence test results.

## Release Liner Peel Test

This test measures the force required to separate the release liner from the adhesive layer of the TDS. The test is performed with a finished product sample. The test sample is conditioned using specific procedures (temperature and time). Then, the release liner is pulled away from the TDS with an instrument that allows for control of the peel angle (e.g., 90° or 180°) and peel rate (e.g., 300 mm/min), and the force profile is recorded. This procedure is repeated using a minimum of 5 independent samples. The product fails the test if the ▲overall▲ (ERR 1-Dec-2023) mean peel force is outside the acceptable range determined during product development.

## Tack Test

A few tack test methods have been developed and the current predominantly used method is the probe tack method. It is up to the TDS manufacturer to decide which tack test is most appropriate for each drug product. The product fails the test if the overall mean of the maximum (tack) force results, using a minimum of 5 independent samples, is outside the acceptable range determined during product development. For additional discussion on the probe tack method, see *Probe Tack Test* ⟨1212⟩.

## Cold Flow Test

Cold flow is the migration of the adhesive matrix beyond the edge of the TDS backing, and through the slit in the release liner, which may occur during the course of product processing and storage. Cold flow is an inherent property of TDS due to the use of pressure-sensitive adhesives that flow when force is applied (i.e., if the adhesive matrix did not flow, the TDS would not stick). The magnitude of the cold flow is generally dependent on the product formulation, packaging design, storage conditions, and storage time. Cold flow should be assessed using a combination of quantitative and qualitative methods. No single quantitative method has been identified to work universally for all TDS. The TDS manufacturer should determine the most suitable cold flow test, or tests, as cold flow may manifest differently for different products. Several different cold flow tests have been developed. Examples include the following:

- Linear measurement of the radial cold flow using microscopy
- Measuring the distance of migrated adhesive matrix at predefined and evenly spaced positions of a TDS

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M4033_08_01

@2024 USPC

- Measuring cold flow by applying a reference plate in the size of the TDS plus the acceptable cold flow
- Swabbing and stripping the migrated part of the matrix and determining it gravimetrically or by assay of the drug substance
- Die cutting and punching out the original size of the TDS and determining the amount of migrated matrix on the outside
- Overall area determining methods of cold flow using image analysis tools

Acceptance criteria are product specific and defined to ensure that the cold flow of each batch of TDS is within the range determined during product development and is consistent between batches.

## Shear Test

The shear test measures the cohesive strength of a TDS. It can be measured under static (see *Static Shear Test*) or dynamic conditions. Shear testing may not be feasible for all TDS because the presence of multiple layers of adhesive in the system, the presence of a membrane or scrim, or the use of an emulsion adhesive system may result in the inability to achieve cohesive failure. TDS that are constructed with a peripheral adhesive ring or form-fill-seal TDS may not be suitable for this test. The TDS manufacturer should decide if a shear test is appropriate, and if so, which shear test is most appropriate for each drug product. Acceptance criteria are product specific and defined to ensure that the shear of each batch of TDS is within the range determined during product development and is consistent between batches.

## Static Shear Test

For the static shear test, the time required to remove a standard area of the TDS from the substrate (i.e., stainless steel test panel) under a standard load (e.g., 250 g) is measured. The TDS is applied to a test panel, and the sample is subjected to a shearing force by means of a given weight suspended from the TDS. The test apparatus holds the test panels at 0°–2° from vertical to ensure that the TDS will not experience peeling action when the weight is attached. Dwell time, weight used, test panel type, mode of failure, and sample size should be noted; the time taken for the TDS sample to detach from the test panel is reported. Cohesive failure, i.e., adhesive matrix is left on the TDS and on the substrate plate, should occur. Suitable methods do not result in undesired adhesion failures, including delamination at an interface, e.g., between a membrane and an adhesive layer, or between two different layers of a bilayer product.This procedure is repeated using a minimum of 5 independent samples yielding results from a suitable method. The product fails the test if the overall mean result, i.e., arithmetic mean or geometric mean as determined by the manufacturer, of each TDS batch is outside of the range determined during product development.

## Leak Test

This test is applicable only for form-fill-seal-type (reservoir or pouched) TDS. Form-fill-seal TDS must be manufactured with zero tolerance for leaks because of their potential for dose dumping if leaking occurs.

In-process control methods to examine TDS for leaks or potential leaks are needed and require considerable development on the part of TDS manufacturers.

### IN-PROCESS TESTING

During the manufacturing process, the presence of leakage (or potential for leakage) due to TDS perforation, cuts, and faulty seals resulting from failures such as air bubbles, gel splash, or misalignment of a TDS backing and release liner layers must be examined. Unless automated process analytical technology is implemented, in-process testing to identify these defects should be performed using the following test procedures.

**Visual inspection:**

- A specified number of TDS, defined on the basis of batch size, should be examined randomly.
- Each sampled TDS should be thoroughly visually inspected for leakage.
- The product fails if any of the TDS examined are detected with a leak.

**Seal integrity:** TDS seals should be stress tested to ensure that the application of pressure does not force seals to open, thereby leading to leakage.

- A specified number of TDS, defined on the basis of batch size, should be randomly examined.
- Each sampled TDS should be thoroughly visually inspected for leakage.
- Each sampled TDS is placed on a hard, flat surface and overlaid with a weight so that it is subjected to 13.6 kg. The weight should be left in place for 2 min. Upon removal of the weight, the TDS should be visually inspected for leakage.
- The product fails if the number of TDS detected with a leak is greater than the acceptable limit established by the manufacturer.

**Packaged product testing:** TDS may leak after they have been individually placed in the primary packaging material as a result of the packaging operation itself or by a user opening the packaging. Therefore, TDS should be tested for leakage after they have been manufactured and packaged in their primary packaging material.

- A specified number of TDS, defined on the basis of batch size, should be randomly examined after they have been placed in their primary packaging material.
- The sampled TDS should be removed from their packaging and thoroughly visually inspected for leakage.
- Each sampled TDS should then be uniformly wiped with a solvent-moistened swab. Both the backing side and the release liner side of the TDS should be wiped. The inside surface of the pouch should also be wiped. The swab(s) is then extracted and assayed for the drug.

Official

https://pharmacopeia.cn/

- The product fails if the total amount of drug from the TDS, and the corresponding pouch, exceed the acceptable limit established by the manufacturer.

# ⟨4⟩ MUCOSAL DRUG PRODUCTS—PRODUCT QUALITY TESTS

## INTRODUCTION

The mucosal route of drug administration is subdivided into seven membrane surfaces for the purposes of taxonomic distinction of dosage forms by route of administration. These membrane surfaces are characterized as otic, ophthalmic, nasal, oropharyngeal, urethral, vaginal, and rectal. This grouping does not include the pulmonary mucosal route addressed in *Inhalation and Nasal Drug Products—General Information and Product Quality Tests* ⟨5⟩. A drug product is administered to any of these seven mucosal surfaces to effect either local action or systemic absorption. Local action is to the area proximate to application. Where local action is intended, systemic absorption is not typically desired and is unnecessary for therapeutic effect. In some cases, however, the mucosal delivery of a drug for systemic absorption is used because it avoids first-pass metabolism, it provides more rapid systemic delivery, or it provides an alternative when oral delivery (to the gastrointestinal tract) is not possible due to a disease state. A large number of the dosage forms listed in *Pharmaceutical Dosage Forms* ⟨1151⟩ can be delivered by way of the various membrane surfaces in the mucosal category. [NOTE—All references to chapters above 1000 are for informational purposes only, for use as a helpful resource. These chapters are not mandatory unless explicitly called out for application.]

Analytical procedures and acceptance criteria for testing drug products are divided into two categories: those that assess general product quality attributes and those that assess product performance. Drug product quality tests assess attributes such as identification, assay (strength), dose content uniformity, and impurities and are usually part of the compendial monograph. Product performance tests include the dissolution test for a solid oral dosage form, *Dissolution* ⟨711⟩, and the drug release test, *Drug Release* ⟨724⟩. Taken together, quality and performance tests ensure the identity, strength, quality, and purity of a mucosal drug product.

This chapter provides lists of consolidated common product quality test requirements in a concise and coherent fashion. This chapter applies, in part or in its entirety, when referenced in a drug product monograph (see *General Notices, 3.10 Applicability of Standards*). The quality tests listed can be used, as appropriate, by manufacturers toward the development of new drug product monographs for submission to the *USP*.

## PRODUCT QUALITY TESTS FOR MUCOSAL DRUG PRODUCTS

This chapter provides product quality tests that are generally necessary, tests that apply to specific products, and tests that apply to one or more of the specific mucosal routes. Quality tests listed under a specific mucosal route in this chapter represent expectations for any dosage form administered by that specific route.

### Generally Necessary Tests

Product quality attributes for mucosal dosage forms should reflect acceptable requirements for marketed products. The following tests should be generally applied to all dosage forms intended for mucosal delivery. Tests that are generally necessary for any article include: *Definition*, *Identification*, *Assay*, and *Impurities* (organic, inorganic, and residual solvents). *Uniformity of Dosage Units* ⟨905⟩ is typically included in a *USP* product monograph.

#### DEFINITION

The definition section (see *General Notices, 4.10 Monographs*) in a *USP* monograph describes the drug product and specifies the range of acceptable assayed content of the drug substance(s) present in the dosage form. For certain products, the definition includes any relevant additional information, such as the presence or absence of other components, excipients, or adjuvants, and cautionary statements on toxicity and stability. Appearance information is used in a regulatory submission to aid in product identification. Because the size, shape, color, and other attributes are attributes of individual marketed products, a qualitative description is typically not required as part of a *USP* monograph (see ⟨1151⟩).

#### IDENTIFICATION

Identification is included in a monograph as an aid in verifying the identity of the article (see *General Notices, 5.40 Identification*.)

#### ASSAY

The assay is used to determine the strength (content) of the drug product. Typically, the assay is specific and stability-indicating. When a nonspecific assay is justified, other supporting analytical procedures should ensure that any interfering species will be detected and can be limited. Assay results are often reported as a percentage of the label claim, with acceptance criteria that are typically in the range from 90.0% to 110.0%. For some antibiotic products, the range may be wider. The width of these limits is intended to allow for manufacturing variability, including changes in stability, as well as analytical variation. The narrower acceptance range of 95.0%–105.0% is used less often and with justification.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M8626_02_01
@2024 USPC

### IMPURITIES

Process impurities include those arising from starting materials, synthetic byproducts, and other inorganic and organic impurities that may be present in the drug substance and in the excipients used in the manufacture of the drug product. These impurities are limited, as specified within the drug substance and excipient monographs. Impurities in the drug product may also result from degradation of the drug substance or excipients, from interactions between the drug substance and an excipient, or from interactions between the drug substance and the packaging components. The procedures and acceptance criteria should specifically limit toxic degradation products as well as degradation products that compromise the quality of the article if they exceed certain levels. A more complete discussion of impurities is provided in *Impurities in Drug Substances and Drug Products* ⟨1086⟩ [1] and in ICH Q3B Impurities in New Drug Products.[1]

### UNIFORMITY OF DOSAGE UNITS

Chapter ⟨905⟩ is used to ensure the consistency of drug substance content in dosage units within a narrow range around the label claim. The test is applied only to dosage forms containing a single dose or a part of a dose of the drug substance in each unit. Uniformity of dosage units may be demonstrated by one of two methods: content uniformity or weight variation. Content uniformity is based on the assays of a number of individual dosage units. Weight variation can be used to estimate content uniformity under certain conditions.

## Dosage Forms by Specific Mucosal Route and Product-Specific Tests

In addition to the generally necessary product quality tests already discussed, the dosage form may require specific quality tests that are common across routes of administration. *Injections and Implanted Drug Products* ⟨1⟩ provides testing requirements common to injectable and implantable products. *Oral Drug Products—Product Quality Tests* ⟨2⟩ provides testing requirements for tablets and lozenges. *Topical and Transdermal Drug Products—Product Quality Tests* ⟨3⟩ provides testing requirements common to semisolids (creams, ointments, and gels). Chapter ⟨5⟩ presents testing requirements for sprays and aerosols. Where a dosage form has no specific test given in this chapter, no additional test is required unless included in the individual monograph specification.

### OTIC ROUTE

The otic route is characterized by administration of a preparation into, or by way of, the ear. Demonstration of sterility (see *Sterility Tests* ⟨71⟩) is not always required for products delivered to the ear. Typically, sterility is required where the product is administered to the inner ear or where the eardrum is damaged. Where sterility is not required, the quantitative enumeration of mesophilic bacteria and fungi that grow under anaerobic conditions, *Microbial Enumeration Tests* ⟨61⟩, or the determination of the absence or limited occurrence of specified organisms, *Tests for Specified Microorganisms* ⟨62⟩, may be required.

If an antimicrobial preservative is used, *Antimicrobial Effectiveness Testing* ⟨51⟩ and *Antimicrobial Agents—Content* ⟨341⟩ may be required.

Dosage forms given by the otic route include liquids, solutions, and suspensions.

### OPHTHALMIC ROUTE

The ophthalmic route is to the eye. In addition to the generally necessary tests, the following specific tests for ophthalmic drug products should be considered (see *Table 1*). For products that are injected or implanted into the eye, see ⟨1⟩. Some of the important product quality tests for products administered by the ophthalmic route are listed below. See *Ophthalmic Products—Quality Tests* ⟨771⟩ for details and other product quality information.

- Particulate and Foreign Matter
- Sterility
- Particle Size and Particle Size Distribution
- Antimicrobial Preservative

| Sprays | ⟨5⟩ |
| Solutions | ⟨5⟩ |

## OROPHARYNGEAL ROUTE

The oropharyngeal route is into the oral cavity and/or pharyngeal region. The oropharyngeal route is subclassified by the specific intra-oral surfaces, such as buccal or sublingual. Buccal and sublingual administrations are typically intended to promote systemic absorption by permeation through the respective mucosa. However, in this context, oral administration may mean topical application for local action (see *Table 3*). Product quality tests for products administered to oropharyngeal surfaces often conform to those for oral administration to the gastrointestinal tract (see ⟨2⟩).

## URETHRAL ROUTE

The urethral route is into the urethra, typically for local action, but systemic distribution is also possible. Chapters ⟨61⟩ and ⟨62⟩ may apply. Drug products in this category include urethral inserts.

## VAGINAL ROUTE

The vaginal route is into the vagina, typically for local action, but systemic distribution is also possible. Chapters ⟨61⟩ and ⟨62⟩ may apply (see *Table 4*).

**Relative foam density:** Determine relative foam density by weighing a mass of foam (*m*) and a mass of the same volume of water (*e*) in a flat-bottom dish. Relative foam density = *m*/*e*.

**Volume of foam expansion:** Estimate the volume of foam expansion at 25° using a graduated buret and a foam-generating container equipped with a dose-actuating device and fitted to the buret.

**Table 4. Drug Products Administered by the Vaginal Route, with Product-Specific Tests**

| Gels | ⟨755⟩ |
| | ⟨3⟩ |
| Inserts | Currently no specific tests (additional specific monograph requirements may apply) |

## RECTAL ROUTE

The rectal route is into the rectum. Rectally administered products may produce local effect(s) or delivery to the systemic circulation.

**Softening time of lipophilic suppositories:** The test is intended to determine, under defined conditions, the time that elapses until a suppository maintained in water at 37 ± 0.5° softens to the extent that it no longer offers resistance when a defined weight is applied (see *Table 5*).

# ⟨5⟩ INHALATION AND NASAL DRUG PRODUCTS—GENERAL INFORMATION AND PRODUCT QUALITY TESTS

***Change to read:***

## 1. INTRODUCTION

Inhalation drug products deliver drugs into the lungs by oral inhalation and include inhalation aerosols, inhalation powders, inhalation sprays, inhalation solutions, inhalation suspensions, solutions for inhalation, and drugs for inhalation solutions dosage forms. Nasal drug products deliver drugs into the nasal cavity and include nasal sprays, nasal solutions, nasal aerosols, and nasal powder dosage forms. This chapter does not address nasal products in gel and ointment form. See *Table 1* for established names and definitions of these dosage forms. Definitions of these drug product dosage forms, brief information about their manufacture, and a glossary of dosage form names can be found in *Pharmaceutical Dosage Forms* ⟨1151⟩. [NOTE—All references to general information chapters are for informational purposes only, for use as a helpful resource. See *General Notices, 3.10 Applicability of Standards* for further information on the applicability of *USP* standards pertaining to a specific monograph requirement.]

**Table 1. Established Names and Definitions**

| Established Name | Definition |
|---|---|
| Inhalation Aerosol | A drug product for oral inhalation that is packaged under pressure, aerosolizes, and delivers a specified amount of active ingredient(s) upon activation of an accurate metering valve system in association with an actuator mechanism. Inhalation aerosol drug products are more commonly known as metered-dose inhalers or MDIs. |
| Inhalation Powder | Drug powder for oral inhalation with the use of a device that aerosolizes and delivers an accurately metered amount of active ingredient(s). Inhalation powder drug products are more commonly known as dry powder inhalers or DPIs. |
| Inhalation Spray | A nonpressurized liquid, sterile (if aqueous-based) drug dosage form for oral inhalation that is packaged in a container–closure system that upon activation aerosolizes and delivers in fine droplets of formulation an accurately metered amount of active ingredient(s). |
| Inhalation Solution | A sterile drug solution for oral inhalation with the use of a nebulization system. |
| Inhalation Suspension | A sterile drug suspension for oral inhalation with the use of a nebulization system. |
| Solution for Inhalation | A sterile drug solution for oral inhalation that must be diluted before it is administered with the use of a nebulization system. |
| [Drug] for Inhalation Solution | A sterile drug powder that, upon the addition of a suitable vehicle, yields a sterile solution conforming in all respects to an inhalation solution. |
| Nasal Spray | A nonpressurized, accurately metered, liquid drug dosage form for local application into the nasal passages that is packaged in a container–closure system that upon activation aerosolizes and delivers in droplets of formulation an accurately metered amount of active ingredient(s). |
| Nasal Aerosol | A drug product for local application into the nasal passages that is packaged under pressure, aerosolizes, and delivers a specified amount of active ingredient(s) upon activation of an accurate metering valve system in association with an actuator mechanism. |
| Nasal Solution | A nonpressurized, liquid drug dosage form for local application into the nasal passages. |
| Nasal Powder | Drug powder for local application into the nasal passages with the use of a device that aerosolizes and delivers an accurately metered amount of active ingredient(s). |

This chapter provides lists of consolidated common product quality test requirements in a concise and coherent fashion. This general chapter applies, in part or in its entirety, when referenced in a drug product monograph (see *General Notices, 3.10 Applicability of Standards*) and includes the quality tests for the specific route of administration. The quality tests listed can be used, as appropriate, by manufacturers toward the development of new drug product monographs for submission to the *USP–NF*. If a validated performance test procedure is available for the specific drug product, it is identified in a general chapter below 1000. Additional information, or information on promising technologies that have not yet been fully validated, may be presented in general information chapters.

### Drug Product General Quality Tests and Performance Quality Tests

A *USP* drug product monograph contains tests, analytical procedures, and acceptance criteria. Drug product tests are divided into two categories: 1) general quality tests; and 2) product performance tests, e.g., delivered dose uniformity and its physical characteristics such as aerodynamic particle size distribution and/or droplet ▲(or particle)▲ (USP 1-Aug-2023) size distribution. General

Official

https://nhathuocngocanh.com/

quality tests assess the integrity of the dosage form, whereas product performance quality tests assess delivery of the drug and other attributes that may relate to in vivo drug performance.

Taken together, general quality and product performance tests ensure the identity, strength, quality, and purity of inhalation and nasal drug products.

The next two sections of this chapter list product quality attributes for inhalation drug products and for nasal drug products, respectively. The final section describes in greater detail the quality tests for inhalation and nasal drug products. *Inhalation and Nasal Drug Products: Aerosols, Sprays, and Powders—Performance Quality Tests* ⟨601⟩ contains product performance tests for inhalation and nasal drug products and ▲*Products for Nebulization—Characterization Tests* ⟨1601⟩ contains performance tests for nebulization products. These two chapters should be used in conjunction with this chapter, ⟨5⟩, as applicable.▲ (USP 1-Aug-2023)

## 2. GENERAL QUALITY TESTS FOR INHALATION DRUG PRODUCTS

### Inhalation Aerosol

DESCRIPTION

Aerosol in this context is a dosage form consisting of a liquid preparation packaged under pressure and intended for administration as a fine mist. The descriptive term "aerosol" also refers to the fine mist of small droplets and/or solid particles that are emitted from the product. Inhalation aerosols, also known as metered-dose inhalers (MDIs), are preparations characterized by dispersion of the active pharmaceutical ingredient into the airways during oral inspiration for either local or systemic effect, and nasal aerosols, also known as nasal MDIs, are characterized by deposition in the nasal cavity for either local or systemic effect.

An aerosol formulation typically contains a drug substance(s) dissolved or suspended in a propellant or a mixture of propellant(s) and co-solvent(s) and possibly other suitable excipients. An inhalation aerosol drug product delivers a specified amount and quality of therapeutically active ingredient(s) upon activation of an accurate metering valve system. General quality tests for inhalation aerosol drug products include the following attributes (see *4. Description of Product Quality Tests* for more detailed discussions of each test):

- *Assay (strength and content uniformity)*
- *Co-Solvent Content [(e.g., ethanol) if present]*
- *Elemental Impurities*
- *Foreign Particulate Matter*
- *Identification*
- *Impurities and Degradation Products*
- *Leachables*
- *Leak Rate*
- *Microbial* ▲*Quality*▲ (USP 1-Aug-2023)
- *Net Fill Weight*
- *Residual Solvents*
- *Spray Pattern*
- *Valve Delivery*
- *Water Content*
- For performance quality tests, refer to ⟨601⟩

### Inhalation Solution

DESCRIPTION

Inhalation solution drug products typically are water-based sterile preparations. They are intended for delivery to the lungs by nebulization with a specified nebulizer. Such drug preparations typically are packaged in single-dose semipermeable containers within protective packaging to minimize ingress of volatile foreign contaminants, loss of solvent, and exposure to oxygen and light. Nebulization involves continuous generation and delivery to the patient of a fine mist of aqueous droplets containing a drug solution by means of ultrasonic energy, Venturi effect, or other appropriate mechanical/electrical means. General quality tests for inhalation solutions include the following attributes (see *4. Description of Product Quality Tests* for more detailed discussions of each test):

- *Assay (strength and content uniformity)*
- *Assay for Antimicrobial Preservative and Stabilizing Excipients (if present)*
- *Content Uniformity for Premetered Dosage Forms*
- *Elemental Impurities*
- *Foreign Particulate Matter*
- *Identification*
- *Impurities and Degradation Products*
- *Leachables*

## Inhalation Suspension

DESCRIPTION

Inhalation suspension drug products typically are water-based sterile preparations. They are intended for delivery to the lungs by nebulization with a specified nebulizer. Such drug preparations typically are packaged in single-dose semipermeable containers within protective packaging to minimize ingress of volatile foreign contaminants, loss of solvent, and exposure to oxygen and light. Nebulization involves continuous generation and delivery to the patient of a fine mist of aqueous droplets containing the formulation components by means of ultrasonic energy, Venturi effect, or other appropriate mechanical means. General quality tests for inhalation suspensions include the following attributes (see *4. Description of Product Quality Tests* for more detailed discussions of each test):

- *Primary Particle Size Distribution*
- For all other general quality attributes, refer to the previous *Inhalation Solution* attributes

## Solution for Inhalation

DESCRIPTION

Solution for inhalation drug products typically are water-based sterile preparations. Upon dilution, in accordance with labeling, including identity and amount of dilution vehicle, they are intended for delivery to the lungs by nebulization with a specified nebulizer. Such drug preparations typically are packaged in single-dose semipermeable containers within protective packaging to minimize ingress of volatile foreign contaminants, loss of solvent, and exposure to oxygen and light. Nebulization involves continuous generation and delivery to the patient of a fine mist of aqueous droplets containing the formulation components by means of ultrasonic energy, Venturi effect, or other appropriate mechanical/electrical means. General quality tests for solutions for inhalation include the following attributes (see *4. Description of Product Quality Tests* for more detailed discussions of each test):

- *Clarity and Color of Solution upon Dilution* in accordance with the labeling
- For all other general quality attributes, refer to the previous *Inhalation Solution* attributes

## Drug for Inhalation Solution

DESCRIPTION (POWDER)

Drug for inhalation solution is a (specified color) sterile drug powder formulation that upon the addition of a suitable vehicle, in accordance with labeling, including identity and amount of dilution vehicle, yields a sterile solution conforming in all respects to the *Inhalation Solution* requirements. General quality tests for drug for inhalation solutions include the following attributes (see *4. Description of Product Quality Tests* for more detailed discussions of each test):

- *Reconstitution Time (powder)*
- *Water Content*
- Clarity, color, and completeness of solution within specified time, upon reconstitution
- For all other general quality attributes, refer to the previous *Inhalation Solution* attributes upon (re)constitution of the drug product

## Inhalation Spray

DESCRIPTION

Inhalation spray drug products typically are water-based sterile formulations packaged in a compact container–closure system containing an integral spray pump unit that, upon activation, delivers an accurately metered amount of fine droplets of the formulation. The droplets can be generated by various means such as mechanical action, power assistance, or energy from the patient's inspiration. The mechanisms by which they generate droplets distinguish the various types of inhalation sprays. These drug products may be unit-dose or multidose presentations. Inhalation spray drug products may be designed as premetered or device-metered presentations. A premetered unit contains a previously measured amount of liquid formulation in an individual container (e.g., a blister) that is inserted in the device by the patient before use. A device-metered product contains a sufficient amount of liquid formulation for a prescribed number of doses in a reservoir, and each dose is delivered as an accurately

metered spray by the device throughout the unit's life. General quality tests for inhalation sprays include the following attributes (see *4. Description of Product Quality Tests* for more detailed discussions of each test):

- *Plume Geometry*
- For all other general quality attributes, refer to the previous *Inhalation Solution* attributes
- For performance quality tests, refer to ⟨601⟩

## Inhalation Powder

DESCRIPTION

Inhalation powder drug products, commonly known as dry powder inhalers (DPIs), dispense powders for inhalation with the use of a device that aerosolizes and delivers an accurately metered amount of active ingredient(s) with consistent physical characteristics alone or with a suitable excipient(s). Current designs include premetered and device-metered DPIs, all of which rely on various energy sources to create and disperse the aerosol during patient inspiration.

Premetered DPIs contain previously measured amounts of formulation in individual containers (e.g., capsules or blisters) that are inserted into the device before use. Premetered DPIs also may contain premetered dose units as ordered multidose assemblies in the delivery system. Device-metered DPIs have an internal reservoir that contains a sufficient quantity of formulation for multiple doses that are metered by the device itself during actuation by the patient. General quality tests for inhalation powders include the following attributes (see *4. Description of Product Quality Tests* for more detailed discussions of each test):

- *Assay (strength and content uniformity)*
- *Content Uniformity for Premetered Dosage Forms*
- *Elemental Impurities*
- *Foreign Particulate Matter*
- *Identification*
- *Impurities and Degradation Products*
- *Leachables*
- *Microbial* ▲*Quality*▲ (USP 1-Aug-2023)
- Net Content (device-metered)
- *Residual Solvents*
- *Water Content*

***Change to read:***

# 3. GENERAL QUALITY TESTS FOR NASAL DRUG PRODUCTS

## Nasal Aerosol

Refer to the above *Inhalation Aerosol* attributes.

## Nasal Spray

DESCRIPTION

Nasal spray drug products typically are water-based formulations applied to the nasal cavity for local and/or systemic effects. They contain therapeutically active ingredient(s) dissolved or suspended in solution or mixtures of excipients in a nonpressurized compact container–closure system. The container–closure system includes an integral spray pump unit that upon activation delivers an accurately metered amount of the formulation as a mist. Dispersion of the formulation as a spray typically is accomplished by forcing the formulation through the nasal actuator and its orifice. Often, such drug products are multidose device-metered (see *Inhalation Spray*) presentations in which the dose is metered by the spray pump. Nasal spray drug products also may be designed as premetered presentations. General quality tests for nasal sprays include the following attributes (see *4. Description of Product Quality Tests* for more detailed discussions of each test):

- *Assay (strength and content uniformity)*
- *Assay for Antimicrobial Preservative and Stabilizing Excipients (if present)*
- *Content Uniformity for Premetered Dosage Forms*
- *Elemental Impurities*
- *Foreign Particulate Matter*
- *Identification*
- *Impurities and Degradation Products*
- *Leachables*
- *Microbial* ▲*Quality*▲ (USP 1-Aug-2023)
- *Net Fill Weight*

### Nasal Powder

Refer to the previous *Inhalation Powder* quality attributes as applicable.

### Nasal Solution

DESCRIPTION

Nasal solutions are drug products that typically are water-based formulations applied to the nasal cavity for local effect. They may contain drug substance(s) dissolved in solution or mixtures of excipients in a nonpressurized compact container–closure system. The container–closure system includes a delivery system that administers nonmetered amounts of drops or a fine mist of droplets of the formulation. Typically, such drug products are multidose presentations. General quality tests for nasal solution drug products include the following attributes (see *4. Description of Product Quality Tests* for more detailed discussions of each test):

- *Assay (strength and content uniformity)*
- *Assay for Antimicrobial Preservative and Stabilizing Excipients (if present)*
- *Elemental Impurities*
- *Foreign Particulate Matter*

- *Viscosity*

***Change to read:***

## 4. DESCRIPTION OF PRODUCT QUALITY TESTS

Product quality tests are listed as follows and should be applied to inhalation and nasal drug products and to products for nebulization. Product-specific quality tests are addressed in product monographs.

### Assay (strength and content uniformity)

The *USP* assay test of a drug substance in the drug product container is determined by means of a validated stability-indicating procedure following *Validation of Compendial Procedures* ⟨1225⟩. The *USP* assay test should measure the amount of drug substance(s) in the unit and its stability throughout the expiration dating period, including adherence of the drug substance to the container–closure components. Appropriate acceptance criteria can provide added assurance of manufacturing reproducibility and may ensure better conformance in performance attributes (e.g., delivered dose uniformity).

If a drug product is labeled to contain a single enantiomer of a chiral drug substance, analysts can use a chiral assay or a combination of an achiral assay and a validated procedure to control the presence of the undesired enantiomer as an impurity.

### Assay for Antimicrobial Preservative and Stabilizing Excipients (if present)

The assay of any preservative (e.g., an antimicrobial) in a multidose container or stabilizing excipient (e.g., an antioxidant, an agent specifically added to minimize or prevent degradation) in a formulation should be determined analytically, typically with a validated stability-indicating procedure following the current International Council for Harmonisation ICH Q2 guidance. The assay acceptance criteria for antimicrobial preservatives normally are based on appropriate preservative effectiveness demonstrated by a microbial challenge test.

DocId: GUID-63942EFA-FA01-4046-BF63-7C0706FD3924_8_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M6156_08_01
@2024 USPC

## Clarity and Color of Solution upon Dilution

Solution for inhalation and drug for inhalation solution dosage forms must be diluted and reconstituted in accordance with labeling before administration by nebulization. The type and amount of the vehicle used for dilution and reconstitution must be specified on the labeling. Appropriate studies must be undertaken to fully assess quantitatively the clarity and color of the solution upon dilution and reconstitution. The studies also should include appropriate physical and chemical stability studies as well as studies of performance characteristics.

## Content Uniformity for Premetered Dosage Forms

See *Uniformity of Dosage Units* ⟨905⟩.

## Co-Solvent Content [(e.g., ethanol) if present]

If a co-solvent is used in a drug product formulation, a specific assay with appropriate acceptance criteria should be included.

## Description

See the previous descriptions corresponding to applicable dosage forms, outlined in *2. General Quality Tests for Inhalation Drug Products* and *3. General Quality Tests for Nasal Drug Products* of this chapter, in association with their container–closure delivery systems and the respective labeling statement of the monograph of a drug product. This test should address the appearance of the contents of the container (i.e., dosage form) and the appearance and integrity of the components of the container–closure system for conformance to their respective descriptions.

## Elemental Impurities

Drug products should be evaluated for elemental impurities (see *Elemental Impurities—Limits* ⟨232⟩). Validated analytical procedures should be used as described in *Elemental Impurities—Procedures* ⟨233⟩.

## Foreign Particulate Matter

▲Foreign particulate matter in these drug products should be adequately controlled. Particulate matter in inhalation and nasal drug products may originate during the manufacturing process and from formulation and container–closure components. Method approaches presented in *Particulate Matter in Injections* ⟨788⟩ and *Light Diffraction Measurement of Particle Size* ⟨429⟩ may be utilized with proper modifications. Following a detailed toxicological assessment of the type, origin, amount, and size of any foreign particulates in the 10–25 µm range, greater than 25-µm range, and fine particulates (e.g., 1–10 µm), appropriate specifications should be established throughout the expiration dating period to confirm overall quality.▲ (USP 1-Aug-2023)

## Identification

A specific identification test or tests are used to verify the identity of the drug substance in the drug product. If a nonspecific method is used for identification, then it should be combined with a second independent and complementary method. A specific identification test for polymorphic forms should be carried out, if applicable. Moreover, if the drug substance is a salt, an appropriate identification test also should be included for the counterion.

## Impurities and Degradation Products

Validated stability-indicating analytical procedure(s) following ⟨1225⟩ should be used to determine the levels of impurities and degradation products in a drug product. Typically, the acceptance criteria are set for ▲specified▲ (USP 1-Aug-2023), unspecified, and total impurities and degradation products following current ICH Q3B guidance. For reporting, identification, and qualification thresholds and other relevant information, follow current ICH Q3B and ICH M7 guidelines.

## Leachables

Inhalation and nasal drug products should be evaluated for compounds that may leach from elastomeric and plastic components and from coatings of components of the container–closure system in direct contact with the formulation. Additionally, the drug product inadvertently may contain other residual contaminants from manufacturing and processing. Leachables may include polynuclear aromatics, nitrosamines, monomers, plasticizers, accelerators, antioxidants, and vulcanizing agents. Processing contaminants may include surface treatment or processing agents that may dissolve, chemically associate, or become suspended in the formulation.

Thus, throughout the expiration-dating period, the drug product should be evaluated for compounds that can migrate into the formulation from a variety of sources. The type of testing that should be performed depends on whether the formulation is a powder or a liquid and the composition of the container–closure system, e.g., a drug product packaged in a semipermeable container should be evaluated for ingress of volatile leachables. Appropriate specifications using validated analytical procedures should be applied to identify, monitor, and quantify the compounds in the drug product with appropriate minimum levels of quantification. Corresponding acceptance criteria should be established and justified from toxicological and safety perspectives.

DOI: https://doi.org/10.31003/USPNF_M6156_08_01
@2024 USPC

▲For additional information and guidance on these and other quality control related issues including extract and leachables identification, characterization, analytical techniques, validation of quantitative leachables, specifications, as well as safety assessment approaches, refer to *Assessment of Extractables Associated with Pharmaceutical Packaging/Delivery Systems* ⟨1663⟩, *Assessment of Drug Product Leachables Associated with Pharmaceutical Packaging/Delivery Systems* ⟨1664⟩, and *Orally Inhaled and Nasal Drug Products* ⟨1664.1⟩.▲ (USP 1-Aug-2023)

## Leak Rate

Leak rate studies of inhalation and nasal aerosol drug products can be used during drug product development and characterization to support the selection of appropriate container–closure components (e.g., valve and canister) and drug product manufacturing parameters, including the crimping process and 100% heat stress test prior to the equilibration/quarantine period. Release and stability specifications for the USP leak rate test can include multiple units from each batch based on weight difference determination with time at a specified temperature. See *Leak Rate* ⟨604⟩ for additional information.

## Microbial ▲Quality▲ (USP 1-Aug-2023)

The microbial quality of dosage forms, where indicated in *2. General Quality Tests for Inhalation Drug Products* and *3. General Quality Tests for Nasal Drug Products*, normally is controlled by appropriate validated test(s) and acceptance criteria for total aerobic count, total yeasts and molds count, and freedom from ▲specified microorganisms.▲ (USP 1-Aug-2023) Acceptance criteria can be expressed on a per-container, ▲per-gram, or per-milliliter▲ (USP 1-Aug-2023) basis. Refer to ▲*Microbiological Examination of Nonsterile Products—Tests for Burkholderia cepacia Complex* ⟨60⟩,▲ (USP 1-Aug-2023) *Microbial Enumeration Tests* ⟨61⟩, ▲*Tests for Specified Microorganisms* ⟨62⟩,▲ (USP 1-Aug-2023) *Alternative Microbiological Sampling Methods for Nonsterile Inhaled and Nasal Products* ⟨610⟩, *Microbiological Examination of Nonsterile Products: Acceptance Criteria for Pharmaceutical Preparations and Substances for Pharmaceutical Use* ⟨1111⟩, and ▲*Bioburden Control of Nonsterile Drug Substances and Products* ⟨1115⟩▲ (USP 1-Aug-2023) for additional information.

## Net Fill Weight

The total net weight of the formulation in the container should be assessed and controlled with a test and acceptance criteria. See *Minimum Fill* ⟨755⟩ for additional information.

## Osmolality

To control the tonicity of the formulation of dosage forms, where indicated in *2. General Quality Tests for Inhalation Drug Products* ▲and in *3. General Quality Tests for Nasal Drug Products*,▲ (USP 1-Aug-2023) the product should be tested for osmolality with appropriate specifications as described in *Osmolality and Osmolarity* ⟨785⟩.

## pH

Appropriate specification for the pH of the formulation of dosage forms, where indicated in *2. General Quality Tests for Inhalation Drug Products* and *3. General Quality Tests for Nasal Drug Products*, should be established as described in *pH* ⟨791⟩.

## Primary Particle Size Distribution

For suspension preparation drug products, appropriate method(s) and corresponding acceptance criteria should be used for the determination of the particle size distribution of the drug substance particles in the formulation within the container. Microscopic examination of the product formulation provides information and changes over product stability on the presence of large particles, morphology of the drug substance and carrier particles, extent of agglomerates, crystal growth, and foreign particulate matters. Additionally, where the crystalline form of the drug substance can affect the bioavailability, performance, stability, or other properties of the drug product, microscopic evaluation or other appropriate methods are recommended to control and monitor the crystalline and amorphous forms if changes are observed on stability. See *Optical Microscopy* ⟨776⟩ for additional information. For aerodynamic particle size distribution and droplet size distribution tests of inhalation and nasal drug products, as applicable, refer to ⟨601⟩.

## Plume Geometry

Because various factors can affect the plume characteristics of the spray of an inhalation aerosol, inhalation spray, nasal aerosol, nasal spray, or nasal powder (if device is pump-dependent) drug product, its full characterization is important for assessing the performance of the delivery system. Plume geometry can be determined by a variety of procedures using appropriately validated methods. Plume geometry also can be controlled by appropriate acceptance criteria that measure spray pattern characteristics, including shape and size of the evolving spray plume under defined experimental and instrumental test conditions.

@2024 USPC

## Pump Delivery

A shot weight test (amount of formulation released per actuation) delivered from the individual pump of the drug product should be performed to better ensure reproducible performance of nasal spray drug products. Appropriate specifications for the pump delivery should be set.

## Reconstitution Time (powder)

Drug for inhalation solution dosage forms must be (re)constituted before administration with the use of a specified nebulization system. Hence, appropriate compatibility studies should be undertaken to fully assess the type and amount of the solvent(s), as well as (re)constitution time for preparation of the final solution for patient administration. The compatibility studies also should include appropriate physical and chemical stability studies on the reconstituted solution, including its performance characterization.

## Residual Solvents

Suitable and validated tests should be used to determine the levels of any solvent(s) in the drug product. Refer to *Residual Solvents* ⟨467⟩ for additional information.

## Spray Pattern

Because various factors can affect the spray pattern of an inhalation aerosol, nasal aerosol, or nasal spray drug product, full spray pattern characterization is important for assessing the performance of the specific valve and the actuator or the pump. The spray pattern can be determined using appropriately validated methods and corresponding acceptance criteria that measure the shape, density, and size of the pattern. The test procedure for spray patterns normally is specific to the drug product and may include, among others, the distance between the mouthpiece and the measurement plane or collection surface, minimum number of actuations per spray pattern to enable discrimination, orientation of the collection surface relative to the mouthpiece, and visualization procedure(s).

## Sterility

All aqueous-based inhalation dosage forms are sterile preparations and should meet the requirements of *Sterility Tests* ⟨71⟩.

## Valve Delivery

A shot weight test (amount of formulation released per actuation) delivered from the individual valve of the drug product should be performed to better ensure reproducible performance of inhalation and nasal aerosol drug products. Appropriate specifications for the valve delivery should be set.

## Viscosity

A test for viscosity with appropriate acceptance criteria should be included for dosage forms, where indicated in *2. General Quality Tests for Inhalation Drug Products* and *3. General Quality Tests for Nasal Drug Products*, as appropriate (see *Viscosity—Capillary Methods* ⟨911⟩, *Viscosity—Rotational Methods* ⟨912⟩, and *Viscosity—Rolling Ball Method* ⟨913⟩).

## Water Content

Appropriate specification for water content of dosage forms, where indicated in *2. General Quality Tests for Inhalation Drug Products* and *3. General Quality Tests for Nasal Drug Products*, should be established to ensure the drug product's continued stability and acceptable performance. Validated analytical procedures should be used as described in *Water Determination* ⟨921⟩. Proceed as directed in ⟨921⟩ with the following modification: provide the closed-system titrating vessel with an opening through which passes a coarse-porosity gas dispersion tube connected to a sampling cylinder.

## Weight Loss

Drug products should be evaluated for weight loss where applicable, e.g., drug products packaged in semipermeable containers, to assess the moisture-loss protective properties of the overall container–closure system.

Official

# ⟨7⟩ LABELING

## INTRODUCTION

This general chapter provides definitions and standards for labeling of official articles. Labeling standards for an article recognized in *USP–NF* are expressed in the article's monograph and applicable general chapters. It is intended that all articles in *USP* or *NF* will be subject to the labeling requirements specified in this chapter by means of a provision in *General Notices, 10 Preservation, Packaging, Storage, and Labeling*, unless different requirements are provided in a specific monograph. As with compendial standards for naming, identity, strength, quality, and purity, compendial requirements for labeling have a role in the adulteration and misbranding provisions of federal law [see the Federal Food, Drug, and Cosmetic Act (FDCA) sections 501(b), 502(e)(3)(b), 502(g), and 502(h)]. Exceptions or additional requirements specific to animal drug products and compounded preparations are provided in separate sections. Vaccine labeling is not included in this general chapter.

## DEFINITIONS

The term "labeling" includes all labels and other written, printed, or graphic matter on an article's immediate container or on, or in, any package or wrapper in which it is enclosed, except any outer shipping container. The term "label" is that part of the labeling on the immediate container.

A shipping container that contains a single article, unless the container also is essentially the immediate container or the outside of the consumer package, must be labeled with a minimum of product identification (except for controlled substances), lot number, expiration date, and conditions for storage and distribution.

Beyond-use dates (BUDs) and expiration dates are not the same. An expiration date identifies the time during which a conventionally manufactured product, active ingredient, or excipient can be expected to meet the requirements of a compendial monograph, if one exists, provided it is kept under the prescribed storage conditions. The expiration date limits the time during which the conventionally manufactured product, active pharmaceutical ingredient (API), or excipient may be dispensed or used. Expiration dates are assigned by manufacturers of conventionally manufactured products based on analytical and performance testing of the sterility, chemical and physical stability, and packaging integrity of the product. Expiration dates are specific for a particular formulation in its container and at stated exposure conditions of illumination and temperature.

The beyond-use date (BUD) is the date or time beyond which a compounded preparation must be discarded. The date or time is determined from the date the preparation was compounded.

## LABELS AND LABELING FOR DRUG PRODUCTS AND COMPOUNDED PREPARATIONS EXPRESSED AS ACTIVE MOIETY IN NAME AND STRENGTH

The names and strengths of drug products and compounded preparations formulated with a salt of an acid or base are to be expressed in terms of the active moiety on the label (see *Nomenclature* ⟨1121⟩*, Monograph Naming Policy for Salt Drug Substances in Drug Products and Compounded Preparations*).

### Labeling

The labeling clearly states the specific salt form of the active moiety that is present in the product or preparation because this information may be useful to practitioners and patients. The names and strengths of both the active moiety and specific salt form (when applicable) are provided in the labeling.

### Exceptions

In rare cases in which the use of the specific salt form of the active moiety in the title provides vital information from a clinical perspective, an exception to this policy may be considered. In such cases, when the monograph title contains the specific salt form of the active moiety, the strength of the product or preparation is also expressed in terms of the specific salt form.

## LABELS AND LABELING FOR INJECTABLE PRODUCTS

The labels[1] and the labeling state the following information:

- Name of the product
  - In the case of a liquid, the quantity or proportion of each active moiety or drug substance in a specified volume
  - In the case of any product to which a diluent must be added before use, the quantity or proportion of each active moiety or drug substance, name and volume of diluent to be added, the concentration after the diluent is added, directions for proper storage of the constituted solution, and a BUD (see *Expiration Date and Beyond-Use Date*)
- Route(s) of administration

[1] If there are space limitations, see 21 CFR§ 201.10(i), 21 CFR§ 201.105(b), 21 CFR§ 610.60.

Do Not Distribute
Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Sep-2023
DOI Ref: yf7ua
DocId: GUID-185A5565-429F-4DF6-A666-1E542B2B2681_11_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M4908_11_01
@2024 USPC

- Name and quantity or proportion of all inactive ingredients except ingredients added to adjust the pH or to make the drug isotonic may be declared by name with a statement of their effect; if the vehicle is *Water for Injection* it need not be named
- Statement of storage conditions
- Name and place of business of the manufacturer, packer, or distributor
- Identifying lot number and expiration date
- "Rx only" for human drugs
- The recommended or usual dosage.

The container must be labeled so that a sufficient area of the container remains uncovered for its full length or circumference to permit inspection of the contents.

The lot number must be traceable to the complete manufacturing history of the specific package, including all manufacturing, filling, sterilizing, and labeling operations.

If the individual monograph permits varying concentrations of active moiety or drug substance in a large-volume injection (LVI), the concentration of each active moiety or drug substance named in the official title is stated as if it were part of the official title (e.g., *5% Dextrose Injection*, or *Dextrose Injection 5%*, or *5% Dextrose and 0.2% Sodium Chloride Injection* or *Dextrose (5%) and Sodium Chloride (0.2%) Injection*).

## Quantity and Total Volume for Injectable Drug Products Packaged in Single- and Multiple-Dose Containers

For injectable drug products greater than 1 mL, whether packaged in single- or multiple-dose containers, the quantity per total volume should be the primary and prominent expression on the principal display panel of the label, followed in close proximity by quantity per milliliter enclosed by parentheses (quantity/mL).

For containers that hold a volume of less than 1 mL, the quantity per fraction of a milliliter should be the only expression of strength. For containers that hold a volume equal to 1 mL, the strength should be expressed as quantity per milliliter (quantity/mL), not quantity/1 mL.

The following example formats are acceptable:

1. For containers less than 1 mL: 12.5 mg/0.625 mL
2. For containers equal to 1 mL: 5 mg/mL (not 5 mg/1 mL)
3. For containers greater than 1 mL:

Example 1: 500 mg/10 mL
(50 mg/mL)

Example 2: 25,000 Units/5 mL
(5,000 Units/mL)

In certain cases, the primary and prominent expression of the total drug content per container is not effective in preventing medication errors and therefore in those cases, the total drug content per container should not be the primary and prominent expression of strength. Insulin products are an example of a product class that is an exception from the total drug content per container requirement. Another exception to expressing strength as quantity per total volume is lidocaine (or similar drugs for local anesthesia) where the product may be ordered and administered by percentage (e.g., 1% or 2%). In such cases, the percentage strength as well as the quantity per total volume followed in close proximity by quantity per milliliter enclosed by parentheses must be used.

Example 1: 1%
(100 mg/10 mL)
(10 mg/mL)

Example 2: 2%
(1000 mg/50 mL)
(20 mg/mL)

Dry solids that must be constituted should follow the same format with the exception that only the quantity of the drug in the container should be listed as the primary expression of strength, not the quantity per total volume or quantity per milliliter (quantity/mL).

Example: 500 mg/vial

## Ratio Expression of Strength

Single-entity injectable drug products must be labeled in terms of quantity per milliliter (quantity/mL) and not as a ratio expression.

Examples:

Epinephrine Injection, 1:1000 must be expressed as 1 mg/mL.
Epinephrine Injection, 1:10,000 must be expressed as 0.1 mg/mL.
Isoproterenol Hydrochloride Injection, 1:5000 must be expressed as 0.2 mg/mL.
Neostigmine Methylsulfate Injection, 1:1000 must be expressed as 1 mg/mL.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M4908_11_01
@2024 USPC

Single-entity injectable drug products greater than 1 mL should be formatted as quantity per total volume on the principal display panel of the label followed in close proximity by quantity per milliliter (quantity/mL) enclosed by parentheses.

When combined with a local anesthetic, the concentration of epinephrine will be expressed as a ratio.

Examples:

Lidocaine Hydrochloride and Epinephrine Injection 1%/1:100,000
or
Lidocaine Hydrochloride 1%
and
Epinephrine Injection 1:100,000

## Pharmacy Bulk Package

Where a container is offered as a Pharmacy Bulk Package, the label must: 1) state prominently "Pharmacy Bulk Package—Not for Direct Infusion"; 2) contain or refer to information on proper techniques to help assure safe use of the product; and 3) bear a statement limiting the time frame in which the container may be used once it has been entered, provided it is held under labeled storage conditions (see *Packaging and Storage Requirements* ⟨659⟩).

## Imaging Bulk Package

Where a container is offered as an Imaging Bulk Package, the label must: 1) state prominently "Imaging Bulk Package" and, in juxtaposition with this statement, include the following use statement: "For use only with an automated contrast injection system, contrast management system, or contrast media transfer set approved or cleared for use with this contrast agent in this Imaging Bulk Package"; 2) bear a statement limiting the time frame in which the container may be used once it has been entered, provided it is held under the labeled storage conditions; 3) bear the statement "See drug and device labeling for information on devices indicated for use with this Imaging Bulk Package and techniques to help assure safe use." (See ⟨659⟩.)

## Ferrules and Cap Overseals

Healthcare practitioners using injectable products must be able to easily see and act on labeling statements that convey important safety messages critical for the prevention of imminent life-threatening situations. These cautionary labeling statements must be simple, concise, and devoid of nonessential information. Products that do not require cautionary statements should be free of information, so that those with cautionary statements are immediately apparent. Accomplishing this requires a systematic approach to the labeling of injectable products, and one that ensures that the ferrule and cap overseal—an area of these products that is highly visible to practitioners as they use these medicines—is reserved for critical safety messages. Accordingly:

1. Only cautionary statements may appear on the top (circle) surface of the ferrule and cap overseal of a vial containing an injectable product. The cautionary statement should appear on both the ferrule and cap, but may appear solely on the ferrule if the cap overseal is transparent and the cautionary statement beneath the cap is readily legible. A cautionary statement is one intended to prevent an imminent life-threatening situation and may include instructional statements that provide potency or other safety-related instructions if warranted. Examples of such statements include, but are not limited to: "Warning—Paralyzing Agent" and "Dilute before Using". The cautionary statement should be printed in a contrasting color and should be clearly visible under ordinary conditions of use.
2. If no cautionary statement is necessary, the top surface of the vial, including the ferrule and cap overseal, must remain blank.
3. Other statements or features including, but not limited to, identifying numbers or letters, such as code numbers, lot numbers, company names, logos, or product names, etc., may appear on the side (skirt) surface of the ferrule on vials containing injectable products, but not on the top (circle) surface of the ferrule or cap overseal. The appearance of such statements or features on the skirt surface of the ferrule should not detract from, or interfere with, the cautionary statement on the top surface.

## Potassium Chloride for Injection Concentrate

The use of a black closure system on a vial (e.g., a black cap overseal and a black ferrule to hold the elastomeric closure) or the use of a black band or series of bands above the constriction on an ampule is prohibited, except for Potassium Chloride for Injection Concentrate (see ⟨659⟩).

## Neuromuscular Blocking and Paralyzing Agents

All injectable neuromuscular blocking agents and paralyzing agents must be packaged in vials with a cautionary statement printed on the ferrules and cap overseals. Both the container cap ferrule and the cap overseal must bear in black or white print (whichever provides the greatest color contrast with the ferrule or cap color) the words: "Warning: Paralyzing Agent" or "Paralyzing Agent" (depending on the size of the closure system). Alternatively, the overseal may be transparent and without words, allowing for visualization of the warning labeling on the closure ferrule.

## Aluminum in Large-Volume Injections (LVIs), Small-Volume Injections (SVIs), and Pharmacy Bulk Packages (PBPs) Used in Parenteral Nutrition (PN) Therapy[2]

1. The aluminum content of LVIs used in PN therapy must not exceed 25 mcg/L.
2. The package insert of LVIs used in PN therapy must state that the drug product contains no more than 25 mcg of aluminum per liter. This information must be contained in the *Precautions* section of the labeling of all LVIs used in PN therapy.
3. If the maximum amount of aluminum in SVIs and PBPs is 25 mcg/L or less, instead of stating the exact amount of aluminum that each contains, as in paragraph (4), the immediate container label for SVIs and PBPs used in the preparation of PN admixtures or formulations (with exceptions as noted below) may state: "Contains no more than 25 mcg/L of aluminum." If the SVI or PBP is a lyophilized powder, the immediate container label may state the following: "When reconstituted in accordance with the package insert instructions, the concentration of aluminum will be no more than 25 mcg/L."
4. The maximum level of aluminum at expiry must be stated on the immediate container label of all SVIs and PBPs used in the preparation of PN admixtures or formulations. The aluminum content must be stated as follows: "Contains no more than ___ mcg/L of aluminum." The immediate container label of all SVIs and PBPs that are lyophilized powders used in the preparation of PN solutions must contain the following statement: "When reconstituted in accordance with the package insert instructions, the concentration of aluminum will be no more than ___ mcg/L." This maximum amount of aluminum must be stated as the highest one of the following three levels:
   - The highest level for the batches produced during the past 3 years
   - The highest level for the latest 5 batches
   - The maximum level in terms of historical levels, but only until completion of production of the first 5 batches.

The package insert for all LVIs, SVIs, and PBPs used in the preparation of PN admixtures or formulations must contain the following statement in the *Warnings* section of the labeling:

> WARNING: This product contains aluminum that may be toxic. Aluminum may reach toxic levels with prolonged parenteral administration if kidney function is impaired. Premature neonates are particularly at risk because their kidneys are immature, and they require large amounts of calcium and phosphate solutions, which contain aluminum.
>
> Research indicates that patients with impaired kidney function, including premature neonates, who receive parenteral levels of aluminum at greater than 4 to 5 mcg/kg/day, accumulate aluminum at levels associated with central nervous system and bone toxicity. Tissue loading may occur at even lower rates of administration.

***Change to read:***

# LABELS AND LABELING FOR PRODUCTS IN OTHER CATEGORIES

## Labels and Labeling of Liquids and Constituted Products

The labels[1] and labeling state the following information:

1. In the case of a liquid product, the percentage content of each active moiety or drug substance or the amount of each active moiety or drug substance in a specified volume.
2. In the case of a product to which a diluent must be added before use, the amount of each active moiety or drug substance, the name and volume of diluent to be added, the final volume of solution, the concentration after the diluent is added (e.g., quantity/mL or quantity/5 mL), directions for proper storage of the constituted solution, and an expiration or BUD (see *Expiration Date and Beyond-Use Date*).

## Amount of Active Moiety or Drug Substance per Dosage Unit

The strength of a drug product is expressed on the container label in terms of micrograms, milligrams, grams, or percentage of the therapeutically active moiety or drug substance, whichever form is used in the title, unless otherwise indicated in an individual monograph. Both the active moiety and drug substance names and their equivalent amounts are then provided on the container label and in the labeling (see *Nomenclature* ⟨1121⟩, *Monograph Naming Policy for Salt Drug Substances in Drug Products and Compounded Preparations*).

Official articles in capsule, tablet, or other dosage forms must be labeled to express the quantity of each active moiety or drug substance contained in each unit. Unit-dose oral solutions or suspensions (whether supplied as liquid products or as liquid products that are constituted from solids upon addition of a designated volume of a specific diluent) must be labeled to express the quantity of each active moiety or drug substance delivered under the conditions prescribed in *Deliverable Volume* ⟨698⟩. Official drug products not in unit-dose packaging must be labeled to show the quantity of each active moiety or drug substance in each milliliter or in each gram, or to express the percentage of each such ingredient (see *General Notices, 8.140 Percentage Concentrations*). Exceptions are oral liquids or solids intended to be constituted to yield oral liquids that, alternatively, can be labeled in terms of each 5-mL portion of the liquid or resulting liquid. Unless otherwise required by regulation [e.g., over-the-counter (OTC) regulation 21 CFR §201.62(b)] or indicated in a monograph or chapter, declarations of strength or quantity must be stated only in metric units [see also *General Notices, 5.50.10 Units of Potency (Biological)*].

[2] See 21 CFR §201.323. USP uses the following terms: large-volume injections (LVIs), small-volume injections (SVIs), and parenteral nutrition (PN), rather than terminology used in 21 CFR §201.323: large-volume parenterals, small-volume parenterals, and total parenteral nutrition.

https://pharmacopeia.cn/v29240/

# Expiration Date and Beyond-Use Date

## ▲EXPIRATION DATE▲ (IRA 1-Sep-2023)

The label of an official drug product ▲must▲ (IRA 1-Sep-2023) bear an expiration date. All products ▲must▲ (IRA 1-Sep-2023) display the expiration date so that it can be read by an ordinary individual under customary conditions of purchase and use. The expiration date ▲must▲ (IRA 1-Sep-2023) be prominently displayed in high contrast to the background ▲and it must▲ (IRA 1-Sep-2023) be ▲printed or▲ (IRA 1-Sep-2023) sharply embossed ▲or debossed,▲ (IRA 1-Sep-2023) and ▲be clear to the user. The term "expiration date" may be abbreviated on the drug package label in a manner that allows the reader to understand the abbreviation to mean "expiration date" (e.g., EXP, Exp Date). The year must always be in a 4-digit format.

When all-numeric dates are used, they must be formatted using the year, the month, and, if applicable, the day, separated by hyphens or forward slashes in one of the following formats:

YYYY-MM-DD (e.g., 2019-06-30, 2019/06/30)

YYYY-MM (e.g., 2019-06, 2019/06)

When alphanumeric dates are used, months must be displayed using at least three letters in one of the following formats:

YYYY-MMM-DD (e.g., 2019-JUN-30, 2019/JUN/30)

YYYY-MMM (e.g., 2019-JUN, 2019/JUN)

If an expiration date is stated only in terms of the year and the month, then the intended expiration date is the last day of the stated month.

For containers that have insufficient space on the primary container to accommodate the full expiration date format described previously (e.g., topical ophthalmic ointment container crimps, blow-fill-seal ampules), use the all-numeric format YYYY-MM or the alphanumeric format YYYYMMM (without a hyphen or forward slash to accommodate space constraints). If there is a lack of space in close proximity to the expiration date, the term designated to represent "expiration date" (e.g., EXP) may be omitted if the specific alphanumeric format, YYYYMMM, is used. However, all other packaging, including but not limited to a carton, tray, or overwrap, must have the full expiration date format as described previously.▲ (IRA 1-Sep-2023)

The monographs for some ▲drug products▲ (IRA 1-Sep-2023) state how the labeled expiration date ▲must▲ (IRA 1-Sep-2023) be determined. In the absence of a specific requirement in the individual monograph for a drug product, ▲▲ (IRA 1-Sep-2023) the label ▲must▲ (IRA 1-Sep-2023) bear an expiration date assigned for the particular formulation and package of the product. ▲The▲ (IRA 1-Sep-2023) label need not show an expiration date ▲for the following exception: if the product is a human OTC drug product for which the labeling states no dosage limitations, it is packaged in a container that is intended for sale without prescription, and if the product is stable for not less than (NLT) 3 years when stored under the prescribed conditions. Refer to 21 CFR 211.137(h).▲ (IRA 1-Sep-2023)

If an official ▲drug▲ (IRA 1-Sep-2023) product is required to bear an expiration date, the product ▲must▲ (IRA 1-Sep-2023) be dispensed solely in or from a container labeled with an expiration date, and the date on which the article is dispensed ▲and intended to be used must▲ (IRA 1-Sep-2023) be within the labeled expiry period. The expiration date identifies the time during which the article can be expected to meet the requirements of the compendial monograph, provided it is kept under the ▲labeled▲ (IRA 1-Sep-2023) storage conditions. The expiration date limits the time during which the article may be dispensed ▲and▲ (IRA 1-Sep-2023) used.

▲The label of a dietary supplement product recognized in *USP* and that claims conformance with *USP* must bear an expiration date for the specific dosage form formulation and package of the product, unless otherwise specified in the individual monograph. See *General Notices, 3.10.20 Applicability of Standards to Medical Devices, Dietary Supplements, and Their Components and Ingredients* for applicability of *USP* dietary supplement standards.

## BEYOND-USE DATE▲ (IRA 1-Sep-2023)

The beyond-use date (BUD) is the date after which a product ▲or preparation must▲ (IRA 1-Sep-2023) not be used. The dispenser ▲must▲ (IRA 1-Sep-2023) place on the label of the prescription container a suitable BUD to limit the patient's use of the article based on any information supplied by the manufacturer or this subsection. The BUD ▲must▲ (IRA 1-Sep-2023) not be later than the expiration date on the manufacturer's container. Also see the *Labels and Labeling for Compounded Preparations* section.

For articles that require constitution before use, a suitable BUD for the constituted product ▲must▲ (IRA 1-Sep-2023) be identified in the labeling.

For all other dosage forms, in determining a BUD the dispenser ▲must▲ (IRA 1-Sep-2023) take into account, in addition to any other relevant factors:

- Nature of the drug
- Container in which it was packaged by the manufacturer and the expiration date thereon
- Characteristics of the patient's container, if the article is repackaged for dispensing
- Expected storage conditions to which the article may be exposed
- Unusual storage conditions to which the article may be exposed
- Expected length of the course of therapy.

After considering these factors, the dispenser ▲must▲ (IRA 1-Sep-2023) label a container with a suitable BUD to limit the patient's use of the article. Unless otherwise specified in the individual monograph or in the absence of stability data to the contrary, the BUD ▲must▲ (IRA 1-Sep-2023) be ▲no▲ (IRA 1-Sep-2023) later than (a) the expiration date on the manufacturer's container; or (b) 1 year from the date the drug is ▲packaged and/or labeled by the dispenser,▲ (IRA 1-Sep-2023) whichever is earlier, unless stability data or the manufacturer's labeling indicates otherwise.

## Labels and Labeling for Compounded Preparations

The labels and labeling state the following information:

In the case of a compounded preparation, list the name(s) and amount(s) or concentrations of active moiety(ies) or drug substance(s) on the immediate container (see *Pharmaceutical Compounding—Sterile Preparations* ⟨797⟩ and *Pharmaceutical Compounding—Nonsterile Preparations* ⟨795⟩.)

In the case of a compounded preparation prepared in 503A facilities as defined by FDCA §503A, the labeling should indicate that "this is a compounded preparation."

The label on the container or package of a compounded preparation must bear a BUD. The BUD is determined from the date the preparation is compounded. Because compounded preparations are intended for administration immediately or following short-term storage, their BUDs may be assigned based on criteria different from those applied to assigning expiration dates to manufactured drug products.

The monograph for an official compounded preparation typically includes a BUD that states the time period following the date of compounding during which the preparation, properly stored, may be used. For guidance regarding the BUD for compounded sterile and nonsterile preparations, see ⟨797⟩ and ⟨795⟩, respectively.

The label on the official compounded preparation must include the word "compounded" after the drug portion of a non-proprietary name (e.g., "*Baclofen Compounded Oral Suspension*").

## Dialysis, Hemofiltration, and Irrigation

Solutions that are intended for use as dialysis, hemofiltration, or irrigation, and are packaged in a container with a volume of more than 1 L, must be labeled to indicate that the contents are not to be administered either intravenously or intra-arterially.

## Use of Leading and Terminal Zeros

To help minimize the possibility of errors in drug dispensing and administration, when the quantity of active moiety or drug substance is expressed in whole numbers it must be shown without a decimal point followed by a terminal zero (e.g., express as 4 mg, not 4.0 mg). When the quantity of active moiety or drug substance is expressed as a decimal number smaller than 1, it must be shown with a zero preceding the decimal point (e.g., express as 0.2 mg, not .2 mg).

## Units

Abbreviations for the terms "Units" or "International Units" must not be used for labeling or prescribing purposes. Examples include "U", "u", and "IU". Medication errors have occurred when these abbreviations have been used. See *General Notices, 9.10 Use of Metric Units*.

## Alcohol

The alcohol content in a liquid formulation must be stated on the label as a percentage (v/v) of alcohol ($C_2H_5OH$).

## Botanicals

The label of an herb or other botanical intended for use as a dietary supplement shall bear the statement, "If you are pregnant or nursing a baby, seek the advice of a health professional before using this product."

## Electrolytes

The concentration of each electrolyte for replacement therapy (e.g., sodium, potassium, chloride) must be stated on the label in milliequivalents per volume (mEq/volume). Phosphorus containing injections must be expressed in milliMoles per volume (e.g., mM/volume). The label of the product must also indicate the quantity of ingredient(s) in terms of weight or percentage concentration.

## Non-Oral Products

Non-oral product labels and labeling must state the names of added substances (as defined in *General Notices, 5.20 Added Substances*) in compliance with 21 CFR §201.100(b)(5).

## Salts of Drugs

It is an established principle that official articles must have only one official title (see *General Notices, 2.20 Official Articles* and compendial nomenclature requirements in ⟨1121⟩). For purposes of saving space on labels and because chemical symbols for the most common inorganic salts of drugs are well known to practitioners, the following alternatives are permitted in labeling official articles that are salts: HCl for hydrochloride; HBr for hydrobromide; Na for sodium; and K for potassium. The symbols Na and K are intended for use in abbreviating names of the salts of organic acids, but these symbols are not used when the word Sodium or Potassium appears at the beginning of an official title (e.g., Phenobarbital Na is acceptable, but Na Salicylate is not).

Official

https://pharmacopeia.com/

## Special Capsules and Tablets

The label of any form of capsule or tablet intended for administration other than by swallowing intact must bear a prominent indication of the manner in which it should be used (see *Compendial Nomenclature, Nomenclature Guidelines* on the USP website at www.usp.org).

## Products That Contain Vitamins

The vitamin content of a drug product must be stated on the label in metric units per dosage unit. The amounts of vitamins A, D, and E may also be stated in USP Units. Quantities of vitamin A declared in metric units refer to the equivalent amounts of retinol (vitamin A alcohol).

## Controlled Room Temperature

Articles may be labeled for storage at "controlled room temperature" or at "20° to 25°", or other equivalent wording based on the same mean kinetic temperature. All three labeling options must ensure not to exceed the mean kinetic temperature of 25° with excursions between 15° and 30° (see ⟨659⟩).

## Light-Resistant Container

When an opaque covering is used to provide protection from light for a light-sensitive product packaged in a clear or colorless or translucent container, the label of the container bears a statement that the opaque covering is needed until the contents are to be used or administered (see *Containers—Performance Testing* ⟨671⟩*, Spectral Transmission* and ⟨659⟩).

## Single-Unit Container

Each single-unit container must be labeled to indicate the identity; quantity and/or strength; name of the manufacturer, packer, or distributor; lot number; and expiration date of the article (see ⟨659⟩).

## Single-Dose Container

When space permits a single-dose container must be labeled as such, and should include on the label appropriate discard instructions (see ⟨659⟩).

## Multiple-Dose Container

When space permits, a multiple-dose container must be labeled as such (see ⟨659⟩).

## Unit-of-Use Container

A unit-of-use container must be labeled as such (see ⟨659⟩).

## Protection from Freezing

The container label must bear an appropriate instruction to protect the article from freezing if subject to loss of strength or potency, or to destructive alteration of its characteristics (see ⟨659⟩).

## Prescription Container Labeling

At a minimum, a prescription container must be labeled in a patient-centered manner. The label must contain essential information that is important for the patient's safe and effective use of the medicine. Labels should be designed and formatted to optimize readability and understanding (see *Prescription Container Labeling* ⟨17⟩).

# GENERAL LABELING

Users are reminded to always refer to the *General Notices* in assessing or applying any compendial standards. *General Notices* addresses a number of labeling-related aspects, including *3.20 Indicating Conformance* (when an article may be labeled *USP*, *NF*, or *USP–NF*, and requirements related to differences in identity, naming, strength, quality, or purity); *General Notices, 5.20.20 Added Substances (Excipients and Ingredients) in Official Products*; *6.70 Reagents*; and *8.240 Weights and Measures* (e.g., microgram may be represented as either µg or mcg. For labeling or prescribing purposes, only "mcg" is to be used).

# LABELS AND LABELING FOR ANIMAL DRUG PRODUCTS

This section provides exceptions or additions to the previous requirements in this chapter. The following requirements are specific to the labeling for animal drug products.

## Definitions

The written printed or graphic matter on the outer shipping container for animal drugs is considered to be part of “labeling”. Shipping labeling for animal drugs should contain, at minimum, product identification, lot number, expiration date, and conditions for storage and handling.

## Labeling for Animal Drug Products

The labeling for animal drugs should identify the animal species and, if applicable, specific subset(s) of the animal species for which the drug is approved, conditionally approved, or indexed. In the case of a compounded preparation for animals, the labeling should indicate that “This is a compounded preparation.”

The labeling for prescription animal drug products must include the following statement:

- "Caution: Federal law restricts this drug to use by or on the order of a licensed veterinarian."

## Labeling for Injectable Animal Drug Products

Labeling for injectable animal drug products includes the following information:

- A statement limiting the time frame in which the container may be used once it has been entered (e.g., needle-punctured), provided it is held under the labeled storage conditions.

## Quantity and Total Volume for Single- and Multiple-Dose Injectable Animal Drug Products

Because of considerable variability in body weight within and among animal species, most injectable animal drugs are approved to be dosed on a mg/kg body weight basis. Thus, strength on labeling for single- and multiple-dose injectable animal drugs should be expressed on the basis of quantity per milliliter (quantity/mL), usually mg/mL. An exception would be for single-dose injectable animal drugs that are dosed regardless of the weight of the animal, in which case strength on labeling should be expressed as quantity per total volume (e.g., 50 mg/5 mL). For single-dose containers holding less than 1 mL, strength on labeling should be expressed as quantity per fraction of a mL (e.g., 12.5 mg/0.625 mL).

Dry solids that must be constituted should provide on labeling the total quantity followed by the quantity per milliliter (quantity/mL) after constitution.

## Compounded Veterinary Preparations

The label on the official compounded veterinary preparation must include the word “compounded” after the drug portion of a non-proprietary name and the word “veterinary” at the end of the full official name (e.g., Atenolol Compounded Oral Suspension, Veterinary).

# ⟨11⟩ USP REFERENCE STANDARDS

***Change to read:***

## ▲INTRODUCTION

Reference Standards provided by the United States Pharmacopeial Convention (USP Reference Standards or USP RS) are highly characterized materials demonstrated to have the appropriate qualities to support their intended use. USP RS are not for use in humans or animals.

USP RS are generally linked to relevant tests and assays in the *United States Pharmacopeia* (*USP*) or *National Formulary* (*NF*) documentary standards. They have been approved and established as suitable for use in the context of these applications. When approved as suitable for use in *USP* or *NF* tests and assays, USP RS also assume official status and legal recognition in the United States and other jurisdictions that recognize the *USP* or *NF* (see *General Notices, 2.30 Legal Recognition*). Where *USP* or *NF* tests or assays call for the use of a USP RS, only those results obtained using the specified USP RS are conclusive (see *General Notices, 5.80 USP Reference Standards*).

USP RS may also be used to support other measurements not necessarily prescribed in *USP–NF*. Assessment of the suitability for use in other applications is the responsibility of the user.

## ESTABLISHMENT APPROACHES AND VALUE ASSIGNMENT

USP RS, when they are physical materials, are Reference Materials as defined in the *International Vocabulary of Metrology—Basic and General Concepts and Associated Terms (VIM)*. The value assigned to quantitative standards relies on a mass determination by a primary reference measurement procedure such as a mass balance determination. If the value has been assigned by using a primary reference measurement procedure, the USP RS in metrology terms can be considered a primary measurement standard. If the value has been assigned by comparison or calibration to another material, the USP RS should be considered a secondary measurement standard; for example, when appropriate, USP RS are calibrated relative to international reference materials such as those provided by the World Health Organization (WHO).

USP may choose to develop USP RS that follow the requirements for the development of Certified Reference Materials (CRMs) in accordance with the relevant International Organization for Standardization (ISO) Guides. Correct use of these CRMs support traceability of results to SI units and comparability of procedures. USP may also provide RS that are traceable to a CRM established by a National Metrology Institute or other official provider as required or referenced by the documentary standard.

USP may issue USP RS that are not required in a documentary standard. The material and performance attributes for these USP RS are described in the supporting documentation supplied with the USP RS.

USP RS go through a rigorous characterization as part of their establishment process. The types and extent of testing (including the number of laboratories) are primarily driven by the official uses of the standard, but material characterization goes beyond the establishment of suitability for use. Typically, a comparison to the previous lot is performed during the study when establishing a replacement lot of a USP RS as an additional verification of the suitability of the new standard lot.

## USP REFERENCE STANDARDS FOR *USP* OR *NF*

Official applications of USP RS are specified in *USP* or *NF* monographs and general chapters. These applications are as follows. Some USP RS could be used for several types of applications listed below.

1. **Quantitative determinations**
   - A. The majority of USP RS for quantitative determinations support measurements for total amounts of material on a mass basis. This category includes USP RS for USP or NF articles and impurity standards labeled for quantitative use. The assigned value of the USP RS is stated on the labeling and should be included in calculations used in the monograph and applicable general chapters.
   - B. USP RS for relative determinations of potency or activity are often required for the measurement of complex materials (e.g., biologics, antibiotics, herbals, some dietary supplements) and quantitative amounts may be expressed in units or relative potency terms other than mass.
     These USP RS are established by calibration to a primary standard where the property of the material determines the unit. For these standards where an International Standard (IS) established by the WHO exist, USP RS are National Measurement Standards. The USP RS documentation will indicate when the USP RS has been established by comparison to an International Standard (IS) established by the WHO. Results may be expressed in USP Units, Units, or International Units. Additional statements about unit/mass relationship, specific activity, or other relevant information related to the measurement may be provided in the USP RS documentation.
     For antibiotics that use microbial assays to determine activity, the potency is determined in units or micrograms per milligram (µg/mg) of activity. The units or µg/mg of activity is established against a WHO IS when one exists for that antibiotic. Where no WHO IS is presently available, USP establishes and maintains the standard to which USP RS lots are calibrated. This approach may also be chosen for other complex materials for which no WHO IS exists. In these instances, the USP standard is established in such a way as to ensure long-term stability and fitness for purpose, which permits the calibration of successive lots of USP RS with increased confidence that drift in the assigned unit can be avoided.
2. **Qualitative determinations**
   - A. Identification USP RS: USP RS for identification tests are typically presented as single components of high chemical purity, but may also be complex materials of natural, synthetic, or recombinant origin (e.g., biologics, natural

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M98740_03_01
@2024 USPC

products, botanicals, complex nonbiologicals, others). For complex materials, the identification attributes are presented in a matrix of other materials and require highly specific measurement systems (e.g., nucleic acid-based identity determination for naturally derived materials).

B. Impurity USP RS: Impurity USP RS are typically used for system suitability or as impurity markers. They may be presented as single-component materials, as mixtures containing more than one impurity, or as drug substance(s) containing one or more impurities.

C. Digital and Visual USP RS: Unlike chemical reference materials, these USP RS are not physical materials used in chemical analyses. Instead, these visual images are used by analysts to compare test articles to ensure that they meet compendial requirements

3. **Performance verification.** These USP RS are typically called for in general tests and assays and are provided to analyze and, where appropriate, to facilitate adjustment of the operation of an instrument to ensure the results obtained are accurate and/or precise or otherwise give acceptable results. The use of these USP RS is generally described in associated general chapters and in the supporting documentation supplied with the USP RS.

## USP REFERENCE STANDARDS FOR OTHER MEASUREMENTS AND DETERMINATIONS

USP also develops Reference Standards that may not be required in official *USP–NF* tests or assays. USP provides RS specified in the current edition of the *Food Chemicals Codex*, the *Herbal Medicines Compendium*, and standards referenced in regulatory requirements.

USP RS without an official use in the *USP–NF* are developed following the same quality systems used for the characterization and release of USP RS used in official tests and assays. These USP RS are generally intended to address common quality issues and challenges inherent to technologies that cut across different types of products (e.g., system suitability samples, calibrators used to demonstrate performance of an analytical procedure, process, or equipment). Extensive characterization of the USP RS candidate is required and the testing plan takes into account the use of different methods to measure the same attribute, demonstrating broader applicability of these standards. In the absence of a companion monograph or chapter, the information generated from these studies may be disseminated to the user via other types of supporting documents including but not limited to the USP Certificate.

## LABELING

The labeling material consists of the label affixed to the USP RS and the associated USP Certificate. Both must be reviewed prior to handling or using the USP RS because in some cases not all of the necessary information can fit on the affixed label. USP Certificates are lot specific and are publicly available on the USP website (www.usp.org). Additional documentation may be provided with the USP RS as needed.

The affixed USP RS label typically contains the RS name, catalog number, lot number, package size, assigned value, storage conditions, handling instructions, and country of origin information. For multi-component items, there is also an outer package and label.

The affixed label also includes hazard and precautionary statements required by the Occupational Safety and Health Administration (OSHA) under the current revision of the Hazard Communication Standard (29 CFR 1910.1200). Terms used in these statements do not necessarily reflect specific definitions in the *USP–NF*. Safety Data Sheets for all USP RS are publicly available on the USP website (www.usp.org).

In addition to the information provided on the affixed USP RS label, the USP Certificate will generally contain the RS chemical name and structure, sequence (if applicable), CAS number, molecular formula, and molecular weight. A typical chromatogram may also be included if necessary for the intended use. Additional information may be included such as special handling instructions or information needed for the use of the USP RS. The USP Certificate also includes a copy of the label text and a series of general instructions.

## PACKAGING

The amount of material per individual USP RS container depends on the application of the standard. Some standards (mainly materials with significant handling requirements or materials that are available only in small amounts) are provided in single-use containers. Some single-use products may be lyophilized with content labeled in mass or activity units per container. If so labeled, the content of the container must be reconstituted in its entirety without any additional weighing. Instructions for use are given either on the label or USP Certificate, or in the monographs where the standard is used.

## STORAGE

USP RS should be stored in the packaging configuration provided by USP, according to the label and USP Certificate instructions. When storage in refrigerator or freezer is stated on the label, follow the definitions given in *Packaging and Storage Requirements* ⟨659⟩. If no specific directions or limitations are provided on the label, the conditions of storage shall be room temperature and protection from moisture, light, freezing, and excessive heat.

Any unused portions remaining after the container has been opened should be carefully stored in accordance with the user's Standard Operating Procedures and good laboratory practices. Decisions concerning the proper use of previously opened USP RS are the responsibility of the user, unless otherwise specified on the labeling. The user is responsible for ensuring that the contents of opened vials continue to be suitable for their intended use.

Official

https://pharmacopeia.cn/v29240/

## CONTINUED SUITABILITY FOR USE

All USP RS are periodically reevaluated by USP throughout their lifecycles. The USP Continued Suitability for Use (CSU) program is designed to monitor real-time suitability for use of all current lots of USP RS. Suitability testing intervals are established based on collaborative study data, manufacturer or supplier data, testing results, and CSU data trending and projections. When and where applicable, an accelerated degradation study may be performed to provide additional information on the stability of the USP RS and to support suitability testing intervals. The goal of the CSU program is to confirm the continued suitability of the material for use of a USP RS in its compendial applications during its valid use period.

## VALID USE DATE

USP RS lots are assigned a valid use date upon depletion. The valid use date is the last day upon which a particular lot of USP RS can be used. Typically, the valid use date assigned is one year from the date the last vial of a lot is sold.

It is the responsibility of the user to ascertain that a particular lot of a USP RS has official status either as a "Current Lot" or as a "Previous Lot" prior to the valid use date. Current and previous lot information, as well as the most current version of the catalog, can be found on the USP website (www.usp.org).

## PROPER USE

Many compendial tests and assays are based on comparison of a sample to a USP RS. In such cases, measurements are made on preparations of both the sample and the USP RS. Where it is directed that a standard solution or a standard preparation be prepared for a quantitative determination, it is intended that the USP RS substance be accurately weighed (see *Balances* ⟨41⟩) and subsequent dilutions be performed using volumetric apparatuses with, at least, the prescribed tolerances (see *Volumetric Apparatus* ⟨31⟩). Potential errors associated with the use of volumetric apparatus of small volume should be taken into account (see also *General Notices, 6.50.20.1 Adjustments to Solutions*).

Whenever the labeled directions for use require either drying or a correction for water and/or volatiles, this should be performed at the time of use. Further experimental details should be controlled by the user's Standard Operating Procedures and good laboratory practices.

The following list of label terms and definitions is provided as guidance for the handling and use of USP RS:

- **Assigned Value (Calculation Value):** The quantity value assigned to a USP RS for its use in the quantitative compendial applications.
- **As Is:** Use the USP RS as received, without drying or additional testing and apply the assigned value to correct the concentration of the standard solution and/or preparation. This is the preferred option, and is selected whenever data indicate the moisture content is constant over time. For the USP RS to be used on the as is basis, the assigned value has already been corrected for volatiles, including moisture.
- **Anhydrous Basis, Determine Water Content Titrimetrically at Time of Use:** Use the USP RS as received, and apply the water content determined to correct the weight of the standard. After the correction for water is applied, use the assigned value to correct the concentration of the standard solution and/or preparation. At the time a USP RS is to be weighed, proceed as directed under *Water Determination* ⟨921⟩, *Method I*, and determine the water content on a separate portion of material. Instrumental or microanalytical methods are acceptable for this purpose. When using typical amounts (about 50 mg of the USP RS), titrate with a 2- to 5-fold dilution of the reagent.
- **Dried Basis, Determine Loss on Drying at Time of Use:** Use the USP RS as received, and apply the loss on drying value obtained to correct the weight of the standard. After the correction for loss on drying is applied, use the assigned value to correct the concentration of the standard solution and/or preparation. Determine the loss on drying value on a separate portion of material, following the monograph procedure under *Loss on Drying*. Sample sizes smaller than those required in the general test chapter may be used for a USP RS provided that the user can obtain a sufficiently accurate result.
- **Dried Material, Dry Before Use, or Use Previously Dried Material:** Dry the USP RS before use. Use immediately after drying under stated conditions. Drying should not be performed in the original container. A portion of the material should be transferred to a separate drying vessel. Apply the assigned value to correct the concentration of the standard solution and/or preparation prepared with the dried USP RS.▲ (USP 1-Aug-2020)

# ⟨ 17⟩ PRESCRIPTION CONTAINER LABELING

***Change to read:***

## INTRODUCTION

This chapter applies to labeling instructions and information on prescription containers that are directly dispensed to the patient to promote better patient understanding. These standards do not apply when a prescription drug will be administered to a patient by licensed personnel who are acting within their scope of practice. Medication misuse has resulted in more than 1 million adverse drug events per year in the United States.[1] One of patients' primary sources▲ (USP 1-Dec-2021) of information regarding the medications they have been prescribed is on the prescription container label. Although other written information and oral counseling may be available, the prescription container label must fulfill the professional obligations of the prescriber and pharmacist. These obligations include giving patients the essential information they will need to understand how to safely and appropriately use the medication and how to adhere to the prescribed medication regimen.

Inadequate understanding of prescription directions for use and auxiliary ▲labels▲ (USP 1-Dec-2021) provided on dispensed containers is widespread. ▲An auxiliary label contains any instruction, warning, or informational statements in addition to primary instructions for use that are affixed to the prescription container.▲ (USP 1-Dec-2021) Studies have found that 46% of patients misunderstood one or more dosage instructions, and 56% misunderstood one or more auxiliary ▲labels.▲ (USP 1-Dec-2021) The problem of misunderstanding is particularly common and troublesome in patients with low or marginal literacy and in patients receiving multiple medications that are scheduled for administration using complex, nonstandardized time periods. In one study, patients with low literacy were 34 times more likely to misinterpret prescription ▲auxiliary▲ (USP 1-Dec-2021) labels than patients with adequate literacy. However, even patients with adequate literacy often misunderstand common prescription directions and ▲auxiliary labels.▲ (USP 1-Dec-2021) In addition, there ▲may be discrepancies between auxiliary label information and other written information provided by the pharmacy (e.g., medication guides).▲ (USP 1-Dec-2021) The specific evidence to support ▲the inclusion of▲ (USP 1-Dec-2021) a given auxiliary statement often is unclear, and patients often ignore such information. ▲▲ (USP 1-Dec-2021)Further study in comparison to explicit, simplified language alone ▲is needed to determine whether auxiliary information should be placed on auxiliary labels or just included as part of the language on the prescription container alone.▲ (USP 1-Dec-2021)

Lack of universal standards for labeling on dispensed prescription containers is a root cause of patient misunderstanding, nonadherence, and medication errors.

USP developed patient-centered label standards for the format, appearance, content, and language of prescription ▲container label▲ (USP 1-Dec-2021) medication instructions to promote patient understanding. These recommendations form the basis of this general chapter.

***Change to read:***

## PRESCRIPTION CONTAINER LABEL STANDARDS TO PROMOTE PATIENT UNDERSTANDING

### Organize the Prescription Label in a Patient-Centered Manner

Information shall be organized in a way that best reflects how most patients seek out and understand medication instructions. Prescription container labeling should feature only the most important patient information needed for safe and effective understanding and use.

### Emphasize Instructions and Other Information Important to Patients

Prominently display information that is critical for the patient's safe and effective use of the medicine. At the top of the label, specify the patient's name, the drug name (spell out full generic and brand name) and drug strength, and explicit clear directions for use in ▲plain▲ (USP 1-Dec-2021) language.

The prescription directions should follow a standard format so that the patient can expect that each element will be presented in a specific, predictable order each time a prescription is received. Use of a methodology that simplifies the administration instructions for the patient's medication should improve the individual's ability to understand prescription instructions, to take the correct dose, and to organize multidrug regimens. Employing best practices of patient-centered instructions—which utilize the principles of health literacy, medication therapy management, and education, to explicitly describe how to take daily-use, solid dose-form medications—has resulted in improved patient understanding. One such patient-centered method is the universal medication schedule (UMS). The UMS shifts medication-taking into four standardized time periods (morning, noon, evening, bedtime) and uses simplified language and formatting to promote understanding (e.g., "take 1 pill in the morning and 1 pill at bedtime" rather than "take one tablet twice daily"). Such methods may be particularly useful for simplifying daily medication regimens that include multiple oral therapies. [NOTE—The word "pill" is used in the UMS to enhance health literacy and may not reflect a USP definition for an oral dosage form (see ▲*Pharmaceutical Dosage Forms* ⟨ 1151⟩ ).▲ (USP 1-Dec-2021)]
▲▲ (USP 1-Dec-2021)

Other, less-critical but important content (e.g., pharmacy name and phone number, prescriber name, fill date, refill information, expiration date, prescription number, drug quantity, physical description, and evidence-based auxiliary information) should not supersede critical patient information. Such less-critical information should be placed away from dosing

@2024 USPC

instructions (e.g., at the bottom of the label or in another less prominent location) because it can distract patients, which can impair their recognition and understanding.

## ▲Oral Liquid Medication Dosing Tools

When oral liquid dosage forms are prescribed, the appropriate "dosing tool" (also known as a dosing component; examples include oral syringe or dosing cup) shall be provided to the patient or caregiver to accurately measure and administer the oral medication. Oral syringes are recommended when dosing accuracy is important, particularly for doses of 5 mL or less. The size of the dosing tool should be considered in the context of the recommended dose volume. The dosing tool volume provided should be the smallest one capable of holding the entire dose volume (e.g., for a 2-mL dose, a 5-mL capacity syringe is preferable to a 10-mL capacity syringe; for a 7.5-mL dose, a 10-mL capacity syringe is preferable to a 5-mL capacity syringe). The volume markings on the dosing tool shall be legible, indelible, and also limited to a single measurement scale that corresponds with the dose instructions on the prescription container label, typically volumetric metric units (see *Packaging and Storage Requirements* 〈 659〉 ).▲ (USP 1-Dec-2021)

## Simplify Language

The language on the label should be clear, simplified, concise, and familiar, and should be used in a standardized manner. Only common terms and sentences should be used. Do not use unfamiliar words (including Latin terms) or medical jargon.

Use of readability formulas and software is not recommended for simplifying short excerpts of text such as those on prescription labels. Instead, use simplified, standardized sentences that were developed by seeking feedback from samples of diverse consumers. Such language will promote correct understanding of the instructions.

## Give Explicit Instructions

Instructions for use (i.e., the SIG or signatura) should clearly separate the dose itself from the timing of each dose in order to explicitly convey the number of dosage units to be taken and when (e.g., specific time periods each day such as morning, noon, evening, and bedtime). Instructions shall include specifics on time periods. Do not use alphabetic characters for numbers. For example, write “Take 2 tablets in the morning and 2 tablets in the evening” rather than “Take two tablets twice daily”).

Whenever available, use standardized directions (e.g., write “Take 1 tablet in the morning and 1 tablet in the evening” if the prescription reads b.i.d.). Vague instructions based on dosing intervals such as twice daily or 3 times daily, or hourly intervals such as every 12 h, generally should be avoided because such instructions are implicit rather than explicit, they may involve numeracy skills, and patient interpretation may differ from prescriber intent. Although instructions that use specific hourly times (e.g., 8 a.m. and 10 p.m.) may seem to be more easily understood than implicit vague instructions, recommending dosing at precise hours of the day is less readily understood and may present greater adherence issues (due to individual lifestyle patterns such as shift work) than more general time frames such as in the morning, in the evening, after breakfast, with lunch, or at bedtime. Consistent use of the same terms should help avoid patient confusion. A set of standardized, explicit instructions [the universal medication schedule (UMS)] were developed and tested in English and other languages to improve patient understanding.[2]

Ambiguous directions such as “take as directed” should be avoided unless clear and unambiguous supplemental instructions and counseling are provided (e.g., directions for use that will not fit on the prescription container label). A clear statement referring the patient to such supplemental materials should be included on the container label.

## Include Purpose for Use

If the purpose of the medication is included on the prescription, it should be included on the prescription container label unless the patient prefers that it not appear. Practitioners should always ask patients their preference when writing the prescription. Confidentiality and FDA approval for intended use (e.g., labeled versus off-label use) may limit inclusion of the purpose on labels. Current evidence supports inclusion of purpose-for-use language in clear, ▲plain▲ (USP 1-Dec-2021) terms (e.g., “for high blood pressure” rather than “for hypertension”).

## Limit Auxiliary Information

Auxiliary information on the prescription container label should be evidence-based and presented in ▲plain▲ (USP 1-Dec-2021) explicit language that is minimized to avoid distracting patients with nonessential information. Most patients, particularly those with limited literacy, pay little attention to auxiliary information. The information should be presented in a standardized manner and should be critical for patient understanding and safe medication use (e.g., warnings and critical administration alerts). Icons are frequently misunderstood by patients. In addition, icons that provide abstract imagery for messages that are difficult to depict visually may be ineffective at improving understanding compared with simplified text alone. Use only icons for which there is adequate evidence, through consumer testing, that they improve patient understanding about correct use. Evidence-based auxiliary information, both text and icons, should be standardized so that it is applied consistently and does not depend on individual practitioner choice.

## ▲Opioid Warning Label Development

Opioids are a class of drugs with a high risk of misuse, abuse, dependence, and addiction. It has been reported that many patients prescribed opioids for pain do not even know that they are taking an opioid. Providing this factual information to patients could be an important first step in helping them understand and minimize their own risks for misuse, abuse, dependence, and addiction.

For these reasons, opioids may warrant a warning label. An example of a warning label would be a message telling the patient the prescription contains an opioid. Another type of warning label would alert patients to the risk of overdose and addiction. Any brief warning could be printed on a sticker and placed on the cap of the prescription vial where it would be seen easily.

Warning labels for opioids may be useful because the prescription container label may be the only source of information patients review, according to some studies. And yet, 46% of patients in one study misunderstood one or more pieces of information on the label. Patients with low health literacy are more likely to ignore the labels.

Although the physical space for labeling on prescription containers is very limited, some of this space could be used in an impactful way to educate patients on the risk of opioid abuse and addiction. This could be an opportunity to provide clearer, more useful information to patients about the risks of prescription opioids. There is also concern, however, that a label identifying the drug as an opioid could lead to diversion.

When developing or choosing opioid warning labels that would be affixed to prescription container labels, the same health literacy principles used for auxiliary labels apply. The following key principles have been shown to convey messaging effectively in other health campaigns:

- All icons should be accompanied by text
- The label should address and emphasize the potential health consequences
- The warning should be frank and direct, clearly stating the serious—even fatal—consequences, in order to capture the reader's attention and have a strong impact
- Additional information should be accessible to the patient (e.g., pamphlet, guide, website)
- The labeling should be supported by established theory, such as behavior change theory, to have a public health impact
- The labeling should be linked to education and a media campaign with high visibility for the target populations▲ (USP 1-Dec-2021)

## Address Limited English Proficiency

Whenever possible, the directions for use on a prescription container label should be provided in the patient's preferred language. Otherwise there is a risk of misinterpretation of instructions by patients with limited English proficiency, which could lead to medication errors and adverse health outcomes. Additionally, whenever possible, directions for use should appear in English as well, to facilitate counseling; the drug name(s) shall be in English so that emergency personnel and other intermediaries can have quick access to the information. Standardized translations of universal medication schedule instructions are available.[3]

Translations of prescription medication labels should be produced using a high-quality translation process. An example of a high-quality translation process is:

- Translation by a trained translator who is a native speaker of the target language
- Review of the translation by a second trained translator and reconciliation of any differences
- Review of the translation by a pharmacist who is a native speaker of the target language and reconciliation of any differences
- Testing of comprehension with target audience

If a high-quality translation process cannot be provided, labels should be printed in English, with the use of trained interpreter services whenever possible to ensure patient comprehension. The use of computer-generated translations should be limited to programs with demonstrated quality because dosage instructions can be translated inconsistently or incorrectly, which is potentially hazardous. Standardized translated instructions and technology advances are needed to ensure the accuracy and safety of prescription container labeling for patients with limited English proficiency.

## Improve Readability

Labels should be designed and formatted so they are easy to read. Currently, no strong evidence supports the superiority, in terms of legibility, of serif versus sans serif typefaces, ▲however there are guidances that support sans serif typeface for labeling.[4, 5, 6]▲ (USP 1-Dec-2021)

Optimize typography by using the following techniques:

- High-contrast print (e.g., black print on white background).
- ▲Plain,▲ (USP 1-Dec-2021) uncondensed familiar fonts with sufficient space within letters and between letters (e.g., Times New Roman or Arial).

DOI: https://doi.org/10.31003/USPNF_M5531_02_01
@2024 USPC

- Sentence case (i.e., punctuated like a sentence in English: Initial capital letter followed by lower-case words except proper nouns).
- Large font size (e.g., minimum 12-point Times New Roman or 11-point Arial) for critical information. Note that point size is not the actual size of the letter, so two fonts with the same nominal point size can have different actual letter sizes. The height of the typeface, x-height, has been used as a more accurate indicator of apparent size than point size. For example, for a given point size, the x-height and apparent size of Arial are actually bigger than those for Times New Roman. Do not use type smaller than 10-point Times New Roman or the equivalent size in another font. Older adults, in particular, have difficulty reading small print.
- Adequate white space between lines of text (25%–30% of the point size).
- White space to separate sections on the label such as directions for use versus pharmacy information.
- Horizontal text only.

Other measures that can also improve readability:

- Minimize the need to turn the container in order to read lines of text
- Never truncate or abbreviate critical information
- Use highlighting, bolding, and other cues to preserve readability (e.g., high-contrast print and light color for highlighting) and emphasize patient-centered information or information that facilitates adherence (e.g., refill ordering)
- Limit the number of colors used for highlighting (i.e., no more than two)
- Use of separate lines to distinguish when each dose should be taken

## Alternative-Access Methods to Address Visual Impairment

Patients with visual impairment who are unable to read printed prescription container labels often report inadvertently taking the wrong medication or amount, or taking it at the wrong time or under the wrong instructions, compromising their own safety. Similarly, if a caregiver is visually impaired, the patient they care for is at risk for medication errors. The magnitude of this problem increases with aging, as the risk of visual impairment and the number of prescribed medications both increase with age.

- Follow standards for patient-centered prescription labels
- Provide alternative access for visually impaired patients (alternative-access methods include tactile, auditory, or enhanced visual systems that may employ advanced mechanics of assistive technology)[7]
- Enhance communication between the pharmacist and visually impaired patients (and their designated representatives) such that the pharmacist can explain alternative-access options and together they can identify those best suited to the patient's needs
- Once an alternative-access method is identified for the individual patient, the pharmacist shall provide the service or direct the patient to a pharmacy that offers that type of alternative access
- Ensure that duplicate accessible labels preserve the integrity of the print prescription drug container label and provide the same sequence of information as the printed label
- Follow specific best practices for each respective alternative-access format employed

# ⟨31⟩ VOLUMETRIC APPARATUS

Most of the volumetric apparatus available in the United States are calibrated at 20°, and the National Institute of Standards and Technology (NIST) has adopted 20° as the reference temperature for the calibration of laboratory glassware, although the temperatures generally prevailing in laboratories are usually between 20° and 25°. To minimize volumetric error, the temperature should be the same for the volumetric apparatus, the material being prepared, the solvents being used to prepare the volumetric solutions, the area in which they are prepared, and the final volume adjustment. To attain the degree of precision required in many Pharmacopeial assays involving volumetric measurements and directing that a quantity be "accurately measured", the apparatus must be chosen and used with care.

***Change to read:***

## STANDARDS OF ACCURACY

The capacity tolerances for volumetric flasks, transfer pipets, and burets are those accepted by NIST (Class A),[1] as indicated in *Table 1*, *Table 2*, and *Table 3*, respectively. [NOTE—The tables in this chapter list the tolerances for the most commonly used sizes. See the referenced ASTM standards for a complete list of tolerances and other applicable criteria.] Use Class A volumetric apparatus unless otherwise specified in the individual monograph. When a plastic volumetric apparatus is specified, the accepted capacity tolerances are equal to Class B glass.[2]

The capacity tolerances for measuring (i.e., "graduated") pipets of up to and including 10-mL capacity are somewhat larger than those for the corresponding sizes of transfer pipets, namely, 10, 20, and 30 µL for the 2-, 5-, and 10-mL sizes, respectively.[3]

Transfer and measuring pipets calibrated "to deliver" should be completely drained in a vertical position and then touched against the wall of the receiving vessel to drain the ▲pipet tip▲ (ERR 1-Nov-2020). Volume readings on burets should be estimated at least to the nearest one-half of a subdivision. Pipets calibrated "to contain" are called for in special cases, generally for measuring viscous fluids such as syrups; however, a volumetric flask may be substituted for a "to contain" pipet. In such cases, the pipet or flask should be washed clean after draining, and the washings should be added to the measured portion.

# ⟨41⟩ BALANCES

This chapter states the requirements for balances used for materials that must be accurately weighed (see *General Notices, 8.20 About*). Unless otherwise specified, when substances must be "accurately weighed", the weighing shall be performed using a balance that is calibrated over the operating range and meets the requirements defined for repeatability and accuracy. For balances used for other applications, the balance repeatability and accuracy should be commensurate with the requirements for its use.

For a discussion of the theoretical basis of these requirements, see *Weighing on an Analytical Balance* ⟨1251⟩, which may be a helpful—but not mandatory—resource.

***Change to read:***

## REPEATABILITY

Repeatability is assessed by weighing one test weight NLT 10 times. [NOTE—The test weight must be within the balance's operating range, but the weight need not be calibrated. Because the standard deviation is virtually independent of sample mass within the balance's capacity, use of a small test weight, which may be difficult to handle, is not required.]

Repeatability is satisfactory if ▲twice▲ (USP 1-Aug-2019) the standard deviation of the weighed value, ▲▲$s$▲ (ERR 1-Aug-2019) ,▲ (USP 1-Aug-2019)divided by the desired smallest net weight (i.e., smallest net weight that the users plan to use on that balance), does not exceed 0.10%. ▲The repeatability measurement establishes the smallest net amount of material that may be weighed on the balance in conformance with the 0.10% limit. The minimum weight, $M_{min}$, is described by the inequality $M_{min} \geq 2000$▲$s$▲ (ERR 1-Aug-2019). For example, if ▲$s$ is found to be 0.00015, then $M_{min}$ must be ≥ 0.30000 g or 300.00 mg.▲ (ERR 1-Aug-2019)▲ (USP 1-Aug-2019) If the standard deviation, $s$, obtained is less than 0.41$d$, where $d$ is the scale ▲interval of the balance, then the inequality becomes $M_{min} \geq 2000\ (0.41d)$. For example, for a 4-place analytical balance, $d$ is 0.0001 so that $M_{min}$ must be ≥ 0.0820 g or 82 mg.▲ (USP 1-Aug-2019)

## ACCURACY

The accuracy of a balance is satisfactory if its weighing value, when tested with a suitable weight(s), is within 0.10% of the test weight value.

A test weight is suitable if it has a mass between 5% and 100% of the balance's capacity. The test weight's maximum permissible error (mpe), or alternatively its calibration uncertainty, shall be NMT one-third of the applied test limit of the accuracy test.

[NOTE—Applicable standards are the following: American Society for Testing and Materials (ASTM) E617 (available from http://www.astm.org) and International Organization of Legal Metrology (OIML) R 111 (available from http://www.oiml.org).]

# ⟨51⟩ ANTIMICROBIAL EFFECTIVENESS TESTING

## INTRODUCTION

Antimicrobial preservatives are substances added to aqueous pharmaceutical products. Nonsterile dosage forms may have preservatives added to protect them from growth of microorganisms inadvertently introduced during or subsequent to the manufacturing process. In the case of sterile articles packaged in multiple-dose containers, antimicrobial preservatives are added to inhibit the growth of microorganisms that may be introduced from repeatedly withdrawing individual doses. One or more antimicrobial preservative(s) are expected in all sterile multidose units.

Antimicrobial preservatives should not be used as a substitute for good manufacturing practices, solely to reduce the viable microbial population of a nonsterile product, or control the presterilization bioburden of a multidose formulation during manufacturing. Antimicrobial preservatives in compendial dosage forms meet the requirements for *General Notices, 5.20 Added Substances*.

All useful antimicrobial agents are toxic substances. For maximum protection of patients, the concentration of the preservative shown to be effective in the final packaged product should be below a level that may be toxic to human beings based on the recommended dosage of the medicinal product.

The concentration of an added antimicrobial preservative can be kept to a minimum if the active ingredients of the formulation possess an intrinsic antimicrobial activity. Antimicrobial effectiveness, whether inherent in the product or produced because of the addition of an antimicrobial preservative, must be demonstrated for all injections packaged in multiple-dose containers or for other products containing antimicrobial preservatives. Antimicrobial effectiveness must be demonstrated for aqueous-based, multiple-dose topical and oral dosage forms and for other dosage forms such as ophthalmic, otic, nasal, irrigation, and dialysis fluids (see *Pharmaceutical Dosage Forms* ⟨1151⟩). For the purpose of the test, aqueous is defined as a water activity of more than 0.6 (see *Application of Water Activity Determination to Nonsterile Pharmaceutical Products* ⟨1112⟩).

Challenge organisms are generally based on likely contaminants to a drug product while considering its physical attributes, formulation, and intended use. The standard battery of challenge organisms described in this test need not prevent the inclusion of other species of microorganisms if deemed useful to measure the biological activity of the preservative system for a specific product. These supplemental challenge organisms are not within the scope of this chapter, but may be added in addition to the described test organisms.

## GENERAL PROCEDURES

This chapter provides procedures to demonstrate the effectiveness of added antimicrobial preservatives. Such antimicrobial preservatives must be declared on the label. The procedures and acceptance criteria for effectiveness apply to a product in the original, sealed container in which it was distributed by the manufacturer (see *Table 1* for categories of products). The test need not be conducted in these containers, but care should be taken to avoid using materials that can interact with the preservative in the containers that are used for antimicrobial effectiveness testing.

### Growth Promotion Procedure and Suitability of the Recovery Method

#### GENERAL CONSIDERATIONS

The ability of the procedure to detect challenge microorganisms in the presence of a suitably neutralized product to be tested must be established. The suitability of the procedure must be reconfirmed if a change is made in materials or methods or if a change is made in the product or direct product contact materials that may affect the outcome of the test.

The growth-promoting capabilities of media used in this procedure must be established.

#### PREPARATION OF TEST STRAINS

Use standardized suspensions of test strains or prepare as stated below. Seed-lot culture maintenance techniques (seed-lot systems) are used so that the viable microorganisms used for inoculation are NMT five passages removed from the original master seed lot. Grow each of the bacterial and fungal test strains separately (see *Table 2*).

Use cultures of the following microorganisms:[1] *Candida albicans* (ATCC No. 10231), *Aspergillus brasiliensis* (ATCC No. 16404), *Escherichia coli* (ATCC No. 8739), *Pseudomonas aeruginosa* (ATCC No. 9027), and *Staphylococcus aureus* (ATCC No. 6538). The viable microorganisms used in the procedure should be part of a freshly growing culture (e.g., in logarithmic growth phase) with the exception of *A. brasiliensis* spores. The culture conditions for the inoculum culture are described (see *Table 2*) in which the suitable media are Soybean–Casein Digest or Sabouraud Dextrose Agar Medium.

To harvest the bacterial and *C. albicans* cultures, use sterile saline TS to wash the surface growth, and collect it in a suitable vessel. To harvest the spores of *A. brasiliensis,* use sterile saline TS containing 0.05% of polysorbate 80. The spore suspension should be aseptically treated (e.g., filtration through sterile glass wool) to remove hyphae. All microbial suspensions should be prepared to ensure that there is no carry over of residual growth medium from the inoculum (e.g., centrifugation followed by resuspension in appropriate sterile suspending fluid.)

Alternatively, the stock culture organisms may be grown in a suitable liquid medium (i.e., Soybean–Casein Digest Broth or Sabouraud Dextrose Broth) and the cells harvested by centrifugation, then washed and resuspended in appropriate sterile suspending fluid. The microbial suspensions used for inoculations should be adjusted to obtain a microbial count of about 1 ×

[1] Available from American Type Culture Collection, 10801 University Boulevard, Manassas, VA 20110-2209 (http://www.atcc.org).

https://nhathuocngocanh.com/

$10^8$ cfu/mL. Use the bacterial and yeast suspensions within 2 h, or within 24 h if stored between 2° and 8°. A stable spore suspension can be prepared and then may be maintained at 2°–8° for up to 7 days. [NOTE—The estimate of inoculum concentration may be obtained by turbidimetric procedures for the challenge microorganisms and later confirmed by plate count.]

### GROWTH PROMOTION OF THE MEDIA

Media used in this procedure must be capable of supporting microbial growth. Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from the ingredients described.

For solid media, counts obtained must be at least 50% of the calculated value for a standardized inoculum. For a freshly prepared inoculum, growth of the microorganisms occurs comparable to that previously obtained with a previously tested and approved batch of medium.

## Suitability of the Counting Method in the Presence of Product

Prepare a $10^{-1}$ dilution by adding 1 mL of product (by volume) to 9 mL of saline or other neutralizing diluent. Continue this dilution scheme to $10^{-2}$ and $10^{-3}$ dilution levels. Add an appropriate number of challenge organisms to each tube of diluted product, mix, and then plate a suitable volume from each dilution to yield less than 250 cfu/plate for bacteria and yeast (ideally between 25 and 250 cfu) or less than 80 cfu/plate for *A. brasiliensis* (ideally between 8 and 80 cfu). This plating should be performed minimally in duplicate (although a greater number of replicates can be useful to minimize variability in the plate count estimate). A positive control for this procedure is to introduce the same inocula into saline, and transfer similar volumes of saline to agar plates. A suitable recovery scheme is the one that provides at least 50% of this saline control count (averaged).

If the diluted product exhibits antimicrobial properties, specific neutralizers may need to be incorporated into the diluents or the recovery media. See *Validation of Microbial Recovery from Pharmacopeial Articles* ⟨1227⟩ for more information.

The ability of the procedure to measure preservative efficacy may be compromised if the method suitability requires significant dilution ($10^{-2}$ or $10^{-3}$) as this will affect the measured recovery (e.g., it may be difficult to measure a 3 log unit reduction for a $10^5$–$10^6$ inoculum). If no suitable neutralizing agent or method is found and method suitability requires significant dilution, a higher level of inoculum (e.g., $10^7$–$10^8$) may be used so that a 3 log unit reduction can be measured. Reported recovery cannot be less than 1 cfu/plate on average (or 100 cfu/mL if 1 mL is plated in duplicate at the $10^{-2}$ dilution).

Membrane filtration may be used to filter larger volumes of dilutions to overcome this difficulty or to assist in the neutralization of antimicrobial properties.

## Testing of Products

### PRODUCT CATEGORIES

For the purpose of testing, compendial articles have been divided into four categories (see *Table 1*). The criteria of antimicrobial effectiveness for these products are a function of the route of administration. It is expected that formulations containing preservatives will meet minimal efficacy standards, whether packaged as multidoses or unit doses.

**Table 1. Compendial Product Categories**

| Category | Product Description |
|---|---|
| 1 | Injections; other parenterals including emulsions, otic products, sterile nasal products, and ophthalmic products made with aqueous bases or vehicles |
| 2 | Topically used products made with aqueous bases or vehicles; nonsterile nasal products and emulsions, including those applied to mucous membranes |
| 3 | Oral products other than antacids, made with aqueous bases or vehicles |
| 4 | Antacids made with an aqueous base |

### PROCEDURE

The procedure can be conducted either in five original containers if a sufficient volume of product is available in each container and if the product container can be entered aseptically (i.e., needle and syringe through an elastomeric rubber stopper), or in five sterile, capped bacteriological containers [inert relative to the antimicrobial agent(s)] of suitable size into which a sufficient volume of product has been transferred. Inoculate each container with one of the prepared and standardized inocula, and mix. The volume of the suspension inoculum used is between 0.5% and 1.0% of the volume of the product to minimize potential effects on the product. The concentration of test microorganisms that is added to the product (*Category 1, 2,* or *3*) is such that the final concentration of the test preparation after inoculation is between $1 \times 10^5$ and $1 \times 10^6$ cfu/mL of the product. For *Category 4* products (antacids), the final concentration of the test preparation after inoculation is between $1 \times 10^3$ and $1 \times 10^4$ cfu/mL of the product.

The initial concentration of viable microorganisms in each test preparation is estimated based on the concentration of microorganisms in each of the standardized inocula as determined by the plate-count method. Incubate the inoculated containers at 22.5 ± 2.5°. Sample each container at the appropriate intervals (specified in *Table 3*). Record any changes observed in appearance at these intervals. Determine, by the plate-count procedure, the number of cfu present in each test preparation for the applicable intervals (see *General Procedures* in *Microbial Enumeration Tests* ⟨61⟩). Plate counts will be conducted using a minimum of duplicate plates, with the cfu averaged before determination of deduced cfu/mL. If membrane filtration is used,

duplicate membrane filters will be used for each estimate. Using the calculated concentrations of cfu/mL present at the start of the test, calculate the change in $\log_{10}$ values of the concentration of cfu/mL for each microorganism at the applicable test intervals, and express the changes in concentration in terms of log reductions. The log reduction is defined as the difference between the $\log_{10}$ unit value of the starting concentration of cfu/mL in the suspension and the $\log_{10}$ unit value of cfu/mL of the survivors at that time point.

**Table 2. Culture Conditions for Inoculum Preparation**

| Organism | Suitable Medium | Incubation Temperature | Inoculum Incubation Time | Microbial Recovery Incubation Time |
|---|---|---|---|---|
| *Escherichia coli* (ATCC No. 8739) | Soybean–Casein Digest Broth; Soybean–Casein Digest Agar | 32.5 ± 2.5° | 18–24 h | 3–5 days |
| *Pseudomonas aeruginosa* (ATCC No. 9027) | Soybean–Casein Digest Broth; Soybean–Casein Digest Agar | 32.5 ± 2.5° | 18–24 h | 3–5 days |
| *Staphylococcus aureus* (ATCC No. 6538) | Soybean–Casein Digest Broth; Soybean–Casein Digest Agar | 32.5 ± 2.5° | 18–24 h | 3–5 days |
| *Candida albicans* (ATCC No. 10231) | Sabouraud Dextrose Agar; Sabouraud Dextrose Broth | 22.5 ± 2.5° | 44–52 h | 3–5 days |
| *Aspergillus brasiliensis* (ATCC No. 16404) | Sabouraud Dextrose Agar; Sabouraud Dextrose Broth | 22.5 ± 2.5° | 6–10 days | 3–7 days |

## Criteria for Antimicrobial Effectiveness

The requirements for antimicrobial effectiveness are met if the criteria specified in *Table 3* are met (see *General Notices, 7. Test Results*). “No increase” in counts is defined as NMT 0.5 $\log_{10}$ unit more than the value to which it is compared.

**Table 3. Criteria for Tested Microorganisms**

| | |
|---|---|
| **For Category 1 Products** | |
| Bacteria | NLT 1.0 log reduction from the initial calculated count at 7 days, NLT 3.0 log reduction from the initial count at 14 days, and no increase from the 14 days’ count at 28 days |
| Yeast and molds | No increase from the initial calculated count at 7, 14, and 28 days |
| **For Category 2 Products** | |
| Bacteria | NLT 2.0 log reduction from the initial count at 14 days, and no increase from the 14 days’ count at 28 days |
| Yeast and molds | No increase from the initial calculated count at 14 and 28 days |
| **For Category 3 Products** | |
| Bacteria | NLT 1.0 log reduction from the initial count at 14 days, and no increase from the 14 days’ count at 28 days |
| Yeast and molds | No increase from the initial calculated count at 14 and 28 days |
| **For Category 4 Products** | |
| Bacteria, yeast, and molds | No increase from the initial calculated count at 14 and 28 days |

# ⟨55⟩ BIOLOGICAL INDICATORS—RESISTANCE PERFORMANCE TESTS

## INTRODUCTION

A biological indicator (BI) is a well-characterized preparation of a specific microorganism with a known resistance to a specific sterilization process. The correct use of BIs in the development, validation, and control of sterilization processes requires that their population and resistance be accurately known. The population and resistance can be selected to confirm the adequacy of individual sterilization process conditions for an article. The recommendations of *Sterilization of Compendial Articles* ⟨1229⟩ should be followed for effective BI usage. The methods described below can be used to establish population and resistance, such that the response of the BI to the subject sterilization process is appropriate. Although the BI manufacturers are required to maintain rigorous control of population and resistance using the number of replicates as specified below, the end users are not required to use the same number of replicates for verification of those determinations. Conduct all of the tests described in this chapter under appropriate microbiological laboratory conditions (see *Microbiological Best Laboratory Practices* ⟨1117⟩).

## TOTAL VIABLE SPORE COUNT

### Sample Collection/Recovery

PAPER/FIBER INDICATORS

For paper/fiber carrier BIs, remove at least four test samples from their individual containers. Disperse the indicator into component fibers by placing the test samples in a sterile vessel containing 100 mL of sterilized *Purified Water* chilled to 2°–8°, and mechanically disrupt to achieve a homogeneous suspension. For self-contained BIs, aseptically remove four BI carriers from their containers and proceed as directed above.

INDICATORS ON OTHER SUBSTRATES

For all other biological indicators, remove at least four samples from their individual containers. Place the test samples in a sterile vessel containing 100 mL of sterilized *Purified Water* chilled to 2°–8°, and mechanically disrupt to achieve a homogeneous suspension of the spores in the water.

SPORE SUSPENSIONS

For spore suspensions of BIs, prepare an appropriate serial dilution of the original spore suspension in sterilized *Purified Water* chilled to 2°–8°, in a sterile container, and follow the viable spore count procedures as specified below. The requirements of the tests are met if the average number of viable spores is within 50%–300% of the labeled count of the spore suspension.

Official

### Viable Spore Count

Transfer a 10-mL aliquot of the suspension to a sterile tube. For BIs using spores of *Geobacillus stearothermophilus*, *Bacillus coagulans*, and other thermophilic spore formers, heat the tube containing the suspension in a water bath at 95°–100° for 15 min (heat shock), starting the timing when the temperature reaches 95°. For BIs containing nonthermophilic spore formers, heat the tube containing the suspension in a water bath at 80°–85° for 10 min, starting the timing when the temperature of the spore suspension reaches 80°. Cool suspensions rapidly in an ice-water bath at 0°–4°. Transfer two 1-mL aliquots to suitable tubes, and make appropriate serial dilutions in sterilized *Purified Water*. Calculate the dilutions to yield 30–300 colonies on each plate in a pair, when treated as described below. Where the BI has a low spore concentration, it may be necessary to modify the dilution series and to use more plates at each dilution.

Prepare a separate series of plates for each aliquot. Place 1.0 mL of each selected dilution in each of two 15 × 100-mm Petri dishes. Within 20 min, add to each plate 20 mL of *Soybean–Casein Digest Agar Medium* that has been melted and cooled to approximately 45°. Swirl to attain a homogeneous suspension, and allow it to solidify. Incubate the plates in an inverted position at 55°–60° for thermophilic spore formers and at 30°–35° for nonthermophilic spore formers or at the optimal recovery temperature specified by the manufacturer. Examine the plates after at least 48 h, recording for each plate the number of colonies. Calculate the average number of spores per test sample from the results, using the appropriate dilution factor. When evaluating vendor-supplied BIs, the viable spore count shall be between 50% and 300% of the manufacturer's stated value.

***Change to read:***

## D-VALUE DETERMINATION

### Apparatus

The test equipment used for the determination of microbial resistance ("D-value") is described in substantial detail in ISO 18472, Sterilization of Health Care Products—Biological and Chemical Indicators—Test Equipment (*1*). The details of individual Biological Indicator Evaluation Resistometers (BIERs) vary with the specifics of their design and the particular sterilization process for which they are used. Provided that the performance of the BIER vessel meets the requirements of the ISO standard for

https://pharmacopeia.com/

exposure of the BI, design differences are acceptable. For single-phase sterilization processes where an acceptable BIER has not been defined, the D-value determination can be accomplished by adapting a BIER design intended for a sterilization process operating in the same phase. There are no current methods available for D-value determination for multiple-phase sterilization processes.

## Procedure

Carry out the tests for D-value at sterilization conditions consistent with those intended for use. Use 20 replicate test sample BIs in their original individual containers, subjected to at least five exposure conditions for a total of 100 tests. The number of exposure conditions is chosen to provide a range of observations from NLT one labeled D-value below the expected survival time through NLT one labeled D-value above the expected kill time. Place each group on a separate suitable sample holder that permits each sample to be exposed to the prescribed sterilizing condition at a specific location in the sterilizing chamber of the BIER. Check the BIER apparatus for operating parameters using sample holders without test samples. Select a series of sterilizing times in increments from the shortest time for the samples to be tested. The differences in sterilizing times over the series are as constant as feasible, and the difference between adjacent times is NMT 75% of the expected D-value. Test procedures for the use of BIER vessels for the evaluation of microbial resistance are defined in a series of ISO standards under the 11138 series (*2*–*5*). The appropriate standard should be followed for the BI. The test methods and carriers used with the BIER may be adapted to the specifics of the BI. The method and apparatus used for paper carriers may differ from those for other carriers and will be substantially different from those used for suspensions of BIs.

The D-value exposure conditions for alternative material carriers are the same as the conditions used to determine the D-value for paper carriers. If a manufacturer's label permits usage of the BI carrier with multiple sterilization methods, then data on D-value, survival time, and kill time will need to be provided by the manufacturer for each sterilization method.

For BIs that are spore suspensions, conduct D-value determinations for each of the microorganisms that are provided as a liquid spore crop suspension. The test is conducted using appropriate serial dilutions predicated upon the stated spore ▲titer▲ (ERR 1-Nov-2019) of the suspension in *Purified Water* in a sterile tube. Where the suspension is placed on or in a substrate such as an elastomeric closure or formulated product, its resistance may differ from that determined in *Purified Water*. That difference may be significant to the usage of the BIs and appropriate measurements made before use in sterilization validation activities.

## Recovery

After completion of the sterilizing procedure for BIs and within a noted time (NMT 4 h), aseptically remove and add each BI to a suitable medium (see media in *Sterility Tests* ⟨71⟩) to submerge the BI completely in a suitable tube. For self-contained BIs, the paper strip is immersed in the self-contained medium according to manufacturers' instructions, within a noted time NMT 4 h. For insoluble items inoculated with a spore suspension, aseptically transfer these items individually to a suitable medium (see media in ⟨71⟩) to submerge the item completely in the medium. When a sealed aqueous filled container has been inoculated, test the units individually, as described within ⟨71⟩.

Incubate each tube at the optimal recovery temperature appropriate for the BI. Observe each inoculated medium-containing tube at appropriate intervals for a total of 7 days after inoculation. Where growth is observed at any particular observation time, further incubation of the test sample(s) concerned may be omitted. Note the number of samples showing no evidence of growth at any time.

Where *Clostridium sporogenes* or another anaerobic microorganism is used as a BI, methods for preparation, inoculation, and recovery methods and media must be adapted to accommodate the use of these anaerobic spore formers.

## Calculation

The determination of D-values of BIs can be performed using the Limited Spearman-Karber, Survival Curve Method, or Stumbo-Murphy-Cochran procedures (*6*–*8*). When the BI has been purchased, use the same method as that defined by the BI manufacturer to subsequently determine D-values. The use of an alternate method can result in differences that are more an artifact of the method than a variation in the performance of the BI.

## Survival Time and Kill Time

Take two groups of BIs, each consisting of 10 test samples, in their original, individual containers. Place the samples of each group in suitable sample holders that permit each sample to be exposed to the sterilizing conditions at a specific location in the BIER chamber.

Expose the samples for the required survival time, enter the chamber, and remove the holder(s) containing the 10 test samples. Repeat the above procedure immediately, or preheat if a substantial interval has elapsed, so as to subject the second holder(s) containing 10 test samples similarly to the first conditions, but for the required kill time. Recover BIs as described above. The *Survival Time and Kill Time* should be provided by the BI manufacturer and verified by the end user.

# ▲⟨56⟩ METHODS FOR DETERMINATION OF RESISTANCE OF MICROORGANISMS TO STERILIZATION PROCESSES

## INTRODUCTION

Sterilization relies on the reliable destruction of microorganisms present in/on the materials being sterilized. Information regarding the resistance of the bioburden to the sterilization process (with the possible exception of overkill processes) is essential to confirm the efficacy of the sterilization process (see *Sterilization of Compendial Articles* ⟨1229⟩) and is also a required component of a parametric release program (*1*,*2*). Spores exhibit inherent and varying levels of resistance to all modalities of sterilization. There are limited resistance data available for some spore-forming and pathogenic microorganisms; however, for the vast majority of microorganisms (including most spores), there is no data available regarding their susceptibility to sterilization processes when present in or on pharmaceutical articles (*3*). Furthermore, wild type microorganisms and spores derived from manufacturing processes are likely distinct from their reference-standard culture-collection counterparts and may exhibit differing levels of resistance to sterilization processes (*3*). This chapter outlines methods that can be used to determine the presence of spores and the resistance of microorganisms, spores, and biologic indicators (BIs) to moist heat sterilization, including variations of the boil test mentioned in *Moist Heat Sterilization of Aqueous Liquids* ⟨1229.2⟩ and *Monitoring of Bioburden* ⟨1229.3⟩. The methods included in this chapter are not intended for use in radiation sterilization where the procedures described in ISO 11137 are to be followed (*4*).

## GENERAL PROCEDURES

Carry out the tests under conditions designed to avoid extrinsic microbial contamination of the materials to be examined. The precautions taken to avoid contamination must be such that they do not affect the microorganisms that are recovered in the test. If the product to be examined has antimicrobial activity, insofar as possible, this should be removed or neutralized during the presence or absence test for spores. If inactivators are used for this purpose, their efficacy and their nontoxicity to the microorganisms must be demonstrated. If surface-active substances are used for sample preparation, their nontoxicity to the microorganisms and compatibility with any inactivators used must be demonstrated.

### Preparation of the Sample

The method for sample preparation depends on the physical characteristics of the pre-sterilization material to be tested. For aqueous products, 10-mL samples should be taken from closed primary containers. Composite sampling may be used. For solid, water-insoluble, or immiscible products, follow the sample preparation details provided in *Microbial Enumeration Tests* ⟨61⟩. Samples should be aseptically transferred (either from 1 unit or composite) to sterile, screw-capped tubes. A minimum of 10 samples should be tested to minimize variability.

## PRESENCE/ABSENCE TEST FOR SPORES (ALL STERILIZATION PROCESSES EXCEPT FILTRATION AND RADIATION)

A universal assumption in overkill sterilization processes is that the resistance of the bioburden microorganisms as compared to the BI is negligible because the BI is specifically chosen as a "worst case" challenge to the sterilization process (*1*). This is predicated upon an assumption of the absence of spores in the pre-sterilization bioburden. A test in which bioburden samples are exposed to 70°–75° for 30 min can be used to confirm the absence of spores. Vegetative microorganisms are seldom resistant to temperatures >70° and are killed under these conditions. However, under these temperature conditions with the presence of non-nutrient germinants (agents not necessary for growth but which promote germination of spores, such as Ca-DPA and dodecylamine), spore germination is promoted by heat activation. This test is suitable where the presence of spores in the pre-sterilization bioburden is associated with a greater chance for survival (*5*). When spores are detected, resistance testing as outlined below for moist heat sterilization or in ISO 11138 series of standards (*6*,*7*) should be conducted to confirm that process lethality is sufficient.

### Heat Treatment

Transfer the screw-capped tubes to a water bath, heat the contents to 70°–75°, and hold at this temperature for 30 min.

### Recovery and Enumeration of Spores

Immediately cool the product to 30°–35°, and aseptically add sterile calcium dipicolinic acid (Ca-DPA) and dodecylamine (non-nutrient germinants) in Buffered Sodium Chloride–Peptone Solution pH 7.0 or in Phosphate Buffer Solution pH 7.2 to generate concentrations of 60 and 1.2 mM, respectively. Maintain the solutions at 30°–35° for 30 min. Use either membrane filtration or plate-count methods per ⟨61⟩ for the recovery and growth of spores with *Soybean–Casein Digest Agar* containing 60 mM Ca-DPA and 1.2 mM dodecylamine, incubated at 30°–35° for 5–7 days.

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:38:34 AM(EST)
Printed by: USP NF
Do Not Distribute

## Positive and Negative Controls

To verify efficacy of heat treatment, a positive control is included by inoculating at least one additional test sample with a countable number of spores such as *Bacillus subtilis*. There must be growth of microorganisms. To verify testing conditions, a negative control is included using the chosen diluent in a screw-capped tube in place of the test sample. There must be no growth of microorganisms.

## Growth Promotion of Media

Test each batch of *Soybean–Casein Digest Agar* containing 60 mM Ca-DPA and 1.2 mM dodecylamine per *Microbial Enumeration Tests* ⟨61⟩, *Table 1*.

## Suitability of Recovery and Enumeration

Perform method suitability per ⟨61⟩ by adding a sufficient volume of microbial suspension of *Bacillus subtilis* ATCC 6633, NCIMB 8054, CIP 52.62, or NBRC 3134 to the cooled product and demonstrating acceptable recovery on *Soybean–Casein Digest Agar* containing 60 mM Ca-DPA and 1.2 mM dodecylamine.

## Interpretation of Results

The presence of colony forming units suggests that spores are on/in the product and more definitive estimation of their resistance should be considered (see below).

# RESISTANCE ESTIMATION (MOIST HEAT PROCESSES ONLY)

This test method, also known as Boil Test, can be applied to estimate moist heat resistance of spores present in pre-sterilization product. Initially, a range of times can be used to estimate moist heat resistance (*Preliminary Resistance Estimation*). The use of a single time period tailored to the pre-established limits for resistance (*Maximum Resistance Estimation*) can be used to support parametric release to confirm sterilization process suitability. Either of these tests can be performed with parallel testing of a biological indicator microorganism for comparison purposes.

## Preliminary Resistance Estimation

Transfer samples in screw-capped tubes to a water bath, heat the contents to 95°–100°, and incubate at this temperature using a range of time periods (see *Table 1*). *Recovery and Enumeration of Spores*, *Positive and Negative Controls*, *Growth Promotion of Media*, and *Suitability of Recovery and Enumeration* are performed as described above.

### INTERPRETATION OF RESULTS

The estimated moist heat resistance of spores is established by the maximum time where colony growth is determined as shown in *Table 1*. Adjustments in dwell time (shorter or longer) at 95°–100° can be used to accommodate the microorganisms detected.

## Maximum Resistance Estimation

Transfer samples in screw-capped tubes to a water bath, heat the contents to 95°–100°, and incubate at this temperature for the desired time. *Recovery and Enumeration of Spores*, *Positive and Negative Controls*, *Growth Promotion of Media*, and *Suitability of Recovery and Enumeration* are performed as described above.

### INTERPRETATION OF RESULTS

The presence of colony forming units suggests that spores are present with a level of moist heat resistance to sterilization and requires further investigation.

**Table 1. Moist Heat Resistance Estimation from Boil Test**

| Exposure Time at 95°–100° with Positive Growth (min) | Approximate $D_{121°}$-Value (min) |
|---|---|
| 10 | ≥0.1 |
| 20 | ≥0.2 |
| 30 | ≥0.3 |
| 40 | ≥0.4 |
| 50 | ≥0.5 |

# *D*-VALUE DETERMINATION (MOIST HEAT PROCESSES ONLY)

The determination of *D*-value for microorganisms and BIs is a required aspect of sterilization cycle development and validation (*1,8*). The established procedures for this determination are focused on moist heat processes performed near 121° and rely upon equipment specifically designed to operate with saturated steam. Accurate resistance determination for biological indicators and bioburden isolates from moist heat processes operating at lower temperatures can benefit from the alternative practices described below.

## *D*-value Determination for >110° Processes

The methods described in *Biological Indicators—Resistance Performance Tests* ⟨55⟩ should be followed. Additional details regarding the procedures and equipment can be found in ISO 18472, *Sterilization of health care products—Biological and chemical indicators—Test equipment* (*9*).

## *D*-value Determination for ≤110° Processes

The apparatuses for *D*-value determination at 121° utilize saturated steam and resemble steam sterilizers in their design and operation. With the use of sterilization processes at temperatures ≤110°, adaptation of the test equipment and methods to better suit the use of lower temperatures is appropriate. Adjustments in dwell time (shorter or longer) and operating temperature may be necessary to accommodate the microorganism being tested (*10*). These methods apply directly to BI's used for low temperature moist heat processes and must be adapted for use with bioburden isolates.

### PROCEDURE

Carry out the tests for *D*-value at sterilization conditions consistent with those intended for use. Use 20 replicate (BI or bioburden isolate) test sample items subjected to NLT 5 exposure conditions for a total of 100 tests. The number of exposure conditions is chosen to provide a range of observations from NLT 1 *D*-value below the expected survival time through NLT 1 *D*-value above the expected kill time. Place each group in a separate suitable sample holder that permits each sample to be exposed to the prescribed temperature condition in a water bath at 95°–100° (other temperatures can be utilized as necessary). Check the apparatus for operating parameters using sample holders with dummy test samples. Select a series of sterilizing times in increments starting with the shortest time for the samples to be tested. The differences in sterilizing times over the series are as constant as feasible, and the difference between adjacent times is NMT 75% of the expected *D*-value. Test procedures for the evaluation of microbial resistance are defined in the ISO 11138-series standards (*6,7*). The test methods and carriers used may be adapted to the specifics of the microorganisms being evaluated.

For microorganisms that are spores in suspension, the test is conducted using appropriate serial dilutions predicated upon the stated spore titer of the suspension in *Sterilized Purified Water* in a sterile tube.

### RECOVERY

After completion of the sterilizing procedure and within a noted time (NMT 4 h), aseptically remove and add each sample to a suitable medium (see *Sterility Tests* ⟨71⟩, *Culture Media and Incubation Temperatures*), submerging the unit completely in a suitable tube. For self-contained BIs, the paper strip is immersed in the self-contained medium according to manufacturers' instructions, within a noted time of NMT 4 h. For insoluble items inoculated with a spore suspension, aseptically transfer these units individually to a suitable medium (see media in ⟨71⟩) supplemented to contain 60 mM Ca-DPA and 1.2 mM dodecylamine and submerge the items completely in the medium. When a sealed aqueous filled container has been inoculated, test the units individually, as described in ⟨71⟩.

Incubate each tube at the optimal recovery temperature. For bioburden isolates, recovery methods and media may be modified as needed. Observe each inoculated medium-containing tube at appropriate intervals for a total of 7 days after inoculation. Where growth is observed at any observation time, further incubation of the test sample(s) concerned may be omitted. Note the number of samples showing no evidence of growth at any time.

Where *Clostridium sporogenes* or another anaerobic microorganism is used as a BI, methods for preparation, inoculation, recovery, and media must be adapted to accommodate the use of these anaerobic spore-formers.

### CALCULATION

The determination of *D*-values of microorganisms can be performed using the limited Spearman-Karber procedure, survival curve method, or Stumbo-Murphy-Cochran procedure (*3,11,12*). When a BI has been purchased, use the same method as that defined by the BI manufacturer to subsequently determine *D*-values. The use of an alternate method can result in differences that may be an artifact of the method rather than a variation in the performance of the BI.

# ▲⟨60⟩ MICROBIOLOGICAL EXAMINATION OF NONSTERILE PRODUCTS —TESTS FOR *BURKHOLDERIA CEPACIA* COMPLEX

## INTRODUCTION

The tests described in this chapter will allow determination of the absence of *Burkholderia cepacia* complex (Bcc), which can be detected under the conditions described.

The tests are designed to determine whether a substance or preparation complies with an established specification for microbiological quality and/or to evaluate whether products—especially those for inhalation use or aqueous preparations for oral, oromucosal, cutaneous, or nasal use—contain members of the Bcc.

## GROWTH-PROMOTING AND INHIBITORY PROPERTIES OF THE MEDIA AND SUITABILITY OF TESTS FOR ABSENCE OF Bcc

Test each batch of ready-prepared medium and each batch of medium prepared from either dehydrated medium or ingredients.

### Preparation of Test Strains

Use standardized stable suspensions of test strains (see *Table 1*) NMT 5 passages removed from the original strain culture.

**Table 1. Test Strains of Microorganisms for Growth Promotion and Suitability Testing**

| Microorganism | Standard Strain |
|---|---|
| *Burkholderia cepacia* | ATCC 25416, NCTC 10743, or CIP 80.24 |
| *Burkholderia cenocepacia* | ATCC BAA-245 or LMG 16656 |
| *Burkholderia multivorans* | ATCC BAA-247, LMG 13010, CCUG 34080, CIP 105495, DSM 13243, or NCTC 13007 |
| *Pseudomonas aeruginosa* | ATCC 9027, NCIMB 8626, CIP 82.118, or NBRC 13275 |
| *Staphylococcus aureus* | ATCC 6538, NCIMB 9518, CIP 4.83, or NBRC 13276 |

### Microorganisms

Grow each of the test strains separately in *Soybean–Casein Digest Broth* or on Soybean–Casein Digest Agar at 30°–35° for 18–24 h.

Use *Buffered Sodium Chloride–Peptone Solution pH 7.0* or *Phosphate Buffer Solution pH 7.2* to make the test suspensions. Use the suspensions within 2 h, or within 24 h if stored at 2°–8°. If purchased, follow the supplier's instructions. If self-prepared cultures are used, follow a validated procedure (such as in *Microbial Enumeration Tests* ⟨61⟩) for preparation. Use a challenge inoculum of NMT 100 colony-forming units (cfu) for growth promotion and suitability testing.

#### NEGATIVE CONTROLS

Include a negative control to verify the testing conditions. There must be no growth of microorganisms. A negative control is also performed when testing the products as described in *Testing of Products*.

#### TEST FOR GROWTH-PROMOTING PROPERTIES, SOLID MEDIA

Perform the *Surface-Spread Method* (see *Microbial Enumeration Tests* ⟨61⟩, *Growth Promotion Test, Suitability of the Counting Method and Negative Controls, Suitability of the Counting Method in the Presence of Product, Recovery of Microorganisms in the Presence of Product, Plate-Count Methods*), inoculating each plate with a small number (NMT 100 cfu) of the appropriate microorganism (see *Table 2*). Incubate at the specified temperature for NMT the shortest period of time specified in the test. Growth of the microorganism comparable to that previously obtained with a previously tested and approved batch of medium occurs.

**Table 2. Microorganisms for the Growth-Promoting, Inhibitory, and Indicative Properties of the Media**

| Medium | Property | Microorganism |
|---|---|---|
| *Burkholderia cepacia* selective agar | Growth-Promoting and Indicative | *Burkholderia cepacia*, *Burkholderia cenocepacia*, or *Burkholderia multivorans* |
| | Inhibitory | *Pseudomonas aeruginosa*, *Staphylococcus aureus* |

TEST FOR INHIBITORY PROPERTIES, SOLID MEDIA

Inoculate the appropriate medium with at least 100 cfu of the appropriate microorganism. Incubate at the specified temperature for NLT the longest period of time specified in the test. Inhibition of growth of the indicated microorganisms occurs (see *Table 2*).

TEST FOR INDICATIVE PROPERTIES

Perform the *Surface-Spread Method* (see *Microbial Enumeration Tests* ⟨61⟩*, Growth Promotion Test, Suitability of the Counting Method and Negative Controls, Suitability of the Counting Method in the Presence of Product, Recovery of Microorganisms in the Presence of Product, Plate-Count Methods*), inoculating each plate with a small number (NMT 100 cfu) of the indicated microorganism. Incubate at the specified temperature for a period of time within the range specified in the test. Colonies are comparable in appearance and indication reactions to those previously obtained with a previously tested and approved batch of medium (see *Table 2*).

### Suitability of the Test Method

The ability of the test to detect Bcc in the presence of the product to be tested must be established. The incubation time for the method suitability should not exceed the shortest incubation period specified. Suitability must be confirmed if there is a change in testing performance or a change in the product that may affect the outcome of the test.

For each new product to be tested, perform the sample preparation as described in *Testing of Products*. At the time of mixing, add each test strain in the prescribed growth medium. Inoculate the test strains individually. Use a number of microorganisms equivalent to NMT 100 cfu in the inoculated test preparation.

Perform the test as described in *Testing of Products*, using the shortest incubation period prescribed. Bcc microorganisms must be detected with the indication reactions described in *Interpretation*.

Any antimicrobial activity of the product necessitates a modification of the test procedure (see *Microbial Enumeration Tests* ⟨61⟩*, Growth Promotion Test, Suitability of the Counting Method and Negative Controls, Suitability of the Counting Method in the Presence of Product, Neutralization/Removal of Antimicrobial Activity*).

## TESTING OF PRODUCTS

### Sample Preparation and Pre-Incubation

Prepare a sample using a 1-in-10 dilution of NLT 1 g of the product to be examined. Use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described in *Suitability of the Test Method*) of *Soybean–Casein Digest Broth* or an appropriate dilution of *Soybean–Casein Digest Broth* as determined during method suitability (for example, a 1:10 dilution may be required when conducting optional testing of pharmaceutical waters). Then mix and incubate at 30°–35° for 48–72 h.

### Selection and Subculture

Subculture by streaking on a plate of *Burkholderia cepacia* selective agar (BCSA), and incubate at 30°–35° for 48–72 h.

### Interpretation

The possible presence of Bcc is indicated by the growth of greenish–brown colonies with yellow halos, or white colonies surrounded by a pink–red zone on BCSA. Any growth on BCSA is confirmed by identification tests. See *Microbial Characterization, Identification, and Strain Typing* ⟨1113⟩ for additional information.

The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

## RECOMMENDED CULTURE MEDIA

[NOTE—This section is given for information.]

The following solutions and culture media have been found satisfactory for the purposes for which they are prescribed in the tests in this Pharmacopeia. Other media may be used provided that their suitability can be demonstrated.

### Stock Buffer Solution

Transfer 34 g of potassium dihydrogen phosphate to a 1000-mL volumetric flask, dissolve in 500 mL of *Purified Water*, adjust with sodium hydroxide to a pH of 7.2 ± 0.2, add *Purified Water* to volume, and mix. Dispense in containers, and sterilize. Store at a temperature of 2°–8°.

## Phosphate Buffer Solution pH 7.2

Prepare a mixture of *Purified Water* and *Stock Buffer Solution* (800:1 v/v), and sterilize.

## Buffered Sodium Chloride–Peptone Solution pH 7.0

Prepare *Buffered Sodium Chloride–Peptone Solution pH 7.0* as directed in *Table 3*. Sterilize in an autoclave using a validated cycle.

**Table 3**

| | |
|---|---|
| Potassium dihydrogen phosphate | 3.6 g |
| Disodium hydrogen phosphate dihydrate | 7.2 g (equivalent to 0.067 M of phosphate) |
| Sodium chloride | 4.3 g |
| Peptone (meat or casein) | 1.0 g |
| *Purified Water* | 1000 mL |

## Soybean–Casein Digest Broth

Prepare *Soybean–Casein Digest Broth* as directed in *Table 4*. Adjust the pH so that after sterilization it is 7.3 ± 0.2 at 25°. Sterilize in an autoclave using a validated cycle.

**Table 4**

| | |
|---|---|
| Pancreatic digest of casein | 17.0 g |
| Papaic digest of soybean | 3.0 g |
| Sodium chloride | 5.0 g |
| Dibasic hydrogen phosphate | 2.5 g |
| Glucose monohydrate | 2.5 g |
| *Purified Water* | 1000 mL |

## *Burkholderia cepacia* Selective Agar

Prepare BCSA as directed in *Table 5*. When preparing media in-house, first prepare the base ingredients without the antibiotics. Adjust the pH so that after sterilization it is 6.8 ± 0.3 at 25°. Sterilize in an autoclave using a validated cycle. Cool the base medium to 45°–50° and add a 1% solution of the sterile filtered antibiotics, mix, and pour into the plates.

**Table 5**

| | |
|---|---|
| Casein peptone | 10.0 g |
| Lactose | 10.0 g |
| Sucrose | 10.0 g |
| Sodium chloride | 5.0 g |
| Yeast extract | 1.5 g |
| Phenol red | 0.08 g |
| Gentamicin | 10.0 mg |
| Vancomycin | 2.5 mg |
| Crystal violet | 2.0 mg |
| Polymyxin B | 600,000 U |
| Agar | 14.0 g |
| Demineralized water | 1000 mL▲ (USP 1-Dec-2019) |

# ⟨61⟩ MICROBIOLOGICAL EXAMINATION OF NONSTERILE PRODUCTS: MICROBIAL ENUMERATION TESTS

## INTRODUCTION

The tests described hereafter will allow quantitative enumeration of mesophilic bacteria and fungi that may grow under aerobic conditions.

The tests are designed primarily to determine whether a substance or preparation complies with an established specification for microbiological quality. When used for such purposes, follow the instructions given below, including the number of samples to be taken, and interpret the results as stated below.

The methods are not applicable to products containing viable microorganisms as active ingredients.

Alternative microbiological procedures, including automated methods, may be used, provided that their equivalence to the Pharmacopeial method has been demonstrated.

## GENERAL PROCEDURES

Carry out the determination under conditions designed to avoid extrinsic microbial contamination of the product to be examined. The precautions taken to avoid contamination must be such that they do not affect any microorganisms that are to be revealed in the test.

If the product to be examined has antimicrobial activity, this is, insofar as possible, removed or neutralized. If inactivators are used for this purpose, their efficacy and their absence of toxicity for microorganisms must be demonstrated.

If surface-active substances are used for sample preparation, their absence of toxicity for microorganisms and their compatibility with any inactivators used must be demonstrated.

## ENUMERATION METHODS

Use the *Membrane Filtration* method or one of the *Plate-Count Methods*, as directed. The *Most-Probable-Number (MPN) Method* is generally the least accurate method for microbial counts; however, for certain product groups with very low bioburden, it may be the most appropriate method.

The choice of a method is based on factors such as the nature of the product and the required limit of microorganisms. The method chosen must allow testing of a sufficient sample size to judge compliance with the specification. The suitability of the chosen method must be established.

## GROWTH PROMOTION TEST, SUITABILITY OF THE COUNTING METHOD AND NEGATIVE CONTROLS

### General Considerations

The ability of the test to detect microorganisms in the presence of product to be tested must be established.

Suitability must be confirmed if a change in testing performance or a change in the product that may affect the outcome of the test, is introduced.

### Preparation of Test Strains

Use standardized stable suspensions of test strains or prepare as stated below. Seed-lot culture maintenance techniques (seed-lot systems) are used so that the viable microorganisms used for inoculation are not more than five passages removed from the original master seed-lot. Grow each of the bacterial and fungal test strains separately as described in *Table 1*.

**Table 1. Preparation and Use of Test Microorganisms**

| | | Growth Promotion | | Suitability of Counting Method in the Presence of Product | |

| *Candida albicans* such as ATCC 10231, NCPF 3179, IP 48.72, or NBRC 1594 | Sabouraud Dextrose Agar or Sabouraud Dextrose Broth<br>20°–25°<br>2–3 days | Soybean–Casein Digest Agar<br>≤100 cfu<br>30°–35°<br>≤5 days | Sabouraud Dextrose Agar<br>≤100 cfu<br>20°–25°<br>≤5 days | Soybean–Casein Digest Agar<br>≤100 cfu<br>30°–35°<br>≤5 days<br>MPN: not applicable | Sabouraud Dextrose Agar<br>≤100 cfu<br>20°–25°<br>≤5 days |
| *Aspergillus brasiliensis* such as ATCC 16404, IMI 149007, IP 1431.83, or NBRC 9455 | Sabouraud Dextrose Agar or Potato–Dextrose Agar<br>20°–25° 5–7 days, or until good sporulation is achieved | Soybean–Casein Digest Agar<br>≤100 cfu<br>30°–35°<br>≤5 days | Sabouraud Dextrose Agar<br>≤100 cfu<br>20°–25°<br>≤5 days | Soybean–Casein Digest Agar<br>≤100 cfu<br>30°–35°<br>≤5 days<br>MPN: not applicable | Sabouraud Dextrose Agar<br>≤100 cfu<br>20°–25°<br>≤5 days |

Use *Buffered Sodium Chloride–Peptone Solution pH 7.0* or *Phosphate Buffer Solution pH 7.2* to make test suspensions; to suspend *A. brasiliensis* spores, 0.05% of polysorbate 80 may be added to the buffer. Use the suspensions within 2 hours, or within 24 hours if stored between 2° and 8°. As an alternative to preparing and then diluting a fresh suspension of vegetative cells of *A. brasiliensis* or *B. subtilis,* a stable spore suspension is prepared and then an appropriate volume of the spore suspension is used for test inoculation. The stable spore suspension may be maintained at 2° to 8° for a validated period of time.

## Negative Control

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of microorganisms. A negative control is also performed when testing the products as described under *Testing of Products*. A failed negative control requires an investigation.

## Growth Promotion of the Media

Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from the ingredients described.

Inoculate portions/plates of *Soybean–Casein Digest Broth* and *Soybean–Casein Digest Agar* with a small number (not more than 100 cfu) of the microorganisms indicated in *Table 1*, using a separate portion/plate of medium for each. Inoculate plates of *Sabouraud Dextrose Agar* with a small number (not more than 100 cfu) of the microorganisms indicated in *Table 1*, using a separate plate of medium for each. Incubate according to the conditions described in *Table 1*.

For solid media, growth obtained must not differ by a factor greater than 2 from the calculated value for a standardized inoculum. For a freshly prepared inoculum, growth of the microorganisms comparable to that previously obtained with a previously tested and approved batch of medium occurs. Liquid media are suitable if clearly visible growth of the microorganisms comparable to that previously obtained with a previously tested and approved batch of medium occurs.

## Suitability of the Counting Method in the Presence of Product

### PREPARATION OF THE SAMPLE

The method for sample preparation depends on the physical characteristics of the product to be tested. If none of the procedures described below can be demonstrated to be satisfactory, a suitable alternative procedure must be developed.

**Water-Soluble Products—**Dissolve or dilute (usually a 1 in 10 dilution is prepared) the product to be examined in *Buffered Sodium Chloride–Peptone Solution pH 7.0, Phosphate Buffer Solution pH 7.2,* or *Soybean–Casein Digest Broth*. If necessary, adjust to a pH of 6 to 8. Further dilutions, where necessary, are prepared with the same diluent.

**Nonfatty Products Insoluble in Water—**Suspend the product to be examined (usually a 1 in 10 dilution is prepared) in *Buffered Sodium Chloride–Peptone Solution pH 7.0, Phosphate Buffer Solution pH 7.2,* or *Soybean–Casein Digest Broth*. A surface-active agent such as 1 g per L of polysorbate 80 may be added to assist the suspension of poorly wettable substances. If necessary, adjust to a pH of 6 to 8. Further dilutions, where necessary, are prepared with the same diluent.

Official

Printed on: Fri Jan 05 2024 06:34:09 AM(EST)
Printed by: USP NF
Do Not Distribute
Status: Currently Official on 05-Jan-2024
Official Date: Official Prior to 2013
DOI Ref: to8bl
DocId: GUID-0392F79D-1F8A-4B8D-BEC8-C6FD7B39966F_1_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M98800_01_01

**Fatty Products**—Dissolve in isopropyl myristate sterilized by filtration, or mix the product to be examined with the minimum necessary quantity of sterile polysorbate 80 or another noninhibitory sterile surface-active reagent heated, if necessary, to not more than 40° or, in exceptional cases, to not more than 45°. Mix carefully and if necessary maintain the temperature in a water bath. Add a sufficient quantity of the prewarmed chosen diluent to make a 1 in 10 dilution of the original product. Mix carefully, while maintaining the temperature for the shortest time necessary for the formation of an emulsion. Further serial 10-fold dilutions may be prepared using the chosen diluent containing a suitable concentration of sterile polysorbate 80 or another noninhibitory sterile surface-active reagent.
**Fluids or Solids in Aerosol Form**—Aseptically transfer the product into a membrane filter apparatus or a sterile container for further sampling. Use either the total contents or a defined number of metered doses from each of the containers tested.
**Transdermal Patches**—Remove the protective cover sheets ("release liners") of the transdermal patches and place them, adhesive side upwards, on sterile glass or plastic trays. Cover the adhesive surface with a suitable sterile porous material (e.g., sterile gauze) to prevent the patches from sticking together, and transfer the patches to a suitable volume of the chosen diluent containing inactivators such as polysorbate 80 and/or lecithin. Shake the preparation vigorously for at least 30 minutes.

## INOCULATION AND DILUTION

Add to the sample prepared as directed above and to a control (with no test material included) a sufficient volume of the microbial suspension to obtain an inoculum of not more than than 100 cfu. The volume of the suspension of the inoculum should not exceed 1% of the volume of diluted product.

To demonstrate acceptable microbial recovery from the product, the lowest possible dilution factor of the prepared sample must be used for the test. Where this is not possible due to antimicrobial activity or poor solubility, further appropriate protocols must be developed. If inhibition of growth by the sample cannot otherwise be avoided, the aliquot of the microbial suspension may be added after neutralization, dilution, or filtration.

## NEUTRALIZATION/REMOVAL OF ANTIMICROBIAL ACTIVITY

The number of microorganisms recovered from the prepared sample diluted as described in *Inoculation and Dilution* and incubated following the procedure described in *Recovery of Microorganisms in the Presence of Product,* is compared to the number of microorganisms recovered from the control preparation.

If growth is inhibited (reduction by a factor greater than 2), then modify the procedure for the particular enumeration test to ensure the validity of the results. Modification of the procedure may include, for example,

1. An increase in the volume of the diluent or culture medium;
2. Incorporation of a specific or general neutralizing agents into the diluent;
3. Membrane filtration; or
4. A combination of the above measures.

**Neutralizing Agents**—Neutralizing agents may be used to neutralize the activity of antimicrobial agents (see *Table 2*). They may be added to the chosen diluent or the medium preferably before sterilization. If used, their efficacy and their absence of toxicity for microorganisms must be demonstrated by carrying out a blank with neutralizer and without product.

**Table 2. Common Neutralizing Agents/Methods for Interfering Substances**

| Interfering Substance | Potential Neutralizing Agents/Method |
|---|---|
| Glutaraldehyde, mercurials | Sodium hydrogen sulfite (Sodium bisulfite) |
| Phenolics, alcohol, aldehydes, sorbate | Dilution |
| Aldehydes | Glycine |
| Quaternary ammonium compounds (QACs), parahydroxybenzoates (parabens), bis-biguanides | Lecithin |
| QACs, iodine, parabens | Polysorbate |
| Mercurials | Thioglycollate |
| Mercurials, halogens, aldehydes | Thiosulfate |
| EDTA (edetate) | Mg or Ca ions |

If no suitable neutralizing method can be found, it can be assumed that the failure to isolate the inoculated organism is attributable to the microbicidal activity of the product. This information serves to indicate that the article is not likely to be contaminated with the given species of the microorganism. However, it is possible that the product inhibits only some of the microorganisms specified herein, but does not inhibit others not included among the test strains or those for which the latter are not representative. Then, perform the test with the highest dilution factor compatible with microbial growth and the specific acceptance criterion.

## RECOVERY OF MICROORGANISMS IN THE PRESENCE OF PRODUCT

For each of the microorganisms listed, separate tests are performed. Only microorganisms of the added test strain are counted.

@2024 USPC

**Membrane Filtration**—Use membrane filters having a nominal pore size not greater than 0.45 µm. The type of filter material is chosen in such a way that the bacteria-retaining efficiency is not affected by the components of the sample to be investigated. For each of the microorganisms listed, one membrane filter is used.

Transfer a suitable quantity of the sample prepared as described under *Preparation of the Sample, Inoculation and Dilution,* and *Neutralization/Removal of Antimicrobial Activity* (preferably representing 1 g of the product, or less if large numbers of cfu are expected) to the membrane filter, filter immediately, and rinse the membrane filter with an appropriate volume of diluent.

For the determination of total aerobic microbial count (TAMC), transfer the membrane filter to the surface of the *Soybean–Casein Digest Agar*. For the determination of total combined yeasts and molds count (TYMC), transfer the membrane to the surface of the *Sabouraud Dextrose Agar.* Incubate the plates as indicated in *Table 1*. Perform the counting.

**Plate-Count Methods**—Perform plate-count methods at least in duplicate for each medium, and use the mean count of the result.

*Pour-Plate Method*—For Petri dishes 9 cm in diameter, add to the dish 1 mL of the sample prepared as described under *Preparation of the Sample, Inoculation and Dilution,* and *Neutralization/Removal of Antimicrobial Activity* and 15 to 20 mL of *Soybean–Casein Digest Agar* or *Sabouraud Dextrose Agar,* both media maintained at not more than 45°. If larger Petri dishes are used, the amount of agar medium is increased accordingly. For each of the microorganisms listed in *Table 1*, at least two Petri dishes are used.

Incubate the plates as indicated in *Table 1*. Take the arithmetic mean of the counts per medium, and calculate the number of cfu in the original inoculum.

*Surface-Spread Method*—For Petri dishes 9 cm in diameter, add 15 to 20 mL of *Soybean–Casein Digest Agar* or *Sabouraud Dextrose Agar* at about 45° to each Petri dish, and allow to solidify. If larger Petri dishes are used, the volume of the agar is increased accordingly. Dry the plates, for example, in a laminar-airflow cabinet or in an incubator. For each of the microorganisms listed in *Table 1*, at least two Petri dishes are used. Spread a measured volume of not less than 0.1 mL of the sample, prepared as directed under *Preparation of the Sample, Inoculation and Dilution,* and *Neutralization/Removal of Antimicrobial Activity* over the surface of the medium. Incubate and count as directed for *Pour-Plate Method*.

**Most-Probable-Number (MPN) Method**—The precision and accuracy of the *MPN Method* is less than that of the *Membrane Filtration* method or the *Plate-Count Method*. Unreliable results are obtained particularly for the enumeration of molds. For these reasons, the *MPN Method* is reserved for the enumeration of TAMC in situations where no other method is available. If the use of the method is justified, proceed as follows.

Prepare a series of at least three serial 10-fold dilutions of the product as described for *Preparation of the Sample, Inoculation and Dilution,* and *Neutralization/Removal of Antimicrobial Activity*. From each level of dilution, three aliquots of 1 g or 1 mL are used to inoculate three tubes with 9 to 10 mL of *Soybean–Casein Digest Broth*. If necessary a surface-active agent such as polysorbate 80, or an inactivator of antimicrobial agents may be added to the medium. Thus, if three levels of dilution are prepared, nine tubes are inoculated.

Incubate all tubes at 30° to 35° for not more than 3 days. If reading of the results is difficult or uncertain owing to the nature of the product to be examined, subculture in the same broth or in *Soybean–Casein Digest Agar* for 1 to 2 days at the same temperature, and use these results. From *Table 3,* determine the most probable number of microorganisms per g or mL of the product to be examined.

**Table 3. Most-Probable-Number Values of Microorganisms**

| Observed Combinations of Numbers of Tubes Showing Growth in Each Set | | | MPN per g or per mL of Product | 95% Confidence Limits |
|---|---|---|---|---|
| Number of g or mL of Product per Tube | | | | |
| 0.1 | 0.01 | 0.001 | | |
| 0 | 0 | 0 | <3 | 0–9.4 |
| 0 | 0 | 1 | 3 | 0.1–9.5 |
| 0 | 1 | 0 | 3 | 0.1–10 |
| 0 | 1 | 1 | 6.1 | 1.2–17 |

RESULTS AND INTERPRETATION

When verifying the suitability of the *Membrane Filtration* method or the *Plate-Count Method,* a mean count of any of the test organisms not differing by a factor greater than 2 from the value of the control defined in *Inoculation and Dilution* in the absence of product must be obtained. When verifying the suitability of the *MPN Method,* the calculated value from the inoculum must be within 95% confidence limits of the results obtained with the control.

If the above criteria cannot be met for one of more of the organisms tested with any of the described methods, the method and test conditions that come closest to the criteria are used to test the product.

## TESTING OF PRODUCTS

### Amount Used for the Test

Unless otherwise directed, use 10 g or 10 mL of the product to be examined taken with the precautions referred to above. For fluids or solids in aerosol form, sample 10 containers. For transdermal patches, sample 10 patches.

The amount to be tested may be reduced for active substances that will be formulated in the following conditions: the amount per dosage unit (e.g., tablet, capsule, injection) is less than or equal to 1 mg, or the amount per g or mL (for preparations not presented in dose units) is less than 1 mg. In these cases, the amount of sample to be tested is not less than the amount present in 10 dosage units or 10 g or 10 mL of the product.

For materials used as active substances where the sample quantity is limited or batch size is extremely small (i.e., less than 1000 mL or 1000 g), the amount tested shall be 1% of the batch unless a lesser amount is prescribed or justified and authorized.

For products where the total number of entities in a batch is less than 200 (e.g., samples used in clinical trials), the sample size may be reduced to two units, or one unit if the size is less than 100.

Select the sample(s) at random from the bulk material or from the available containers of the preparation. To obtain the required quantity, mix the contents of a sufficient number of containers to provide the sample.

https://pharmacopeia.cn/v-prod/

## Examination of the Product

### MEMBRANE FILTRATION

Use a filtration apparatus designed to allow the transfer of the filter to the medium. Prepare the sample using a method that has been shown to be suitable as described in *Growth Promotion Test and Suitability of the Counting Method,* transfer the appropriate amount to each of two membrane filters, and filter immediately. Wash each filter following the procedure shown to be suitable.

For the determination of TAMC, transfer one of the membrane filters to the surface of *Soybean–Casein Digest Agar*. For the determination of TYMC, transfer the other membrane to the surface of *Sabouraud Dextrose Agar*. Incubate the plate of *Soybean–Casein Digest Agar* at 30° to 35° for 3 to 5 days and the plate of *Sabouraud Dextrose Agar* at 20° to 25° for 5 to 7 days. Calculate the number of cfu per g or per mL of product.

When examining transdermal patches, separately filter 10% of the volume of the preparation described for *Preparation of the Sample* through each of two sterile filter membranes. Transfer one membrane to *Soybean–Casein Digest Agar* for TAMC and the other membrane to *Sabouraud Dextrose Agar* for TYMC.

### PLATE-COUNT METHODS

**Pour-Plate Method**—Prepare the sample using a method that has been shown to be suitable as described in *Growth Promotion Test and Suitability of the Counting Method*. Prepare for each medium at least two Petri dishes for each level of dilution. Incubate the plates of *Soybean–Casein Digest Agar* at 30° to 35° for 3 to 5 days and the plates of *Sabouraud Dextrose Agar* at 20° to 25° for 5 to 7 days. Select the plates corresponding to a given dilution and showing the highest number of colonies less than 250 for TAMC and 50 for TYMC. Take the arithmetic mean per culture medium of the counts, and calculate the number of cfu per g or per mL of product.

**Surface-Spread Method**—Prepare the sample using a method that has been shown to be suitable as described in *Growth Promotion Test and Suitability of the Counting Method*. Prepare at least two Petri dishes for each medium and each level of dilution. For incubation and calculation of the number of cfu, proceed as directed for the *Pour-Plate Method.*

### MOST-PROBABLE-NUMBER METHOD

Prepare and dilute the sample using a method that has been shown to be suitable as decribed in *Growth Promotion Test and Suitability of the Counting Method*. Incubate all tubes for 3 to 5 days at 30° to 35°. Subculture if necessary, using the procedure shown to be suitable. Record for each level of dilution the number of tubes showing microbial growth. Determine the most probable number of microorganisms per g or mL of the product to be examined from *Table 3*.

## Interpretation of the Results

The total aerobic microbial count (TAMC) is considered to be equal to the number of cfu found using *Soybean–Casein Digest Agar;* if colonies of fungi are detected on this medium, they are counted as part of TAMC. The total combined yeasts and molds count (TYMC) is considered to be equal to the number of cfu found using *Sabouraud Dextrose Agar;* if colonies of bacteria are detected on this medium, they are counted as part of TYMC. When the TYMC is expected to exceed the acceptance criterion due to the bacterial growth, *Sabouraud Dextrose Agar* containing antibiotics may be used. If the count is carried out by the *MPN Method,* the calculated value is TAMC.

When an acceptance criterion for microbiological quality is prescribed, it is interpreted as follows:

- $10^1$ cfu: maximum acceptable count = 20;
- $10^2$ cfu: maximum acceptable count = 200;
- $10^3$ cfu: maximum acceptable count = 2000;

and so forth.

The recommended solutions and media are described in *Tests for Specified Microorganisms* ⟨62⟩.

# ⟨62⟩ MICROBIOLOGICAL EXAMINATION OF NONSTERILE PRODUCTS: TESTS FOR SPECIFIED MICROORGANISMS

## INTRODUCTION

The tests described hereafter will allow determination of the absence of, or limited occurrence of, specified microorganisms that may be detected under the conditions described.

The tests are designed primarily to determine whether a substance or preparation complies with an established specification for microbiological quality. When used for such purposes, follow the instructions given below, including the number of samples to be taken, and interpret the results as stated below.

Alternative microbiological procedures, including automated methods, may be used, provided that their equivalence to the Pharmacopeial method has been demonstrated.

## GENERAL PROCEDURES

The preparation of samples is carried out as described in *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* ⟨61⟩.

If the product to be examined has antimicrobial activity, this is insofar as possible removed or neutralized as described in *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* ⟨61⟩.

If surface-active substances are used for sample preparation, their absence of toxicity for microorganisms and their compatibility with any inactivators used must be demonstrated as described in *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* ⟨61⟩.

## GROWTH-PROMOTING AND INHIBITORY PROPERTIES OF THE MEDIA, SUITABILITY OF THE TEST AND NEGATIVE CONTROLS

The ability of the test to detect microorganisms in the presence of the product to be tested must be established. Suitability must be confirmed if a change in testing performance or a change in the product that may affect the outcome of the test is introduced.

### Preparation of Test Strains

Use standardized stable suspensions of test strains as stated below. Seed-lot culture maintenance techniques (seed-lot systems) are used so that the viable microorganisms used for inoculation are not more than five passages removed from the original master seed-lot.

#### AEROBIC MICROORGANISMS

Grow each of the bacterial test strains separately in containers containing *Soybean–Casein Digest Broth* or on *Soybean–Casein Digest Agar* at 30° to 35° for 18 to 24 hours. Grow the test strain for *Candida albicans* separately on *Sabouraud Dextrose Agar* or in *Sabouraud Dextrose Broth* at 20° to 25° for 2 to 3 days.

| | |
|---|---|
| *Staphylococcus aureus* | such as ATCC 6538, NCIMB 9518, CIP 4.83, or NBRC 13276 |
| *Pseudomonas aeruginosa* | such as ATCC 9027, NCIMB 8626, CIP 82.118, or NBRC 13275 |
| *Escherichia coli* | such as ATCC 8739, NCIMB 8545, CIP 53.126, or NBRC 3972 |
| *Salmonella enterica* subsp. *enterica* serovar Typhimurium or, as an alternative, | such as ATCC 14028 |
| *Salmonella enterica* subsp. *enterica* serovar Abony | such as NBRC 100797, NCTC 6017, or CIP 80.39 |
| *Candida albicans* | such as ATCC 10231, NCPF 3179, IP 48.72, or NBRC 1594 |

Use *Buffered Sodium Chloride–Peptone Solution pH 7.0* or *Phosphate Buffer Solution pH 7.2* to make test suspensions. Use the suspensions within 2 hours or within 24 hours if stored at 2° to 8°.

#### CLOSTRIDIA

Use *Clostridium sporogenes* such as ATCC 11437 (NBRC 14293, NCIMB 12343, CIP 100651) or ATCC 19404 (NCTC 532 or CIP 79.3). Grow the clostridial test strain under anaerobic conditions in *Reinforced Medium for Clostridia* at 30° to 35° for 24 to 48 hours. As an alternative to preparing and then diluting down a fresh suspension of vegetative cells of *Cl. sporogenes,* a stable spore suspension is used for test inoculation. The stable spore suspension may be maintained at 2° to 8° for a validated period.

Official

https://pharmacopeia.cn/v-cn/

## Negative Control

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of microorganisms. A negative control is also performed when testing the products as described under *Testing of Products*. A failed negative control requires an investigation.

## Growth Promotion and Inhibitory Properties of the Media

Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from ingredients. Verify suitable properties of relevant media as described in *Table 1*.

**Table 1. Growth Promoting, Inhibitory, and Indicative Properties of Media**

| Test/Medium | Property | Test Strains |
|---|---|---|
| *Test for bile-tolerant Gram-negative bacteria* | | |
| Enterobacteria Enrichment Broth Mossel | Growth promoting | *E. coli* |
| | | *P. aeruginosa* |
| | Inhibitory | *S. aureus* |
| Violet Red Bile Glucose Agar | Growth promoting + Indicative | *E. coli* |
| | | *P. aeruginosa* |
| *Test for Escherichia coli* | | |
| MacConkey Broth | Growth promoting | *E. coli* |
| | Inhibitory | *S. aureus* |
| MacConkey Agar | Growth promoting + Indicative | *E. coli* |
| *Test for Salmonella* | | |
| Rappaport Vassiliadis Salmonella Enrichment Broth | Growth promoting | *Salmonella enterica* subsp. *enterica* serovar *Typhimurium* or |
| | | *Salmonella enterica* subsp. *enterica* serovar *Abony* |
| | Inhibitory | *S. aureus* |
| Xylose Lysine Deoxycholate Agar | Growth promoting + Indicative | *Salmonella enterica* subsp. *enterica* serovar *Typhimurium* or |
| | | *Salmonella enterica* subsp. *enterica* serovar *Abony* |
| *Test for Pseudomonas aeruginosa* | | |
| Cetrimide Agar | Growth promoting | *P. aeruginosa* |
| | Inhibitory | *E. coli* |
| *Test for Staphylococcus aureus* | | |
| Mannitol Salt Agar | Growth promoting + Indicative | *S. aureus* |
| | Inhibitory | *E. coli* |
| *Test for Clostridia* | | |
| Reinforced Medium for Clostridia | Growth promoting | *Cl. sporogenes* |
| Columbia Agar | Growth promoting | *Cl. sporogenes* |
| *Test for Candida albicans* | | |
| Sabouraud Dextrose Broth | Growth promoting | *C. albicans* |
| Sabouraud Dextrose Agar | Growth promoting + Indicative | *C. albicans* |

### Test for Growth-Promoting Properties, Liquid Media

Inoculate a portion of the appropriate medium with a small number (not more than 100 cfu) of the appropriate microorganism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Clearly visible growth of the microorganism comparable to that previously obtained with a previously tested and approved batch of medium occurs.

Official

https://pharmacopeia.cn/
Printed on: Fri Jan 05 2024 06:36:18 AM(EST)
Printed by: USP NF
Do Not Distribute

### Test for Growth-Promoting Properties, Solid Media

Perform *Surface-Spread Method* (see *Plate-Count Methods* under *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* ⟨61⟩), inoculating each plate with a small number (not more than 100 cfu) of the appropriate microorganism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Growth of the microorganism comparable to that previously obtained with a previously tested and approved batch of medium occurs.

### Test for Inhibitory Properties, Liquid or Solid Media

Inoculate the appropriate medium with at least 100 cfu of the appropriate microorganism. Incubate at the specified temperature for not less than the longest period of time specified in the test. No growth of the test microorganism occurs.

### Test for Indicative Properties

Perform *Surface-Spread Method* (see *Plate-Count Methods* under *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* ⟨61⟩), inoculating each plate with a small number (not more than 100 cfu) of the appropriate microorganism. Incubate at the specified temperature for a period of time within the range specified in the test. Colonies are comparable in appearance and indication reactions to those previously obtained with a previously tested and approved batch of medium.

## Suitability of the Test Method

For each new product to be tested perform sample preparation as described in the relevant paragraph under *Testing of Products*. At the time of mixing, add each test strain in the prescribed growth medium. Inoculate the test strains individually. Use a number of microorganisms equivalent to not more than 100 cfu in the inoculated test preparation.

Perform the test as described in the relevant paragraph under *Testing of Products* using the shortest incubation period prescribed.

The specified microorganisms must be detected with the indication reactions as described under *Testing of Products*.

Any antimicrobial activity of the product necessitates a modification of the test procedure (see *Neutralization/Removal of Antimicrobial Activity* under *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* ⟨61⟩).

For a given product, if the antimicrobial activity with respect to a microorganism for which testing is prescribed cannot be neutralized, then it is to be assumed that the inhibited microorganism will not be present in the product.

# TESTING OF PRODUCTS

## Bile-Tolerant Gram-Negative Bacteria

### Sample Preparation and Pre-Incubation

Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* ⟨61⟩, but using *Soybean–Casein Digest Broth* as the chosen diluent, mix, and incubate at 20° to 25° for a time sufficient to resuscitate the bacteria but not sufficient to encourage multiplication of the organisms (usually 2 hours but not more than 5 hours).

### Test for Absence

Unless otherwise prescribed, use the volume corresponding to 1 g of the product, as prepared in *Sample Preparation and Pre-Incubation,* to inoculate *Enterobacteria Enrichment Broth Mossel*. Incubate at 30° to 35° for 24 to 48 hours. Subculture on plates of *Violet Red Bile Glucose Agar*. Incubate at 30° to 35° for 18 to 24 hours.

The product complies with the test if there is no growth of colonies.

### Quantitative Test

**Selection and Subculture**—Inoculate suitable quantities of *Enterobacteria Enrichment Broth Mossel* with the preparation as directed under *Sample Preparation and Pre-Incubation* and/or dilutions of it containing respectively 0.1 g, 0.01 g, and 0.001 g (or 0.1 mL, 0.01 mL, and 0.001 mL) of the product to be examined. Incubate at 30° to 35° for 24 to 48 hours. Subculture each of the cultures on a plate of *Violet Red Bile Glucose Agar*. Incubate at 30° to 35° for 18 to 24 hours.

**Interpretation**—Growth of colonies constitutes a positive result. Note the smallest quantity of the product that gives a positive result and the largest quantity that gives a negative result. Determine from *Table 2* the probable number of bacteria.

**Table 2. Interpretation of Results**

| Results for Each Quantity of Product | | | |
|---|---|---|---|
| **0.1 g or 0.1 mL** | **0.01 g or 0.01 mL** | **0.001 g or 0.001 mL** | **Probable Number of Bacteria per g or mL of Product** |
| + | + | + | more than $10^3$ |
| + | + | – | less than $10^3$ and more than $10^2$ |

| – | – | – | less than 10 |

## *Escherichia coli*

### Sample Preparation and Pre-Incubation

Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* ⟨61⟩,and use 10 mL or the quantity corresponding to 1 g or 1 mL, to inoculate a suitable amount (determined as described under *Suitability of the Test Method*) of *Soybean–Casein Digest Broth,* mix, and incubate at 30° to 35° for 18 to 24 hours.

### Selection and Subculture

Shake the container, transfer 1 mL of *Soybean–Casein Digest Broth* to 100 mL of *MacConkey Broth,* and incubate at 42° to 44° for 24 to 48 hours. Subculture on a plate of *MacConkey Agar* at 30° to 35° for 18 to 72 hours.

### Interpretation

Growth of colonies indicates the possible presence of *E. coli*. This is confirmed by identification tests.
The product complies with the test if no colonies are present or if the identification tests are negative.

## *Salmonella*

### Sample Preparation and Pre-Incubation

Prepare the product to be examined as described in *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* ⟨61⟩, and use the quantity corresponding to not less than 10 g or 10 mL to inoculate a suitable amount (determined as described under *Suitability of the Test Method*) of *Soybean–Casein Digest Broth,* mix, and incubate at 30° to 35° for 18 to 24 hours.

### Selection and Subculture

Transfer 0.1 mL of *Soybean–Casein Digest Broth* to 10 mL of *Rappaport Vassiliadis Salmonella Enrichment Broth,* and incubate at 30° to 35° for 18 to 24 hours. Subculture on plates of *Xylose Lysine Deoxycholate Agar*. Incubate at 30° to 35° for 18 to 48 hours.

### Interpretation

The possible presence of *Salmonella* is indicated by the growth of well-developed, red colonies, with or without black centers. This is confirmed by identification tests.
The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

## *Pseudomonas aeruginosa*

### Sample Preparation and Pre-Incubation

Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* ⟨61⟩, and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under *Suitability of the Test Method*) of *Soybean–Casein Digest Broth,* and mix. When testing transdermal patches, filter the volume of sample corresponding to one patch of the preparation (see *Transdermal Patches* under *Preparation of the Sample* in *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* ⟨61⟩) through a sterile filter membrane, and place in 100 mL of *Soybean–Casein Digest Broth*. Incubate at 30° to 35° for 18 to 24 hours.

### Selection and Subculture

Subculture on a plate of *Cetrimide Agar,* and incubate at 30° to 35° for 18 to 72 hours.

Official

DocId: GUID-A68DE4C6-A898-490B-8198-C9FE1ADF1B60_1_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M98802_01_01

#### Interpretation

Growth of colonies indicates the possible presence of *P. aeruginosa*. This is confirmed by identification tests.
The product complies with the test if colonies are not present or if the confirmatory identification tests are negative.

### *Staphylococcus aureus*

#### Sample Preparation and Pre-Incubation

Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* ⟨61⟩, and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under *Suitability of the Test Method*) of *Soybean–Casein Digest Broth*, and homogenize. When testing transdermal patches, filter the volume of sample corresponding to one patch of the preparation (see *Transdermal Patches* under *Preparation of the Sample* in *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* ⟨61⟩) through a sterile filter membrane, and place in 100 mL of *Soybean–Casein Digest Broth*. Incubate at 30° to 35° for 18 to 24 hours.

#### Selection and Subculture

Subculture on a plate of *Mannitol Salt Agar*, and incubate at 30° to 35° for 18 to 72 hours.

#### Interpretation

The possible presence of *S. aureus* is indicated by the growth of yellow or white colonies surrounded by a yellow zone. This is confirmed by identification tests.
The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

## Clostridia

#### Sample Preparation and Heat Treatment

Prepare a sample using a 1 in 10 dilution (with a minimum total volume of 20 mL) of not less than 2 g or 2 mL of the product to be examined as described in *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* ⟨61⟩. Divide the sample into two portions of at least 10 mL. Heat one portion at 80° for 10 minutes, and cool rapidly. Do not heat the other portion.

#### Selection and Subculture

Use 10 mL or the quantity corresponding to 1 g or 1 mL of the product to be examined of both portions to inoculate suitable amounts (determined as described under *Suitability of the Test Method*) of *Reinforced Medium for Clostridia*. Incubate under anaerobic conditions at 30° to 35° for 48 hours. After incubation, make subcultures from each container on *Columbia Agar*, and incubate under anaerobic conditions at 30° to 35° for 48 to 72 hours.

#### Interpretation

The occurrence of anaerobic growth of rods (with or without endospores) giving a negative catalase reaction indicates the presence of Clostridia.
This is confirmed by identification tests. The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

### *Candida albicans*

#### Sample Preparation and Pre-Incubation

Prepare the product to be examined as described in *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* ⟨61⟩, and use 10 mL or the quantity corresponding to not less than 1 g or 1 mL, to inoculate 100 mL of *Sabouraud Dextrose Broth*, and mix. Incubate at 30° to 35° for 3 to 5 days.

#### Selection and Subculture

Subculture on a plate of *Sabouraud Dextrose Agar*, and incubate at 30° to 35° for 24 to 48 hours.

#### Interpretation

Growth of white colonies may indicate the presence of *C. albicans*. This is confirmed by identification tests.
The product complies with the test if such colonies are not present or if the confirmatory identification tests are negative.

# RECOMMENDED SOLUTIONS AND CULTURE MEDIA

[NOTE—This section is given for information.]

The following solutions and culture media have been found satisfactory for the purposes for which they are prescribed in the test for microbial contamination in the Pharmacopeia. Other media may be used provided that their suitability can be demonstrated.

**Stock Buffer Solution—**Transfer 34 g of potassium dihydrogen phosphate to a 1000-mL volumetric flask, dissolve in 500 mL of Purified Water, adjust with sodium hydroxide to a pH of 7.2 ± 0.2, add Purified Water to volume, and mix. Dispense in containers, and sterilize. Store at a temperature of 2° to 8°.

**Phosphate Buffer Solution pH 7.2—**Prepare a mixture of Purified Water and *Stock Buffer Solution* (800:1 v/v), and sterilize.

| **Buffered Sodium Chloride–Peptone Solution pH 7.0** | |
|---|---|
| Potassium Dihydrogen Phosphate | 3.6 g |
| Disodium Hydrogen Phosphate Dihydrate | 7.2 g (equivalent to 0.067 M phosphate) |
| Sodium Chloride | 4.3 g |
| Peptone (meat or casein) | 1.0 g |
| Purified Water | 1000 mL |

Sterilize in an autoclave using a validated cycle.

| **Soybean–Casein Digest Broth** | |
|---|---|
| Pancreatic Digest of Casein | 17.0 g |
| Papaic Digest of Soybean | 3.0 g |
| Sodium Chloride | 5.0 g |
| Dibasic Hydrogen Phosphate | 2.5 g |
| Glucose Monohydrate | 2.5 g |
| Purified Water | 1000 mL |

Adjust the pH so that after sterilization it is 7.3 ± 0.2 at 25°. Sterilize in an autoclave using a validated cycle.

| **Soybean–Casein Digest Agar** | |
|---|---|
| Pancreatic Digest of Casein | 15.0 g |
| Papaic Digest of Soybean | 5.0 g |
| Sodium Chloride | 5.0 g |
| Agar | 15.0 g |
| Purified Water | 1000 mL |

Adjust the pH so that after sterilization it is 7.3 ± 0.2 at 25°. Sterilize in an autoclave using a validated cycle.

| **Sabouraud Dextrose Agar** | |
|---|---|
| Dextrose | 40.0 g |
| Mixture of Peptic Digest of Animal Tissue and Pancreatic Digest of Casein (1:1) | 10.0 g |
| Agar | 15.0 g |
| Purified Water | 1000 mL |

Adjust the pH so that after sterilization it is 5.6 ± 0.2 at 25°. Sterilize in an autoclave using a validated cycle.

| **Potato Dextrose Agar** | |
|---|---|
| Infusion from potatoes | 200 g |
| Dextrose | 20.0 g |
| Agar | 15.0 g |
| Purified Water | 1000 mL |

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M98802_01_01

Adjust the pH so that after sterilization it is 5.6 ± 0.2 at 25°. Sterilize in an autoclave using a validated cycle.

| Sabouraud Dextrose Broth | |
|---|---|
| Dextrose | 20.0 g |
| Mixture of Peptic Digest of Animal Tissue and Pancreatic Digest of Casein (1:1) | 10.0 g |
| Purified Water | 1000 mL |

Adjust the pH so that after sterilization it is 5.6 ± 0.2 at 25°. Sterilize in an autoclave using a validated cycle.

| Enterobacteria Enrichment Broth Mossel | |
|---|---|
| Pancreatic Digest of Gelatin | 10.0 g |
| Glucose Monohydrate | 5.0 g |
| Dehydrated Ox Bile | 20.0 g |
| Potassium Dihydrogen Phosphate | 2.0 g |
| Disodium Hydrogen Phosphate Dihydrate | 8.0 g |
| Brilliant Green | 15 mg |
| Purified Water | 1000 mL |

Adjust the pH so that after heating it is 7.2 ± 0.2 at 25°. Heat at 100° for 30 minutes, and cool immediately.

| Violet Red Bile Glucose Agar | |
|---|---|
| Yeast Extract | 3.0 g |
| Pancreatic Digest of Gelatin | 7.0 g |
| Bile Salts | 1.5 g |
| Sodium Chloride | 5.0 g |
| Glucose Monohydrate | 10.0 g |
| Agar | 15.0 g |
| Neutral Red | 30 mg |
| Crystal Violet | 2 mg |
| Purified Water | 1000 mL |

Official

Adjust the pH so that after heating it is 7.4 ± 0.2 at 25°. Heat to boiling; do not heat in an autoclave.

| MacConkey Broth | |
|---|---|
| Pancreatic Digest of Gelatin | 20.0 g |
| Lactose Monohydrate | 10.0 g |
| Dehydrated Ox Bile | 5.0 g |
| Bromocresol Purple | 10 mg |
| Purified Water | 1000 mL |

Adjust the pH so that after sterilization it is 7.3 ± 0.2 at 25°. Sterilize in an autoclave using a validated cycle.

| MacConkey Agar | |
|---|---|
| Pancreatic Digest of Gelatin | 17.0 g |
| Peptones (meat and casein) | 3.0 g |
| Lactose Monohydrate | 10.0 g |
| Sodium Chloride | 5.0 g |
| Bile Salts | 1.5 g |
| Agar | 13.5 g |
| Neutral Red | 30.0 mg |
| Crystal Violet | 1 mg |

https://pharmacopeia.cn/v29240/

| MacConkey Agar | |
|---|---|
| Purified Water | 1000 mL |

Adjust the pH so that after sterilization it is 7.1 ± 0.2 at 25°. Boil for 1 minute with constant shaking, then sterilize in an autoclave using a validated cycle.

| Rappaport Vassiliadis Salmonella Enrichment Broth | |
|---|---|
| Soya Peptone | 4.5 g |
| Magnesium Chloride Hexahydrate | 29.0 g |
| Sodium Chloride | 8.0 g |
| Dipotassium Phosphate | 0.4 g |
| Potassium Dihydrogen Phosphate | 0.6 g |
| Malachite Green | 0.036 g |
| Purified Water | 1000 mL |

Dissolve, warming slightly. Sterilize in an autoclave using a validated cycle, at a temperature not exceeding 115°. The pH is to be 5.2 ± 0.2 at 25° after heating and autoclaving.

| Xylose Lysine Deoxycholate Agar | |
|---|---|
| Xylose | 3.5 g |
| L-Lysine | 5.0 g |
| Lactose Monohydrate | 7.5 g |
| Sucrose | 7.5 g |
| Sodium Chloride | 5.0 g |
| Yeast Extract | 3.0 g |
| Phenol Red | 80 mg |
| Agar | 13.5 g |
| Sodium Deoxycholate | 2.5 g |
| Sodium Thiosulfate | 6.8 g |
| Ferric Ammonium Citrate | 0.8 g |
| Purified Water | 1000 mL |

Adjust the pH so that after heating it is 7.4 ± 0.2 at 25°. Heat to boiling, cool to 50°, and pour into Petri dishes. Do not heat in an autoclave.

| Cetrimide Agar | |
|---|---|
| Pancreatic Digest of Gelatin | 20.0 g |
| Magnesium Chloride | 1.4 g |
| Dipotassium Sulfate | 10.0 g |
| Cetrimide | 0.3 g |
| Agar | 13.6 g |
| Purified Water | 1000 mL |
| Glycerol | 10.0 mL |

Heat to boiling for 1 minute with shaking. Adjust the pH so that after sterilization it is 7.2 ± 0.2 at 25°. Sterilize in an autoclave using a validated cycle.

| Mannitol Salt Agar | |
|---|---|
| Pancreatic Digest of Casein | 5.0 g |
| Peptic Digest of Animal Tissue | 5.0 g |
| Beef Extract | 1.0 g |

@2024 USPC

| Mannitol Salt Agar | |
|---|---|
| D-Mannitol | 10.0 g |
| Sodium Chloride | 75.0 g |
| Agar | 15.0 g |
| Phenol Red | 0.025 g |
| Purified Water | 1000 mL |

Heat to boiling for 1 minute with shaking. Adjust the pH so that after sterilization it is 7.4 ± 0.2 at 25°. Sterilize in an autoclave using a validated cycle.

| Reinforced Medium for Clostridia | |
|---|---|
| Beef Extract | 10.0 g |
| Peptone | 10.0 g |
| Yeast Extract | 3.0 g |
| Soluble Starch | 1.0 g |
| Glucose Monohydrate | 5.0 g |
| Cysteine Hydrochloride | 0.5 g |
| Sodium Chloride | 5.0 g |
| Sodium Acetate | 3.0 g |
| Agar | 0.5 g |
| Purified Water | 1000 mL |

Hydrate the agar, and dissolve by heating to boiling with continuous stirring. If necessary, adjust the pH so that after sterilization it is about 6.8 ± 0.2 at 25°. Sterilize in an autoclave using a validated cycle.

| Columbia Agar | |
|---|---|
| Pancreatic Digest of Casein | 10.0 g |
| Meat Peptic Digest | 5.0 g |
| Heart Pancreatic Digest | 3.0 g |
| Yeast Extract | 5.0 g |
| Maize Starch | 1.0 g |
| Sodium Chloride | 5.0 g |
| Agar, according to gelling power | 10.0–15.0 g |
| Purified Water | 1000 mL |

Hydrate the agar, and dissolve by heating to boiling with continuous stirring. If necessary, adjust the pH so that after sterilization it is 7.3 ± 0.2 at 25°. Sterilize in an autoclave using a validated cycle. Allow to cool to 45° to 50°; add, where necessary, gentamicin sulfate corresponding to 20 mg of gentamicin base, and pour into Petri dishes.

# ⟨63⟩ MYCOPLASMA TESTS

## INTRODUCTION

The genus Mycoplasma represents a group of minute bacteria which have no cell walls. The genus comprises more than 120 species. They are the smallest self-replicating prokaryotic organisms. The cells vary in size and morphology and cannot be Gram stained, but impressions of colonies on solid agar can be stained with methylene blue or equivalent stain. Mycoplasma are parasites and commensals, and some may be pathogenic to a variety of animal and plant hosts. In humans, Mycoplasma are usually surface parasites that colonize the epithelial lining of the respiratory and urogenital tracts. Mycoplasma are common and may cause serious contamination in cell and/or tissue cultures used to generate compendial articles. They may also cause contamination of filtered sterilized soybean casein digest broth. A cell culture infection may persist for an extended period of time without causing apparent cell damage. Infection of cells in a culture can affect nearly every pathway of cell metabolism, including alteration of the cells' phenotypical characteristics and normal growth. The presence of Mycoplasma species does not always result in turbid growth in cultures or visible alteration of the cells.

Testing for Mycoplasma is a necessary quality control requirement to assure reliably pure biotechnological products and allied materials used to generate these products. This general test chapter describes two methods required to detect Mycoplasma contamination of test articles, tissues and/or cell cultures used to produce test articles, digest broth, or any other material in which Mycoplasma contamination is suspected. These are: (A) the agar and broth media procedure and (B) the indicator cell culture procedure. These tests require careful aseptic technique and suitable laboratory conditions. In order to ensure appropriate testing and interpretation of results, personnel should be properly trained and qualified. A validated nucleic acid amplification technique (NAT) or an enzymatic activity based method may be used to detect Mycoplasma, provided such a method is shown to be comparable to both methods (A) and (B). Alternative methods must be suitably validated. Validation requirements for alternate methods will not be addressed in this chapter.

## CULTURE METHOD

### Choice of Media

The test is carried out using a sufficient number of both solid and liquid media to ensure growth in the chosen incubation conditions of small numbers (approximately 100 colony-forming units, cfu; or 100 color-changing units, ccu) of Mycoplasmas that may be present in the test article/material. Liquid media must contain phenol red. The range of media chosen is shown to have satisfactory nutritive properties for at least the microorganisms shown in *Quality Control Test Strain Organisms* (below). The nutritive properties of each new batch of medium are verified for the appropriate microorganisms in the list. When testing for Mycoplasmas include in each test at least two known Mycoplasma species or strains (listed in *Quality Control Test Strain Organisms*) as positive controls, one of which should be a dextrose fermenter (i.e., *M. pneumoniae* or equivalent species and strain) and one of which should be an arginine hydrolyzer (i.e., *M. orale* or equivalent species and strain). Only when testing insect cell lines should one include a *Spiroplasma* control strain (e.g., *S. citri* ATCC 29747, *S. melliferum* ATCC 29416, or equivalent species and strains). Additionally, these strains may be a little more fastidious in their nutritional requirements. They require lower incubation temperatures (as do insect cell lines).

### Quality Control Test Strain Organisms

Positive control cultures should be not more than 15 passages from isolation. Mycoplasma species or strains suitable for use are listed below:

- *Acholeplasma laidlawii* (vaccines and/or cell-derived materials/cultures for human and veterinary use when an antibiotic has been used during production)
- *M. gallisepticum* (when avian material has been used during production or when the vaccine or cell culture is intended for use in poultry)
- *M. hyorhinis* (nonavian veterinary vaccines or cell cultures)
- *M. orale* (vaccines for human and veterinary use)
- *M. pneumoniae* (vaccines or cell banks for human use) or another suitable species of D-glucose fermenter such as *M. fermentans*
- *M. synoviae* (when avian material has been used during production or when the vaccine or cell bank is intended for use in poultry)

The test strains may be field isolates that have undergone a limited number of subcultures (not more than 15), are stored frozen (−20° or lower) or freeze-dried, and are identified as being of the required species by comparison with type cultures, for example, those shown in *Table 1*.

**Table 1. Type Cultures for Identifying Field Isolates Used as Test Strains**

| Test Organism | NCTC Number | CIP Number | ATCC Number |
|---|---|---|---|
| *A. laidlawii* | NCTC 10116 | CIP 75.27 | ATCC 23206 |
| *M. gallisepticum* | NCTC 10115 | CIP 104967 | ATCC 19610 |

Official

https://nhathuocngocanh.com/

**Table 1. Type Cultures for Identifying Field Isolates Used as Test Strains** *(continued)*

| Test Organism | NCTC Number | CIP Number | ATCC Number |
|---|---|---|---|
| *M. fermentans* | NCTC 10117 | CIP 105680 | ATCC 19989 |
| *M. hyorhinis* | NCTC 10130 | CIP 104968 | ATCC 17981 |
| *M. orale* | NCTC 10112 | CIP 104969 | ATCC 23714 |
| *M. pneumoniae* | NCTC 10119 | CIP 103766 | ATCC 15531 |
| *M. synoviae* | NCTC 10124 | CIP 104970 | ATCC 25204 |

## Incubation Conditions

Incubate liquid media in tightly stoppered containers at 36 ± 1°. Incubate solid media in microaerophilic conditions (hydrogen atmosphere containing < 0.5% oxygen and/or nitrogen containing 5%–10% carbon dioxide in nitrogen). Sufficient humidity should be available to prevent desiccation of the agar surface at 36 ± 1°.

## Nutritive Properties

Carry out the test for nutritive properties for each new batch of medium. Inoculate the chosen media with the appropriate test microorganisms; use not more than 100 cfu per plate containing at least 9 mL of solid media and per 100-mL container of liquid medium; use a separate plate and container for each species of microorganism. Incubate the media and make subcultures from 0.2 mL of liquid medium to solid medium at the specified intervals (see below under *Test for Mycoplasma in the Test Article/Material*). The solid medium complies with the test if a count within a 0.5-log unit range of the inoculate amount is found for each test microorganism. The liquid medium complies with the test if growth is found on agar plates subcultured from the broth, for at least 1 subculture for each test microorganism. The use of a microscope at 100× or greater may be helpful.

## Inhibitory Substances

The test for inhibitory substances is carried out once for a given product and is repeated whenever there is a change in production method that may affect the detection of Mycoplasma. To demonstrate absence of inhibitory substances, carry out the test for nutritive properties in the presence and absence of the test article/material. If growth of a test microorganism occurs more than 1 subculture sooner in the absence of the test article/material than in its presence, inhibitory substances are present. The same is true if plates directly inoculated with the test article/material are not within a 0.5-log unit range of the number of colonies of those inoculated without the test article/material. In both cases, inhibitory substances must be neutralized or their effect otherwise countered, by an appropriate method, for example, by passage in substrates not containing inhibitors or dilution in a larger volume of medium, before the test. If dilution is used, larger medium volumes may be used or the inoculums' volume may be divided among several 100-mL flasks. The effectiveness of the neutralization or other process is checked by repeating the test for inhibitory substances after neutralization.

## Test for Mycoplasma in the Test Article/Material

Inoculate no less than 10 mL of the test article/material per 100 mL of each liquid medium. If a significant pH change occurs upon the addition of the test article/material, the liquid medium is restored to its original pH value by the addition of a sterile solution of either sodium hydroxide or hydrochloric acid. Inoculate 0.2 mL of the test article/material on each plate of each solid medium. Incubate liquid media for 20–21 days. Incubate solid media for not less than 14 days, except those plates corresponding to the 20–21 day subculture, which are incubated for 7 days. Concurrently, incubate an uninoculated 100-mL portion of each liquid medium and agar plate, as a negative control. On days 2–4 after inoculation, subculture each liquid medium by inoculating 0.2 mL on at least 1 plate of each solid medium. Repeat the procedure between days 6 and 8, again between days 13 and 15, and again between days 19 and 21 of the test. Observe the liquid media every 2 or 3 days and if a color change occurs, subculture. If a liquid medium shows bacterial or fungal contamination, the test is invalid. The test is valid if at least 1 plate per medium and per inoculation day can be read. Include in the test positive controls prepared by inoculation of not more than 100 cfu of at least 1 test microorganism on agar medium or into broth medium. Where the test for Mycoplasmas is carried out regularly, it is recommended to use the test microorganisms in regular rotation. The test microorganisms used are those listed under *Choice of Media*. Incubate broths and plates in a humidified atmosphere with microaerophilic conditions (5%–10% $CO_2$).

## Interpretation of Results

At the end of the prescribed incubation period, examine all inoculated solid media for the presence of Mycoplasma colonies. The product complies with the test if growth of typical Mycoplasma colonies has not occurred. The product does not comply with the test if growth of typical Mycoplasma colonies has occurred on any of the solid media. The test is invalid if 1 or more of the positive controls do not show growth of Mycoplasmas on at least 1 subculture plate. The test is invalid if 1 or more of the negative controls show growth of Mycoplasmas. If suspect colonies are observed, use a suitable validated method to determine whether they are due to Mycoplasmas.

## Recommended Solutions and Media for the Culture Method

## SOLUTIONS

### Beef Heart Infusion Broth

| | |
|---|---|
| Beef heart (for preparation of the infusion) | 500 g |
| Peptone | 10 g |
| Sodium chloride | 5 g |
| Distilled water | to 1000 mL |

### Essential Vitamins

| | |
|---|---|
| Biotin | 100 mg |
| Calcium pantothenate | 100 mg |
| Choline chloride | 100 mg |
| Folic acid | 100 mg |
| *i*-Inositol | 200 mg |
| Nicotinamide | 100 mg |
| Pyridoxal hydrochloride | 100 mg |
| Riboflavine | 10 mg |
| Thiamine hydrochloride | 100 mg |
| Distilled water | to 1000 mL |

### Agar, Purified

| A highly refined agar for use in microbiology and immunology, prepared by an ion-exchange procedure that results in a product having superior purity, clarity, and gel strength. It contains the following ingredients: | |
|---|---|
| Water | 12.2% |
| Ash | 1.5% |
| Acid-insoluble ash | 0.2% |
| Chlorine | 0 |
| Phosphate (calculated as $P_2O_5$) | 0.3% |
| Total nitrogen | 0.3% |
| Copper | 8 ppm |
| Iron | 170 ppm |
| Calcium | 0.28% |
| Magnesium | 0.32% |

### Hanks' Balanced Salt Solution (modified)

| | |
|---|---|
| Sodium chloride | 6.4 g |
| Potassium chloride | 0.32 g |
| Magnesium sulphate heptahydrate | 0.08 g |
| Magnesium chloride hexahydrate | 0.08 g |
| Calcium chloride, anhydrous | 0.112 g |
| Disodium hydrogen phosphate dihydrate | 0.0596 g |
| Potassium dihydrogen phosphate, anhydrous | 0.048 g |
| Distilled water | to 800 mL |

### Brain Heart Infusion

| | |
|---|---|
| Calf-brain infusion | 200 g |
| Beef-heart infusion | 250 g |
| Proteose peptone | 10 g |
| Glucose monohydrate | 2 g |
| Sodium chloride | 5 g |

@2024 USPC

**Brain Heart Infusion** *(continued)*

| | |
|---|---|
| Disodium hydrogen phosphate, anhydrous | 2.5 g |
| Distilled water | to 1000 mL |

**PPLO Broth**

| | |
|---|---|
| Beef-heart infusion | 50 g |
| Peptone | 10 g |
| Sodium chloride | 5 g |
| Distilled water | to 1000 mL |

## MEDIA

The following media are recommended. Other media may be used, provided they meet the criteria given in the sections *Choice of Culture Media, Incubation Conditions, Nutritive Properties,* and *Inhibitory Substances.*

**Hayflick Media (Recommended for the general detection of Mycoplasmas)**

| | |
|---|---|
| **Liquid Medium** | |
| Beef heart infusion broth | 90.0 mL |
| Horse serum (unheated) | 20.0 mL |
| Yeast extract (250 g/L) (fresh yeast extract is recommended) | 10.0 mL |
| Phenol red (0.6 g/L solution) | 5.0 mL |
| Penicillin (20,000 IU/mL) | 0.25 mL |
| Deoxyribonucleic acid (2 g/L solution) | 1.2 mL |
| Adjust to a pH of 7.8 | |
| **Solid Medium** | |
| Prepare as described above replacing beef heart infusion broth by beef heart infusion agar containing 15 g/L of agar. | |

**Frey Media (Recommended for the detection of *M. synoviae*)**

| | |
|---|---|
| **Liquid Medium** | |
| Beef heart infusion broth | 90.0 mL |
| Essential vitamins | 0.025 mL |
| Glucose monohydrate (500 g/L solution) | 2.0 mL |
| Swine serum (inactivated at 56° for 30 min) | 12.0 mL |
| β-Nicotinamide adenine dinucleotide (10 g/L solution) | 1.0 mL |
| Cysteine hydrochloride (10 g/L solution) | 1.0 mL |
| Phenol red (0.6 g/L solution) | 5.0 mL |
| Penicillin (20,000 IU/mL) | 0.25 mL |
| Mix the solutions of β-nicotinamide adenine dinucleotide and cysteine hydrochloride and after 10 min add to the other ingredients. Adjust to a pH of 7.8. | |
| **Solid Medium** | |
| Beef heart infusion broth | 90.0 mL |
| Agar, purified | 1.4 g |
| Adjust to pH 7.8, sterilize by autoclaving then add: | |
| Essential vitamins | 0.025 mL |
| Glucose monohydrate (500 g/L solution) | 2.0 mL |
| Swine serum (unheated) | 12.0 mL |
| β-Nicotinamide adenine dinucleotide (10 g/L solution) | 1.0 mL |
| Cysteine hydrochloride (10 g/L solution) | 1.0 mL |
| Phenol red (0.6 g/L solution) | 5.0 mL |
| Penicillin (20,000 IU/mL) | 0.25 mL |

**Friis Media (Recommended for the detection of nonavian Mycoplasmas)**

| | |
|---|---|
| **Liquid Medium** | |
| Hanks' balanced salt solution (modified) | 800 mL |
| Distilled water | 67 mL |
| Brain heart infusion | 135 mL |
| PPLO Broth | 248 mL |
| Yeast extract (170 g/L) | 60 mL |
| Bacitracin | 250 mg |
| Meticillin | 250 mg |
| Phenol red (5 g/L) | 4.5 mL |
| Horse serum | 165 mL |
| Swine serum | 165 mL |
| Adjust to a pH of 7.40–7.45 | |
| **Solid Medium** | |
| Hanks' balanced salt solution (modified) | 200 mL |
| DEAE-dextran | 200 mg |
| Agar, purified | 15.65 g |
| Mix well and sterilize by autoclaving. Cool to 100°. Add to 1740 mL of *Liquid Medium* as described above. | |

## INDICATOR CELL CULTURE METHOD

Cell cultures are stained with a fluorescent dye that binds to DNA. Mycoplasmas are detected by their characteristic particulate or filamentous pattern of fluorescence on the cell surface and, if contamination is heavy, in surrounding areas. Mitochondria in the cytoplasm may be stained but are readily distinguished from Mycoplasmas. For viral suspensions, if the interpretation of results is affected by marked cytopathic effects, neutralize the virus using a specific antiserum that has no inhibitory effects on Mycoplasmas, or use a cell culture substrate that does not allow growth of the virus. To demonstrate the absence of inhibitory effects of serum, carry out the positive control tests in the presence and absence of the antiserum.

### Verification of the Substrate

Use Vero cells or equivalent cell culture (for example, the production cell line) that is equivalent in effectiveness for detecting Mycoplasmas. Test the effectiveness of the cells to be used by applying the procedure shown below and inoculating not more than 100 cfu or ccu microorganisms of suitable reference strains of *M. hyorhinis* and *M. orale.* The cells are suitable if both reference strains are detected. The indicator cells must be subcultured without an antibiotic before use in the test.

### Test Method

[NOTE—The following is provided for information.]

SOLUTIONS

**Phosphate Buffered Saline**

*2.0 M Monobasic Potassium Phosphate*—Dissolve 13.61 g of anhydrous monobasic potassium phosphate in 50 mL of water.

*2.0 M Dibasic Potassium Phosphate*—Dissolve 17.42 g of anhydrous dibasic potassium phosphate in 50 mL of water.

*Phosphate Buffered Saline Solution (pH 7.4)*—Combine 3.6 mL of *2.0 M Monobasic Potassium Phosphate,* 16.4 mL of *2.0 M Dibasic Potassium Phosphate,* 8 g of sodium chloride, and 1 L of water. Mix thoroughly. Adjust the pH if necessary.

**Bisbenzimide Stock Solution—**Dissolve 5 mg of bisbenzimide in water, and dilute with the same solvent to 100 mL. Store in the dark.

**Bisbenzimide Working Solution**—Immediately before use, dilute 100 µL of *Bisbenzimide Stock Solution* with *Phosphate Buffered Saline Solution (pH 7.4)* to 100 mL.

**Phosphate-Citrate Buffer Solution pH 5.5—**Mix 56.85 mL of a 28.4-g/L solution of anhydrous disodium hydrogen phosphate and 43.15 mL of a 21-g/L solution of citric acid.

METHOD

1. Seed the indicator cell culture at a suitable density (for example, $2 \times 10^4$ to $2 \times 10^5$ cells/mL, $4 \times 10^3$ to $2.5 \times 10^4$ cells/$cm^2$) that will yield confluence after 3 days of growth. Inoculate 1 mL of the product to be examined into the cell culture vessel, and incubate at 36 ± 1°.

Official

https://pharmacopeia.cn/v-download/

2. After at least 3 days of incubation, when the cells have grown to confluence, make a subculture on cover slips in suitable containers or on some other surface (for example, chambered slides) suitable for the test procedure. Seed the cells at low density so that they reach 50% confluence after 3–5 days of incubation. Complete confluence impairs visualization of Mycoplasmas after staining and must be avoided.
3. Remove the medium and rinse the indicator cells with phosphate buffered saline, pH 7.4, then add a suitable fixing solution (a freshly prepared mixture of 1 volume of acetic acid, glacial, TS and 3 volumes of methanol, is suitable when bisbenzimide is used for staining).
4. Remove the fixing solution and wash the cells with sterile Purified Water. Dry the slides completely if they are to be stained more than 1 hour later (particular care is needed for staining of slides after drying owing to artifacts that may be produced).
5. Add a suitable DNA stain and allow standing for a suitable time (bisbenzimide working solution and a standing time of 10 minutes are suitable).
6. Remove the stain and rinse the monolayer with Purified Water.
7. Mount each coverslip, where applicable (a mixture of equal volumes of glycerol and *Phosphate-Citrate Buffer Solution pH 5.5* is suitable for mounting). Examine by fluorescence (for bisbenzimide stain a 330 nm/380 nm excitation filter and an LP 440 nm barrier filter are suitable) at 400× magnification or greater.
8. Compare the microscopic appearance of the test cultures with that of the negative and positive controls, examining for extranuclear fluorescence. Mycoplasmas produce pinpoints or filaments over the indicator cell cytoplasm. They may also produce pinpoints and filaments in the intercellular spaces. Multiple microscopic fields are examined according to the protocol established during validation.

## Interpretation of Results

The product to be examined complies with the test if fluorescence typical of Mycoplasmas is not present. The test is invalid if the positive controls do not show fluorescence typical of Mycoplasmas. The test is invalid if the negative controls show fluorescence typical of Mycoplasmas.

# ▲⟨64⟩ PROBIOTIC TESTS

## INTRODUCTION

This chapter provides testing procedures for identification, enumeration, contamination, and other requirements for probiotics. Probiotics are live microorganisms that, when administered in adequate amounts, confer health benefits to the host. Probiotics are typically identified at the strain level as their characteristics are considered strain-specific.

This chapter applies to probiotics produced in specialized fermenters under strict hygiene conditions for dietary supplements or pharmaceutical applications. Fermentation media are tailored to the specific requirements of the microbial species or strain and typically contain nutrients such as proteins, carbohydrates, vitamins, and minerals. The culture is allowed to multiply and grow under carefully defined conditions. After the microbial cells are grown, the cultured cells are harvested, often by centrifugation. Suitable protectants may be added to the concentrated probiotic microorganisms (biomass), and the biomass is freeze-dried or spray-dried to a powdered form. The dried biomass then undergoes formulation, which may involve blending one or more strains with suitable excipients. Formulated probiotic ingredients can be further processed into dosage forms, e.g., tablets, capsules, softgels, powders, or gels.

## IDENTIFICATION

Probiotics as defined in this chapter can be identified at the genus and species level or at the strain level according to the monograph requirements. Since regulatory filings for commercial probiotics are commonly made at the strain level supported by information from safety assessment and human studies, identification at the strain level may be required to verify the strain declared in labeling of commercial products. In this chapter, strain-specific identification using polymerase chain reaction (PCR) with strain-specific primers is recommended for the identification of probiotics. Currently, a testing procedure for identification of *Lactobacillus* and *Bifidobacterium* strains by PCR with specific primers is listed in this chapter. Additional testing procedures for identification of probiotic strains including non-spore-forming bacteria, spore-forming bacteria, and yeasts or molds will be listed in this chapter once they become available.

• **IDENTIFICATION FOR NON-SPORE-FORMING BACTERIAL STRAINS**

**Identification for *Lactobacillus* and *Bifidobacterium* strains by PCR with specific primers**

Unless otherwise specified in the individual monograph, use the following general procedure. All reagents and solutions used in this test should be molecular biology grade.

**Buffer:** 10 mM tris-hydrochloride, 1 mM sodium ethylenediaminetetraacetic acid (EDTA) buffer[1]

**PCR master mix:** *Taq* DNA polymerase (62.5 U/mL), 2.5X *Taq* reaction buffer [125 mM potassium chloride (KCl), 75 mM tris-hydrochloride pH 8.3, and 4 mM magnesium ($Mg^{+2}$)], and 500 µM of each deoxynucleotide (dNTP). Prepared *PCR master mix* solutions are commercially available.[2]

**Sample:** 100 mg/mL suspension of the probiotic powder in *Buffer*

**Primer set:** Use the primers for the strain specified in the individual monograph. Dilute the forward and reverse primers in *Buffer* to a stock concentration of 100 µM, and dilute further with *Buffer* to 25 µM. The diluted forward primer and diluted reverse primer 25-µM dilutions can be stored at –20°.[3]

**PCR sample preparations:** For each *Primer set*, prepare a solution containing 1 µL of the *Sample*, 10 µL of *PCR master mix*, 1 µL of the diluted forward primer (25 µM), 1 µL of the diluted reverse primer (25 µM), and 12 µL of *Sterile Purified Water*.

**PCR negative control:** Prepare as directed for the *PCR sample preparations*, replacing the *Sample* with 1 µL of *Sterile Purified Water*.

**PCR positive control** (if available)**:** Prepare as directed for the *PCR sample preparations*, replacing the *Sample* with 1 µL of the corresponding Reference Standard.

**Analysis:** Perform PCR amplification on each of the *PCR sample preparations*, *PCR positive control*, and the *PCR negative control* using an appropriate thermal cycler.[4] Unless otherwise specified in the individual monograph, incubate at 95° for 7 min (step 1) for direct heat-induced DNA extraction.

**Thermal cycle:** 95° for 30 s (step 2); annealing temperature specified in the individual monograph for 30 s (step 3); and at 72° for 30 s (step 4). Repeat steps 2–4 for between 30 and 34 cycles, incubate at 72° for 5 min, and hold at 4°. Perform electrophoretic separation of the PCR amplification products for each of the *PCR sample preparations*, *PCR positive control*, and for the *PCR negative control*. An automated on-chip electrophoresis system with a DNA kit can be used.

Prepare or use a commercially available 1% (w/v) agarose gel in a 1X tris-acetic acid–EDTA buffer (40 mM tris-hydrochloride, 1% glacial acetic acid, and 1 mM EDTA). Stain the gel with 0.5 mg/mL of ethidium bromide in water and de-stain with water. [**CAUTION**—Ethidium bromide is considered a toxic substance and a potential mutagen. Use appropriate personal protective equipment (including nitrile gloves) when handling this reagent.]

Use a DNA ladder standard (1 KB plus)[5] suitable for determining the size of linear double-stranded DNA fragments between 100 and 12,000 base pairs. The ladder standard should be used in the first and last lanes on the gel to allow for proper comparison of amplicons. Analysis of the *PCR negative control* must result in the absence of any amplification products. If amplification occurs, repeat the *PCR sample preparations*, and the *PCR negative control*, followed by PCR amplification and analysis.

**Acceptance criteria:** Refer to the acceptance criteria in the individual monograph.

## ENUMERATION

Currently, a testing procedure for enumeration of *Lactobacillus* and *Bifidobacterium* species is listed in this chapter. Additional testing procedures for enumeration of probiotic strains, including non-spore-forming bacteria, spore-forming bacteria, and yeasts and molds, will be listed in this chapter once they become available. Alternative microbiological procedures, including automated methods, may be used provided that their equivalence has been demonstrated.

- **ENUMERATION FOR NON-SPORE-FORMING BACTERIA STRAINS**

***Lactobacillus* and *Bifidobacterium* species**

Unless otherwise specified in the individual monograph, use the following general procedure.

***Lactobacilli* MRS agar** (medium for *Lactobacillus* and *Bifidobacterium* species)**:** Prepare according to *Table 1* or use a commercially available mixture.[6]

**Table 1. *Lactobacilli* MRS Agar**

| Reagent | Quantity (g) |
|---|---|
| Proteose peptone #3[a] | 10.0 |
| Beef extract | 10.0 |
| Yeast extract | 5.0 |
| Dextrose | 20.0 |
| Polysorbate 80 | 1.0 |
| Ammonium citrate | 2.0 |
| Sodium acetate | 5.0 |
| Magnesium sulfate | 0.1 |
| Manganese sulfate[b] | 0.05 |
| Dipotassium phosphate | 2.0 |
| Agar | 15.0 |

[a] A suitable peptone for microbiological analysis is available from BD Bacto™ (www.bd.com).
[b] A suitable manganese sulfate is available from Sigma-Aldrich (www.sigmaaldrich.com).

Suspend the *Lactobacilli MRS agar* in 1 L of *Purified Water* in an appropriately sized conical flask or beaker (sufficiently large to not boil over). Cover the flask or beaker with aluminum foil and heat to boiling with stirring on a hot plate. Allow to boil for 1 min to completely dissolve the medium, and then autoclave the solution at 121° for 15 min. Cool to 45° and use immediately. Boiled agar medium may also be aseptically transferred into individual media bottles in 100- or 200-mL aliquots before sterilizing, and then autoclaved and stored for later use. The agar can be stored at a temperature between 2° and 8° in a sterile well-closed container unless it is intended for immediate use. Do not use the medium for a longer storage period than has been validated. Allow the agar to come to room temperature before use.

***Lactobacilli* MRS broth:** Prepare according to *Table 2* or use a suitable commercially available broth.[7]

**Table 2. *Lactobacilli* MRS Broth**

| Reagent | Quantity (g) |
|---|---|
| Proteose peptone #3[a] | 10.0 |
| Beef extract | 10.0 |
| Yeast extract | 5.0 |
| Dextrose | 20.0 |
| Polysorbate 80 | 1.0 |
| Ammonium citrate | 2.0 |
| Sodium acetate | 5.0 |
| Magnesium sulfate | 0.1 |
| Manganese sulfate[b] | 0.05 |
| Dipotassium phosphate | 2.0 |

[a] A suitable peptone for microbiological analysis is available from BD Bacto™ (www.bd.com).

[6] Difco™ *Lactobacilli* MRS Agar, or equivalent. Suitable *Lactobacilli* MRS agars are available from VWR Scientific (www.vwr.com) or other chemical/microbiological suppliers.
[7] Difco™ *Lactobacilli* MRS Broth or equivalent. Suitable *Lactobacilli* MRS broths are available from VWR Scientific (www.vwr.com) or other chemical/microbiological suppliers.

@2024 USPC

[b] A suitable manganese sulfate is available from Sigma-Aldrich (www.sigmaaldrich.com).

Suspend *Lactobacilli MRS broth* in 1 L of *Purified Water* in an appropriately sized conical flask or beaker (sufficiently large to not boil over). Cover the flask or beaker with aluminum foil and heat to boiling with stirring on a hot plate. Allow to boil for 1 min to completely dissolve the broth ingredients, and then autoclave the solution at 121° for 15 min. Broth may also be aseptically transferred into individual media bottles in 100- or 200-mL aliquots before sterilizing, and then autoclaved and stored for later use. The broth can be stored at a temperature between 2° and 8° in a sterile well-closed container unless it is intended for immediate use. Do not use the medium for a longer storage period than has been validated. Allow broth to come to room temperature before use.

**Peptone diluent:** Prepare a solution of 0.1% peptone[8] in water (w/v) and adjust with a lactic acid solution to a pH of 7.0. Using an autoclave, steam sterilize the solution at 121° for NLT 15 min, and then allow to cool in the unopened autoclave. Dispense into sterile containers as needed for preparing samples.

**Sample preparation:** Unless otherwise specified in the individual monograph, transfer an amount equivalent to 11.0 g of probiotic powder into a sterile polyethylene bag, commercially known as a stomacher bag. Add 99 mL of previously sterilized (room temperature) *Lactobacilli MRS broth* to the bag. Blend in a mechanical blender until a uniform mixture is achieved or in a stomacher[9] at 230 rpm for 30 s. Hold the mixture at room temperature for 30 min to allow rehydration of the sample, and then blend for an additional 30 s at 230 rpm. This is the primary $10^{-1}$ dilution. Using sterilized, filtered pipet tips, make serial dilutions by aseptically transferring 1.0 mL of the primary $10^{-1}$ dilution to sterile media bottles, each containing 99.0 mL of *Peptone diluent* ($10^{-3}$ dilution). Repeat this operation until the desired dilution series is obtained. Dilutions are expected to contain 25–250 cfu/mL. Shake the media bottles to mix completely before proceeding with the *Analysis*.

**Analysis:** Using three sterile, filtered 1-mL pipet tips, aseptically transfer 1.0 mL of the *Sample preparation* separately into three appropriately labeled, sterile 15-mm × 100-mm Petri plates, and then pour about 10–15 mL of the *Lactobacilli MRS agar* at about 45° onto each plate, flaming the lip of the bottle between pours. Place the lid on each plate after adding the agar medium, and then gently swirl the plates to mix the *Sample preparation* and the agar medium. Avoid spillage onto the lid of the dish when swirling the plates. Repeat this procedure for additional dilutions of the *Sample preparation*. Prepare a blank plate containing only *Lactobacilli MRS agar* and a second blank plate containing 1.0 mL of *Peptone diluent* mixed with *Lactobacilli MRS agar*. Allow the plates to sit at room temperature on a level surface until the agar solidifies, and then incubate the plates at 36°–40° for 3–5 days under anaerobic conditions.[10] After the incubation period, count the colonies and record the results as viable colony-forming units (cfu) per gram, taking into account the appropriate dilution factor of the *Sample preparation*. Only count plates containing 25–250 colonies. Determine the average plate count, in colony-forming units per gram.

**Acceptance criteria:** Refer to the acceptance criteria in the individual monograph.

## PERFORMANCE TESTS

Performance tests are recommended for any dosage forms of probiotics, including tablets, capsules, softgels, gelcaps, powders, or chewable gels, etc.

- **Disintegration and Dissolution** ⟨2040⟩, *Disintegration*: Meet the requirements
- **Weight Variation** ⟨2091⟩: Meet the requirements

## CONTAMINANTS

The level of the standard contaminant-indicator organisms as well as the absence of pathogenic microorganisms specified in the individual monographs must be determined to ensure the quality of probiotics. Recommended standard indicator organisms and specified microorganisms are listed in *Table 3* and *Table 4*. Alternative microbiological procedures, including automated methods, may be used, provided that their equivalence has been demonstrated. Principles of validation of alternative microbiological methods are also described in *Validation of Alternative Microbiological Methods* ⟨1223⟩. Methods (e.g., dilution, buffer, or membrane filtration) may be suitably modified to overcome potential interferences such as acid production resulting from growth of probiotic organisms during the enrichment step, leading to possible false-negative results. Method suitability to detect the presence of microorganisms in the product to be tested must be established. Method suitability must be confirmed if changes in the testing performance occur, or changes in the product composition that may affect the outcome of the test are introduced.

- **Contaminant Microorganisms**

  Unless otherwise specified in the individual monograph, the recommended tests and acceptance criteria for contaminant microorganisms in probiotic ingredients or finished products for oral use are listed in *Table 3*.

**Table 3. Recommended Tests for Contaminant Microorganisms in Probiotic Ingredients or Finished Products for Oral Use**

| Probiotic Classification | Test | Test Methods | Acceptance Criteria (cfu/g) |
|---|---|---|---|
| Non-spore-forming bacteria | Non-lactic acid bacteria | ISO 13559 (IDF 153)[a] | NMT $5 \times 10^3$ |
| | Total yeasts and molds | *Microbial Enumeration Tests* ⟨2021⟩ | NMT 100 |
| Spore-forming bacteria | Total yeasts and molds | *Microbial Enumeration Tests* ⟨2021⟩ | NMT 100 |
| Yeasts and molds | Total aerobic microbial count | *Microbial Enumeration Tests* ⟨2021⟩ | NMT $1 \times 10^3$ |

[a] Available from the International Organization for Standardization (www.iso.org).

[8] Suitable peptone for microbiological analysis is available from BD Bacto (www.bd.com).
[9] Suitable stomacher (e.g., Stomacher 400 Circulator) for mechanical sample blending is available from Seward (www.seward.co.uk).
[10] Suitable anaerobic systems are available from BD GasPak EZ Container System (www.bd.com).

DOI: https://doi.org/10.31003/USPNF_M11076_02_01
@2024 USPC

- **Specified Microorganisms**

Unless otherwise specified in the individual monograph, the recommended tests and acceptance criteria for specified microorganisms in probiotics or finished products for oral use are listed in *Table 4*.

**Table 4. Recommended Tests for Specified Microorganisms in Probiotic Ingredients or Finished Products for Oral Use**

| Probiotic Strain | Test | Test Methods | Acceptance Criteria |
|---|---|---|---|
| Non-spore-forming bacteria, spore-forming bacteria, or yeasts and molds | *Escherichia coli* | *Absence of Specified Microorganisms* ⟨2022⟩ | None detected in 10 g |
| | *Salmonella* species | *Absence of Specified Microorganisms* ⟨2022⟩ | None detected in 10 g |

The absence of *Listeria monocytogenes*, *Staphylococcus aureus*, or *Pseudomonas aeruginosa* in addition to the absence of the specified microorganisms listed in *Table 4* should be tested and confirmed if a probiotic ingredient or a finished product containing a probiotic ingredient(s) poses a risk associated with the contamination of the above microorganisms based on formal risk assessment programs such as Hazard Analysis and Critical Control Points (HACCP). The absence of *Clostridium perfringens* and *Cronobacter sakazakii* in addition to the absence of the listed specified microorganisms should be tested and confirmed if a probiotic ingredient or finished product is intended for infant use. The methods for *Listeria monocytogenes*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Clostridium perfringens*, and *Cronobacter sakazakii* must be officially accepted methods or appropriately validated methods.

## ADDITIONAL REQUIREMENTS

- **Packaging and Storage**

Shipping and storage conditions will necessarily be adapted to the particular strains being sold. Unless otherwise specified in the individual monograph, probiotic ingredients should be stored in high-barrier foil-laminate bags and kept at or below 4° for long-term storage. Dosage forms of probiotics should be stored in tight containers in a cool, dry place.

- **Labeling**

For probiotic ingredients, the strain designation should be listed on the label for each strain. An ingredient or a dosage form of probiotics should be labeled with the genus, species, and strain names. In cases where there is suitable scientific rationale, such as scientific substantiation of health benefits that are not strain specific, a dosage form of probiotics may be labeled with the genus and species names. A total formulated enumeration of all probiotic ingredients throughout the product shelf life should be included at minimum in cfu/g or cfu/serving.▲ (USP 1-Aug-2019)

# ⟨71⟩ STERILITY TESTS

•Portions of this general chapter have been harmonized with the corresponding texts of the European Pharmacopeia and/or the Japanese Pharmacopeia. Those portions that are not harmonized are marked with symbols (•,•) to specify this fact.•

These Pharmacopeial procedures are not by themselves designed to ensure that a batch of product is sterile or has been sterilized. This is accomplished primarily by validation of the sterilization process or of the aseptic processing procedures.

*The test is applied to substances, preparations, or articles which, according to the Pharmacopeia, are required to be sterile. However, a satisfactory result only indicates that no contaminating microorganism has been found in the sample examined under the conditions of the test.*

## PRECAUTIONS AGAINST MICROBIAL CONTAMINATION

The test for sterility is carried out under aseptic conditions. In order to achieve such conditions, the test environment has to be adapted to the way in which the sterility test is performed. The precautions taken to avoid contamination are such that they do not affect any microorganisms that are to be revealed in the test. The working conditions in which the tests are performed are monitored regularly by appropriate sampling of the working area and by carrying out appropriate controls.

## CULTURE MEDIA AND INCUBATION TEMPERATURES

Media for the test may be prepared as described below or equivalent commercial media may be used provided that they comply with the requirements of the *Growth Promotion Test of Aerobes, Anaerobes, and Fungi*.

The following culture media have been found to be suitable for the test for sterility. *Fluid Thioglycollate Medium* is primarily intended for the culture of anaerobic bacteria. However, it will also detect aerobic bacteria. *Soybean–Casein Digest Medium* is suitable for the culture of both fungi and aerobic bacteria.

**Fluid Thioglycollate Medium**

| | |
|---|---|
| L-Cystine | 0.5 g |
| Sodium Chloride | 2.5 g |
| Dextrose Monohydrate/Anhydrous | 5.5/5.0 g |
| Agar | 0.75 g |
| Yeast Extract (water-soluble) | 5.0 g |
| Pancreatic Digest of Casein | 15.0 g |
| Sodium Thioglycollate | 0.5 g |
| or Thioglycolic Acid | 0.3 mL |
| Resazurin Sodium Solution (1 in 1000), freshly prepared | 1.0 mL |
| Purified Water | 1000 mL |

pH after sterilization: 7.1±0.2.

Mix the L-cystine, agar, sodium chloride, dextrose, yeast extract, and pancreatic digest of casein with the purified water, and heat until solution is effected. Dissolve the sodium thioglycollate or thioglycolic acid in the solution and, if necessary, add 1 N sodium hydroxide so that, after sterilization, the solution will have a pH of 7.1 ± 0.2. If filtration is necessary, heat the solution again without boiling, and filter while hot through moistened filter paper. Add the resazurin sodium solution, mix, and place the medium in suitable vessels that provide a ratio of surface to depth of medium such that not more than the upper half of the medium has undergone a color change indicative of oxygen uptake at the end of the incubation period. Sterilize using a validated process. If the medium is stored, store at a temperature between 2° and 25° in a sterile, airtight container. If more than the upper one-third of the medium has acquired a pink color, the medium may be restored once by heating the containers in a water-bath or in free-flowing steam until the pink color disappears and by cooling quickly, taking care to prevent the introduction of nonsterile air into the container. Do not use the medium for a longer storage period than has been validated.

*Fluid Thioglycollate Medium* is to be incubated at 30°–35°. For products containing a mercurial preservative that cannot be tested by the membrane filtration method, *Fluid Thioglycollate Medium* incubated at 20°–25° may be used instead of *Soybean–Casein Digest Medium* provided that it has been validated as described in *Growth Promotion Test of Aerobes, Anaerobes, and Fungi*. Where prescribed or justified and authorized, the following alternative thioglycollate medium might be used. Prepare a mixture having the same composition as that of the *Fluid Thioglycollate Medium*, but omitting the agar and the resazurin sodium solution. Sterilize as directed above. The pH after sterilization is 7.1 ± 0.2. Heat in a water bath prior to use and incubate at 30°–35° under anaerobic conditions.

**Soybean–Casein Digest Medium**

| | |
|---|---|
| Pancreatic Digest of Casein | 17.0 g |
| Papaic Digest of Soybean Meal | 3.0 g |

Official

https://pharmacopeia.cn/v-download/

**Soybean–Casein Digest Medium** *(continued)*

| | |
|---|---|
| Sodium Chloride | 5.0 g |
| Dibasic Potassium Phosphate | 2.5 g |
| Dextrose Monohydrate/Anhydrous | 2.5/2.3 g |
| Purified Water | 1000 mL |

pH after sterilization: 7.3±0.2.

Dissolve the solids in the Purified Water, heating slightly to effect a solution. Cool the solution to room temperature, and adjust the pH with 1 N sodium hydroxide so that, after sterilization, it will have a pH of 7.3 ± 0.2. Filter, if necessary to clarify, dispense into suitable containers, and sterilize using a validated procedure. Store at a temperature between 2° and 25° in a sterile well-closed container, unless it is intended for immediate use. Do not use the medium for a longer storage period than has been validated.

*Soybean–Casein Digest Medium* is to be incubated at 22.5 ± 2.5°.

## ♦Media for Penicillins or Cephalosporins

Where sterility test media are to be used in the *Direct Inoculation of the Culture Medium* method under *Test for Sterility of the Product to be Examined*, modify the preparation of *Fluid Thioglycollate Medium* and the *Soybean–Casein Digest Medium* as follows. To the containers of each medium, transfer aseptically a quantity of β-lactamase sufficient to inactivate the amount of antibiotic in the specimen under test. Determine the quantity of β-lactamase required to inactivate the antibiotic by using a β-lactamase preparation that has been assayed previously for its penicillin- or cephalosporin-inactivating power. [NOTE—Supplemented β-lactamase media can also be used in the membrane filtration test.]

Alternatively (in an area completely separate from that used for sterility testing), confirm that an appropriate amount of β-lactamase is incorporated into the medium, following either method under *Method Suitability Test*, using less than 100 colony-forming units (cfu) of *Staphylococcus aureus* (see *Table 1*) as the challenge. Typical microbial growth of the inoculated culture must be observed as a confirmation that the β-lactamase concentration is appropriate.♦

**Table 1. Strains of the Test Microorganisms Suitable for Use in the Growth Promotion Test and the Method Suitability Test**

| | |
|---|---|
| **Aerobic bacteria** | |
| *Staphylococcus aureus* | ATCC 6538, CIP 4.83, NCTC 10788, NCIMB 9518, NBRC 13276 |
| *Bacillus subtilis* | ATCC 6633, CIP 52.62, NCIMB 8054, NBRC 3134 |
| *Pseudomonas aeruginosa*♦[1]♦ | ATCC 9027, NCIMB 8626, CIP 82.118, NBRC 13275 |
| **Anaerobic bacterium** | |
| *Clostridium sporogenes*♦[2]♦ | ATCC 19404, CIP 79.3, NCTC 532 or ATCC 11437, NBRC 14293 |
| **Fungi** | |
| *Candida albicans* | ATCC 10231, IP 48.72, NCPF 3179, NBRC 1594 |
| *Aspergillus brasiliensis* (*Aspergillus Niger*) | ATCC 16404, IP 1431.83, IMI 149007, NBRC 9455 |

♦[1] An alternative microorganism is *Kocuria rhizophila (Micrococcus luteus)* ATCC 9341.♦

♦[2] An alternative to *Clostridium sporogenes,* when a nonspore-forming microorganism is desired, is *Bacteroides vulgatus* (ATCC 8482).♦

The media used comply with the following tests, carried out before, or in parallel, with the test on the product to be examined.

## Sterility

Incubate portions of the media for 14 days. No growth of microorganisms occurs.

## Growth Promotion Test of Aerobes, Anaerobes, and Fungi

Test each lot of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from ingredients. Suitable strains of microorganisms are indicated in *Table 1*.

Inoculate portions of *Fluid Thioglycollate Medium* with a small number (not more than 100 cfu) of the following microorganisms, using a separate portion of medium for each of the following species of microorganism: *Clostridium sporogenes*, *Pseudomonas aeruginosa*, and *Staphylococcus aureus*. ♦Inoculate portions of alternative thioglycollate medium with a small number (not more than 100 cfu) of *Clostridium sporogenes*.♦ Inoculate portions of *Soybean–Casein Digest Medium* with a small number (not more than 100 cfu) of the following microorganisms, using a separate portion of medium for each of the following species of microorganism: *Aspergillus brasiliensis*, *Bacillus subtilis,* and *Candida albicans*. Incubate for not more than 3 days in the case of bacteria and not more than 5 days in the case of fungi. Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable microorganisms used for inoculation are not more than five passages removed from the original master seed-lot.

Official

https://pharmacopeia.cn/

The media are suitable if a clearly visible growth of the microorganisms occurs.

## ♦DILUTING AND RINSING FLUIDS FOR MEMBRANE FILTRATION

### Fluid A

PREPARATION

Dissolve 1 g of peptic digest of animal tissue in water to make 1 L, filter or centrifuge to clarify, if necessary, and adjust to a pH of 7.1 ± 0.2. Dispense into containers, and sterilize using a validated process.

PREPARATION FOR PENICILLINS OR CEPHALOSPORINS

Aseptically add to the above *Preparation*, if necessary, a quantity of sterile β-lactamase sufficient to inactivate any residual antibiotic activity on the membranes after the solution of the test specimen has been filtered (see *Media for Penicillins or Cephalosporins*).

### Fluid D

To each L of *Fluid A* add 1 mL of polysorbate 80, adjust to a pH of 7.1 ± 0.2, dispense into containers, and sterilize using a validated process. Use this fluid for articles containing lecithin or oil, or for devices labeled as "sterile pathway."

### Fluid K

Dissolve 5.0 g of peptic digest of animal tissue, 3.0 g of beef extract, and 10.0 g of polysorbate 80 in water to make 1 L. Adjust the pH to obtain, after sterilization, a pH of 6.9 ± 0.2. Dispense into containers, and sterilize using a validated process.♦

## METHOD SUITABILITY TEST

Carry out a test as described below under *Test for Sterility of the Product to be Examined* using exactly the same methods, except for the following modifications.

### Membrane Filtration

After transferring the content of the container or containers to be tested to the membrane, add an inoculum of a small number of viable microorganisms (not more than 100 cfu) to the final portion of sterile diluent used to rinse the filter.

### Direct Inoculation

After transferring the contents of the container or containers to be tested (for catgut and other surgical sutures for veterinary use: strands) to the culture medium, add an inoculum of a small number of viable microorganisms (not more than 100 cfu) to the medium.

In both cases use the same microorganisms as those described above under *Growth Promotion Test of Aerobes, Anaerobes, and Fungi*. Perform a growth promotion test as a positive control. Incubate all the containers containing medium for not more than 5 days.

If clearly visible growth of microorganisms is obtained after the incubation, visually comparable to that in the control vessel without product, either the product possesses no antimicrobial activity under the conditions of the test or such activity has been satisfactorily eliminated. The test for sterility may then be carried out without further modification.

If clearly visible growth is not obtained in the presence of the product to be tested, visually comparable to that in the control vessels without product, the product possesses antimicrobial activity that has not been satisfactorily eliminated under the conditions of the test. Modify the conditions in order to eliminate the antimicrobial activity, and repeat the *Method Suitability Test*.

This method suitability is performed (a) when the test for sterility has to be carried out on a new product; and (b) whenever there is a change in the experimental conditions of the test. The method suitability may be performed simultaneously with the *Test for Sterility of the Product to be Examined*.

## TEST FOR STERILITY OF THE PRODUCT TO BE EXAMINED

### ♦Number of Articles to Be Tested

Unless otherwise specified elsewhere in this chapter or in the individual monograph, test the number of articles specified in *Table 3*. If the contents of each article are of sufficient quantity (see *Table 2*), they may be divided so that equal appropriate portions are added to each of the specified media. [NOTE—Perform sterility testing employing two or more of the specified

media.] If each article does not contain sufficient quantities for each medium, use twice the number of articles indicated in *Table 3*.

**Table 2. Minimum Quantity to be Used for Each Medium**

| Quantity per Container | Minimum Quantity to be Used (unless otherwise justified and authorized) |
|---|---|
| *Liquids* | |
| Less than 1 mL | The whole contents of each container |
| 1–40 mL | Half the contents of each container, but not less than 1 mL |
| Greater than 40 mL, and not greater than 100 mL | 20 mL |
| Greater than 100 mL | 10% of the contents of the container, but not less than 20 mL |
| *Antibiotic liquids* | 1 mL |
| *Insoluble preparations, creams, and ointments to be suspended or emulsified* | Use the contents of each container to provide not less than 200 mg |
| *Solids* | |
| Less than 50 mg | The whole contents of each container |
| 50 mg or more, but less than 300 mg | Half the contents of each container, but not less than 50 mg |
| 300 mg–5 g | 150 mg |
| Greater than 5 g | 500 mg |
| Catgut and other surgical sutures for veterinary use | 3 sections of a strand (each 30-cm long) |
| •Surgical dressing/cotton/gauze (in packages) | 100 mg per package |
| Sutures and other individually packaged single-use material | The whole device |
| Other medical devices | The whole device, cut into pieces or disassembled• |

**Table 3. Minimum Number of Articles to be Tested in Relation to the Number of Articles in the Batch**

| Number of Items in the Batch* | Minimum Number of Items to be Tested for Each Medium (unless otherwise justified and authorized)** |
|---|---|
| *Parenteral preparations* | |
| Not more than 100 containers | 10% or 4 containers, whichever is the greater |
| More than 100 but not more than 500 containers | 10 containers |
| More than 500 containers | 2% or 20 containers, whichever is less |
| • *For large-volume parenterals* | 2% or 10 containers, whichever is less |
| *Antibiotic solids* | |
| Pharmacy bulk packages (<5 g) | 20 containers |
| Pharmacy bulk packages (≥5 g) | 6 containers |
| Bulks and blends | See *Bulk solid products*• |
| | |
| *Ophthalmic and other noninjectable preparations* | |
| Not more than 200 containers | 5% or 2 containers, whichever is the greater |
| More than 200 containers | 10 containers |
| If the product is presented in the form of single-dose containers, apply the scheme shown above for preparations for parenteral use. | |
| Catgut and other surgical sutures for veterinary use | 2% or 5 packages, whichever is the greater, up to a maximum total of 20 packages |
| •Not more than 100 articles | 10% or 4 articles, whichever is greater |
| More than 100, but not more than 500 articles | 10 articles |
| More than 500 articles | 2% or 20 articles, whichever is less• |
| *Bulk solid products* | |
| Up to 4 containers | Each container |
| More than 4 containers, but not more than 50 containers | 20% or 4 containers, whichever is greater |
| More than 50 containers | 2% or 10 containers, whichever is greater |

* If the batch size is unknown, use the maximum number of items prescribed.
** If the contents of one container are enough to inoculate the two media, this column gives the number of containers needed for both the media together.

The test may be carried out using the technique of *Membrane Filtration* or by *Direct Inoculation of the Culture Medium* with the product to be examined. Appropriate negative controls are included. The technique of membrane filtration is used whenever the nature of the product permits; that is, for filterable aqueous preparations, for alcoholic or oily preparations, and for preparations miscible with, or soluble in, aqueous or oily solvents, provided these solvents do not have an antimicrobial effect in the conditions of the test.

## Membrane Filtration

Use membrane filters having a nominal pore size not greater than 0.45 µm, in which the effectiveness to retain microorganisms has been established. Cellulose nitrate filters, for example, are used for aqueous, oily, and weakly alcoholic solutions; and cellulose acetate filters, for example, are used for strongly alcoholic solutions. Specially adapted filters may be needed for certain products (e.g., for antibiotics).

The technique described below assumes that membranes about 50 mm in diameter will be used. If filters of a different diameter are used, the volumes of the dilutions and the washings should be adjusted accordingly. The filtration apparatus and membrane are sterilized by appropriate means. The apparatus is designed so that the solution to be examined can be introduced and filtered under aseptic conditions: it permits the aseptic removal of the membrane for transfer to the medium, or it is suitable for carrying out the incubation after adding the medium to the apparatus itself.

### AQUEOUS SOLUTIONS

If appropriate, transfer a small quantity of a suitable, sterile diluent such as ♦*Fluid A* (see *Diluting and Rinsing Fluids for Membrane Filtration*)♦ onto the membrane in the apparatus and filter. The diluent may contain suitable neutralizing substances and/or appropriate inactivating substances, for example, in the case of antibiotics.

Transfer the contents of the container or containers to be tested to the membrane or membranes, if necessary, after diluting to the volume used in the *Method Suitability Test* with the chosen sterile diluent, but using not less than the quantities of the product to be examined prescribed in *Tables 2* and *3*. Filter immediately. If the product has antimicrobial properties, wash the membrane not less than three times by filtering through it each time the volume of the chosen sterile diluent used in the *Method Suitability Test.* Do not exceed a washing cycle of five times 100 mL per filter, even if during method suitability it has been demonstrated that such a cycle does not fully eliminate the antimicrobial activity. Transfer the whole membrane to the culture medium or cut it aseptically into two equal parts, and transfer one half to each of two suitable media. Use the same volume of each medium as in the *Method Suitability Test.* Alternatively, transfer the medium onto the membrane in the apparatus. Incubate the media for not less than 14 days.

### SOLUBLE SOLIDS

Use for each medium not less than the quantity prescribed in *Tables 2* and *3* of the product dissolved in a suitable solvent, such as the solvent provided with the preparation, Sterile Water for Injection, sterile saline, or a suitable sterile solution such as ♦*Fluid A* (*Diluting and Rinsing Fluids for Membrane Filtration*),♦ and proceed with the test as described above for *Aqueous Solutions* using a membrane appropriate to the chosen solvent.

### OILS and OILY SOLUTIONS

Use for each medium not less than the quantity of the product prescribed in *Tables 2* and *3*. Oils and oily solutions of sufficiently low viscosity may be filtered without dilution through a dry membrane. Viscous oils may be diluted as necessary with a suitable sterile diluent such as isopropyl myristate shown not to have antimicrobial activity in the conditions of the test. Allow the oil to penetrate the membrane by its own weight, and then filter, applying the pressure or suction gradually. Wash the membrane at least three times by filtering through it each time about 100 mL of a suitable sterile solution such as ♦*Fluid A* (see *Diluting and Rinsing Fluids for Membrane Filtration*)♦ containing a suitable emulsifying agent at a concentration shown to be appropriate in the *Method Suitability Test,* for example polysorbate 80 at a concentration of 10 g per L ♦(*Fluid K*)♦. Transfer the membrane or membranes to the culture medium or media, or vice versa, as described above for *Aqueous Solutions*, and incubate at the same temperatures and for the same times.

### OINTMENTS and CREAMS

Use for each medium not less than the quantities of the product prescribed in *Tables 2* and *3*. Ointments in a fatty base and emulsions of the water-in-oil type may be diluted to 1% in isopropyl myristate as described above, by heating, if necessary, to not more than 40°. In exceptional cases it may be necessary to heat to not more than 44°. Filter as rapidly as possible, and proceed as described above for *Oils and Oily Solutions*.

### ♦PREFILLED SYRINGES

For prefilled syringes without attached sterile needles, expel the contents of each syringe into one or two separate membrane filter funnels or into separate pooling vessels prior to transfer. If a separate sterile needle is attached, directly expel the syringe contents as indicated above, and proceed as directed for *Aqueous Solutions*. Test the sterility of the needle, using *Direct Inoculation* under *Method Suitability Test*.

Official

https://mhattacharjee.github.io/

### SOLIDS FOR INJECTION OTHER THAN ANTIBIOTICS

Constitute the test articles as directed on the label, and proceed as directed for *Aqueous Solutions* or *Oils and Oily Solutions*, whichever applies. [NOTE—If necessary, excess diluent can be added to aid in the constitution and filtration of the constituted test article.]

### ANTIBIOTIC SOLIDS FOR INJECTION

**Pharmacy Bulk Packages, <5 g**—From each of 20 containers, aseptically transfer about 300 mg of solids, into a sterile 500-mL conical flask, dissolve in about 200 mL of *Fluid A* (see *Diluting and Rinsing Fluids for Membrane Filtration*), and mix; or constitute, as directed in the labeling, each of 20 containers and transfer a quantity of liquid or suspension, equivalent to about 300 mg of solids, into a sterile 500-mL conical flask, dissolve in about 200 mL of *Fluid A*, and mix. Proceed as directed for *Aqueous Solutions* or *Oils and Oily Solutions*, whichever applies.
**Pharmacy Bulk Packages, ≥5 g**—From each of 6 containers, aseptically transfer about 1 g of solids into a sterile 500-mL conical flask, dissolve in about 200 mL of *Fluid A*, and mix; or constitute, as directed in the labeling, each of 6 containers and transfer a quantity of liquid, equivalent to about 1 g of solids, into a sterile 500-mL conical flask, dissolve in about 200 mL of *Fluid A*, and mix. Proceed as directed for *Aqueous Solutions*.

### ANTIBIOTIC SOLIDS, BULKS, and BLENDS

Aseptically remove a sufficient quantity of solids from the appropriate amount of containers (see *Table 2*), mix to obtain a composite, equivalent to about 6 g of solids, and transfer to a sterile 500-mL conical flask. Dissolve in about 200 mL of *Fluid A*, and mix. Proceed as directed for *Aqueous Solutions*.

### STERILE AEROSOL PRODUCTS

For fluid products in pressurized aerosol form, freeze the containers in an alcohol-dry ice mixture at least at –20° for about 1 hour. If feasible, allow the propellant to escape before aseptically opening the container, and transfer the contents to a sterile pooling vessel. Add 100 mL of *Fluid D* to the pooling vessel, and mix gently. Proceed as directed for *Aqueous Solutions* or *Oils and Oily Solutions*, whichever applies.

### DEVICES WITH PATHWAYS LABELED STERILE

Aseptically pass not less than 10 pathway volumes of *Fluid D* through each device tested. Collect the fluids in an appropriate sterile vessel, and proceed as directed for *Aqueous Solutions* or *Oils and Oily Solutions*, whichever applies.
In the case of sterile, empty syringes, draw sterile diluent into the barrel through the sterile needle, if attached, or through a sterile needle attached for the purpose of the test, and express the contents into a sterile pooling vessel. Proceed as directed above.

## Direct Inoculation of the Culture Medium

Transfer the quantity of the preparation to be examined prescribed in *Tables 2* and *3* directly into the culture medium so that the volume of the product is not more than 10% of the volume of the medium, unless otherwise prescribed.
If the product to be examined has antimicrobial activity, carry out the test after neutralizing this with a suitable neutralizing substance or by dilution in a sufficient quantity of culture medium. When it is necessary to use a large volume of the product, it may be preferable to use a concentrated culture medium prepared in such a way that it takes into account the subsequent dilution. Where appropriate, the concentrated medium may be added directly to the product in its container.

### OILY LIQUIDS

Use media to which have been added a suitable emulsifying agent at a concentration shown to be appropriate in the *Method Suitability Test,* for example polysorbate 80 at a concentration of 10 g per L.

### OINTMENTS and CREAMS

Prepare by diluting to about 1 in 10 by emulsifying with the chosen emulsifying agent in a suitable sterile diluent such as *Fluid A* (see *Diluting and Rinsing Fluids for Membrane Filtration*). Transfer the diluted product to a medium not containing an emulsifying agent.
Incubate the inoculated media for not less than 14 days. Observe the cultures several times during the incubation period. Shake cultures containing oily products gently each day. However, when *Fluid Thioglycollate Medium* is used for the detection of anaerobic microorganisms, keep shaking or mixing to a minimum in order to maintain anaerobic conditions.

### CATGUT and OTHER SURGICAL SUTURES FOR VETERINARIAN USE

Use for each medium not less than the quantities of the product prescribed in *Tables 2* and *3*. Open the sealed package using aseptic precautions, and remove three sections of the strand for each culture medium. Carry out the test on three sections, each 30-cm long, which have been cut off from the beginning, the center, and the end of the strand. Use whole strands from freshly opened cassette packs. Transfer each section of the strand to the selected medium. Use sufficient medium to cover adequately the material to be tested (20 mL to 150 mL).

Official

https://pharmacopeia.cn/

### ♦SOLIDS

Transfer a quantity of the product in the form of a dry solid (or prepare a suspension of the product by adding sterile diluent to the immediate container), corresponding to not less than the quantity indicated in *Tables 2* and *3*. Transfer the material so obtained to 200 mL of *Fluid Thioglycollate Medium,* and mix. Similarly, transfer the same quantity to 200 mL of *Soybean–Casein Digest Medium,* and mix. Proceed as directed above.

### PURIFIED COTTON, GAUZE, SURGICAL DRESSINGS, and RELATED ARTICLES

From each package of cotton, rolled gauze bandage, or large surgical dressings being tested, aseptically remove two or more portions of 100- to 500-mg each from the innermost part of the sample. From individually packaged, single-use materials, aseptically remove the entire article. Immerse the portions or article in each medium, and proceed as directed above.

### STERILE DEVICES

Articles can be immersed intact or disassembled. To ensure that device pathways are also in contact with the media, immerse the appropriate number of units per medium in a volume of medium sufficient to immerse the device completely, and proceed as directed above. For extremely large devices, immerse those portions of the device that are to come into contact with the patient in a volume of medium sufficient to achieve complete immersion of those portions.

For catheters where the inside lumen and outside are required to be sterile, either cut them into pieces such that the medium is in contact with the entire lumen or fill the lumen with medium, and then immerse the intact unit.♦

## OBSERVATION AND INTERPRETATION OF RESULTS

At intervals during the incubation period and at its conclusion, examine the media for macroscopic evidence of microbial growth. If the material being tested renders the medium turbid so that the presence or absence of microbial growth cannot be readily determined by visual examination, 14 days after the beginning of incubation transfer portions (each not less than 1 mL) of the medium to fresh vessels of the same medium, and then incubate the original and transfer vessels for not less than 4 days.

If no evidence of microbial growth is found, the product to be examined complies with the test for sterility. If evidence of microbial growth is found, the product to be examined does not comply with the test for sterility, unless it can be clearly demonstrated that the test was invalid for causes unrelated to the product to be examined. The test may be considered invalid only if one or more of the following conditions are fulfilled:

1. The data of the microbiological monitoring of the sterility testing facility show a fault.
2. A review of the testing procedure used during the test in question reveals a fault.
3. Microbial growth is found in the negative controls.
4. After determination of the identity of the microorganisms isolated from the test, the growth of this species (or these species) may be ascribed unequivocally to faults with respect to the material and or the technique used in conducting the sterility test procedure.

If the test is declared to be invalid, it is repeated with the same number of units as in the original test. If no evidence of microbial growth is found in the repeat test, the product examined complies with the test for sterility. If microbial growth is found in the repeat test, the product examined does not comply with the test for sterility.

## APPLICATION OF THE TEST TO PARENTERAL PREPARATIONS, OPHTHALMIC, AND OTHER NONINJECTABLE PREPARATIONS REQUIRED TO COMPLY WITH THE TEST FOR STERILITY

When using the technique of membrane filtration, use, whenever possible, the whole contents of the container, but not less than the quantities indicated in *Table 2,* diluting where necessary to about 100 mL with a suitable sterile solution, such as ♦*Fluid A* (see *Diluting and Rinsing Fluids for Membrane Filtration*).♦

When using the technique of direct inoculation of media, use the quantities shown in *Table 2,* unless otherwise justified and authorized. The tests for bacterial and fungal sterility are carried out on the same sample of the product to be examined. When the volume or the quantity in a single container is insufficient to carry out the tests, the contents of two or more containers are used to inoculate the different media.

## MINIMUM NUMBER OF ITEMS TO BE TESTED

The minimum number of items to be tested in relation to the size of the batch is given in *Table 3*.

# ⟨81⟩ ANTIBIOTICS—MICROBIAL ASSAYS

## INTRODUCTION AND GENERAL INFORMATION

The activity (potency) of antibiotics can be demonstrated by their inhibitory effect on microorganisms under suitable conditions. A reduction in antimicrobial activity may not be adequately demonstrated by chemical methods. This chapter summarizes procedures for the antibiotics recognized in the *United States Pharmacopeia* (*USP*) for which the microbiological assay is the standard analytical method.

Two general techniques are employed: the cylinder-plate (or plate) assay and the turbidimetric (or tube) assay. *Table 1* lists all the antibiotics that contain microbial assays and specifies the type of assay (cylinder-plate or turbidimetric).

**Table 1**

| Antibiotic | Type of Assay |
|---|---|
| Amoxicillin | Cylinder-plate |
| Amphotericin B | Cylinder-plate |
| Bacitracin | Cylinder-plate |
| Bleomycin | Cylinder-plate |
| Capreomycin | Turbidimetric |
| Chloramphenicol | Turbidimetric |
| Chlortetracycline | Turbidimetric |
| Cloxacillin | Cylinder-plate |
| Colistemethate | Cylinder-plate |
| Colistin | Cylinder-plate |
| Dihydrostreptomycin | Cylinder-plate |
| | Turbidimetric |
| Erythromycin | Cylinder-plate |
| Gentamicin | Cylinder-plate |
| Gramicidin | Turbidimetric |
| Nafcillin | Cylinder-plate |
| Neomycin | Cylinder-plate |
| | Turbidimetric |
| Novobiocin | Cylinder-plate |
| Nystatin | Cylinder-plate |
| Oxytetracycline | Turbidimetric |
| Paromomycin | Cylinder-plate |
| Penicillin G | Cylinder-plate |
| Polymyxin B | Cylinder-plate |
| Tetracycline | Turbidimetric |
| Thiostrepton | Turbidimetric |
| Tylosin | Turbidimetric |
| Vancomycin | Cylinder-plate |

[NOTE—Perform all procedures under conditions designed to avoid extrinsic microbial contamination. Take adequate safety precautions while performing these assays because of possible allergies to drugs and because live cultures of organisms are used in the procedures.]

### Cylinder-Plate Assay

The cylinder-plate assay depends on diffusion of the antibiotic from a vertical cylinder through a solidified agar layer in a Petri dish or plate. The growth of the specific microorganisms inoculated into the agar is prevented in a circular area or "zone" around the cylinder containing the solution of the antibiotic.

Official

https://pharmacopeia.cn/v29240/

## Turbidimetric Assay

The turbidimetric assay depends on the inhibition of growth of a microorganism in a uniform solution of the antibiotic in a fluid medium that is favorable to the growth of the microorganism in the absence of the antibiotic.

## Units and Reference Standards

For substances like the antibiotics quantified using the method in this chapter which are not easily characterized by chemical or physical means, it is still necessary to express quantities of biological activity in units of biological potency, each defined by an authoritative reference standard. The potency of antibiotics is designated in either units (U) or µg of activity. In each case, the unit or µg of antibiotic activity was originally established against a US Federal Master Standard for that antibiotic. This practice started because originally the antibiotic selected as a reference standard was thought to consist entirely of a single chemical entity and was therefore assigned a potency of 1000 µg/mg. In several such instances, as the manufacturing and purification methods for particular antibiotics became more advanced, antibiotics containing more than 1000 µg of activity/mg became possible. Since relative potency was used to assign this value and not the mass of the antibiotics themselves, such antibiotics had an "activity" equivalent to a given number of µg of the original reference standard (rather than a µg of mass as would be expected). Over time, less complex antibiotics or those with a single primary active substance were demonstrated to have µg of activity equivalent numerically to the µg (weight) of the pure substance. In these cases, the antibiotics have moved away from the microbial assay methods and are assigned by a mass balance approach; until that exercise is completed for a given antibiotic, manufacturers cannot assume that the µg of activity corresponds to the µg (weight) of the antibiotic substance. Since the US Federal Master antibiotic standards are no longer available, USP Reference Standards for antibiotics that are assigned relative potency by the methods in this chapter are calibrated either against the World Health Organization (WHO) International Standard for Antibiotics (ISA), if it exists, or the previous USP lot when a WHO ISA or another authoritative reference standard calibrated against an ISA does not exist. Once assigned, the International Units (IUs), when used, are converted to USP units by the previously agreed upon bridging value between the two when the respective Reference Standards were originally assigned. Over time, it may be possible to convert the assay methods of more antibiotics from the microbial bioassay to a physicochemical method much like that suggested in *Validation of Alternative Methods to Antibiotic Microbial Assays* ⟨1223.1⟩ or other suitable strategies that include validated methods with associated bridging data.

## Apparatus

Labware used for the storage and transfer of test dilutions and microorganisms must be sterile and free of interfering residues (see *Cleaning Glass Apparatus* ⟨1051⟩). Use a validated sterilization method, such as dry heat, steam, or radiation; or use sterile, disposable labware.

## Temperature Control

Thermostatic control is required in several stages of a microbial assay: when culturing a microorganism and preparing its inoculum, and during incubation in plate and tube assays. Refer to specific temperature requirements below for each type of assay.

## Test Organisms

The test organism for each antibiotic is listed in *Table 3* for the cylinder-plate assay and *Table 8* for the turbidimetric assay. The test organisms are specified by the American Type Culture Collection (ATCC) number.

In order to ensure acceptable performance of test organisms, store and maintain them properly. Establish the specific storage conditions during method validation or verification. Discard cultures if a change in the organism's characteristics is observed.

## Prolonged Storage

For prolonged storage, maintain test organisms in a suitable storage solution such as 50% fetal calf serum in broth, 10%–15% glycerol in tryptic soy broth, defibrinated sheep blood, or skim milk. Prolonged-storage cultures are best stored in the freeze-dried state; temperatures of –60° or below are preferred; temperatures below –20° are acceptable.

## Primary Cultures

Prepare primary cultures by transferring test organisms from prolonged-storage vials onto appropriate media, and incubate under appropriate growth conditions. Store primary cultures at the appropriate temperature, usually 2°–8°, and discard after 3 weeks. A single primary culture can be used to prepare working cultures only for as many as 7 days.

## Working Cultures

Prepare working cultures by transferring the primary culture onto appropriate solid media to obtain isolated colonies. Incubate working cultures under appropriate conditions to obtain satisfactory growth for preparation of test inocula. Prepare fresh working cultures for each test day.

## Uncharacteristic Growth or Performance of a Test Organism

Use new stock cultures, primary cultures, or working cultures when a test organism shows uncharacteristic growth or performance.

## Assay Designs

Suitable experimental designs are key to increasing precision and minimizing bias. Control of the incubation parameters, temperature distribution and time, is critical for minimizing bias; it can be accomplished by staging the plates and racks as described for each assay.

### CYLINDER-PLATE ASSAY

The comparisons are restricted to relationships between zone diameter measurements within plates, excluding the variation between plates. Individual plate responses are normalized on the basis of the relative zone size of the standard compared to the mean zone size of the standard across all plates.

### TURBIDIMETRIC ASSAY

To avoid systematic bias, place replicate tubes randomly in separate racks so that each rack contains one complete set of treatments. The purpose of this configuration is to minimize the influence of temperature distribution on the replicate samples. The turbidimetric assay, because of the configuration of the samples in test tube racks, is sensitive to slight variations in temperature. The influence of temperature variation can also be decreased by ensuring proper airflow or heat convection during incubation. At least 3 tubes for each sample and Standard concentration (one complete set of samples) should be placed in a single rack. The comparisons are restricted to relationships between the observed turbidities within racks.

## Potency Considerations

Within the restrictions listed above, the recommended assay design employs a five-concentration standard curve and a single concentration of each sample preparation.

For the cylinder-plate assay, each plate includes only 2 treatments, the reference treatment (median level standard, i.e., $S_3$) and one of the other 4 concentrations of the standard ($S_1$, $S_2$, $S_4$, and $S_5$) or the sample ($U_3$). The concentration of the sample is an estimate based on the target concentration. The sample should be diluted to give a nominal concentration that is estimated to be equivalent to the median reference concentration ($S_3$) of the standard. The purpose of diluting to the median reference concentration is to ensure that the sample result will fall within the linear portion of the standard curve. The test determines the relative potency of $U_3$ against the standard curve. The sample ($U_3$) should have a relative potency of about 100%. The final potency of the sample is obtained by multiplying the $U_3$ result by the dilution factor.

An assay should be considered preliminary if the computed potency value of the sample is less than 80% or more than 125%. In this case, the results suggest that the sample concentration assumed during preparation of the sample stock solution was not correct. In such a case, one can adjust the assumed potency of the sample on the basis of the preliminary potency value and repeat the assay. Otherwise, the potency will be derived from a portion of the curve where the Standard and sample responses will likely not be parallel.

Microbial determinations of potency are subject to inter-assay as well as intra-assay variables; therefore three or more independent assays are required for a reliable estimate of the potency of a given sample. Starting with separately prepared stock solutions and test dilutions of both the Standard and the sample, perform additional assays of a given sample. The mean potency should include the results from all the valid independent assays. The latter is assessed by the width of the confidence interval (refer to *Confidence Limits and Combination of Assays Calculations*). The combined result of a series of smaller, independent assays is a more reliable estimate of potency than one from a single large assay with the same total number of plates or tubes. Note that additional assays or lower variability allows the product to meet tighter specification ranges. Reducing assay variability achieves the required confidence limit with fewer assays.

# CYLINDER-PLATE METHOD

## Temperature Control

Use appropriately qualified and calibrated equipment to obtain the temperature ranges specified in *Table 3*.

## Apparatus

### PLATES

Use glass or disposable plastic Petri dishes (approximately 20 mm × 100 mm or other appropriate dimensions) with lids.

CYLINDERS

Use stainless steel or porcelain cylinders; 8 ± 0.1-mm o.d.; 6 ± 0.1-mm i.d.; 10 ± 0.1-mm high. [NOTE—Carefully clean cylinders to remove all residues; occasional cleaning in an acid bath, e.g., with about 2 N nitric acid or with chromic acid (see ⟨1051⟩) is required.]

## Standard Solutions

To prepare a stock solution, dissolve a suitable quantity of the USP Reference Standard of a given antibiotic, or the entire contents of a vial of USP Reference Standard, where appropriate, in the solvent specified in *Table 2*; and dilute to the specified concentration. Store at 2°–8°, and use within the period indicated. On the day of the assay, prepare from the stock solution five or more test dilutions, in which the successive solutions increase stepwise in concentration, usually in the ratio of 1:1.25. Use the final diluent specified such that the median has the concentration suggested in *Table 2*.

## Sample Solutions

Assign an assumed potency per unit weight or volume to the sample. On the day of the assay, prepare a stock solution in the same manner specified for the USP Reference Standard (see *Table 2*). Dilute the sample stock solution in the specified final diluent to obtain a nominal concentration equal to the median concentration of the standard ($S_3$).

**Table 2**

| Antibiotic | Stock Solution | | | | | Test Dilution | |
|---|---|---|---|---|---|---|---|
| | Initial Solvent | Initial Concentration | Further Diluent | Final Concentration | Use Within (days) | Final Diluent | Median Concentration ($S_3$)[a, b] |
| Amoxicillin[c] | Water | — | — | 100 µg/mL | 7 | B.3[d] | 0.1 µg/mL |
| Amphotericin B[c, e] | Dimethyl sulfoxide | — | — | 1 mg/mL | Same day | B.10[d] | 1 µg/mL |
| Bacitracin[f] | 0.01 N hydrochloric acid | — | — | 100 U/mL | Same day | B.1[d] | 1 U/mL |
| Bleomycin | B.16[d] | — | — | 2 U/mL | 14 | B.16[d] | 0.04 U/mL |
| Cloxacillin | B.1[d] | — | — | 1 mg/mL | 7 | B.1[d] | 5 µg/mL |
| Colistimethate[c] | Water | 10 mg/mL | B.6[d] | 1 mg/mL | Same day | B.6[d] | 1 µg/mL |
| Colistin | Water | 10 mg/mL | B.6[d] | 1 mg/mL | 14 | B.6[d] | 1 µg/mL |
| Dihydrostreptomycin[g] | B.3[d] | — | — | 1 mg/mL | 30 | B.3[d] | 1 µg/mL |
| Erythromycin | Methanol | 10 mg/mL | B.3[d] | 1 mg/mL | 14 | B.3[d] | 1 µg/mL |
| Gentamicin | B.3[d] | — | — | 1 mg/mL | 30 | B.3[d] | 0.1 µg/mL |
| Nafcillin | B.1[d] | — | — | 1 mg/mL | 2 | B.1[d] | 2 µg/mL |
| Neomycin[g] | B.3[d] | — | — | 1 mg/mL | 14 | B.3[d] | 1 µg/mL |
| Novobiocin | alcohol | 10 mg/mL | B.3[d] | 1 mg/mL | 5 | B.6[d] | 0.5 µg/mL |
| Nystatin[c, h] | Dimethylformamide | — | — | 1000 U/mL | Same day | B.6[d] | 20 U/mL |
| Paromomycin | B.3[d] | — | — | 1 mg/mL | 21 | B.3[d] | 1 µg/mL |
| Penicillin G | B.1[d] | — | — | 1000 U/mL | 4 | B.1[d] | 1 U/mL |
| Polymyxin B[i] | Water | — | B.6[d] | 10,000 U/mL | 14 | B.6[d] | 10 U/mL |
| Vancomycin | Water | — | — | 1 mg/mL | 7 | B.4[d] | 10 µg/mL |

[a] It is acceptable to adjust the median concentration to optimize zone sizes if the data remain in the linear range.
[b] µg in this column refers to µg of activity.
[c] Prepare the USP Reference Standard and sample test dilutions simultaneously.
[d] The letter B refers to buffer. See *Buffers* for a description of each buffer listed in this table.
[e] Further dilute the stock solution with dimethyl sulfoxide to give concentrations of 12.8, 16, 20, 25, and 31.2 µg/mL before making the test dilutions. The test dilution of the sample should contain the same amount of dimethyl sulfoxide as the test dilutions of the USP Reference Standard.
[f] Each of the standard test dilutions should contain the same amount of hydrochloric acid as the test dilution of the sample.
[g] The turbidimetric assay can be used as an alternative procedure.
[h] Further dilute the stock solution with dimethylformamide to give concentrations of 256, 320, 400, 500, and 624 U/mL before making the test dilutions. Prepare the standard test dilutions simultaneously with test dilutions of the sample to be tested. The test dilution of the sample should contain the same amount of dimethylformamide as the test dilutions of the standard. Use low-actinic glassware.
[i] Prepare the stock solution by adding 2 mL of water for each 5 mg of the USP Reference Standard.

## Inocula

Suspend the test organism from a freshly grown slant or culture in 3 mL of sterile saline TS. Glass beads can be used to facilitate the suspension. Spread the saline suspension onto the surface of two or more agar plates (covering the entire surface) or onto the surface of a Roux bottle containing 250 mL of the specified medium (see *Table 3*).

Incubate for the specified time and at the temperature as specified in *Table 3*, or until growth is apparent.

After incubation, harvest the organism from the plates or Roux bottle with approximately 50 mL of sterile saline TS (except use *Medium 34* for bleomycin; see *Media and Solutions*), using a sterile bent glass rod or sterile glass beads. Pipet the suspension into a sterile glass container. This is the harvest suspension.

To make the stock suspension, dilute an appropriate amount of the harvest suspension with sterile saline TS. Using the UV-Vis spectrophotometer, measure the percentage transmittance at 580 nm. The target value is approximately 25% transmittance at 580 nm. This value is used to standardize the harvest suspension volume added to the seed layer agar.

Starting with the suggested volumes indicated in *Table 3*, determine during method verification the proportions of stock suspension to be added to the inoculum medium that result in satisfactory zones of inhibition of approximately 14–16 mm in diameter for the median concentration of the Standard ($S_3$).

[NOTE—Zone sizes that are outside the 11–19-mm range are not desirable, because these contribute to assay variability.]

If the dilution percentage transmittance is above 25%, a ratio may be used to normalize the addition of organism to the seed layer. The normalization factor can be determined by dividing the percentage transmittance obtained from the dilution by 25. This ratio can then be multiplied by the suggested inoculum amount to obtain the volume (mL) of harvest suspension that needs to be added to the seed layer. Adjust the quantity of inoculum on a daily basis, if necessary, to obtain an optimum concentration–response relationship.

Alternatively, determine during method verification the proportion of harvest suspension to be incorporated into the inoculum, starting with the volumes indicated in *Table 3*, that result in satisfactory demarcation of the zones of inhibition of about 14–16 mm in diameter for the median concentration of the Standard ($S_3$) and giving a reproducible concentration–response relationship. Prepare the inoculum by adding a portion of stock suspension to a sufficient amount of agar medium that has been melted and cooled to 45°–50°. Swirl the mixture without creating bubbles in order to obtain a homogeneous suspension.

**Table 3**

| Antibiotic | Test Organism | ATCC[a] Number | Incubation Conditions | | | Suggested Inoculum Composition | |
|---|---|---|---|---|---|---|---|
| | | | Medium[b] | Temperature (°) | Time | Medium[b] | Amount (mL/100 mL) |

## Analysis

Prepare the base layer for the required number of assay Petri plates, using the medium and volume shown in *Table 4*. Allow it to harden into a smooth base layer of uniform depth. Prepare the appropriate amount of seed layer inoculum (see *Table 5*) as directed for the given antibiotic (see *Table 3*) with any adjustments made based on the preparatory trial analysis. Tilt the plate back and forth to spread the inoculum evenly over the base layer surface, and allow it to harden.

**Table 4. Base Layer**

| Antibiotic | Medium[a] | Target Volume (mL) |
|---|---|---|
| Amoxicillin | 11 | 21 |
| Amphotericin B[b] | — | — |
| Bleomycin | 35 | 10 |
| Colistimethate | 9 | 21 |
| Colistin | 9 | 21 |
| Dihydrostreptomycin | 5 | 21 |
| Erythromycin | 11 | 21 |
| Gentamicin | 11 | 21 |
| Neomycin | 11 | 21 |
| Nystatin[b] | — | — |
| Paromomycin | 11 | 21 |
| Polymyxin B | 9 | 21 |
| Vancomycin | 8 | 10 |
| All others | 2 | 21 |

[a] See *Media*.
[b] No base layer is used. [NOTE—The base layer may be warmed to facilitate a uniform seed layer.]

**Table 5. Seed Layer**

| Antibiotic | Medium[a] | Target Volume (mL) |
|---|---|---|
| Amphotericin B | Refer to *Table 3* | 8 |
| Bleomycin | | 6 |
| Nystatin | | 8 |
| All others | | 4 |

[a] See *Media*.

Drop 6 assay cylinders on the inoculated surface from a height of 12 mm, using a mechanical guide or other device to ensure even spacing on a radius of 2.8 cm, and cover the plates to avoid contamination. Fill the 6 cylinders on each plate with the same volume of dilutions of antibiotic containing the test levels ($S_1$–$S_5$ and $U_3$) specified in the following paragraph. Incubate the plates as specified in *Table 6* for 16–18 h, and remove the cylinders. Measure and record the diameter of each zone of growth inhibition to the nearest 0.1 mm.

**Table 6**

| Antibiotic | Incubation Temperature (°) |
|---|---|
| Amphotericin B | 29–31 |
| Colistimethate | 36–37.5 |
| Colistin | 36–37.5 |
| Dihydrostreptomycin | 36–37.5 |
| Gentamicin | 36–37.5 |
| Neomycin | 36–37.5 |
| Novobiocin | 34–36 |
| Nystatin | 29–31 |
| Paromomycin | 36–37.5 |
| Polymyxin B | 36–37.5 |
| Vancomycin | 36–37.5 |
| All others | 32–35 |

The Standards ($S_1$–$S_5$) and a single test level of the sample ($U_3$) corresponding to $S_3$ of the standard curve, as defined in *Standard Solutions* and *Sample Solutions* will be used in the assay. For deriving the standard curve, fill alternate cylinders on each of 3 plates with the median test dilution ($S_3$) of the Standard and each of the remaining 9 cylinders with one of the other four test dilutions of the standard. Repeat the process for the three test dilutions of the Standard. For the sample, fill alternate cylinders on each of 3 plates with the median test dilution of the Standard ($S_3$), and fill the remaining 9 cylinders with the corresponding test dilution ($U_3$) of the sample.

## TURBIDIMETRIC METHOD

### Temperature Control

Use appropriately qualified and calibrated equipment to obtain the temperature ranges specified in *Table 8*. [NOTE—Temperature control can be achieved using either circulating air or water. The greater heat capacity of water lends it some advantage over circulating air.]

### Spectrophotometer

Measuring absorbance or transmittance within a fairly narrow frequency band requires a suitable spectrophotometer in which the wavelength can be varied or restricted by the use of 580- or 530-nm filters. Alternatively, a variable-wavelength spectrophotometer can be used and set to a wavelength of 580 or 530 nm.

The instrument may be modified as follows:

1. To accept the tube in which incubation takes place (see *Apparatus* below)
2. To accept a modified cell fitted with a drain that facilitates rapid change of contents
3. To contain a flow cell for a continuous flowthrough analysis

Autozero the instrument with clear, uninoculated broth prepared as specified for the particular antibiotic, including the same amount of test dilution (including formaldehyde if specified) as found in each sample.

Either absorbance or transmittance can be measured while preparing inocula.

### Apparatus

Use glass or plastic test tubes, e.g., 16 mm × 125 mm or 18 mm × 150 mm. [NOTE—Use tubes that are relatively uniform in length, diameter, and thickness and substantially free from surface blemishes and scratches. In the spectrophotometer, use matched tubes that are free from scratches or blemishes. Clean tubes thoroughly to remove all antibiotic residues and traces of cleaning solution. Sterilize tubes before use.]

### Standard Solutions

To prepare a stock solution, dissolve a quantity of the USP Reference Standard of a given antibiotic or the entire contents of a vial of USP Reference Standard, where appropriate, in the solvent specified in *Table 7*, and dilute to the required concentration. Store at 2°–8°, and use within the period indicated. On the day of the assay, prepare from the stock solution five or more test dilutions, the successive solutions increasing stepwise in concentration, usually in the ratio of 1:1.25. [NOTE—It may be necessary to use smaller ratios for the successive dilutions from the stock solution for the turbidimetric assay.] Use the final diluent specified such that the median level of the Standard ($S_3$) has the concentration suggested in *Table 7*.

## Sample Solutions

Assign an assumed potency per unit weight or volume to the unknown, and on the day of the assay prepare a stock solution in the same manner specified for the USP Reference Standard (see *Table 7*). Dilute the sample stock solution in the specified final diluent at a nominal concentration equal to the median concentration of the Standard ($S_3$) as specified in *Table 7*.

**Table 7**

| Antibiotic | Stock Solution | | | | | Test Dilution | |
|---|---|---|---|---|---|---|---|
| | Initial Solvent | Initial Concentration | Further Diluent | Final Stock Concentration | Use Within (days) | Final Diluent | Median Concentration ($S_3$)[a] |
| Capreomycin | Water | — | — | 1 mg/mL | 7 | Water | 100 µg/mL |
| Chloramphenicol | Alcohol | 10 mg/mL | Water | 1 mg/mL | 30 | Water | 2.5 µg/mL |
| Chlortetracycline | 0.1 N hydrochloric acid | — | — | 1 mg/mL | 4 | Water | 0.06 µg/mL |
| Dihydrostreptomycin[b] | Water | — | — | 1 mg/mL | 30 | Water | 30 µg/mL |
| Gramicidin | Alcohol | — | — | 1 mg/mL | 30 | Alcohol | 0.04 µg/mL |
| Neomycin[b, c] | B.3[d] | — | — | 100 µg/mL | 14 | B.3[d] | 1.0 µg/mL |
| Oxytetracycline | 0.1 N hydrochloric acid | — | — | 1 mg/mL | 4 | Water | 0.24 µg/mL |
| Tetracycline | 0.1 N hydrochloric acid | — | — | 1 mg/mL | 1 | Water | 0.24 µg/mL |
| Thiostrepton | Dimethyl sulfoxide | — | — | 100 U/mL | Same day | Dimethyl sulfoxide | 0.80 U/mL |
| Tylosin | Methanol | 10 mg/mL | B.16[d] | 1 mg/mL | 30 | Methanol and B.3[d] (1:1) | 4 µg/mL |

[a] µg in this column refers to µg of activity.
[b] The cylinder-plate assay can be used as an alternative procedure.
[c] Dilute the 100-µg/mL stock solution with *Buffer B.3* to obtain a solution having a concentration equivalent to 25 µg/mL of neomycin. To separate 50-mL volumetric flasks add 1.39, 1.67, 2.00, 2.40, and 2.88 mL of this solution. Add 5.0 mL of 0.1 N hydrochloric acid to each flask, dilute with *Buffer B.3* to volume, and mix to obtain solutions having concentrations of 0.69, 0.83, 1.0, 1.2, and 1.44 µg/mL of neomycin. Use these solutions to prepare the standard response line.
[d] The letter B refers to buffer. See *Buffers* for a description of each buffer listed in this table.

Official

## Inocula

Suspend the test organism from a freshly grown slant or culture in 3 mL of sterile saline TS. Glass beads can be used to facilitate the suspension. *Enterococcus hirae* (ATCC 10541) (when used for the gramicidin assay), and *Staphylococcus aureus* (ATCC 9144) are grown in a liquid medium, not on agar. Spread the saline suspension onto the surface of two or more agar plates (covering the entire surface) or onto the surface of a Roux bottle containing 250 mL of the specified medium (see *Table 8*). Incubate at the time and temperature specified in *Table 8*, or until growth is apparent.

After incubation, harvest the organism from the plates or Roux bottle with approximately 50 mL of sterile saline TS, using a sterile bent glass rod or sterile glass beads. Pipet the suspension into a sterile glass bottle. This is the harvest suspension.

Determine during method verification the quantity of harvest suspension that will be used as the inoculum, starting with the volume suggested in *Table 8*. Prepare also an extra Standard ($S_3$) as a test of growth. Incubate the trial tests for the times indicated in *Table 11*. Adjust the quantity of inoculum daily, if necessary, to obtain the optimum concentration–response relationship from the amount of growth of the test organism in the assay tubes. At the completion of the specified incubation periods, tubes containing the median concentration of the Standard should have absorbance values as specified in *Table 9*. Determine the exact duration of incubation by observing the growth in the reference concentration (median concentration) of the standard ($S_3$).

**Table 8**

| Antibiotic | Test Organism | ATCC[a] Number | Incubation Conditions | | | Suggested Inoculum Composition | |
|---|---|---|---|---|---|---|---|
| | | | Medium[b] | Temperature (°) | Time (h) | Medium[b] | Amount (mL/100 mL) |
| Capreomycin | *Klebsiella pneumoniae* | 10031 | 1 | 36–37.5 | 16–24 | 3 | 0.05 |
| Chloramphenicol | *Escherichia coli* | 10536 | 1 | 32–35 | 24 | 3 | 0.7 |
| Chlortetracycline | *Staphylococcus aureus* | 29737 | 1 | 32–35 | 24 | 3 | 0.1 |

## Analysis

On the day of the assay, prepare the necessary concentration of antibiotic by dilution of stock solutions of the Standard and of each sample as specified under *Standard Solutions* and *Sample Solutions*. Prepare 5 test levels, each in triplicate, of the Standard ($S_1$–$S_5$) and a single test level ($U_3$), also in triplicate, of up to 20 samples corresponding to $S_3$ (median concentration) of the Standard.

Place the tubes in test tube racks or other carriers. Include in each rack 1–2 control tubes containing 0.1 mL of the test diluent for gramicidin, thiostrepton, and tylosin, or 1 mL of the test diluent for all others (see *Table 7*), but no antibiotic. Add the volumes of the Standard and sample test dilutions as indicated in *Table 10*. Randomly distribute one complete set, including the controls, in a tube rack. Add the volume of inoculum specified in *Table 10* to each tube in the rack in turn, and place the completed rack immediately in an incubator or a water bath maintained at 36.0°–37.5° for the time specified in *Table 11*.

**Table 10**

| Antibiotic | Volume of Test Dilution (mL) | Volume of Inoculum (mL) |
|---|---|---|
| Gramicidin | 0.10 | 9.0 |
| Thiostrepton | 0.10 | 10.0 |
| Tylosin | 0.10 | 9.0 |
| All others | 1.0 | 9.0 |

**Table 11**

| Antibiotic | Incubation Time (h) |
|---|---|
| Capreomycin | 3–4 |
| Chloramphenicol | 3–4 |
| Cycloserine | 3–4 |
| Dihydrostreptomycin | 3–4 |
| Tylosin | 3–5 |

| Antibiotic | Incubation Time (h) |
|---|---|
| All others | 4–5 |

After incubation, immediately inhibit the growth of the organism by adding 0.5 mL of dilute formaldehyde to each tube, except for tylosin. For tylosin, heat the rack in a water bath at 80°–90° for 2–6 min or in a steam bath for 5–10 min, and bring to room temperature. Read absorbance or transmittance at 530 or 580 nm, analyzing one rack at a time.

## MEDIA AND SOLUTIONS

The media required for the preparation of test organism inocula are made from the ingredients listed herein. Minor modifications of the individual ingredients are acceptable; and reconstituted dehydrated media can be substituted, provided that the resulting media possess equal or better growth-promoting properties and give a similar standard curve response.

### Media

Dissolve the ingredients in water to make 1 L, and adjust the solutions with either 1 N sodium hydroxide or 1 N hydrochloric acid as required, so that after steam sterilization the pH is as specified.

[a] Adjust the pH with 18 N phosphoric acid or 10 N Potassium Hydroxide TS.

**Other solutions:** See *Reagents, Indicators, and Solutions*.
**Water:** Use *Purified Water*.
**Saline:** Use saline TS.
**Dilute formaldehyde:** Formaldehyde solution and water (1:3)

# CALCULATIONS

## Introduction

Antibiotic potency is calculated by interpolation from a standard curve using a log-transformed straight-line method with a least-squares fitting procedure (see below for calculation details). The analyst must consider three essential concepts in interpreting antibiotic potency results:

1. Biological concentration–response relationships generally are not linear. The antibiotic potency method allows fitting the data to a straight line by evaluating a narrow concentration range where the results approach linearity. The assay results can be considered valid only if the computed potency is 80%–125% of that assumed in preparing the sample stock solution. When the calculated potency value falls outside 80%–125%, the result for the sample may fall outside the narrow concentration range where linearity has been established. In such a case, adjust the assumed potency of the sample accordingly, and repeat the assay to obtain a valid result.
2. The most effective means of reducing the variability of the reportable value (the geometric mean potency across runs and replicates) is through independent runs of the assay procedure. The combined result of a series of smaller, independent assays is a more reliable estimate of potency than that from a single large assay with the same total number of plates or tubes. Three or more independent assays are required for antibiotic potency determinations.
3. The number of assays needed in order to obtain a reliable estimate of antibiotic potency depends on the required specification range and the assay variability. The confidence limit calculation described below is determined from several estimated log potencies that are approximately equal in precision. If the value calculated for the half-width of the confidence interval, *W*, is too wide, no useful decision can be made about whether the potency meets its specification.

The laboratory should predetermine in its standard operating procedures a maximum acceptable value for the confidence interval half-width. This maximum value should be determined during development and confirmed during validation or verification. If the calculated confidence interval half-width exceeds this limit, the analyst must perform additional independent potency determinations to meet the limit requirement. Note that the decision to perform additional determinations does not depend on the estimated potency but only on the uncertainty in that estimate as determined by the confidence interval half-width. *Assay* variability has a greater impact on the calculated confidence limit than does the number of independent potency determinations. As a result, the analyst should first consider decreasing variability to the extent possible before conducting potency determinations.

The following sections describe the calculations for determining antibiotic potency as well as for performing the confidence limit calculation. Methods for calculating standard error are also shown in order to allow estimates of assay variance. Where logarithms are used, any base log is acceptable. *Appendix 1: Formulas for Manual Calculations of Regression and Sample Concentration* provides formulas for hand calculations applicable when the concentrations are equally spaced in the log scale. Alternative statistical methods may be used if appropriately validated.

## Cylinder-Plate Assay

This section details analysis of the sample data and determination of the potency of an unknown, using the cylinder-plate assay.

### SAMPLE DATA

*Table 13* shows the data from one assay that will be used as an example throughout this section. For each of the 15 plates, zones 1, 3, and 5 are for the reference concentration, ($S_3$), and the other three zones are for one of the other four standard concentrations, ($S_1$, $S_2$, $S_4$, and $S_5$) or the sample ($U_3$), as shown. Other columns are needed for calculations and are explained below.

**Step 1:** Perform initial calculations and variability suitability check.

For each set of 3 plates, average the 9 reference values and average the 9 Standard values.

*Example:* See *Table 13*.

$$15.867 = \overline{X}(16.1, 15.6, \ldots, 15.8)$$
$$14.167 = \overline{X}(14.6, 14.1, \ldots, 14.8)$$

https://pharmacopeia.cn/
Printed on: Fri Jan 05 2024 06:40:34 AM(EST)
Printed by: USP NF
Do Not Distribute
Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Jan-2024
DOI Ref: 1q9xk
DocId: GUID-05E7D599-06FC-451A-A82C-01014B49FA5E_5_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M98820_05_01
@2024 USPC

For each set of 3 plates, determine the standard deviation of the 9 reference values and the standard deviation of the 9 Standard values. For each standard deviation, determine the corresponding relative standard deviation.

*Example:* See *Table 13*.

$$0.200 = \sigma(16.1, \ldots, 15.8)$$
$$1.3\% = (0.200/15.867) \times 100$$
$$0.324 = \sigma(14.6, \ldots, 14.1)$$
$$2.3\% = (0.324/14.167) \times 100$$

For a variability suitability criterion, each laboratory should determine a maximum acceptable value for the relative standard deviation. If any of the eight relative standard deviations (four for the reference and four for the Standard) exceed this predetermined maximum, the assay data are not suitable and should be discarded. [NOTE—The suggested limit for relative standard deviation is NMT 10%.]

**Step 2:** Perform a plate-to-plate variation correction.

This correction is applied to convert the average zone measurement obtained for each concentration to the value it would be if the average reference concentration measurement for that set of 3 replicate plates were the same as the value of the correction point:

$$\overline{X}_C = \overline{X}_S - (\overline{X}_R - P)$$

$\overline{X}_C$ = corrected standard mean
$\overline{X}_S$ = original standard mean
$\overline{X}_R$ = reference mean
$P$ = correction point

*Example:* For the first set of 3 plates in *Table 13* ($S_1$), the correction is:

$$14.022 = 14.167 - (15.867 - 15.722) = 14.167 - 0.145$$

**Step 3:** Determine the standard curve line.

Generate the standard curve line by plotting the corrected zone measurements versus the log of the standard concentration values. Calculate the equation of the standard curve line by performing a standard unweighted linear regression on these values, using appropriate software or the manual calculations of *Appendix 1: Formulas for Manual Calculations of Regression and Sample Concentration*. [NOTE—Use either the natural log or the base 10 log to plot the standard curve and determine the regression equation; both provide the same final test result.] Each laboratory should determine a minimum value of the coefficient of determination (%$R^2$) for an acceptable regression. The regression is acceptable only if the obtained %$R^2$ exceeds this predetermined value. [NOTE—The suggested limit for the percentage coefficient of determination is NLT 95%.]

**Table 13. Sample Data (Cylinder-Plate Assay)**

| Standard | Concentration (U/mL) | Plate Replicate | Reference ($S_3$) Zone 1 (mm) | Zone 3 (mm) | Zone 5 (mm) | Mean (mm) | SD | %RSD | Standard Zone 2 (mm) | Zone 4 (mm) | Zone 6 (mm) | Mean (mm) | SD | %RSD | Corrected Mean (mm) |

[a] This is the value of the overall reference mean, referred to as the "correction point" below.

*Example:* *Table 14* summarizes the portion of *Table 13* needed for this part of the calculation.

**Table 14**

| Standard Set | Corrected Zone Measurements (mm) | Concentration (U/mL) |
|---|---|---|
| $S_1$ | 14.022 | 3.2 |
| $S_2$ | 14.989 | 4.0 |
| Reference ($S_3$) | 15.722 | 5 |
| $S_4$ | 16.511 | 6.25 |
| $S_5$ | 17.222 | 7.8125 |

LINEAR REGRESSION RESULTS

**Standard curve line:**

$$Z = [3.551 \times \ln(C)] + 9.978$$

$Z$ = corrected zone measurement
$C$ = concentration
$\%R^2$ = 99.7

SAMPLE POTENCY DETERMINATION

To estimate the potency of the unknown sample, average the zone measurements of the Standard and the zone measurements of the sample on the 3 plates used. Correct for plate-to-plate variation using the correction point determined above to obtain a corrected average for the unknown, $\overline{U}$. [NOTE—An acceptable alternative to using the correction point is to correct using the value on the estimated regression line corresponding to the log concentration of $S_3$.] Use the corrected average zone measurement in the equation of the standard curve line to determine the log concentration of the sample, $L_U$, by:

$$L_U = (\overline{U} - a)/b$$

$a$ = intercept of the regression line
$b$ = slope of the regression line

To obtain the potency of the unknown, take the antilog of $L_U$ and multiply the result by any applicable dilution factor. This value can also be expressed as a percentage of the reference concentration value.

**Example:** Corrected sample zone measurement (see *Table 13*) = 15.522

Natural log of the sample concentration:

$$L_U = (15.522 - 9.978)/3.551 = 1.561$$

Sample concentration:

$$C_U = e^{1.561} = 4.765$$

Percentage of reference concentration:

$$\text{Result} = (4.765/5.000) \times 100 = 95.3\%$$

## Turbidimetric Assay

This section details analysis of the sample data and determination of the potency of an unknown using the turbidimetric assay. The method assumes that the tubes are randomly distributed within the heat block or other temperature control device. If the device has a temperature profile that is not uniform, a randomized blocks design is preferred. In such a design, the rack is divided into areas ("blocks") of relatively uniform temperature and at least one tube of each Standard concentration and of each unknown is placed in each area. The data analysis of a randomized block design is different from the following.

SAMPLE DATA

*Table 15* shows the data from one assay that will be used for an example throughout this section. Other columns are needed for calculations and are explained below.

**Table 15. Sample Data (Turbidimetric Assay)**

| Standard | Concentration (µg/mL) | Replicate | Absorbance (a.u.) | Average (a.u.) | Standard Deviation |
|---|---|---|---|---|---|
| | | 1 | 0.8545 | | |
| | | 2 | 0.8422 | | |
| $S_1$ | 64 | 3 | 0.8495 | 0.8487 | 0.0062 |
| | | 1 | 0.8142 | | |
| | | 2 | 0.8273 | | |
| $S_2$ | 80 | 3 | 0.8392 | 0.8269 | 0.0125 |
| | | 1 | 0.6284 | | |
| | | 2 | 0.6947 | | |
| $S_3$ | 100 | 3 | 0.7563 | 0.6931 | 0.0640 |
| | | 1 | 0.6933 | | |
| | | 2 | 0.6850 | | |
| $S_4$ | 125 | 3 | 0.6699 | 0.6827 | 0.0119 |
| | | 1 | 0.5299 | | |
| | | 2 | 0.5779 | | |
| $S_5$ | 156 | 3 | 0.5316 | 0.5465 | 0.0272 |
| | | 1 | 0.7130 | | |
| | | 2 | 0.7960 | | |
| $U_3$ | Unknown | 3 | 0.7201 | 0.7430 | 0.0460 |

**Step 1:** Perform initial calculations and variability suitability check.

For each concentration (including the sample), average the three absorbance values.

*Example:* See $S_1$ in *Table 15*.

$$0.8487 = \bar{X}(0.8545, 0.8422, 0.8495)$$

For each concentration, determine the standard deviation of the three readings and a combined standard deviation for all the concentrations.

*Example:* See $S_1$ in *Table 15*.

$$0.0062 = SD(0.8545, 0.8422, 0.8495)$$

The combined value is calculated by taking the square root of the average of the five variances:

$$0.0322 = \{[(0.0062)^2 + (0.0125)^2 + (0.0640)^2 + (0.0119)^2 + (0.0272)^2]/5\}^{1/2}$$

For a variability suitability criterion, each laboratory should determine a maximum acceptable combined standard deviation. If the combined standard deviation exceeds this predetermined maximum, the assay data are not suitable and should be discarded. [NOTE—The suggested limit for the combined standard deviation is NMT 10% of the average absorbance value across the five concentrations.] If the number of replicates per concentration is at least 5, then a relative standard deviation can be computed for each concentration after checking for outliers and compared to a maximum acceptable relative standard deviation. [NOTE—The suggested limit for the relative standard deviation is NMT 10%.]

**Step 2:** Determine the standard curve line.

Generate the standard curve line by plotting the average absorbance values versus the log of the standard concentration values. Calculate the equation of the standard curve line by performing an unweighted linear regression on these values using appropriate software or the manual calculations of *Appendix 1: Formulas for Manual Calculations of Regression and Sample Concentration*. [NOTE—Use either the natural log or the base 10 log to plot the standard curve and determine the regression equation; both provide the same final test result.] Each laboratory should determine a minimum value of the percentage coefficient of determination (%$R^2$) for an acceptable regression. The regression is acceptable only if the %$R^2$ value obtained exceeds this predetermined value. [NOTE—The suggested limit for the percentage coefficient of determination is NLT 90%.]

*Example: Table 16* summarizes the portion of *Table 15* needed for this part of the calculation.

**Table 16**

| Set of Standards | Average Absorbance Values (a.u.) | Concentration (µg/mL) |
|---|---|---|
| $S_1$ | 0.8487 | 64 |

@2024 USPC

**Table 16** *(continued)*

| Set of Standards | Average Absorbance Values (a.u.) | Concentration (µg/mL) |
|---|---|---|
| $S_2$ | 0.8269 | 80 |
| $S_3$ | 0.6931 | 100 |
| $S_4$ | 0.6827 | 125 |
| $S_5$ | 0.5465 | 156 |

LINEAR REGRESSION RESULTS

**Standard curve line:**

$$\text{Absorbance} = 2.2665 - [0.7735 \times \log_{10}(\text{concentration})]$$

$\%R^2$ = 93.0%

SAMPLE POTENCY DETERMINATION

To estimate the potency of the unknown sample, average the three absorbance measurements to obtain an average for the unknown, $\overline{U}$. Use this average measurement in the equation of the standard curve line to determine the log concentration of the unknown sample, $L_U$, by:

$$L_U = (\overline{U} - a)/b$$

$a$ = intercept of the regression line
$b$ = slope of the regression line

To obtain the potency of the unknown, take the antilog of $L_U$ and multiply the result by any applicable dilution factor. This value can also be expressed as a percentage of the reference concentration value.
**Example:** Average sample absorbance (see *Table 15*) = 0.7430.

$$\log_{10}(C_U) = (0.7430 - 2.2665)/(-0.7735) = 1.9696$$
$$C_U = 10^{1.9696} = 93.2$$
$$\text{Percentage of reference concentration} = (93.2/100.0) \times 100 = 93.2\%$$

$C_U$ = concentration of the sample

## Confidence Limits and Combination of Assays Calculations

Because of interassay variability, three or more independent determinations are required for a reliable estimate of the sample potency. For each independent determination, start with separately prepared stock solutions and test dilutions of both the Standard and the sample, and repeat the assay of a given sample.

Given a set of at least three determinations of the unknown potency, use the method of *Appendix 2: Procedure for Checking for Outliers; Rejection of Outlying or Aberrant Measurements* to check for any outlier values. This determination should be done in the log scale.

To obtain a combined estimate of the unknown potency, calculate the average, $M$, and the standard deviation of the accepted log potencies. [NOTE—Use either the natural log or the base 10 log.] Determine the confidence interval for the potency as follows:

$$\text{antilog}[M - t(0.05, N - 1) \times SD/\sqrt{N}],\ \text{antilog}[M + t(0.05, N - 1) \times SD/\sqrt{N}]$$

$M$ = average
$t(0.05, N–1)$ = the two-sided 5% point of a Student's $t$-distribution with $N$–1 degrees of freedom
[NOTE—The $t$ value is available in spreadsheets, statistics texts, and statistics software.]
$SD$ = standard deviation
$N$ = number of assays

$$W = \text{antilog}\{[t(0.05, N - 1) \times SD/\sqrt{N}]\}$$

$W$ = half-width of the confidence interval

Compare the half-width of the confidence interval to a predetermined maximum acceptable value. If the half-width is larger than the acceptance limit, continue with additional assays.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M98820_05_01
@2024 USPC

EXAMPLE

Suppose the sample is assayed four times, with potency results in the natural log scale of 1.561, 1.444, 1.517, and 1.535. Then:

$$N = 4$$
$$M = \overline{X}(1.561, 1.444, 1.517, 1.535) = 1.514$$
$$SD = \sigma(1.561, 1.444, 1.517, 1.535) = 0.050$$
$$t = 3.182$$

The confidence interval in the log scale is

$$1.514 \pm (3.182 \times 0.050/\sqrt{4}) = (1.434, 1.594)$$

Taking antilogs, the estimated potency is

$$e^{1.514} = 4.546$$

with a 95% confidence interval for the potency of $e^{1.434}$, $e^{1.594}$ = (4.197, 4.924).

The half-width of the confidence interval to compare to an acceptance value is the ratio 4.924/4.546 = 1.083.

***Change to read:***

# APPENDICES

## Appendix 1: Formulas for Manual Calculations of Regression and Sample Concentration

If the concentrations are equally spaced in the logarithmic scale, the calculations can be performed using the following formula. Let:

$\overline{S}_k$ = mean corrected zone measurement (cylinder-plate assay) or average absorbance value (turbidimetric assay) for standard set $k$

$k$ = 1, 2, 3, 4, 5

$\overline{S}$ = mean of the five $\overline{S}_k$ values

$L_k$ = logarithm of the $k$th concentration. [NOTE—Use either the natural log or the base 10 log. Slope of the regression line is calculated by:]

$$b = (Y_{high} - Y_{low})/(X_{high} - X_{low})$$
$$Y_{high} = \tfrac{1}{5}(3\overline{S}_5 + 2\overline{S}_4 + \overline{S}_3 - \overline{S}_1)$$
$$Y_{low} = \tfrac{1}{5}(3\overline{S}_1 + 2\overline{S}_2 + \overline{S}_3 - \overline{S}_5)$$

$X_{high}$ = $L_5$

$X_{low}$ = $L_1$

Combine and simplify to:

$$b = (4\overline{S}_5 + 2\overline{S}_4 - 2\overline{S}_2 - 4\overline{S}_1)/[5(L_5 - L_1)]$$

The log of the concentration of the sample is found using:

$$L_U = L_{reference} + [(\overline{U} - \overline{S})/b]$$

For example, using the data for the cylinder-plate assay in *Table 13* and natural logarithms:

$$b = [(4 \times 17.222) + (2 \times 16.511) - (2 \times 14.989) - (4 \times \text{▲}14.022\text{▲}_{(ERR\ 1\text{-}Jan\text{-}2024)})]/\{5[\ln(7.81) - \ln(3.2)]\} = 3.551$$
$$\overline{S} = (\text{▲}14.022\text{▲}_{(ERR\ 1\text{-}Jan\text{-}2024)} + 14.989 + 15.722 + 16.511 + 17.222)/5 = 15.693$$
$$\text{Natural log of sample concentration} = \ln(5) + [(15.522 - 15.693)/3.551] = 1.561$$
$$\text{Sample concentration} = e^{1.561} = 4.765$$

## Appendix 2: Procedure for Checking for Outliers—Rejection of Outlying or Aberrant Measurements

A measurement that is clearly questionable because of a failure in the assay procedure should be rejected, whether it is discovered during the measuring or tabulation procedure. The arbitrary rejection or retention of an apparently aberrant measurement can be a serious source of bias. In general, the rejection of measurements solely on the basis of their relative magnitudes is a procedure that should be used sparingly.

Each suspected potency measurement, or outlier, may be tested against the following criterion. This criterion is based on the variation within a single group of supposedly equivalent measurements from a normal distribution. At a confidence level

https://pharmacopeia.cn/

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Jan-2024
DOI Ref: 1q9xk
DocId: GUID-05E7D599-06FC-451A-A82C-01014B49FA5E_5_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M98820_05_01
@2024 USPC

of 99%, a valid observation will be rejected once in 100 trials (when the suspected outlier can occur at only one end) or once in 50 trials (when the suspected outlier can occur at either end), provided that relatively few, if any, responses within the group are identical. Arrange the responses in order of magnitude from $y_1$ to $y_N$, where $N$ is the number of observations in the group. Compute the relative gap by using *Table A2-1*, and the formulas below:

When $N$ = 3–7:

$$G_1 = (y_2 - y_1)/(y_N - y_1) \text{ Candidate Outlier is Smallest } (y_1)$$
$$G_1 = (y_N - y_{N-1})/(y_N - y_1) \text{ Candidate Outlier is Largest } (y_N)$$

When $N$ = 8–10:

$$G_2 = (y_2 - y_1)/(y_{N-1} - y_1) \text{ Candidate Outlier is Smallest } (y_1)$$
$$G_2 = (y_N - y_{N-1})/(y_N - y_2) \text{ Candidate Outlier is Largest } (y_N)$$

When $N$ = 11–13:

$$G_3 = (y_3 - y_1)/(y_{N-1} - y_1) \text{ Candidate Outlier is Smallest } (y_1)$$
$$G_3 = (y_N - y_{N-2})/(y_N - y_2) \text{ Candidate Outlier is Largest } (y_N)$$

If $G_1$, $G_2$, or $G_3$, as appropriate, exceeds the critical value in *Table A2-1*, for the observed $N$, there is a statistical basis for identifying the discordant measurement as an outlier and considering its removal.

**Table A2-1. Test for Outlier Measurements**

| In samples from a normal population, gaps equal to or larger than the following values of $G_1$, $G_2$, and $G_3$ occur with a probability $P$ = 0.01, when outlier measurements can occur only at one end; or with $P$ = 0.02, when they may occur at either end. | | | | | |
|---|---|---|---|---|---|
| $N$ | 3 | 4 | 5 | 6 | 7 |
| $G_1$ | 0.988 | 0.889 | 0.780 | 0.698 | 0.637 |
| $N$ | 8 | 9 | 10 | — | — |
| $G_2$ | 0.683 | 0.635 | 0.597 | — | — |
| $N$ | 11 | 12 | 13 | — | — |
| $G_3$ | 0.679 | 0.642 | 0.615 | — | — |

EXAMPLE

Estimated potencies of sample in log scale = 1.561, 1.444, 1.517, 1.535.

Check the lowest potency for outlier:

$$G_1 = (1.517 - 1.444)/(1.561 - 1.444) = 0.624 < 0.889$$

Therefore, 1.444 is not an outlier.

Check the highest potency for outlier:

$$G_1 = (1.561 - 1.535)/(1.561 - 1.444) = 0.222 < 0.889$$

Therefore, 1.561 is not an outlier.

Outlier potencies should be marked as outlier values and excluded from the assay calculations. NMT 1 potency can be excluded as an outlier.

# ⟨85⟩ BACTERIAL ENDOTOXINS TEST

♦Portions of this general chapter have been harmonized with the corresponding texts of the *European Pharmacopoeia* and/or the *Japanese Pharmacopoeia*. Those portions that are not harmonized are marked with symbols (♦ ♦) to specify this fact.♦

The Bacterial Endotoxins Test (BET) is a test to detect or quantify endotoxins from Gram-negative bacteria using amoebocyte lysate from the horseshoe crab (*Limulus polyphemus* or *Tachypleus tridentatus*).

There are three techniques for this test: the gel-clot technique, which is based on gel formation; the turbidimetric technique, based on the development of turbidity after cleavage of an endogenous substrate; and the chromogenic technique, based on the development of color after cleavage of a synthetic peptide-chromogen complex. Proceed by any of the three techniques for the test. In the event of doubt or dispute, the final decision is made based upon the gel-clot limit test unless otherwise indicated in the monograph for the product being tested. The test is carried out in a manner that avoids endotoxin contamination.

## APPARATUS

Depyrogenate all glassware and other heat-stable materials in a hot air oven using a validated process.♦[1] ♦ A commonly used minimum time and temperature is 30 min at 250°. If employing plastic apparatus, such as microplates and pipet tips for automatic pipetters, use apparatus that is shown to be free of detectable endotoxin and does not interfere in the test. [NOTE—In this chapter, the term "tube" includes any other receptacle such as a microtiter well.]

## REAGENTS AND TEST SOLUTIONS

### Amoebocyte Lysate

A lyophilized product obtained from the lysate of amoebocytes (white blood cells) from the horseshoe crab (*Limulus polyphemus* or *Tachypleus tridentatus*). This reagent refers only to a product manufactured in accordance with the regulations of the competent authority. [NOTE—*Amoebocyte Lysate* reacts to some β-glucans in addition to endotoxins. *Amoebocyte Lysate* preparations that do not react to glucans are available: they are prepared by removing the G factor reacting to glucans from *Amoebocyte Lysate* or by inhibiting the G factor reacting system of *Amoebocyte Lysate* and may be used for endotoxin testing in the presence of glucans.]

### Water for Bacterial Endotoxins Test (BET)

Use Water for Injection or water produced by other procedures that shows no reaction with the lysate employed, at the detection limit of the reagent.

### Lysate TS

Dissolve *Amoebocyte Lysate* in *Water for BET*, or in a buffer recommended by the lysate manufacturer, by gentle stirring. Store the reconstituted lysate, refrigerated or frozen, according to the specifications of the manufacturer.

## PREPARATION OF SOLUTIONS

### Standard Endotoxin Stock Solution

A *Standard Endotoxin Stock Solution* is prepared from a USP Endotoxin Reference Standard that has been calibrated to the current WHO International Standard for Endotoxin. Follow the specifications in the package leaflet and on the label for preparation and storage of the *Standard Endotoxin Stock Solution*. Endotoxin is expressed in Endotoxin Units (EU). [NOTE—One USP Endotoxin Unit (EU) is equal to one International Unit (IU) of endotoxin.]

### Standard Endotoxin Solutions

After mixing the *Standard Endotoxin Stock Solution* vigorously, prepare appropriate serial dilutions of *Standard Endotoxin Solution*, using *Water for BET*. Use dilutions as soon as possible to avoid loss of activity by adsorption.

### Sample Solutions

Prepare the *Sample Solutions* by dissolving or diluting drugs using *Water for BET*. Some substances or preparations may be more appropriately dissolved, or diluted in other aqueous solutions. If necessary, adjust the pH of the solution to be examined (or dilution thereof) so that the pH of the mixture of the lysate and *Sample Solution* falls within the pH range specified by the

♦[1] For a validity test of the procedure for inactivating endotoxins, see *Dry-Heat Sterilization* under *Sterility Assurance* ⟨1211⟩. Use *Lysate TS* having a sensitivity of not less than 0.15 Endotoxin Unit per mL.♦

lysate manufacturer, usually 6.0–8.0. The pH may be adjusted by use of an acid, base, or suitable buffer as recommended by the lysate manufacturer. Acids and bases may be prepared from concentrates or solids with *Water for BET* in containers free of detectable endotoxin. Buffers must be validated to be free of detectable endotoxin and interfering factors.

## DETERMINATION OF MAXIMUM VALID DILUTION (MVD)

The maximum valid dilution is the maximum allowable dilution of a specimen at which the endotoxin limit can be determined. Determine the MVD from the following equation:

$$MVD = (\text{endotoxin limit} \times \text{concentration of } \textit{Sample Solution})/(\lambda)$$

### Endotoxin Limit

The endotoxin limit for parenteral drugs, defined on the basis of dose, equals $K/M$ ♦[2] ♦, where $K$ is a threshold pyrogenic dose of endotoxin per kg of body weight, and $M$ is equal to the maximum recommended bolus dose of product per kg of body weight. When the product is to be injected at frequent intervals or infused continuously, $M$ is the maximum total dose administered in a single hour period. The endotoxin limit for parenteral drugs is specified in the individual monograph in units such as EU/mL, EU/mg, EU/Unit of biological activity, etc.

### Concentration of Sample Solution

mg/mL: in the case of endotoxin limit specified by weight (EU/mg);
Units/mL: in the case of endotoxin limit specified by unit of biological activity (EU/Unit);
mL/mL: when the endotoxin limit is specified by volume (EU/mL).
λ: the labeled sensitivity in the *Gel-Clot Technique* (EU/mL) or the lowest concentration used in the standard curve for the *Turbidimetric Technique* or *Chromogenic Technique*.

## GEL-CLOT TECHNIQUE

The gel-clot technique is used for detecting or quantifying endotoxins based on clotting of the lysate reagent in the presence of endotoxin. The minimum concentration of endotoxin required to cause the lysate to clot under standard conditions is the labeled sensitivity of the lysate reagent. To ensure both the precision and validity of the test, perform the tests for confirming the labeled lysate sensitivity and for interfering factors as described in *Preparatory Testing*, immediately below.

### Preparatory Testing

TEST FOR CONFIRMATION OF LABELED LYSATE SENSITIVITY

Confirm in four replicates the labeled sensitivity, λ, expressed in EU/mL of the lysate prior to use in the test. The test for confirmation of lysate sensitivity is to be carried out when a new batch of lysate is used or when there is any change in the test conditions that may affect the outcome of the test. Prepare standard solutions having at least four concentrations equivalent to 2λ, λ, 0.5λ, and 0.25λ by diluting the USP Endotoxin RS with *Water for BET*.

Mix a volume of the *Lysate TS* with an equal volume (such as 0.1-mL aliquots) of one of the *Standard Endotoxin Solutions* in each test tube. When single test vials or ampuls containing lyophilized lysate are used, add solutions directly to the vial or ampul. Incubate the reaction mixture for a constant period according to the directions of the lysate manufacturer (usually at 37 ± 1° for 60 ± 2 min), avoiding vibration. To test the integrity of the gel, take each tube in turn directly from the incubator, and invert it through about 180° in one smooth motion. If a firm gel has formed that remains in place upon inversion, record the result as positive. A result is negative if an intact gel is not formed. The test is considered valid when the lowest concentration of the standard solutions shows a negative result in all replicate tests.

The endpoint is the smallest concentration in the series of decreasing concentrations of standard endotoxin that clots the lysate. Determine the geometric mean endpoint by calculating the mean of the logarithms of the endpoint concentrations of the four replicate series and then taking the antilogarithm of the mean value, as indicated in the following formula:

$$\text{geometric mean endpoint concentration} = \text{antilog}\,(\Sigma e/f)$$

where $\Sigma e$ is the sum of the log endpoint concentrations of the dilution series used, and $f$ is the number of replicate test tubes. The geometric mean endpoint concentration is the measured sensitivity of the lysate (in EU/mL). If this is not less than 0.5λ and not more than 2λ, the labeled sensitivity is confirmed and is used in tests performed with this lysate.

♦[2] $K$ is 5 USP-EU/kg of body weight for any route of administration other than intrathecal (for which $K$ is 0.2 USP-EU/kg of body weight). For radiopharmaceutical products not administered intrathecally, the endotoxin limit is calculated as 175 EU/$V$, where $V$ is the maximum recommended dose in mL. For intrathecally administered radiopharmaceuticals, the endotoxin limit is obtained by the formula 14 EU/$V$. For formulations (usually anticancer products) administered on a per square meter of body surface, the formula is $K/M$, where $K$ = 100 EU/m$^2$ and $M$ is the maximum dose/m$^2$. ♦

### TEST FOR INTERFERING FACTORS

Usually prepare solutions *(A–D)* as shown in *Table 1*, and perform the inhibition/enhancement test on the *Sample Solutions* at a dilution less than the MVD, not containing any detectable endotoxins, operating as described for *Test for Confirmation of Labeled Lysate Sensitivity*. The geometric mean endpoint concentrations of *Solutions B* and *C* are determined using the formula described in the *Test for Confirmation of Labeled Lysate Sensitivity*. The test for interfering factors must be repeated when any condition changes that is likely to influence the result of the test.

**Table 1. Preparation of Solutions for the Inhibition/Enhancement Test for Gel-Clot Techniques**

| Solution | Endotoxin Concentration/ Solution to Which Endotoxin Is Added | Diluent | Dilution Factor | Endotoxin Concentration | Number of Replicates |
|---|---|---|---|---|---|
| A[a] | None/*Sample Solution* | — | — | — | 4 |
| B[b] | 2λ/*Sample Solution* | *Sample Solution* | 1 | 2λ | 4 |
| | | | 2 | 1λ | 4 |
| | | | 4 | 0.5λ | 4 |
| | | | 8 | 0.25λ | 4 |
| C[c] | 2λ/*Water for BET* | *Water for BET* | 1 | 2λ | 2 |
| | | | 2 | 1λ | 2 |
| | | | 4 | 0.5λ | 2 |
| | | | 8 | 0.25λ | 2 |
| D[d] | None/*Water for BET* | — | — | — | 2 |

[a] *Solution A*: A *Sample Solution* of the preparation under test that is free of detectable endotoxins.
[b] *Solution B*: Test for interference.
[c] *Solution C*: Control for labeled lysate sensitivity.
[d] *Solution D*: Negative control of *Water for BET*.

The test is considered valid when all replicates of *Solutions A* and *D* show no reaction and the result of *Solution C* confirms the labeled sensitivity.

If the sensitivity of the lysate determined in the presence of *Solution B* is not less than 0.5λ and not greater than 2λ, the *Sample Solution* does not contain factors that interfere under the experimental conditions used. Otherwise, the *Sample Solution* to be examined interferes with the test.

If the sample under test does not comply with the test at a dilution less than the MVD, repeat the test using a greater dilution, not exceeding the MVD. The use of a more sensitive lysate permits a greater dilution of the sample to be examined, and this may contribute to the elimination of interference.

Interference may be overcome by suitable treatment such as filtration, neutralization, dialysis, or heating. To establish that the chosen treatment effectively eliminates interference without loss of endotoxins, perform the assay described above using the preparation to be examined to which Standard Endotoxin has been added and which has then been submitted to the chosen treatment.

## Limit Test

### PROCEDURE

Prepare *Solutions A, B, C,* and *D* as shown in *Table 2*, and perform the test on these solutions following the procedure above for *Preparatory Testing*, *Test for Confirmation of Labeled Lysate Sensitivity*.

**Table 2. Preparation of Solutions for the Gel-Clot Limit Test**

| Solution* | Endotoxin Concentration/ Solution to Which Endotoxin Is Added | Number of Replicates |
|---|---|---|
| A | None/Diluted *Sample Solution* | 2 |
| B | 2λ/Diluted *Sample Solution* | 2 |
| C | 2λ/*Water for BET* | 2 |
| D | None/*Water for BET* | 2 |

* Prepare *Solution A* and the positive product control *Solution B* using a dilution not greater than the MVD and treatments as described for the *Test for Interfering Factors* in *Preparatory Testing*. The positive control *Solutions B* and *C* contain the *Standard Endotoxin Solution* at a concentration corresponding to twice the labeled lysate sensitivity. The negative control *Solution D* consists of *Water for BET*.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M98830_02_01
@2024 USPC

### INTERPRETATION

The test is considered valid when both replicates of *Solutions B* and *C* are positive and those of *Solution D* are negative. When a negative result is found for both replicates of *Solution A*, the preparation under test complies with the test. When a positive result is found for both replicates of *Solution A*, the preparation under test does not comply with the test.

When a positive result is found for one replicate of *Solution A* and a negative result is found for the other, repeat the test. In the repeat test, the preparation under test complies with the test if a negative result is found for both replicates of *Solution A*. The preparation does not comply with the test if a positive result is found for one or both replicates of *Solution A.* However, if the preparation does not comply with the test at a dilution less than the MVD, the test may be repeated using a greater dilution, not exceeding the MVD.

## Quantitative Test

### PROCEDURE

The test quantifies bacterial endotoxins in *Sample Solutions* by titration to an endpoint. Prepare *Solutions A, B, C,* and *D* as shown in *Table 3*, and test these solutions by following the procedure in *Preparatory Testing*, *Test for Confirmation of Labeled Lysate Sensitivity.*

**Table 3. Preparation of Solutions for the Gel-Clot Assay**

| Solution | Endotoxin Concentration/ Solution to Which Endotoxin Is Added | Diluent | Dilution Factor | Endotoxin Concentration | Number of Replicates |
|---|---|---|---|---|---|
| A[a] | None/*Sample Solution* | *Water for BET* | 1 | — | 2 |
| | | | 2 | — | 2 |
| | | | 4 | — | 2 |
| | | | 8 | — | 2 |
| B[b] | 2λ/*Sample Solution* | — | 1 | 2λ | 2 |
| C[c] | 2λ/*Water for BET* | *Water for BET* | 1 | 2λ | 2 |
| | | | 2 | 1λ | 2 |
| | | | 4 | 0.5λ | 2 |
| | | | 8 | 0.25λ | 2 |
| D[d] | None/*Water for BET* | — | — | — | 2 |

[a] *Solution A*: *Sample Solution* under test at the dilution, not to exceed the MVD, with which the *Test for Interfering Factors* was completed. Subsequent dilution of the *Sample Solution* must not exceed the MVD. Use *Water for BET* to make a dilution series of four tubes containing the *Sample Solution* under test at concentrations of 1, ½, ¼, and ⅛ relative to the concentration used in the *Test for Interfering Factors*. Other dilutions up to the MVD may be used as appropriate.
[b] *Solution B*: *Solution A* containing standard endotoxin at a concentration of 2λ (positive product control).
[c] *Solution C*: Two replicates of four tubes of *Water for BET* containing the standard endotoxin at concentrations of 2λ, λ, 0.5λ, and 0.25λ, respectively.
[d] *Solution D*: *Water for BET* (negative control).

### CALCULATION AND INTERPRETATION

The test is considered valid when the following three conditions are met: (1) Both replicates of negative control *Solution D* are negative; (2) Both replicates of positive product control *Solution B* are positive; and (3) The geometric mean endpoint concentration of *Solution C* is in the range of 0.5λ to 2λ.

To determine the endotoxin concentration of *Solution A*, calculate the endpoint concentration for each replicate by multiplying each endpoint dilution factor by λ. The endotoxin concentration in the *Sample Solution* is the endpoint concentration of the replicates. If the test is conducted with a diluted *Sample Solution*, calculate the concentration of endotoxin in the original *Sample Solution* by multiplying by the dilution factor. If none of the dilutions of the *Sample Solution* is positive in a valid assay, report the endotoxin concentration as less than λ (if the diluted sample was tested, report as less than λ times the lowest dilution factor of the sample). If all dilutions are positive, the endotoxin concentration is reported as equal to or greater than the greatest dilution factor multiplied by λ (e.g., initial dilution factor times eight times λ in *Table 3*).

The preparation under test meets the requirements of the test if the concentration of endotoxin in both replicates is less than that specified in the individual monograph.

# PHOTOMETRIC QUANTITATIVE TECHNIQUES

## Turbidimetric Technique

This technique is a photometric assay measuring increases in reactant turbidity. On the basis of the particular assay principle employed, this technique may be classified as either an endpoint-turbidimetric assay or a kinetic-turbidimetric assay. The endpoint-turbidimetric assay is based on the quantitative relationship between the concentration of endotoxins and the

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-May-2018
DOI Ref: m30r7
DocId: GUID-F9D9BFA5-099F-452C-9711-47674B37C1CC_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M98830_02_01
@2024 USPC

turbidity (absorbance or transmission) of the reaction mixture at the end of an incubation period. The kinetic-turbidimetric assay is a method to measure either the time (onset time) needed to reach a predetermined absorbance or transmission of the reaction mixture, or the rate of turbidity development. The test is carried out at the incubation temperature recommended by the lysate manufacturer (which is usually 37 ± 1°).

## Chromogenic Technique

This technique is an assay to measure the chromophore released from a suitable chromogenic peptide by the reaction of endotoxins with lysate. On the basis of the particular assay principle employed, this technique may be classified as either an endpoint-chromogenic assay or a kinetic-chromogenic assay. The endpoint-chromogenic assay is based on the quantitative relationship between the concentration of endotoxins and the release of chromophore at the end of an incubation period. The kinetic-chromogenic assay is a method to measure either the time (onset time) needed to reach a predetermined absorbance of the reaction mixture, or the rate of color development. The test is carried out at the incubation temperature recommended by the lysate manufacturer (which is usually 37 ± 1°).

## Preparatory Testing

To assure the precision or validity of the turbidimetric and chromogenic techniques, preparatory tests are conducted to verify that the criteria for the standard curve are valid and that the sample solution does not interfere with the test. Validation for the test method is required when conditions that are likely to influence the test result change.

### ASSURANCE OF CRITERIA FOR THE STANDARD CURVE

The test must be carried out for each lot of lysate reagent. Using the *Standard Endotoxin Solution,* prepare at least three endotoxin concentrations within the range indicated by the lysate manufacturer to generate the standard curve. Perform the assay using at least three replicates of each standard endotoxin concentration according to the manufacturer's instructions for the lysate (volume ratios, incubation time, temperature, pH, etc.). If the desired range is greater than two logs in the kinetic methods, additional standards should be included to bracket each log increase in the range of the standard curve. The absolute value of the correlation coefficient, *r*, must be greater than or equal to 0.980 for the range of endotoxin concentrations set up.

### TEST FOR INTERFERING FACTORS

Select an endotoxin concentration at or near the middle of the endotoxin standard curve. Prepare *Solutions A, B, C,* and *D* as shown in *Table 4*. Perform the test on *Solutions A, B, C,* and *D* at least in duplicate, according to the instructions for the lysate employed, for example, concerning volume of *Sample Solution* and *Lysate TS,* volume ratio of *Sample Solution* to *Lysate TS,* incubation time, etc.

**Table 4. Preparation of Solutions for the Inhibition/Enhancement Test for Photometric Techniques**

| Solution | Endotoxin Concentration | Solution to Which Endotoxin Is Added | Number of Replicates |
|---|---|---|---|
| A[a] | None | *Sample Solution* | Not less than 2 |
| B[b] | Middle concentration of the standard curve | *Sample Solution* | Not less than 2 |
| C[c] | At least three concentrations (lowest concentration is designated λ) | *Water for BET* | Each not less than 2 |
| D[d] | None | *Water for BET* | Not less than 2 |

[a] *Solution A*: The *Sample Solution* may be diluted not to exceed MVD.
[b] *Solution B*: The preparation under test at the same dilution as *Solution A,* containing added endotoxin at a concentration equal to or near the middle of the standard curve.
[c] *Solution C*: The standard endotoxin at the concentrations used in the validation of the method described for *Assurance of Criteria for the Standard Curve* under *Preparatory Testing* (positive controls).
[d] *Solution D*: *Water for BET* (negative control).

The test is considered valid when the following conditions are met.

1. The absolute value of the correlation coefficient of the standard curve generated using *Solution C* is greater than or equal to 0.980.
2. The result with *Solution D* does not exceed the limit of the blank value required in the description of the lysate reagent employed, or it is less than the endotoxin detection limit of the lysate reagent employed.

Calculate the mean recovery of the added endotoxin by subtracting the mean endotoxin concentration in the solution, if any (*Solution A, Table 4*), from that containing the added endotoxin (*Solution B, Table 4*). In order to be considered free of factors that interfere with the assay under the conditions of the test, the measured concentration of the endotoxin added to the *Sample Solution* must be within 50%–200% of the known added endotoxin concentration after subtraction of any endotoxin detected in the solution without added endotoxin.

When the endotoxin recovery is out of the specified range, the *Sample Solution* under test is considered to contain interfering factors. Then, repeat the test using a greater dilution, not exceeding the MVD. Furthermore, interference of the *Sample Solution* or diluted *Sample Solution* not to exceed the MVD may be eliminated by suitable validated treatment such as filtration, neutralization, dialysis, or heat treatment. To establish that the chosen treatment effectively eliminates interference without loss

of endotoxins, perform the assay described above, using the preparation to be examined to which Standard Endotoxin has been added and which has then been submitted to the chosen treatment.

## Test Procedure

Follow the procedure described for *Test for Interfering Factors* under *Preparatory Testing*, immediately above.

## Calculation

Calculate the endotoxin concentration of each of the replicates of *Solution A*, using the standard curve generated by the positive control *Solution C*. The test is considered valid when the following three requirements are met.

1. The results of the control *Solution C* comply with the requirements for validation defined for *Assurance of Criteria for the Standard Curve* under *Preparatory Testing*.
2. The endotoxin recovery, calculated from the concentration found in *Solution B* after subtracting the concentration of endotoxin found in *Solution A*, is within the range of 50%–200%.
3. The result of the negative control *Solution D* does not exceed the limit of the blank value required in the description of the lysate employed, or it is less than the endotoxin detection limit of the lysate reagent employed.

## Interpretation

In photometric assays, the preparation under test complies with the test if the mean endotoxin concentration of the replicates of *Solution A*, after correction for dilution and concentration, is less than the endotoxin limit for the product.

# ⟨87⟩ BIOLOGICAL REACTIVITY TESTS, IN VITRO

The following tests are designed to determine the biological reactivity of mammalian cell cultures following contact with the elastomeric plastics and other polymeric materials with direct or indirect patient contact or of specific extracts prepared from the materials under test. It is essential that the tests be performed on the specified surface area. When the surface area of the specimen cannot be determined, use 0.1 g of elastomer or 0.2 g of plastic or other material for every mL of extraction fluid. Exercise care in the preparation of the materials to prevent contamination with microorganisms and other foreign matter.

Three tests are described (i.e., the *Agar Diffusion Test*, the *Direct Contact Test*, and the *Elution Test*).[1] The decision as to which type of test or the number of tests to be performed to assess the potential biological response of a specific sample or extract depends upon the material, the final product, and its intended use. Other factors that may also affect the suitability of a sample for a specific use are the polymeric composition; processing and cleaning procedures; contacting media; inks; adhesives; absorption, adsorption, and permeability of preservatives; and conditions of storage. Evaluation of such factors should be made by appropriate additional specific tests before determining that a product made from a specific material is suitable for its intended use. Materials that fail the *in vitro* tests are candidates for the *in vivo* tests described in *Biological Reactivity Tests, In Vivo* ⟨88⟩.

## PROCEDURES

- **Test Control**

**Positive control:** Polyurethane film containing zinc diethyldithiocarbamate (ZDEC)[2] or zinc dibutyldithiocarbamate (ZDBC)

**Cell culture preparation:** Prepare multiple cultures of L-929 (ATCC cell line CCL 1, NCTC clone 929; alternative cell lines obtained from a standard repository may be used with suitable validation) mammalian fibroblast cells in serum-supplemented minimum essential medium having a seeding density of about $10^5$ cells per mL. Incubate the cultures at 37 ± 1° in a humidified incubator for NLT 24 h in a 5 ± 1% carbon dioxide atmosphere until a monolayer, with greater than 80% confluence, is obtained. Examine the prepared cultures under a microscope to ensure uniform, near-confluent monolayers. [Note—The reproducibility of the in vitro biological reactivity tests depends upon obtaining uniform cell culture density.]

**Extraction solvents:** *Sodium Chloride Injection* [see monograph—use *Sodium Chloride Injection* containing 0.9% of sodium chloride (NaCl)]. Alternatively, serum-free mammalian cell culture media or serum-supplemented mammalian cell culture media may be used. Serum supplementation is used when extraction is done at 37° for 24 h.

- **Apparatus**

**Autoclave:** Employ an autoclave capable of maintaining a temperature of 121 ± 2°, equipped with a thermometer, a pressure gauge, a vent cock, a rack adequate to accommodate the test containers above the water level, and a water cooling system that will allow for cooling of the test containers to about 20°, but not below 20°, immediately following the heating cycle.

**Oven:** Use an oven, preferably a mechanical convection model, that will maintain operating temperatures in the range of 50°–70° within ±2°.

**Incubator:** Use an incubator capable of maintaining a temperature of 37 ± 1° and a humidified atmosphere of 5 ± 1% carbon dioxide in air.

**Extraction containers:** Use only containers, such as ampuls or screw-cap culture test tubes, or their equivalent, of Type I glass. If used, culture test tubes, or their equivalent, are closed with a screw cap having a suitable elastomeric liner. The exposed surface of the elastomeric liner is completely protected with an inert solid disk 50–75 µm in thickness. A suitable disk can be fabricated from polytef.

**Preparation of apparatus:** Cleanse all glassware thoroughly with chromic acid cleansing mixture and, if necessary, with hot nitric acid followed by prolonged rinsing with *Sterile Water for Injection*. Sterilize and dry by a suitable process for containers and devices used for extraction, transfer, or administration of test material. If ethylene oxide is used as the sterilizing agent, allow NLT 48 h for complete degassing.

- **Procedure**

**Preparation of sample for extracts:** Prepare as directed in the *Procedure* in ⟨88⟩.

**Preparation of extracts:** Prepare as directed for *Preparation of extracts* in ⟨88⟩ using either *Sodium Chloride Injection* [0.9% sodium chloride (NaCl)] or serum-free mammalian cell culture media as *Extraction solvents*. [Note—If extraction is done at 37° for 24 h in an incubator, use cell culture media supplemented by serum. The extraction conditions should not in any instance cause physical changes, such as fusion or melting of the material pieces, other than a slight adherence.]

- **Agar Diffusion Test**

This test is designed for elastomeric closures in a variety of shapes. The agar layer acts as a cushion to protect the cells from mechanical damage while allowing the diffusion of leachable chemicals from the polymeric specimens. Extracts of materials that are to be tested are applied to a piece of filter paper.

**Sample preparation:** Use extracts prepared as directed, or use portions of the test specimens having flat surfaces NLT 100 $mm^2$ in surface area.

**Positive control preparation:** Proceed as directed for *Sample preparation*.

**Negative control preparation:** Proceed as directed for *Sample preparation*.

**Procedure:** Using 7 mL of cell suspension prepared as directed in *Cell culture preparation*, prepare the monolayers in plates having a 60-mm diameter. Following incubation, aspirate the culture medium from the monolayers, and replace it with serum-supplemented culture medium containing NMT 2% of agar. [Note—The quality of the agar must be adequate to

[1] Further details are given in the following publications of the American Society for Testing and Materials, 1916 Race St., Philadelphia, PA 19103: Standard test method for agar diffusion cell culture screening for cytotoxicity, ASTM Designation F 895-84; Standard practice for direct contact cell culture evaluation of materials for medical devices, ASTM Designation F 813-83.

@2024 USPC

support cell growth. The agar layer must be thin enough to permit diffusion of leached chemicals.] Place the flat surfaces of *Sample preparation*, *Positive control preparation*, and *Negative control preparation* or their extracts in an appropriate extracting medium, in duplicate cultures in contact with the solidified agar surface. Use no more than three specimens per prepared plate. Incubate all cultures for NLT 24 h at 37 ± 1°, preferably in a humidified incubator containing 5 ± 1% of carbon dioxide. Examine each culture around each sample, negative control, and positive control under a microscope, using a suitable stain, if desired.

**Interpretation of results:** The biological reactivity (cellular degeneration and malformation) is described and rated on a scale of 0–4 (see *Table 1*). Measure the responses of the cell cultures to the *Sample preparation*, the *Positive control preparation*, and the *Negative control preparation*. The cell culture test system is suitable if the observed responses to the *Negative control preparation* is grade 0 (no reactivity) and to the *Positive control preparation* is at least grade 3 (moderate). The sample meets the requirements of the test if the response to the *Sample preparation* is not greater than grade 2 (mildly reactive). Repeat the procedure if the suitability of the system is not confirmed.

**Table 1. Reactivity Grades for Agar Diffusion Test and Direct Contact Test**

| Grade | Reactivity | Description of Reactivity Zone |
|---|---|---|
| 0 | None | No detectable zone around or under specimen |
| 1 | Slight | Some malformed or degenerated cells under specimen |
| 2 | Mild | Zone limited to area under specimen and less than 0.45 cm beyond specimen |
| 3 | Moderate | Zone extends 0.45–1.0 cm beyond specimen |
| 4 | Severe | Zone extends greater than 1.0 cm beyond specimen |

- **Direct Contact Test**

This test is designed for materials in a variety of shapes. The procedure allows for simultaneous extraction and testing of leachable chemicals from the specimen with a serum-supplemented medium. The procedure is not appropriate for very low- or high-density materials that could cause mechanical damage to the cells.

**Sample preparation:** Use portions of the test specimen having flat surfaces NLT 100 $mm^2$ in surface area.

**Positive control preparation:** Proceed as directed for *Sample preparation*.

**Negative control preparation:** Proceed as directed for *Sample preparation*.

**Procedure:** Using 2 mL of cell suspension prepared as directed in *Cell culture preparation*, prepare the monolayers in plates having a 35-mm diameter. Following incubation, aspirate the culture medium from the cultures, and replace it with 0.8 mL of fresh culture medium. Place a single *Sample preparation*, a *Positive control preparation*, and a *Negative control preparation* in each of the duplicate cultures. Incubate all cultures for NLT 24 h at 37 ± 1° in a humidified incubator containing 5 ± 1% of carbon dioxide. Examine each culture around each *Sample preparation*, a *Positive control preparation*, and a *Negative control preparation*, under a microscope, using a suitable stain, if desired.

**Interpretation of results:** Proceed as directed for *Interpretation of results* in *Agar Diffusion Test*. The sample meets the requirements of the test if the response to the *Sample preparation* is not greater than grade 2 (mildly reactive). Repeat the procedure if the suitability of the system is not confirmed.

- **Elution Test**

This test is designed for the evaluation of extracts of polymeric materials. The procedure allows for extraction of the specimens at physiological or nonphysiological temperatures for varying time intervals. It is appropriate for high-density materials and for dose-response evaluations.

**Sample preparation:** Prepare as directed in *Preparation of extracts*, using either *Sodium Chloride Injection* [0.9% sodium chloride (NaCl)] or serum-free mammalian cell culture media as *Extraction solvents*. If the size of the sample cannot be readily measured, a mass of NLT 0.1 g of elastomeric material or 0.2 g of plastic or polymeric material per mL of extraction medium may be used. Alternatively, use serum-supplemented mammalian cell culture media as the extracting medium to simulate more closely physiological conditions. Prepare the extracts by heating for 24 h in an incubator containing 5 ± 1% of carbon dioxide. Maintain the extraction temperature at 37 ± 1°, because higher temperatures may cause denaturation of serum proteins.

**Positive control preparation:** Proceed as directed for *Sample preparation*.

**Negative control preparation:** Proceed as directed for *Sample preparation*.

**Procedure:** Using 2 mL of cell suspension prepared as directed in *Cell culture preparation*, prepare the monolayers in plates having a 35-mm diameter. Following incubation, aspirate the culture medium from the monolayers, and replace it with extracts of the *Sample preparation*, *Positive control preparation*, or *Negative control preparation*. The serum-supplemented and serum-free cell culture media extracts are tested in duplicate without dilution (100%). The *Sodium Chloride Injection* extract is diluted with serum-supplemented cell culture medium and tested in duplicate at 25% extract concentration. Incubate all cultures for 48 h at 37 ± 1° in a humidified incubator preferably containing 5 ± 1% of carbon dioxide. Examine each culture at 48 h, under a microscope, using a suitable stain, if desired.

**Interpretation of results:** Proceed as directed for *Interpretation of results* in *Agar Diffusion Test* but use *Table 2*. The sample meets the requirements of the test if the response to the *Sample preparation* is not greater than grade 2 (mildly reactive). Repeat the procedure if the suitability of the system is not confirmed. For dose-response evaluations, repeat the procedure, using quantitative dilutions of the sample extract.

**Table 2. Reactivity Grades for Elution Test**

| Grade | Reactivity | Conditions of All Cultures |
|---|---|---|
| 0 | None | Discrete intracytoplasmic granules; no cell lysis |

Official

https://pharmacopeia.cn/v-prod/

**Table 2. Reactivity Grades for Elution Test** *(continued)*

| Grade | Reactivity | Conditions of All Cultures |
|---|---|---|
| 1 | Slight | Less than or equal to 20% of the cells are round, loosely attached, and without intracytoplasmic granules; occasional lysed cells are present |
| 2 | Mild | Greater than 20% to less than or equal to 50% of the cells are round and devoid of intracytoplasmic granules; no extensive cell lysis and empty areas between cells |
| 3 | Moderate | Greater than 50% to less than 70% of the cell layers contain rounded cells or are lysed |
| 4 | Severe | Nearly complete destruction of the cell layers |

# ⟨88⟩ BIOLOGICAL REACTIVITY TESTS, IN VIVO

The following tests are designed to determine the biological response of animals to elastomerics, plastics, and other polymeric material with direct or indirect patient contact, or by the injection of specific extracts prepared from the material under test. It is essential to make available the specific surface area for extraction. When the surface area of the specimen cannot be determined, use 0.1 g of elastomer or 0.2 g of plastic or other material for every mL of extraction fluid. Also, it is essential to exercise care in the preparation of the materials to be injected or instilled to prevent contamination with microorganisms and other foreign matter. Three tests are described. The *Systemic Injection Test* and the *Intracutaneous Test* are used for elastomeric materials, especially to elastomeric closures for which the appropriate *Biological Reactivity Tests, In Vitro* ⟨87⟩ have indicated significant biological reactivity. These two tests are used for plastics and other polymers, in addition to a third test, the *Implantation Test*, to test the suitability of these materials intended for use in fabricating containers and accessories thereto, for use in parenteral preparations, and for use in medical devices, implants, and other systems.

These three tests are applied to materials or medical devices, if there is a need for classification of plastics and other polymers based on in vivo biological reactivity testing.

For the purpose of this chapter, these definitions apply: the *Sample* is the specimen under test or an extract prepared from such a specimen. A *Blank* consists of the same quantity of the same extracting medium that is used for the extraction of the specimen under test, treated in the same manner as the extracting medium containing the specimen under test. A *Negative Control*[1] is a specimen that gives no reaction under the conditions of the test.

## CLASSIFICATION OF PLASTICS

Six Plastic Classes are defined (see *Table 1*). This classification is based on responses to a series of in vivo tests for which extracts, materials, and routes of administration are specified. These tests are directly related to the intended end-use of the plastic articles. The choice of extractants is representative of the vehicles in preparations with which the plastics are likely to be in contact. The *Table 1* classification facilitates communication among suppliers, users, and manufacturers of plastics by summarizing the tests to be performed for containers for injections and medical devices if a need for classification exists.

**Table 1. Classification of Plastics**

| Plastic Classes[a] | | | | | | Tests to be Conducted | | | |
|---|---|---|---|---|---|---|---|---|---|
| I | II | III | IV | V | VI | Test Material | Animal | Dose | Procedure[b] |
| x | x | x | x | x | x | Extract of *Sample* in *Sodium Chloride Injection* | Mouse | 50 mL/kg | A (IV) |
| x | x | x | x | x | x | | Rabbit or Guinea Pig | 0.2 mL/animal at each of 10 or 6 sites | B (IC) |
| | x | x | x | x | x | Extract of *Sample* in *1 in 20 Solution of Alcohol in Sodium Chloride Injection* | Mouse | 50 mL/kg | A (IP) |
| | x | x | x | x | x | | Rabbit or Guinea Pig | 0.2 mL/animal at each of 10 or 6 sites | B (IC) |
| | | x | | x | x | Extract of *Sample* in *Polyethylene Glycol 400* | Mouse | 10 g/kg | A (IP) |
| | | | | x | x | | Rabbit or Guinea Pig | 0.2 mL/animal at each of 10 or 6 sites | B (IC) |
| | | x | x | x | x | Extract of *Sample* in *Vegetable Oil* | Mouse | 50 mL/kg | A (IP) |
| | | | x | x | x | | Rabbit or Guinea Pig | 0.2 mL/animal at each of 10 or 6 sites | B (IC) |
| | | | x | | x | Implant strips of *Sample* | Rabbit | 4 strips/animal | C |
| | | | x | | x | Implant *Sample* | Rat | 2 *Samples*/animal | C |

[a] Tests required for each class are indicated by "x" in appropriate columns.
[b] Legend: A (IP)—Systemic Injection Test (intraperitoneal); B (IC)—Intracutaneous Test (intracutaneous); C—Implantation Test (intramuscular or subcutaneous implantation).

With the exception of the *Implantation Test*, the procedures are based on the use of extracts that, depending on the heat resistance of the material, are prepared at one of three standard temperatures: 50°, 70°, and 121°. Therefore, the class designation of a plastic must be accompanied by an indication of the temperature of extraction (e.g., IV-121°, which represents a class IV plastic extracted at 121°, or I-50°, which represents a class I plastic extracted at 50°).

Plastics may be classified as USP Plastic Classes I–VI only on the basis of the response criteria prescribed in *Table 1*.

This classification does not apply to plastics that are intended for use as containers for oral or topical products, or that may be used as an integral part of a drug formulation. *Table 1* does not apply to natural elastomers, which are to be tested in Sodium Chloride Injection and vegetable oils only.

The *Systemic Injection Test* and the *Intracutaneous Test* are designed to determine the systemic and local, respectively, biological responses of animals to plastics and other polymers by the single-dose injection of specific extracts prepared from a

[1] USP High-Density Polyethylene RS.

https://nhathuocngocanh.com/

*Sample*. The *Implantation Test* is designed to evaluate the reaction of living tissue to the plastic and other polymers by the implantation of the *Sample* itself into animal tissue. The proper preparation and placement of the specimens under aseptic conditions are important in the conduct of the *Implantation Test*.

These tests are designed for application to plastics and other polymers in the condition in which they are used. If the material is to be exposed to any cleansing or sterilization process prior to its end-use, then the tests are to be conducted on a *Sample* prepared from a specimen preconditioned by the same processing.

Factors such as material composition, processing and cleaning procedures, contacting media, inks, adhesives, absorption, adsorption and permeability of preservatives, and conditions of storage may also affect the suitability of a material for a specific use. Evaluation of such factors should be made by appropriate additional specific tests to determine the suitability of a material for its intended use.

*USP Reference Standards* ⟨11⟩—*USP High-Density Polyethylene RS*.

**Extracting Media—**

**SODIUM CHLORIDE INJECTION** (see monograph). Use Sodium Chloride Injection containing 0.9% of NaCl.

**1 IN 20 SOLUTION OF ALCOHOL IN SODIUM CHLORIDE INJECTION.**

**POLYETHYLENE GLYCOL 400** (see monograph).

**VEGETABLE OIL**—Use freshly refined Sesame Oil (see monograph) or Cottonseed Oil (see monograph) or other suitable vegetable oils.

**DRUG PRODUCT VEHICLE** (where applicable).

**WATER FOR INJECTION** (see monograph).

[NOTE—The Sesame Oil or Cottonseed Oil or other suitable vegetable oil meets the following additional requirements. Obtain, if possible, freshly refined oil. Use three properly prepared animals, and inject the oil intracutaneously in a dose of 0.2 mL into each of 10 sites per animal, and observe the animals at 24, 48, and 72 h following injection. Rate the observations at each site on the numerical scale indicated in *Table 2*. For the 3 rabbits or guinea pigs (30 or 18 injection sites), at any observation time, the average response for erythema is not greater than 0.5 and for edema is not greater than 1.0, and no site shows a tissue reaction larger than 10 mm in overall diameter. The residue of oil at the injection site should not be misinterpreted as edema. Edematous tissue blanches when gentle pressure is applied.]

**Table 2. Evaluation of Skin Reactions[a]**

| Erythema and Eschar Formation | Score |
|---|---|
| No erythema | 0 |
| Very slight erythema (barely perceptible) | 1 |
| Well-defined erythema | 2 |
| Moderate to severe erythema | 3 |
| Severe erythema (beet-redness) to slight eschar formation (injuries in depth) | 4 |
| **Edema Formation[b]** | **Score** |
| No edema | 0 |
| Very slight edema (barely perceptible) | 1 |
| Slight edema (edges of area well defined by definite raising) | 2 |
| Moderate edema (raised approximately 1 mm) | 3 |
| Severe edema (raised more than 1 mm and extending beyond the area of exposure) | 4 |

[a] Draize JH, Woodward G, Calvery HO. Methods for the study of irritation and toxicity of substances applied topically to the skin and mucous membranes. *J Pharmacol Exp Ther* 1944;82:377–390.

[b] Excludes noninflammatory (mechanical) edema from the blank or extraction fluid.

**Apparatus**—The apparatus for the tests includes the following.

**AUTOCLAVE**—Use an autoclave capable of maintaining a temperature of 121 ± 2.0°, equipped with a thermometer, a pressure gauge, a vent cock, a rack adequate to accommodate the test containers above the water level, and a water cooling system that will allow for cooling of the test containers to about, but not below, 20° immediately following the heating cycle.

**OVEN**—Use an oven, preferably a forced-circulation model, that will maintain operating temperatures of 50° or 70° within ±2°.

**EXTRACTION CONTAINERS**—Use only containers, such as ampuls or screw-cap culture test tubes, of Type I glass. If used, culture test tubes are closed with screw caps having suitable elastomeric liners. The exposed surface of the elastomeric liner is completely protected with an inert solid disk 0.05–0.075 mm in thickness. A suitable disk may be fabricated from a polytef resin.

**Preparation of Apparatus**—Cleanse all glassware thoroughly with chromic acid cleansing mixture, or if necessary, with hot nitric acid, followed by prolonged rinsing with water. Clean cutting utensils by an appropriate method (e.g., successive cleaning with acetone and methylene chloride) prior to use in subdividing a specimen. Clean all other equipment by thorough scrubbing with a suitable detergent and prolonged rinsing with water.

Render containers and equipment used for extraction, and in transfer and administration of test material, sterile and dry by a suitable process. [NOTE—If ethylene oxide is used as the sterilizing agent, allow adequate time for complete degassing.]

Official

https://nhathuocngocanh.com/

**Procedure—**

**PREPARATION OF SAMPLE—**Both the *Systemic Injection Test* and the *Intracutaneous Test* may be performed using the same extract, if desired, or separate extracts may be made for each test. Select and subdivide into portions a *Sample* of the size indicated in *Table 3*. Remove particulate matter, such as lint and free particles, by treating each subdivided *Sample* or *Negative Control* as follows. Place the *Sample* into a clean, glass-stoppered, 100-mL graduated cylinder of Type I glass, and add about 70 mL of *Water for Injection*. Agitate for about 30 s, and drain off the water. Repeat this step, and dry those pieces prepared for the extraction with *Vegetable Oil* in an oven at a temperature not exceeding 50°. [NOTE—Do not clean the *Sample* with a dry or wet cloth or by rinsing or washing with an organic solvent, surfactant, etc.]

**Table 3. Surface Area of Specimen To Be Used[a]**

| Form of Material | Thickness | Amount of Sample for each 20 mL of Extracting Medium | Subdivided into |
|---|---|---|---|
| Film or sheet | <0.5 mm | Equivalent of 120 $cm^2$ total surface area (both sides combined) | Strips of about 5 × 0.3 cm |
| | 0.5–1 mm | Equivalent of 60 $cm^2$ total surface area (both sides combined) | |
| Tubing | <0.5 mm (wall) | Length (in cm) = 120 $cm^2$/(sum of ID and OD circumferences) | Sections of about 5 × 0.3 cm |
| | 0.5–1 mm (wall) | Length (in cm) = 60 $cm^2$/(sum of ID and OD circumferences) | |
| Slabs, tubing, and molded items | >1 mm | Equivalent of 60 $cm^2$ total surface area (all exposed surfaces combined) | Pieces up to about 5 × 0.3 cm |
| Elastomers | >1 mm | Equivalent of 25 $cm^2$ total surface area (all exposed surfaces combined) | Do not subdivide[b] |

[a] When surface area cannot be determined due to the configuration of the specimen, use 0.1 g of elastomer or 0.2 g of plastic or other polymers for every 1 mL of extracting fluid.
[b] Molded elastomeric closures are tested intact.

**PREPARATION OF EXTRACTS—**Place a properly prepared *Sample* to be tested in an extraction container, and add 20 mL of the appropriate extracting medium. Repeat these directions for each extracting medium required for testing. Also, prepare one 20-mL blank of each medium for parallel injections and comparisons. Extract by heating in an autoclave at 121° for 60 min, in an oven at 70° for 24 h, or at 50° for 72 h. Allow adequate time for the liquid within the container to reach the extraction temperature.

[NOTE—The extraction conditions should not in any instance cause physical changes such as fusion or melting of the *Sample* pieces, which result in a decrease in the available surface area. A slight adherence of the pieces can be tolerated. Always add the cleaned pieces individually to the extracting medium. If culture tubes are used for autoclave extractions with *Vegetable Oil*, seal screw caps adequately with pressure-sensitive tape.]

Cool to about room temperature but not below 20°, shake vigorously for several minutes, and decant each extract immediately, using aseptic precautions, into a dry, sterile vessel. Store the extracts at a temperature of 20°–30°, and do not use for tests after 24 h. Of importance are the contact of the extracting medium with the available surface area of the plastic and the time and temperature during extraction, the proper cooling, agitation, and decanting process, and the aseptic handling and storage of the extracts following extraction.

## SYSTEMIC INJECTION TEST

This test is designed to evaluate systemic responses to the extracts of materials under test following injection into mice. Alternate routes of injection may be used with justification.

**Test Animals—**Use healthy, not previously used albino mice weighing 17–23 g. For each test group use only mice of the same source. Allow water and food, commonly used for laboratory animals and of known composition, ad libitum.

**Procedure—** [NOTE—Agitate each extract vigorously prior to withdrawal of injection doses to ensure even distribution of the extracted matter.] Inject each of the five mice in a test group with the *Sample* or the *Blank* as outlined in *Table 4*, except to dilute each g of the extract of the *Sample* prepared with *Polyethylene Glycol 400*, and the corresponding *Blank*, with 4.1 volumes of *Sodium Chloride Injection* to obtain a solution having a concentration of about 200 mg of polyethylene glycol per mL.

**Table 4. Injection Procedure—Systemic Injection Test**

| Extract or Blank | Dose per kg | Route[a] |
|---|---|---|
| Sodium Chloride Injection | 50 mL | IV |
| 1 in 20 solution of Alcohol in Sodium Chloride Injection | 50 mL | IV |
| Polyethylene Glycol 400 | 10 g | IP |
| Drug product vehicle (where applicable) | 50 mL | IV |
| | 50 mL | IP |

Official

https://nhathuocngocanh.com/

**Table 4. Injection Procedure—Systemic Injection Test** *(continued)*

| Extract or Blank | Dose per kg | Route[a] |
|---|---|---|
| Vegetable Oil | 50 mL | IP |

[a] IV = intravenous (aqueous sample and blank); IP = intraperitoneal (oleaginous sample and blank).

Observe the animals immediately after injection, again 4 h after injection, and then at least at 24, 48, and 72 h. If during the observation period none of the animals treated with the extract of the *Sample* shows a significantly greater biological reactivity than the animals treated with the *Blank*, the *Sample* meets the requirements of this test. If two or more mice die, or if abnormal behavior such as convulsions or prostration occurs in two or more mice, or if a body weight loss greater than 2 g occurs in three or more mice, the *Sample* does not meet the requirements of the test. If any animals treated with the *Sample* show only slight signs of biological reactivity, and not more than one animal shows gross symptoms of biological reactivity or dies, repeat the test using groups of 10 mice. On the repeat test, all 10 animals treated with the *Sample* show no significant biological reactivity above the *Blank* animals during the observation period.

## INTRACUTANEOUS TEST

This test is designed to evaluate local responses to the extracts of materials under test following intracutaneous injection into rabbits or guinea pigs.

**Test Animals—**Select healthy, rabbits or guinea pigs with fur that can be clipped closely and skin that is free from mechanical irritation or trauma. In handling the animals, avoid touching the injection sites during observation periods, except to discriminate between edema and an oil residue.

**Procedure—** [NOTE—Agitate each extract vigorously prior to withdrawal of injection doses to ensure even distribution of the extracted matter.] On the day of the test, closely clip the fur on the animal's back on both sides of the spinal column over a sufficiently large test area. Avoid mechanical irritation and trauma. Remove loose hair by means of vacuum. If necessary, swab the skin lightly with diluted alcohol, and dry the skin prior to injection. More than one extract from a given material can be used per rabbit or guinea pig, if it is determined that the test results will not be affected. For each *Sample* use two animals and inject each intracutaneously, using one side of the animal for the *Sample* and the other side for the *Blank*, as outlined in *Table 5*. [NOTE—Dilute each g of the extract of the *Sample* prepared with *Polyethylene Glycol 400*, and the corresponding *Blank*, with 7.4 volumes of *Sodium Chloride Injection* to obtain a solution having a concentration of about 120 mg of polyethylene glycol per mL.]

**Table 5. Intracutaneous Test**

| Extract or Blank | Number of Sites (per animal) | Dose (µL per site) |
|---|---|---|
| Sample | 5 | 200 |
| Blank | 5 | 200 |

Examine injection sites for evidence of any tissue reaction such as erythema, edema, and necrosis. Swab the skin lightly, if necessary, with diluted alcohol to facilitate reading of injection sites. Observe all animals at 24, 48, and 72 h after injection. Rate the observations on a numerical scale for the extract of the *Sample* and for the *Blank*, using *Table 2*. Reclip the fur as necessary during the observation period. The average erythema and edema scores for *Sample* and *Blank* sites are determined at every scoring interval (24, 48, and 72 h) for each rabbit or guinea pig. After the 72-hour scoring, all erythema scores plus edema scores are totalled separately for each *Sample* and *Blank*. Divide each of the totals by 12 (2 animals × 3 scoring periods × 2 scoring categories) to determine the overall mean score for each *Sample* versus each corresponding *Blank*. The requirements of the test are met if the difference between the *Sample* and the *Blank* mean score is 1.0 or less. If at any observation period the average reaction to the *Sample* is questionably greater than the average reaction to the *Blank*, repeat the test using three additional rabbits or guinea pigs. The requirements of the test are met if the difference between the *Sample* and the *Blank* mean score is 1.0 or less.

## IMPLANTATION TEST

The implantation test is designed for the evaluation of plastic materials and other polymeric materials in direct contact with living tissue. Of importance are the proper preparation of the implant strips and their proper implantation under aseptic conditions. The intramuscular implantation test requires healthy adult New Zealand rabbits. The test specimens are placed into needles as the delivery system for implantation. Although most materials lend themselves readily to this method, there are a number of materials that are unsuitable for intramuscular implantation. For materials with physical characteristics unsuitable for routine intramuscular implantation, the subcutaneous rat implantation model is a viable alternative.

### Intramuscular Implantation in Rabbits

Prepare for implantation 8 strips of the *Sample* and 4 strips of USP High-Density Polyethylene RS. Each strip should measure not less than 10 × 1 mm. The edges of the strips should be as smooth as possible to avoid additional mechanical trauma upon

Official

https://nhathuocngocanh.com/

implantation. Strips of the specified minimum size are implanted by means of a hypodermic needle (15–19 gauge) with intravenous point and a sterile trocar. Use either presterilized needles into which the sterile plastic strips are aseptically inserted, or insert each clean strip into a needle, the cannula and hub of which are protected with an appropriate cover, and then subjected to the appropriate sterilization procedure. [NOTE—Allow for proper degassing if agents such as ethylene oxide are used.]

**Test Animals—**Select healthy, adult rabbits weighing not less than 2.5 kg, and with paravertebral muscles that are sufficiently large in size to allow for implantation of the test strips. Do not use any muscular tissue other than the paravertebral site. The animals must be anesthetized with a commonly used anesthetic agent to a degree deep enough to prevent muscular movements, such as twitching. See the Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC) guidelines.

**Procedure—**Perform the test in a clean area. On the day of the test or up to 20 h before testing, clip the fur of the animals on both sides of the spinal column. Remove loose hair by means of vacuum. Swab the skin lightly with diluted alcohol, and dry the skin prior to injection.

Implant four strips of the *Sample* into the paravertebral muscle on one side of the spine of each of two rabbits, 2.5–5 cm from the midline and parallel to the spinal column, and about 2.5 cm apart from each other. In a similar fashion implant two strips of USP High-Density Polyethylene RS in the opposite muscle of each animal. Insert a sterile stylet into the needle to hold the implant strip in the tissue while withdrawing the needle. If excessive bleeding is observed after implantation of a strip, place a duplicate strip at another site.

Keep the animals for a period of not less than 120 h, and sacrifice them at the end of the observation period by administering an overdose of an anesthetic agent or other suitable agents. Allow sufficient time to elapse for the tissue to be cut without bleeding. Examine macroscopically the area of the tissue surrounding the center portion of each implant strip. Use a magnifying lens and auxiliary light source. Observe the *Sample* and *Control* implant sites for hemorrhage, necrosis, discolorations, and infections, and record the observations. Measure encapsulation, if present, by recording the width of the capsule (from the periphery of the space occupied by the implant *Control* or *Sample* to the periphery of the capsule) rounded to the nearest 0.1 mm. Score encapsulation according to *Table 6*.

**Table 6. Evaluation of Encapsulation in the Implantation Test**

| Capsule Width | Score |
|---|---|
| None | 0 |
| Up to 0.5 mm | 1 |
| 0.6–1.0 mm | 2 |
| 1.1–2.0 mm | 3 |
| Greater than 2.0 mm | 4 |

Calculate the differences between average scores for the *Sample* and *Control* sites. The requirements of the test are met if the difference does not exceed 1.0, or if the difference between the *Sample* and *Control* mean scores for more than one of the four implant sites does not exceed 1 for any implanted animal.

## Subcutaneous Implantation in Rats

Prepare for implantation 10 sample specimens and 10 control specimens. The size and shape of the control specimens shall be as similar to that of the test specimens as practically possible. For example, specimens made of sheeting material shall be 10–12 mm in diameter and from 0.3–1 mm in thickness. The edges of the specimens should be as smooth as possible to avoid additional mechanical trauma upon implantation.

**Test Animals—**Select healthy albino rats weighing 225–350 g at the time of implantation.

**Procedure—**Perform the test in a clean area. Anesthetize (see AAALAC guidelines) the animal until a surgical plane is achieved. Clip the fur of the animals on both sides of the spinal column. Remove loose hair by means of vacuum. Clean the clipped area with povidone–iodine solution. Using aseptic technique, make two midline incisions (approximately 1.0 cm long) through the skin at the cranial and caudal regions on the dorsal surface. Using blunt dissection, separate the fascia connecting skin to muscle to form a pocket underneath the skin lateral to each side of the incision (base of pocket approximately 20 mm from the line of implant). Insert a sterile sample into each pocket, and close the incision with wound clips or sutures. Implant two test samples and two control samples in each of five rats. Keep the animals for a period of at least seven days, and sacrifice them at the end of the observation period by $CO_2$ induced hypoxia or administering an overdose of an anesthetic agent. Allow sufficient time to elapse for the tissue to be cut without bleeding. Cut the skin (dorsal surface) longitudinally and lay back. Carefully examine macroscopically the area of the tissue surrounding the implant. Cut the sample in half and remove for close examination of the tissue in direct contact with the sample. Use a magnifying lens and auxiliary light source, if appropriate. Observe the *Sample* and *Control* implant sites for hemorrhage, necrosis, discolorations, and infections, and record the observations. Measure encapsulation, if present, by recording the width of the capsule (from the periphery of the space occupied by the implant *Control* or *Sample* to the periphery of the capsule) rounded to the nearest 0.1 mm. Score encapsulation according to *Table 6*. Calculate the differences between average scores for the *Sample* and *Control* sites. The requirements of the test are met if the difference does not exceed 1.0.

# SAFETY TESTS—BIOLOGICALS

The safety test set forth here is intended to detect in an article any unexpected, unacceptable biological reactivity. This in vivo test is provided for the safety assessment of biotechnology-derived products.

## Safety Test

Select five healthy mice not previously used for testing, weighing 17–23 g, unless otherwise directed in the individual monograph or elsewhere in this chapter, and maintained on an adequate balanced diet. Prepare a test solution as directed in the individual monograph. Unless otherwise directed in the individual monograph or elsewhere in this chapter, inject a dose of 0.5 mL of the test solution into each of the mice, using a 26-gauge needle of suitable length, or of the length specified below as applicable. Observe the animals over the 48 h following the injection. If, at the end of 48 h, all of the animals survive and not more than one of the animals shows outward symptoms of a reaction not normally expected of the level of toxicity related to the article, the requirements of this test are met. If one or more animals die or if more than one of the animals shows signs of abnormal or untoward toxicity of the article under test, repeat the test using at least another 10 mice similar to those used in the initial test, but weighing 20 ± 1 g. In either case, if all of the animals survive for 48 h and show no symptoms of a reaction indicative of an abnormal or undue level of toxicity of the article, the requirements of the test are met. Body weights of mice before and at the end of the test should be obtained to detect any untoward effects. Animals that show signs of toxicity should be grossly necropsied and subjected to histopathology if necessary.

For biologics, perform the test according to the procedures prescribed in the *Code of Federal Regulations,* Section 610.11.

## DEFINITION

Collagenase I (EC 3.4.24.3), isolated from *Clostridium histolyticum* and encoded by *colG* gene (GenBank accession number BAA77453.1), is a key raw material used in the dissociation or destruction of a broad range of tissue types. Collagenase I is a metalloprotease that acts as an endoprotease and also exhibits a tripeptidylcarboxypeptidase activity. It shows endopeptidic activity with the main cleavage site found in front of the human collagen duplex amino acids glycine–proline. Hydrolysis takes place near the ends of the triple helical domains of collagen.

Collagenase I is also known as class I collagenase and consists of three subtypes: α, β, and γ. Collagenase I β is the full-length enzyme while collagenase I α (68,000 Da) and collagenase I γ (79,000 Da) are thought to be proteolytic degradation products of collagenase I β caused by other proteases present in *C. histolyticum* (mainly a trypsin-like enzyme and clostripain/endoproteinase Arg C).

Collagenase I can be provided in a liquid formulation consisting of 5 mM *N*-2-hydroxyethylpiperazine-*N*′-2-ethanesulfonic acid (HEPES) and 1 mM calcium chloride pH 7.5, and stored as a frozen liquid. The specific activity of collagenase I is 0.10–0.60 units/mg of protein using 4-phenylazobenzyloxycarbonyl (PZ)-Pro-Leu-Gly-Pro-D-Arg as the substrate described in the *Assay*. The peak area for collagenase I is NLT 90% as determined by HPLC described in the test for *Purity*. The test for *Clostripain Activity* is used to assess the activity of the clostripain impurity and the acceptance criterion is NMT 0.5 units/mg of protein. The test for *Trypsin Activity* is used to assess the activity of the trypsin-like enzyme impurity and the acceptance criterion is NMT 0.5 units/mg of protein.

## IDENTIFICATION

- **A.** It meets the requirements in the *Assay*.
- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the test for *Purity*.

## ASSAY

- **PROCEDURE**

**Tris buffer:** 0.1 M Tris pH 7.1, prepared as follows. Dissolve 6.05 g of tris(hydroxymethyl)aminomethane (Tris) in 400 mL of water, and adjust with 2 N hydrochloric acid to a pH of 7.1 (at 25 ± 1°). Dilute with water to a final volume of 500 mL.

**Substrate solution:** Dissolve 10 mg of PZ-Pro-Leu-Gly-Pro-D-Arg in 0.2 mL of methanol, and dilute this solution with *Tris buffer* to a final volume of 10 mL. [NOTE—Use a freshly prepared solution only.]

**Calcium chloride solution:** 0.1 M, prepared as follows. Weigh 1.47 g of calcium chloride dihydrate in a volumetric flask, and dilute with water to a final volume of 100 mL.

**Citric acid solution:** 0.025 M, prepared as follows. Weigh 525 mg of citric acid monohydrate in a volumetric flask, and dilute with water to a final volume of 100 mL.

**Extraction mixture:** To one test tube per sample to be assayed, pipette 5.0 mL of ethyl acetate and 1.0 mL of *Citric acid solution*. [NOTE—Use a freshly prepared mixture only.]

**Drying tube:** Into one test tube per sample to be assayed, add 0.35–0.40 g of sodium sulfate anhydrous. Seal the test tube with parafilm.

**Standard solution:** Dilute USP Collagenase I RS with *Tris buffer* in the range of 1:50 to 1:100 (v/v). [NOTE—Avoid freezing and thawing USP Collagenase I RS. After withdrawing USP Collagenase I RS, wipe off the outside of the plastic pipette tips to remove any residual solution.]

**Sample solutions:** Dilute collagenase I with *Tris buffer* to an appropriate dilution to achieve the absorbance range of 0.3–0.9 from the *Analysis*. Prepare in triplicate. [NOTE—Avoid freezing and thawing the collagenase I sample. After withdrawing the collagenase I sample, wipe off the outside of the tip to remove any residual solution.]

**Instrumental conditions**

(See *Ultraviolet-Visible Spectroscopy* ⟨857⟩.)

**Mode:** UV

**Analytical wavelength:** 320 nm

**Path length:** 1 cm

**Temperature:** 25°

**Analysis**

**Samples:** *Standard solution* and *Sample solutions*

Transfer 1.0 mL of *Substrate solution* and 0.2 mL of *Calcium chloride solution* into a test tube, and equilibrate the test tube to 25°. Start the reaction by adding 0.05 mL of *Standard solution* or each *Sample solution*. Prepare a blank by replacing the *Standard solution* or *Sample solution* with 0.05 mL of *Tris buffer*. Mix and incubate for exactly 15 min at 25°. Transfer 0.5 mL of the reaction to the test tube containing 6.0 mL of *Extraction mixture*. Vortex immediately for 20 s. Transfer 3 mL of the ethyl acetate phase (upper layer) into a *Drying tube* using a glass pipette, and vortex thoroughly. Transfer the supernatant to a disposable, semi-micro cuvette suitable for UV absorbance with a Pasteur pipette. Record the absorbance.

Calculate the activity of collagenase I in units/mL:

$$\text{Result} = (A - A_B) \times [V_T \times V_E/(\varepsilon \times V \times V_R \times B \times T)] \times D$$

$A$ = absorbance of the *Standard solution* or *Sample solution*
$A_B$ = absorbance of the blank
$V_T$ = volume of the reaction mixture, 1.25 mL
$V_E$ = volume of ethyl acetate in the *Extraction mixture*, 5.0 mL
$\varepsilon$ = extinction coefficient for 320 nm, 21 ($1\ cm^2 \cdot \mu mol^{-1}$)
$V$ = volume of the *Standard solution* or *Sample solution*, 0.05 mL
$V_R$ = volume of the reaction transferred to *Extraction mixture*, 0.5 mL
$B$ = absorption path length, 1 cm
$T$ = incubation time, 15 min
$D$ = dilution factor

[NOTE—One unit will release the equivalent of 1 µmol of PZ-Pro-Leu from PZ-Pro-Leu-Gly-Pro-D-Arg per minute under the conditions of the *Assay*.]

Calculate the specific activity of collagenase I in units/mg of protein:

$$\text{Result} = \textit{Activity}/C$$

*Activity* = activity of collagenase I (units/mL)
$C$ = protein concentration (mg/mL)

**System suitability**

**Samples:** *Standard solution* and *Sample solutions*

**Suitability requirements**

**Average calculated activity:** 85%–115% of the value on the label, *Standard solution*

**Absorbance:** 0.3–0.9, *Standard solution* and *Sample solutions*

**Acceptance criteria:** 0.10–0.60 units/mg of protein

## PURITY

• **PROCEDURE**

**Solution A:** 20 mM Tris and 1 mM calcium chloride pH 7.5, prepared as follows. Dissolve 2.42 g of Tris and 147 mg of calcium chloride dihydrate in 900 mL of water. Adjust with 2 N hydrochloric acid to a pH of 7.5. Dilute with water to a final volume of 1000 mL.

**Solution B:** 20 mM Tris, 1 mM calcium chloride, and 1 M sodium chloride pH 7.5, prepared as follows. Dissolve 2.42 g of Tris, 147 mg of calcium chloride dihydrate, and 58.44 g of sodium chloride in 900 mL of water. Adjust with 2 N hydrochloric acid to a pH of 7.5. Dilute with water to a final volume of 1000 mL.

**Mobile phase:** See *Table 1*.

**Table 1**

| Time (min) | Solution A (%) | Solution B (%) |
|---|---|---|
| 0 | 100 | 0 |
| 2 | 100 | 0 |
| 22 | 85 | 15 |
| 32 | 0 | 100 |
| 34 | 100 | 0 |
| 40 | 100 | 0 |

**Storage buffer:** 5 mM HEPES and 1 mM calcium chloride pH 7.5, prepared as follows. Dissolve 1.19 g of HEPES and 147 mg of calcium chloride dihydrate in 900 mL of water. Adjust with 4 N sodium hydroxide solution to a pH of 7.5. Dilute with water to a final volume of 1000 mL.

**Standard solution:** Thaw USP Collagenase I RS at room temperature shortly before use and mix. Store on ice or at 5°. Dilute with *Storage buffer* to achieve a protein concentration of 5.5 mg/mL. Transfer to an HPLC vial and keep at 5°. Prepare in duplicate, and inject each duplicate once.

**Collagenase II solution:** Thaw USP Collagenase II RS at room temperature shortly before use and mix. Store on ice or at 5°. Dilute with *Storage buffer* to achieve a protein concentration of 5.5 mg/mL. Transfer to an HPLC vial and keep at 5°. Prepare in duplicate, and inject each duplicate once.
**Sample solution:** Dilute collagenase I with *Storage buffer* to achieve a protein concentration of 5.5 mg/mL and keep at 5°.
**Blank:** *Storage buffer*
**Chromatographic system**
(See *Chromatography* ⟨621⟩, *System Suitability*.)
**Mode:** LC
**Detector:** UV 280 nm
**Column:** 5-mm × 5-cm; 10-µm packing L91
**Temperatures**
**Column:** 25°
**Autosampler:** 5°
**Flow rate:** 1.5 mL/min
**Injection volume:** 20 µL
**System suitability**
**Sample:** *Standard solution*
**Suitability requirement:** The chromatogram from the *Standard solution* corresponds to the typical chromatogram provided with USP Collagenase I RS.
**Analysis**
**Sample:** *Sample solution*
The *Blank* should be considered for integration. Identify the peak corresponding to collagenase II by comparing its retention time to the main peak from the *Collagenase II solution*. Evaluate the purity of collagenase I using the area–% method but excluding peaks associated with the *Blank*. All shoulders in the fronting and tailing of the main peak are integrated by dropping a perpendicular line at the inflection points and considered as separate impurities. Disregard any peaks having retention times greater than 25 min.
**Acceptance criteria:** NLT 90% for the main peak of collagenase I and NMT 3% of collagenase II

## IMPURITIES

• **CLOSTRIPAIN ACTIVITY**

**Potassium phosphate buffer:** 0.1 M pH 7.6, prepared as follows. Dissolve 1.36 g of monobasic potassium phosphate in water, and dilute to 100 mL. Dissolve 2.28 g of dibasic potassium phosphate trihydrate in water, and dilute to 100 mL. Adjust the pH of the second solution to 7.6 with the first solution.
**Dithiothreitol solution:** 0.194 M, prepared as follows. Dissolve 60 mg of dithiothreitol (DTT) in 2 mL of *Potassium phosphate buffer*.
**Calcium chloride solution:** 0.01 M, prepared as follows. Dissolve 147 mg of calcium chloride dihydrate in 100 mL of water.
**Substrate stock solution:** 38 mM, prepared as follows. Dissolve 13 mg of *N*-benzoyl-L-arginine ethyl ester hydrochloride (BAEE · HCl) in 1 mL of *Potassium phosphate buffer*.
**Substrate solution:** 0.73 mM BAEE · HCl, 7.8 mM DTT, and 0.4 mM calcium chloride, prepared as follows. Transfer 0.5 mL of *Substrate stock solution*, 1.0 mL of *Dithiothreitol solution*, and 1.0 mL of *Calcium chloride solution* to a 25-mL volumetric flask, and dilute with *Potassium phosphate buffer* to volume.
**Sample solution:** Prepare in such a way that $\Delta A$/min lies in the 0.02–0.06 range. Dilute with ice-cold *Potassium phosphate buffer* if necessary.
**Instrumental conditions**

**Standard solution:** Dilute USP Collagenase II RS with *Tris buffer* ▲to an appropriate dilution to achieve the absorbance range of 0.3–0.9 from the *Analysis*.▲ (IRA 1-Sep-2022) [NOTE—Avoid freezing and thawing USP Collagenase II RS. After withdrawing USP Collagenase II RS, wipe off the outside of the plastic pipette tip to remove any residual solution.]

**Sample solutions:** Dilute Collagenase II with *Tris buffer* to an appropriate dilution to achieve the absorbance range of 0.3–0.9 from the *Analysis*. Prepare in triplicate. [NOTE—Avoid freezing and thawing the Collagenase II sample. After withdrawing the Collagenase II sample, wipe off the outside of the pipette tip to remove any residual solution.]

**Instrumental conditions**

(See *Ultraviolet-Visible Spectroscopy* ⟨857⟩.)

**Mode:** UV

**Analytical wavelength:** 320 nm

**Path length:** 1 cm

**Temperature:** 25°

**Analysis**

**Samples:** *Standard solution* and *Sample solutions*

Transfer 1.0 mL of *Substrate solution* and 0.2 mL of *Calcium chloride solution* into a test tube, and equilibrate the test tube to 25°. Start the reaction by adding 0.05 mL of *Standard solution* or each *Sample solution*. Prepare a blank by replacing the *Standard solution* or *Sample solution* with 0.05 mL of *Tris buffer*. Mix and incubate for exactly 15 min at 25°. Transfer 0.5 mL of the reaction to the test tube containing 6.0 mL of *Extraction mixture*. Vortex immediately for 20 s. Transfer 3 mL of the ethyl acetate phase (upper layer) into a *Drying tube* using a glass pipette, and vortex thoroughly. Transfer the supernatant to a disposable, semi-micro cuvette suitable for UV absorbance with a Pasteur pipette. Record the absorbance.

Calculate the activity of collagenase II in units per milliliter:

$$\text{Result} = (A - A_B) \times [V_T \times V_E/(\varepsilon \times V \times V_R \times B \times T)] \times D$$

$A$ = absorbance of the *Standard solution* or *Sample solution*
$A_B$ = absorbance of the blank
$V_T$ = volume of the reaction mixture, 1.25 mL
$V_E$ = volume of ethyl acetate in the *Extraction mixture*, 5.0 mL
$\varepsilon$ = extinction coefficient for 320 nm, 21 ($1\ cm^2 \cdot \mu mol^{-1}$)
$V$ = volume of the *Standard solution* or *Sample solution*, 0.05 mL
$V_R$ = volume of the reaction transferred to *Extraction mixture*, 0.5 mL
$B$ = absorption path length, 1 cm
$T$ = incubation time, 15 min
$D$ = dilution factor

[NOTE—One unit will release the equivalent of 1 µmol of PZ-Pro-Leu from PZ-Pro-Leu-Gly-Pro-D-Arg per minute under the conditions of the *Assay*.]

Calculate the specific activity of collagenase II in units per milligram of protein:

$$\text{Result} = \text{Activity}/C$$

Activity = activity of collagenase II (units/mL)
$C$ = protein concentration (mg/mL)

**System suitability**

**Samples:** *Standard solution* and *Sample solutions*

**Suitability requirements**

**Average calculated activity:** 85%–115% of the value on the label, *Standard solution*

**Absorbance:** 0.3–0.9, *Standard solution* and *Sample solutions*

**Acceptance criteria:** 10–16 units/mg of protein

## PURITY

• **PROCEDURE**

**Solution A:** 20 mM Tris and 1 mM calcium chloride pH 7.5, prepared as follows. Dissolve 2.42 g of Tris and 147 mg of calcium chloride dihydrate in 900 mL of water. Adjust with 2 N hydrochloric acid to a pH of 7.5. Dilute with water to a final volume of 1000 mL.

**Solution B:** 20 mM Tris, 1 mM calcium chloride, and 1 M sodium chloride pH 7.5, prepared as follows. Dissolve 2.42 g of Tris, 147 mg of calcium chloride dihydrate, and 58.44 g of sodium chloride in 900 mL of water. Adjust with 2 N hydrochloric acid to a pH of 7.5. Dilute with water to a final volume of 1000 mL.

**Mobile phase:** See *Table 1*.

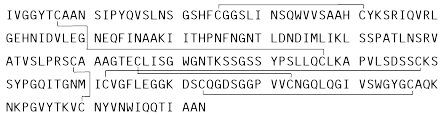
# ⟨89⟩ ENZYMES USED AS ANCILLARY MATERIALS IN PHARMACEUTICAL MANUFACTURING

## INTRODUCTION

The purpose of this chapter is to describe the quality attributes and associated tests with acceptance criteria for enzymatic preparations used in biopharmaceutical manufacturing. The quality of ancillary materials, including enzymes, used in biopharmaceutical manufacturing can have an impact on the therapeutic products. Several enzymes are used in this type of cell processing. Examples include trypsin, collagenase, pepsin, and papain. This chapter does not discuss applications of these enzymes but rather focuses on tests to assess their quality as process materials.

**Recombinant Trypsin**



$C_{1020}H_{1597}N_{287}O_{321}S_{14}$
23,463 (for β-Trypsin)
CAS RN®: 9002-07-7

## DEFINITION

Recombinant trypsin, a key raw material in biopharmaceutical manufacturing, is a serine protease that cleaves peptide chains mainly at the carboxyl end of the amino acids arginine and lysine. The amino acid sequence of recombinant trypsin is identical to that of trypsin from porcine pancreas, and the recombinant trypsin is produced by methods based on recombinant DNA technology in the yeast *Pichia pastoris*. Therefore, the specifications described in this chapter apply only to recombinant porcine trypsin produced in yeast. Because of the recombinant production process, recombinant trypsin is free of chymotrypsin. Two active forms of trypsin are known: β-trypsin (23,463 daltons) and α-trypsin (23,481 daltons). Autolysis of β-trypsin at the peptide bond between $Arg^{99}$ and $Val^{100}$, $Lys^{125}$ and $Ser^{126}$, or $Lys^{139}$ and $Ala^{140}$ results in three possible isoforms of α-trypsin. All isoforms are held together by disulfide bridges and remain correctly folded. As a consequence of hydrolysis of a peptide bond, the molecular weight of α-trypsin is more than that of β-trypsin by 18 daltons. The peak area for β-trypsin is NLT 70%, and the peak area for α-trypsin is NMT 20% as determined by the HPLC procedure described in the test for *Purity*. The specific activity is NLT 180 Units/mg of protein using carbobenzoxy-valyl-glycyl-arginine-4-nitril-anilide acetate as the substrate described in the *Assay*.

[NOTE—One Unit of trypsin activity using carbobenzoxy-valyl-glycyl-arginine-4-nitril-anilide acetate as the substrate corresponds to 21 USP Trypsin Units. One USP Trypsin Unit is the activity causing a change in absorbance of 0.003/min under the conditions specified in the *Assay* in the *Trypsin* monograph using *N*-benzoyl-L-arginine ethyl ester hydrochloride as the substrate. Therefore, the specific activity of 180 Units/mg of protein using carbobenzoxy-valyl-glycyl-arginine-4-nitril-anilide acetate as the substrate for recombinant trypsin corresponds to 3800 USP Trypsin Units/mg of protein.]

## IDENTIFICATION

- **A.** It meets the requirements in the *Assay*.
- **B.** The retention time of the major peak of β-trypsin from the *Sample solution* corresponds to that from the *Standard solution*, as obtained in the test for *Purity*.

## ASSAY

***Change to read:***

- **PROCEDURE**

**Buffer:** Dissolve 1.21 g of tris(hydroxymethyl)aminomethane and 0.29 g of calcium chloride dihydrate in 100 mL of water, and adjust with 2 N hydrochloric acid to a pH of 8.0 (at 25 ± 1°).

**Substrate stock solution:** Dissolve 20 mg of carbobenzoxy-valyl-glycyl-arginine-4-nitril-anilide acetate,[1] accurately weighed, in 3.0 mL of water. [NOTE—Use a freshly prepared solution only.]

**Substrate solution:** Prepare a solution by mixing 28 mL of *Buffer* and 2.8 mL of *Substrate stock solution*. [NOTE—Use a freshly prepared solution only.]

**Standard solutions:** Precool USP Trypsin Recombinant Porcine RS and water to approximately 4°. Start preparing *Standard solutions* immediately when the temperature has reached 4°. Prepare each *Standard solution* by diluting USP Trypsin Recombinant Porcine RS with water, at 1:68,921 dilution. Prepare at least five *Standard solutions* in parallel. Assay each *Standard solution* in duplicate. [NOTE—Use an adjustable pipettor for each measurement and dilution operation. Use ▲low protein binding▲ (USP 1-Dec-2021) test tubes for preparing *Standard solutions* and *Sample solutions*, and use ▲low protein binding▲ (USP 1-Dec-2021) pipet tips containing ▲low protein binding▲ (USP 1-Dec-2021) filters to transfer samples. The pipet tip should not be wet before transfer, and each pipet tip should be used only for transferring one sample.] [NOTE—A dilution of 1:68,921 can be achieved by three dilution steps in which each step has a 1:41 dilution (1:41/1:41/1:41). For example, for the initial dilution withdraw 0.1 mL of USP Trypsin Recombinant Porcine RS using a pipettor with a ▲low protein binding▲ (USP 1-Dec-2021) tip containing ▲low protein binding▲ (USP 1-Dec-2021) filters, wipe off the outside of the tip to remove any residual solution, add the Reference Standard to a ▲low protein binding▲ (USP 1-Dec-2021) test tube containing 4.0 mL of precooled water, rinse the tip by pipetting the solution up and down for 2–3 times, discard the tip, and mix the solution

[1] A suitable carbobenzoxy-valyl-glycyl-arginine-4-nitril-anilide acetate is Chromozym TRY from Roche ▲CustomBiotech▲ (USP 1-Dec-2021) (catalog number 10378496103) or equivalent.

on a vortex mixer for approximately 2 s with maximum speed. For the second and third dilution steps, proceed as described for the initial dilution except for transferring 0.1 mL of solution from the previous dilution step.]

**Sample solutions:** Prepare at least five *Sample solutions* of recombinant trypsin in parallel as directed for the *Standard solutions* to obtain a final concentration of at least 0.16 Units/mL using precooled water, as the diluent. Each *Sample solution* is assayed in duplicate.

**Instrumental conditions**

(See *Ultraviolet-Visible Spectroscopy* ⟨857⟩.)

**Mode:** UV

**Analytical wavelength:** 405 nm

**Path length:** 1 cm

**Temperature:** 25°

**System suitability**

**Samples:** *Standard solutions* and *Sample solutions*

**Suitability requirement:** $\Delta A$/min (calculated below) should be 0.03–0.07 for *Standard solutions* and *Sample solutions*. The average calculated activity for the *Standard solutions* is 90%–110% of the value on the label.

**Analysis**

**Samples:** *Standard solutions* and *Sample solutions*

Transfer 1.10 mL of *Substrate solution* into a ▲low protein binding▲ (USP 1-Dec-2021) semimicro cuvette, allow the temperature to stabilize, check the cuvette for the specified temperature, and wait for 10 min. Start the reaction by adding 0.020 mL of *Standard solution* or *Sample solution*. Record the absorbance for at least 5 min, and determine the change in absorbance per minute, $\Delta A$/min, from the linear range of the reaction.

Calculate the activity of recombinant trypsin in Units/mL:

$$\text{Activity} = [V_T/(\varepsilon \times V \times B)] \times (\Delta A/\text{min}) \times D$$

$V_T$ = volume of the reaction mixture, 1.12 mL
$\varepsilon$ = extinction coefficient for 405 nm, 10.4 ($\text{mmol}^{-1} \cdot 1\ \text{cm}^{-1}$)
$V$ = volume of *Standard solution* or *Sample solution*, 0.020 mL
$B$ = absorption path length, 1 cm
$\Delta A$/min = change in absorbance per minute
$D$ = dilution factor

[NOTE—One Unit will release the equivalent of 1 mmol of 4-nitril aniline from carbobenzoxy-valyl-glycyl-arginine-4-nitril-anilide acetate per min under the conditions of the *Assay*.]

Calculate the specific activity of recombinant trypsin in Units/mg of protein:

$$\text{Result} = \text{Activity}/C$$

Activity = activity of recombinant trypsin as previously calculated (Units/mL)
$C$ = protein concentration of recombinant trypsin (mg/mL)

**Acceptance criteria**

**Specific activity:** NLT 180 Units/mg of protein

**Relative standard deviation:** NMT 5% for the activities determined from 5 replicates

## PURITY

• **PROCEDURE**

**Solution A:** Dilute 1 mL of phosphoric acid (85%) with water, to 1000 mL.

**Solution B:** Dilute 1 mL of phosphoric acid (85%) with acetonitrile to 1000 mL.

**Mobile phase:** See *Table 1*.

**Table 1**

| Time (min) | Solution A (%) | Solution B (%) |
|---|---|---|
| 0 | 75 | 25 |
| 25 | 55 | 45 |
| 30 | 10 | 90 |
| 34 | 10 | 90 |
| 35 | 75 | 25 |
| 45 | 75 | 25 |

**Standard solution:** Thaw 100 µL of USP Trypsin Recombinant Porcine RS at room temperature for about 1 h, mix, and transfer to an HPLC vial. The target protein concentration should be 70 ± 10 mg/mL.

**Sample solution:** Thaw 100 µL of recombinant trypsin at room temperature for about 1 h, mix, and transfer to an HPLC vial. The target protein concentration should be 70 ± 10 mg/mL.

[NOTE—Keep *Standard solution* and *Sample solution* at 2°–8° if they are not ready to be injected immediately after preparation.]

# ⟨90⟩ FETAL BOVINE SERUM—QUALITY ATTRIBUTES AND FUNCTIONALITY TESTS

## INTRODUCTION

Fetal bovine serum (FBS) is the light-brown liquid fraction of clotted fetal bovine blood. It is depleted of cells, fibrin, and clotting factors. Although the complete composition of FBS is undefined, FBS contains high levels of growth factors and low levels of immunoglobulins. In addition, it contains other key ingredients that are essential in supporting proliferation of cells in culture. This product is used both in life science basic research and industrial manufacturing. FBS is a by-product of the meat industry and is collected from bovine fetuses removed from cattle found to be pregnant at slaughter. FBS is harvested from abattoirs that are inspected by the competent authority in the country of origin. Trained personnel following written and approved procedures should perform collection and processing. Blood is collected in a closed system in a dedicated area within the facility, and processed quickly to prevent hemolysis. The blood is allowed to clot and then typically is centrifuged in a refrigerated centrifuge to separate the serum from the other components. Serum typically is removed from the clot, transferred to labeled containers, and frozen. All manufacturers employ sterile filtration before final packaging. Additionally, gamma irradiation provides the highest assurance of the absence of viral activity. Gamma irradiation doses of 25–40 kGy provide significant log reduction of viral and other adventitious agents while preserving cellular growth performance.

The screening of FBS for viral contamination is accomplished by using all applicable testing described in the Code of Federal Regulations 9 CFR 113.53 (known as full 9 CFR testing). Mycoplasma assays are performed as described in *Mycoplasma Tests* ⟨63⟩.

## IDENTIFICATION

- **IDENTIFICATION—RADIAL IMMUNODIFFUSION**

**Reagents**

- FBS test samples
- Horse serum, negative control samples
- Bovine IgG calibrator (500 mg/L)
- Sheep albumin diluent (1% Sheep albumin, 0.18% EDTA, 1.75% NaCl, and 1.21% Tris/HCl pH 7.4).

**Materials/Apparatus:** Ring measuring device is calibrated in 0.1-mm increments. Radial immunodiffusion (RID) plates are commercially available and contain anti-bovine IgG antiserum in a 1.5% agarose gel, 0.1 M phosphate buffer, pH 7.0, 0.1% sodium azide as bacteriostatic agent, and 1 µg/mL amphotericin B as an antifungal agent. Store at 2°–8°. Use RID plates that can measure bovine IgG in the range of 50–500 mg/L.

**Standard curve:** Use the bovine IgG calibrators for system suitability and for generation of a calibration curve. Prepare two dilutions from a 500 mg/L bovine IgG stock solution. Dilute 120 µL of the 500 mg/L stock with 80 µL of diluent (medium dilution) and 25 µL of the 500 mg/L stock with 225 µL diluent (low dilution). Label each dilution respectively as 300 mg/L and 50 mg/L calibrators. Use the 500 mg/L, 300 mg/L, and 50 mg/L solutions to generate the standard curve. [NOTE—Prepare and analyse the calibrator bovine IgG solutions in duplicate.] Load 5 µL of each sample into the 2.5-mm wells of the plate. At 72 h of incubation, measure ring diameters to the nearest 0.1 mm using an appropriate ring measuring device. Record the results and proceed to the generation of a standard curve.

The ring diameter should develop to completion at room temperature for 72 h. Using the result from each data point of the standard curve, generate a single linearity plot where y is the squared diameter ($mm^2$) of precipitin ring around the well and x is the Bovine IgG concentration (mg/L). Calculate the linear least-squares-fit regression line of the form $y = m(x) + b$ with the help of suitable software and determine the values for slope (m), y-intercept (b), and coefficient of determination ($R^2$). The standard curve for the method is linear if $R^2$ is $\geq 0.98$.

**Analysis:** Frozen undiluted samples of FBS are thawed and tested within 24 h if stored at 4°. Testing of FBS test and USP Fetal Bovine Serum RS samples is performed in triplicate. Prepare RID plates containing anti-bovine IgG to be tested for the various types of sera. Allow plates and reagents to equilibrate to room temperature before use by leaving the plates open for 10–15 min at room temperature to allow any condensation in the wells or on the gel surface to evaporate. Samples should not be applied to wells where moisture is visible. Prepare serial dilutions, if necessary, of FBS test and USP Fetal Bovine Serum RS samples in diluent. Dilute the negative control horse serum in diluent. Load 5 µL of each sample into the 2.5-mm wells of the plate, and incubate at room temperature for 72 h. [NOTE—The test samples and the negative control are loaded on the same plate.]

**Calculation:** After 72 h, measure the diameters of the rings using the ring measuring device, and record the results. Using the regression equation developed under standard curve deviation, calculate the concentration of bovine IgG in FBS samples. Concentration is expressed as mg/L.

**Acceptance criteria:** Horse serum is negative (should not give a precipitation ring). FBS test and USP Fetal Bovine Serum RS samples are positive and contain NMT 500 mg/L of IgG.

- **HEMOGLOBIN CONTENT**

(See *Ultraviolet-Visible Spectroscopy* ⟨857⟩.)

**Sample preparation:** FBS samples are thawed, are stored at 4°, and are tested within the same day.

**Analysis:** Determine the absorbance of the serum sample using a spectrophotometric cell of 1-cm path length at the wavelengths of absorbance at 576, 623, and 700 nm and using water as a blank. Calculate the concentration of hemoglobin in mg/dL:

$$(Abs_{576} \times 115) - (Abs_{623} \times 102) - (Abs_{700} \times 39.1)$$

**Acceptance criteria:** NMT 30 mg/dL

## SPECIFIC TESTS

- **FBS Functionality Tests**

In the absence of a user-defined functionality assay, the following tests are suitable to determine the functionality of specific lots of FBS and to aid in the optimization of the growth conditions of mammalian cell cultures in the presence of FBS. For valid functionality confirmation independent of user-specific applications, tests are performed on the specified cell lines. For in-house validation of specialized cell culture applications, cell line(s) specific to those applications should be used and characterized. Use appropriate tissue culture vessels. Two tests described in this chapter are the *Growth-Promotion Curve* and the *Clonal Assay*. The decision about which type of test or the number of tests to be performed to assess suitability of a specific lot of FBS depends on the type of cell line used. For adherent cell lines, the number of colonies at the end of the culturing period represents a good assessment of the capacity of these cells, at low concentration, to grow in the presence of a specific lot of FBS. For cell lines growing in suspension cultures, the optimum growth kinetics is measured by counting viable cells after 7 days of culture.

**Cell lines:** Five cell lines are recommended for use:

1. HFL1 (ATCC CCL-153) normal lung, fibroblast
2. Mv1 Lu (ATCC CCL-64) mink lung, epithelial
3. HL-60 (ATCC CCL-240) peripheral blood promyeloblast, suspension
4. VERO (ATCC CCL-81) monkey kidney fibroblast
5. CHO (CCL-61) Chinese hamster ovary

The functionality tests described are to be performed on three cell lines, two of which are drawn from the five recommended cell lines and the third of which is the cell line relevant to the user's application. Cell lines are cultured with specific media as recommended by ATCC.

**Materials**

- Suitable growth vessel/container
- Biological Safety Cabinet Class II, Type A
- Cell counter/hemacytometer
- Inverted microscope with digital camera accessory
- Tissue culture vessels: T25 $cm^2$

**Preparation of cells for assays:** Quick-thaw a vial in a 37° water bath, and determine cell count and viability. Prepare multiple cultures from each cell line in serum-supplemented growth medium. Incubate the cultures at 37° following instructions provided by ATCC for each of the cell lines used for the test. Examine the prepared cultures under a microscope to ensure uniform, near-confluent monolayers or suspensions. Expand cells until there are enough for assay (about $1 \times 10^7$ total cells; >90% viability).

**Harvesting of cultures**

1. Remove and discard the growth medium, and then rinse each culture with media lacking FBS.
2. For adherent cells, add 1 mL of Trypsin/EDTA for a few minutes for cells to disperse. Incubate at 37°, if necessary. Neutralize with 1 mL culture medium containing at least 10% FBS.
3. Spin down the cells in a centrifuge. Aspirate off wash media, and resuspend cells in an appropriate volume for seeding.

**Seeding of cells**

1. On day 0: For the three cell lines to be tested prepare multiple cultures using seeding densities that range between $2 \times 10^3$ and $2 \times 10^4$ viable cells/mL. (Different inocula are chosen initially to determine optimum growth conditions. Once the appropriate inoculum is chosen, that condition is used to propagate the cells.) Following are the recommended seeding densities:
   Low seeding density: $2 \times 10^3$ viable cells/mL
   Mid seeding density: $6 \times 10^3$ viable cells/mL
   High seeding density: $2 \times 10^4$ viable cells/mL
2. Prepare cultures in triplicate for at least five time points (in days or hours according to the cell line), to determine the seeding density that will yield the optimal growth conditions for each cell line used.
3. Incubate the cultures at 37° in a humidified incubator saturated with 5% $CO_2$.
4. For each time point of measurement (days 0, 1, 2, 3, 4, and 7), take a photograph of each culture, in triplicate, for both the FBS test material and the USP Fetal Bovine Serum RS at each of the three concentrations for each cell line, and record the percentage of confluency for each of the conditions. [Note—Perform this step before trypsinization and cell counting.]
5. Harvest the cells from the three different seeding density cultures for each specific time point. For adherent cultures, harvest cells as described above.
6. Perform and record total cell count and viability for each of the nine cultures for the FBS test and the USP Fetal Bovine Serum RS for each cell line using an appropriate cell counter or hemacytometer. [Note—The schedule for counting may have to be changed for fast-growing cell lines or large cells that would become confluent before day 7 and/or for slow-growing lines that need to be in culture 8–10 days before reaching a plateau. Some adherent cell lines will never reach confluency.]

- **Growth-Promotion Curve**

Measurements of cell proliferation rates often are used to determine the response of cells to exogenous stimuli. Quantitative assessment of cell growth conditions is an important factor in monitoring consistency of culture conditions. The optimal cell concentration range for subculturing, optimum inoculum, and doubling time are parameters that can be quantified and trended. Information about the growth kinetics of a culture is critical in the design of cell-based experiments. Cultures

vary significantly in their growth properties from lag phase, log phase, and stationary phase. Document the growth characteristics of the culture during the three growth stages to determine population doubling time and cell cycle time. Cells that have entered the stationary phase may demonstrate reduced growth potential and change in morphology. Cells may become polarized and may secrete more extracellular matrix, making them difficult to remove from the substratum. Cells at the end of the log phase give the highest yield and greatest reproducibility.

**Reagents**

- Growth media without FBS
- FBS test samples
- Growth medium + 10% FBS
- Trypsin/EDTA solution (0.25%/0.53 mM) in Hank's Balanced Salt Solution (HBSS)

**Analysis:** Once the cells have reached the end of the log phase, subculture the cells for the test. Follow the procedure described in *Specific Tests, FBS Functionality Tests, Seeding of cells* and prepare multiple cultures for the USP Fetal Bovine Serum RS, and test FBS for different cell lines at three seeding densities for which at least one growth curve displays a lag phase, log phase, and stationary phase and for which the log phase is linear at three or more time points. Viable cell counts are determined on days 0, 1, 2, 3, 4, and 7.

**Calculation** and **Data analysis:** Calculate the mean viable count [cells/$cm^2$ (adherent) or cells/mL (suspension)] and the mean percent viability for each data point. Plot the data on a semi-log scale graph with the viable count on the log scale on the *y*-axis and days (or hours) in culture on an arithmetic scale on the *x*-axis. Estimate the doubling time using a growth curve that is linear over three or more time points.

**Acceptance criteria:** The $R^2$ value of the line should be equal to or greater than 0.98 in order to support calculation of a valid doubling time. The doubling time of the test sample should be no less than 90% of the doubling time of USP Fetal Bovine Serum RS.

- **Clonal Assay**

This assay is designed to assess the optimal growth for adherent cell lines. Plating efficiency or colony formation at low cell density is a preferred method for analyzing the proliferative capacity and survival of single cells under optimal growth conditions. This is a very sensitive test and is often used for assessing the quality of serum lots. This technique reveals differences in the growth rate within the cell population and is capable of distinguishing between changes in growth rate (colony size) and cell survival (colony number). Because of the heterogeneous cell population of some cell cultures, remember that cells grow differently as isolated colonies at low densities. Consequently, few cells survive even under ideal conditions because all cell interaction is lost. Cloning is a survival assay that is also used for optimizing growth conditions (selection of medium and serum). If it can be confirmed that a single colony arose from a single cell, then cloning efficiency can be determined.

**Reagents**

- Growth medium + 10% FBS (test serum)—Eagle minimum essential medium (EMEM) with 2 mM L-glutamine and Earle's BSS adjusted to contain 1.5 g/L sodium carbonate, 0.1 mM nonessential amino acids, and sodium pyruvate containing 100 U/mL penicillin and 100 g/mL streptomycin plus 10% FBS.
- Trypsin/EDTA solution (0.25%/0.53 mM) in HBSS.
- Dulbecco's Phosphate Buffer Saline without calcium or magnesium.
- Carbol Fuchsin–Methylene Blue Solution—Mix 20 g carbol fuchsin stock in 2 L methanol and stir for 10 min (1% carbol fuchsin). Mix 50 g methylene blue in 5 L methanol, and stir for 10 min (1% methylene blue). Prepare Carbol Fuschin–Methylene Blue working solution by mixing methylene blue, methanol, and carbol fuchsin in a ratio of 3:2:1. Mix for 20 min and filter through four folds of cheesecloth in a funnel. Aliquot and store in brown glass bottles at 15° to 25°.

**Sample:** Multiple lots of FBS are used for this assay. For each lot of serum to be tested, add 20 mL of FBS to 180 mL of EMEM, and use the same sample for the entire test. Sterilize using 0.22-m low protein binding filter units. Store growth medium at 4° until ready to use.

**Cell preparation:** This test is only for adherent cultures and is performed with the adherent cell lines described under *Cell Lines* (HFL1 and Mv 1 Lu). One week before testing serum, expand the cell lines as described under *Seeding of Cells*, change the medium every 2–3 days, and subculture the cells when they are about 90% confluent. Determine the cell count and viability (viability should be >90%) before performing the assay. Harvest cells as described under *Harvesting of Cultures*, wash twice, and resuspend cells in basal EMEM.

**Analysis:** The procedure involves plating single-cell suspension at low densities (2–50 cells/$cm^2$) from which discrete colonies will form. At the end of the assay, fix, stain, and count the number of colonies as directed below.

1. For each cell line label ten 60-mm × 15-mm tissue culture dishes for each serum lot that will be tested. Label the side of the lower half of each dish, including controls.
2. Transfer 5 mL of medium containing 10% of the appropriate test serum (10 replicates). Add 400 cells per culture dish (aim for a cell concentration of about 800 cells/mL).
3. Incubate for 10–14 days at 37° in a humidified incubator saturated with 5% $CO^2$.
4. Remove the supernatant and add enough Carbol Fuchsin–Methylene Blue Solution to cover each of the culture dishes for 10 min.
5. Remove the stain; rinse the culture dishes with several changes of distilled water; invert the dishes on paper towels; and allow to dry.
6. Count and record (1) the number of colonies and (2) the total surface of stained colonies ($mm^2$). Calculate means and standard deviations.

**Acceptance criteria:** Percent plating efficiency is expressed by counting the number of colonies in a defined area divided by the number of cells seeded multiplied by 100. Compare results between lots of FBS, and select a serum lot that is good for various types of cells and optimal for a specific cell culture application.

# ⟨91⟩ CALCIUM PANTOTHENATE ASSAY

## INTRODUCTION

The following liquid chromatographic procedures are provided for the determination of calcium pantothenate as an active pharmaceutical ingredient, a dietary supplement ingredient, or a component in dietary supplements or pharmaceutical dosage forms.

While conducting these procedures, protect solutions containing and derived from the test specimen and the Reference Standards from atmosphere and light, preferably with the use of low-actinic glassware. Use the appropriate USP Reference Standards.

## ASSAY

• **Chromatographic Methods, Procedure 1**

This procedure can be used to determine calcium pantothenate in:

- *Oil- and Water-Soluble Vitamins Capsules*
- *Oil- and Water-Soluble Vitamins Tablets*
- *Oil- and Water-Soluble Vitamins with Minerals Capsules*
- *Oil- and Water-Soluble Vitamins with Minerals Tablets*
- *Water-Soluble Vitamins Capsules*
- *Water-Soluble Vitamins Tablets*
- *Water-Soluble Vitamins with Minerals Capsules*
- *Water-Soluble Vitamins with Minerals Tablets*

This procedure involves the extraction of calcium pantothenate from the formulation by the *Internal standard solution*.

Unless specified in the individual monographs, the *Internal standard solution*, *Standard solution*, *Sample solution*, and reagent solutions are prepared as follows.

**Mobile phase:** Phosphoric acid and water (1:1000)

**Internal standard solution:** 80 mg of *p*-hydroxybenzoic acid in 3 mL of alcohol. Add 50 mL of water and 7.1 g of dibasic sodium phosphate, and dilute with water to 1000 mL. Adjust with phosphoric acid to a pH of 6.7.

**Standard solution:** 0.6 mg/mL of USP Calcium Pantothenate RS in *Internal standard solution*

**Sample solution** (for capsules)**:** Weigh NLT 20 capsules in a tared weighing bottle. Open the capsules, without losing shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing, if necessary, with several portions of ether. Discard the washings, and dry the capsule shells with the aid of a current of dry air until the odor of ether is no longer perceptible. Weigh the empty capsule shells in the tared weighing bottle, and calculate the average net weight per capsule. Transfer a quantity of mixed capsule contents and a volume of *Internal standard solution* to a centrifuge tube to obtain a concentration of 0.6 mg/mL in the *Sample solution*.

**Sample solution** (for tablets)**:** Finely powder NLT 30 tablets. Transfer a portion of the powder, equivalent to a nominal amount of 15 mg of calcium pantothenate, to a centrifuge tube. Add 25.0 mL of the *Internal standard solution*, and shake vigorously for 10 min. Centrifuge, filter, and use the clear filtrate.

**Chromatographic system**

(See *Chromatography* ⟨621⟩*, System Suitability*.)

**Mode:** LC

**Detector:** UV 210 nm

**Column:** 3.9-mm × 15-cm; packing L1

**Flow rate:** 1.5 mL/min

**Injection volume:** 10 µL

**System suitability**

**Sample:** *Standard solution*

[Note—The relative retention times for calcium pantothenate and *p*-hydroxybenzoic acid are about 0.5 and 1.0, respectively.]

**Suitability requirements**

**Relative standard deviation:** NMT 3.0%

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of calcium pantothenate ($C_{18}H_{32}CaN_2O_{10}$) in the portion of the sample taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

$R_U$ = peak response ratio of calcium pantothenate to *p*-hydroxybenzoic acid from the *Sample solution*
$R_S$ = peak response ratio of calcium pantothenate to *p*-hydroxybenzoic acid from the *Standard solution*
$C_S$ = concentration of USP Calcium Pantothenate RS in the *Standard solution* (mg/mL)
$C_U$ = nominal concentration of calcium pantothenate in the *Sample solution* (mg/mL)

• **Chromatographic Methods, Procedure 2**

This procedure can be used to determine calcium pantothenate in:

- *Oil- and Water-Soluble Vitamins Capsules*
- *Oil- and Water-Soluble Vitamins Tablets*
- *Oil- and Water-Soluble Vitamins with Minerals Capsules*

Official

https://pharmacopeia.cn/v-pharm/

- *Oil- and Water-Soluble Vitamins with Minerals Tablets*
- *Water-Soluble Vitamins Capsules*
- *Water-Soluble Vitamins Tablets*
- *Water-Soluble Vitamins with Minerals Capsules*
- *Water-Soluble Vitamins with Minerals Tablets*

This procedure involves dissolving an appropriate quantity of the sample equivalent to 10 mg of calcium pantothenate in 10 mL of methanol and diluting with water to 250 mL.

Unless specified in the individual monographs, the *Standard solution*, *Sample solution*, and reagent solutions are prepared as follows.

**Buffer solution:** Dissolve 10.0 g of monobasic potassium phosphate in 2000 mL of water, and adjust with phosphoric acid to a pH of 3.5.

**Mobile phase:** Methanol and *Buffer solution* (1:9)

**Standard stock solution:** 0.25 mg/mL of USP Calcium Pantothenate RS in water. Prepare fresh every 4 weeks. Store in a refrigerator.

**Standard solution:** 40 µg/mL of USP Calcium Pantothenate RS from the *Standard stock solution* diluted with water

**Sample solution** (for capsules)**:** Weigh NLT 20 capsules in a tared weighing bottle. Open the capsules, without losing shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing, if necessary, with several portions of ether. Discard the washings, and dry the capsule shells with the aid of a current of dry air until the odor of ether is no longer perceptible. Weigh the empty capsule shells in the tared weighing bottle, and calculate the average net weight per capsule. Transfer a portion of the capsule contents, equivalent to 10 mg of calcium pantothenate, to a 250-mL volumetric flask. Add 10 mL of methanol, and swirl the flask to disperse the capsule contents. Dilute with water to volume, mix, and filter.

**Sample solution** (for tablets)**:** Finely powder NLT 20 tablets. Transfer a portion of the powder, equivalent to 10 mg of calcium pantothenate, to a 250-mL volumetric flask. Add 10 mL of methanol, and swirl the flask to disperse. Dilute with water to volume, mix, and filter.

**Chromatographic system**

(See *Chromatography* ⟨621⟩*, System Suitability*.)

**Mode:** LC

**Detector:** UV 205 nm

**Column:** 3.9-mm × 30-cm; 5-µm packing L1

**Column temperature:** 50°

**Flow rate:** 2 mL/min

**Injection volume:** 25 µL

**System suitability**

**Sample:** *Standard solution*

**Suitability requirements**

**Relative standard deviation:** NMT 3.0%

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of calcium pantothenate ($C_{18}H_{32}CaN_2O_{10}$) in the portion of the sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of calcium pantothenate from the *Sample solution*
$r_S$ = peak response of calcium pantothenate from the *Standard solution*
$C_S$ = concentration of USP Calcium Pantothenate RS in the *Standard solution* (mg/mL)
$C_U$ = nominal concentration of calcium pantothenate in the *Sample solution* (mg/mL)

- **Chromatographic Methods, Procedure 3**

This procedure can be used to determine calcium pantothenate in:

- *Oil- and Water-Soluble Vitamins Oral Solution*
- *Oil- and Water-Soluble Vitamins with Minerals Oral Solution*
- *Water-Soluble Vitamins with Minerals Oral Solution*

This procedure involves diluting an appropriate quantity of the liquid sample with water to a final concentration of 80 µg/mL of calcium pantothenate.

Unless specified in the individual monographs, the *Standard solution*, *System suitability solution*, *Sample solution*, and reagent solutions are prepared as follows.

**Mobile phase:** 0.2 M monobasic sodium phosphate and methanol (97:3). Adjust with 1.7 M phosphoric acid to a pH of 3.2 ± 0.1.

**Standard solution:** 80 µg/mL of USP Calcium Pantothenate RS in *Mobile phase*

**System suitability solution:** 80 µg/mL of USP Racemic Panthenol RS in *Mobile phase*. Mix the resulting solution and *Standard solution* (1:1).

**Sample solution:** Equivalent to 80 µg/mL of calcium pantothenate from the oral solution in *Mobile phase*

**Chromatographic system**

(See *Chromatography* ⟨621⟩*, System Suitability*.)

**Mode:** LC

**Detector:** UV 210 nm

$C_U$ = nominal concentration of calcium pantothenate in the *Sample solution* (mg/mL)

• **Chromatographic Methods, Procedure 4**
This procedure can be used to determine calcium pantothenate in:
- Active pharmaceutical ingredients
- Dietary ingredients

This procedure involves the dissolution of the sample directly into water.
Unless specified in the individual monographs, the *Standard solution*, *System suitability solution*, *Sample solution*, and reagent solutions are prepared as follows.
**Buffer solution:** Dissolve 3.2 g of monobasic sodium phosphate in 1 L of water and adjust with 1 N sodium hydroxide to a pH of 5.5.
**Mobile phase:** Acetonitrile and *Buffer solution* (2:98)
**System suitability solution:** 0.1 mg/mL of USP Calcium Pantothenate RS and 0.5 mg/mL each of USP Beta Alanine RS, USP Sodium D-Pantoate RS, and USP Pantolactone RS in water
**Standard solution:** 0.5 mg/mL of USP Calcium Pantothenate RS in water
**Sample solution:** 0.5 mg/mL of Calcium Pantothenate in water
**Chromatographic system**
(See *Chromatography* ⟨621⟩, *System Suitability*.)
**Mode:** LC
**Detector:** UV 200 nm
**Column:** 4.6-mm × 25-cm; 5-µm packing L1
**Column temperature:** 35°
**Flow rate:** 2 mL/min
**Injection volume:** 10 µL

**System suitability**
**Samples:** *System suitability solution* and *Standard solution*
[Note—The relative retention times for beta alanine, pantoic acid, pantothenic acid, and pantolactone are 0.3, 0.6, 1.0, and 1.9 min, respectively.]
**Suitability requirements**
**Resolution:** NLT 5.0 between the pantothenic acid and pantoic acid peaks, *System suitability solution*
**Tailing factor:** NMT 2.0, *Standard solution*
**Relative standard deviation:** NMT 2.0%, *Standard solution*

**Analysis**
**Samples:** *Standard solution* and *Sample solution*
Calculate the percentage of calcium pantothenate ($C_{18}H_{32}CaN_2O_{10}$) in the portion of the sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of calcium pantothenate from the *Sample solution*
$r_S$ = peak response of calcium pantothenate from the *Standard solution*
$C_S$ = concentration of USP Calcium Pantothenate RS in the *Standard solution* (mg/mL)
$C_U$ = concentration of Calcium Pantothenate in the *Sample solution* (mg/mL)

# ⟨92⟩ GROWTH FACTORS AND CYTOKINES USED IN CELL THERAPY MANUFACTURING

## INTRODUCTION

Qualification of reagents, source materials, and control of the manufacturing process are key elements that ensure the quality and safety of cell therapies. Growth factors and cytokines are important for the maintenance, growth, selection, and purification of cultures of cell therapy products. This chapter describes the accepted tests, procedures, and acceptance criteria for growth factors and cytokines that may be involved in the manufacturing of cell therapy products.

**RECOMBINANT HUMAN INTERLEUKIN 4 (rhIL-4)**

| MREKYSKCSS | | | |

$C_{658}H_{1071}N_{193}O_{197}S_8$ 15,096 Da

rhIL-4 is a single-chain polypeptide of 130 amino acid residues expressed in *Escherichia coli*. It is produced as a lyophilized powder and contains NLT $0.5 \times 10^7$ USP Units of IL-4/mg of total protein. Process specific host-cell DNA impurities in IL-4 with limits of less than 1 ng/mg are determined as described in *Nucleic Acid-Based Techniques—Approaches for Detecting Trace Nucleic Acids (Residual DNA Testing)* ⟨1130⟩. Neither manufacturing license nor market approval is required for IL-4 intended for use as an ancillary material during manufacturing. Following are typical IL-4 quality attributes.

## IDENTIFICATION

- **A.** Amino-terminal sequence analysis of at least eight amino acids is performed with an automated sequencer. Stepwise-released phenylthiohydantoin amino acids are identified with on-line reversed-phase high-performance liquid chromatography, on the basis of their elution times.
- **B.** Use the electrophoresis method followed by western blotting analysis to visualize the IL-4 protein. The method is sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE), described in the test for *Purity*.

  **Phosphate buffered saline; Laemmli sample buffer, reducing;** and **Laemmli sample buffer, nonreducing:** Proceed as directed in the test for *Purity* in the *Assay*.

  **Standard stock solution:** 50 µg/mL of reconstituted USP rHuman Interleukin 4 RS in *Phosphate buffered saline*. [NOTE—Do not agitate while mixing; swirl gently.]

  **Standard solution:** 20 µg/mL of IL-4, from *Standard stock solution*, in *Phosphate buffered saline*

  **Standard solution, reducing:** Combine 20 µL of *Standard solution* and 5 µL of *Laemmli sample buffer, reducing*.

  **Standard solution, nonreducing:** Combine 20 µL of *Standard solution* and 5 µL of *Laemmli sample buffer, nonreducing*.

  **Sample stock solution:** 50 µg/mL of reconstituted IL-4 in *Phosphate buffered saline*. [NOTE—Do not agitate while mixing; swirl gently.]

  **Sample solution:** 20 µg/mL of IL-4, from *Sample stock solution*, in *Phosphate buffered saline*

  **Sample solution, reducing:** Combine 20 µL of *Sample solution* and 5 µL of *Laemmli sample buffer, reducing*.

  **Sample solution, nonreducing:** Combine 20 µL of *Sample solution* and 5 µL of *Laemmli sample buffer, nonreducing*.

  **Analysis**

  **Samples:** *Standard solution, reducing; Standard solution, nonreducing; Sample solution, reducing;* and *Sample solution, nonreducing*

  **Western blotting:** After electrophoresis, the proteins are transferred onto a polyvinylidene fluoride (PVDF) membrane using standard procedures. Incubate the membrane for 1 h at room temperature with *Phosphate buffered saline* containing 0.1% Tween 20 and 5% skim milk powder. The membrane is then incubated with an anti-IL-4 antibody[1] (diluted appropriately in *Phosphate buffered saline*), followed by incubation with a secondary antibody at room temperature under gentle agitation for 1 h for each of the antibodies. The IL-4 protein band is identified by developing the membrane using a suitable detection system.[2]

  **Acceptance criteria:** The developed Western blot should give a positive signal equivalent to the USP rHuman Interleukin 4 RS.

## ASSAY

- **PURITY:** [NOTE—Purity is determined on the bulk material.] SDS-PAGE is performed as described under *Biotechnology-Derived Articles—Polyacrylamide Gel Electrophoresis* ⟨1056⟩ under reducing and nonreducing conditions.

  **Molecular weight marker:** Use a suitable molecular weight marker containing protein bands between 10 and 200 kDa.

  **Phosphate buffered saline:** 2.67 mM of potassium chloride, 1.47 mM of potassium phosphate ($KH_2PO_4$), 137.93 mM of sodium chloride, and 8.06 mM of dibasic sodium phosphate in water. Adjust to a pH of 7.0–7.3.

  **Laemmli sample buffer, nonreducing:** 100 mM TRIS-HCl, pH 6.8, 50% glycerol, 0.25% bromophenol blue indicator, and 10% sodium lauryl sulfate in water

  **Laemmli sample buffer, reducing:** Add 2.5 µL mercaptoethanol to 50 µL of *Laemmli sample buffer, nonreducing*.

  **Sample stock solution:** 400 µg/mL of bulk IL-4 in *Phosphate buffered saline*

[1] A suitable anti-IL-4 antibody can be obtained from commercial sources (e.g., Dianova Inc.).
[2] A suitable detection system can be obtained from commercial sources (e.g., Pierce/Perbio Science).

**Sample solution 1:** Combine 20 µL of *Sample stock solution* and 5 µL of *Laemmli sample buffer, nonreducing*.
**Sample solution 2:** Combine 20 µL of *Sample stock solution* and 5 µL of *Laemmli sample buffer, reducing*.
**Control A stock solution:** 4 µg/mL of IL-4, from *Sample stock solution*, in *Phosphate buffered saline*. [NOTE—*Control A solutions* are run in triplicates in both reducing and nonreducing conditions.]
**Control A solution 1:** Combine 20 µL of *Control A stock solution* and 5 µL of *Laemmli sample buffer, nonreducing*.
**Control A solution 2:** Combine 20 µL of *Control A stock solution* and 5 µL of *Laemmli sample buffer, reducing*.
**Control B stock solution:** 12 µg/mL of IL-4, from *Sample stock solution*, in *Phosphate buffered saline*. [NOTE—*Control B solutions* are run in duplicates in both reducing and nonreducing conditions.]
**Control B solution 1:** Combine 20 µL of *Control B stock solution* and 5 µL of *Laemmli sample buffer, nonreducing*.
**Control B solution 2:** Combine 20 µL of *Control B stock solution* and 5 µL of *Laemmli sample buffer, reducing*.
**Electrophoretic conditions**
(See *Biotechnology-Derived Articles—Polyacrylamide Gel Electrophoresis* ⟨1056⟩.)
**Mode:** Discontinuous PAGE gel
**Stacking gel:** 4% acrylamide
**Resolving gel:** 12% acrylamide
**Run conditions:** 10 min at 100 V; then 30 min at 200 V
**Protein detection:** Silver stain
**Analysis**
**Samples:** *Sample solution 1, Sample solution 2, Control A solution 1, Control A solution 2, Control B solution 1*, and *Control B solution 2*
Incubate 25 µL of each *Sample solution* and *Control solution* under nonreducing conditions for 5 min at 60°, and load onto the gel. Incubate 20 µL of each *Sample solution* and *Control solution* under reducing conditions for 5 min at 60°, and load onto the gel. After silver staining and scanning the whole gel, determine the intensity of all detectable protein bands by densitometry, and calculate the percentage of each detectable protein band, in the *Sample solution*, twice by comparing the pixel intensity of each contaminating band with the mean value of *Control solutions A* and *B*, respectively, by the formulas:

$$\text{Result} = (A_{100}) \times 1/(A_1) \text{ and}$$

$$\text{Result} = (A_{100}) \times 3/(A_3)$$

$A_{100}$ = intensity of one contaminating band of the *Sample solution*
$A_1$ = mean intensity of all detectable bands of *Control A solution*
$A_3$ = mean intensity of all detectable bands of *Control B solution*

IL-4 control solutions analysis should yield one detectable band with an apparent molecular weight of approximately 15 kDa. If values calculated by means of *Control A solution* are different from those revealed by comparison with *Control B solution*, the value corresponding to the highest amount of impurity should be taken. If the intensity of one of the contaminating bands is lower than the value of *Control A solution* (corresponding to 1%), the value of this contamination is set to 1%. The purity of the sample solution is then calculated:

$$\text{Result} = 100 - \Sigma\, C_n$$

C = percentage of each contamination given in rounded whole numbers
n = number of contaminants of the IL-4 *Sample solution*

**Acceptance criteria:** The purity of IL-4 is NLT 97%, as determined by SDS-PAGE.

• **PROTEIN CONTENT:** [NOTE—Protein content is determined on the basis of the packaged product.]
**Phosphate buffered saline:** Proceed as directed in the test for *Purity*.
**Sample solution:** 50 µg/mL of IL-4 in *Phosphate buffered saline*. [NOTE—Do not agitate while mixing; swirl gently.]
**Blank:** *Phosphate buffered saline*
**Spectrometric conditions**
(See *Ultraviolet-Visible Spectroscopy* ⟨857⟩.)
**Mode:** UV
**Pathlength:** 1 cm
**Analytical wavelength:** 280 nm
**Analysis**
**Samples:** *Sample solution* and *Blank*
Calculate the protein concentration:

$$C = A_{280}/0.63$$

C = IL-4 concentration of the *Sample solution* (mg/mL)
$A_{280}$ = absorbance at 280 nm

## SPECIFIC TESTS

| | |
|---|---|
| Human rGM-CSF[a] | $3 \times 10^4$ International Units |

[a] Granulocyte-Macrophage Colony-Stimulating Factor (GM-CSF) is added extemporaneously.

Sterilize by filtration, and store at between 2° to 8°. Use within 1 month. Add GM-CSF immediately before use.

**Assay medium:** Use *Growth medium* containing no GM-CSF.

**Phosphate buffered saline:** Proceed as directed in the test for *Purity* in the *Assay*.

**Resazurin solution:** 11 mg of resazurin in 100 mL of *Phosphate buffered saline*. [NOTE—Sterile filter and store solution protected from light at 4°. *Resazurin solution* is stable for at least 6 months if treated under sterile conditions.]

[NOTE—For all *Standard* and *Sample solutions*, IL-4 concentration is determined by photometry at 280 nm using an extinction coefficient (ε) of 0.63 $mg^{-1}cm^{-1}$.]

**Standard stock solution:** 50 µg/mL of USP rHuman Interleukin 4 RS in *Phosphate buffered saline*. [NOTE—Do not agitate while mixing; swirl gently.]

**Standard solutions:** 36, 12, 4, 1.33, 0.44, 0.15, 0.05, 0.016, 0.006 ng/mL of IL-4, from *Standard stock solution* in *Assay medium*

**Sample stock solution:** 50 µg/mL of IL-4 in *Phosphate buffered saline*. [NOTE—Do not agitate while mixing; swirl gently.]

**Sample solutions:** 36, 12, 4, 1.33, 0.44, 0.15, 0.05, 0.016, 0.006 ng/mL of IL-4, from *Sample stock solution* in *Assay medium*

**Control solution:** Use the *Assay medium*.

**Cell culture preparation:** Prepare cell cultures of the human factor-dependent TF-1 cell line (ATCC No. CRL-2003), following the protocol described in the ATCC information sheet. Passage the cultures every 2–3 days, using 1:3 subcultures of the cells for up to 1 month. Seed density should be $0.5 \times 10^6$ cells/mL, and maximal density should be $3 \times 10^6$ cells/mL. Viability of the cells should be >90%. Maximal passage number is 24, and maximal cultivation time from thawing is 28 days. After 28 days, initiate a new culture. Cells are propagated using *Growth medium* at 37°, supplemented with air and 5% carbon dioxide.

**Analysis**

**Samples:** *Standard solutions, Sample solutions,* and *Control solution*

The activity of the *Sample solution* is determined in duplicate. Wash the cells three times in *Phosphate buffered saline*. Plate $2 \times 10^4$ TF-1 cells resuspended in 100 µL of *Assay medium* per well in 96-well, flat-bottom microplates. Incubate for 72 h at 37° and 5% $CO_2$ atmosphere in a humidified incubator in the presence or absence of various concentrations of *Standard solution, Sample solution*, or *Control solution* by adding 100 µL of the corresponding solution to each well. Add 30 µL of *Resazurin solution* to each well and incubate for another 24 h. Determine the fluorescence intensity per well by reading the plate with a microplate reader using 544 nm (excitation) and 590 nm (emission). Convert the fluorescence intensity in each well to a percentage of the maximum fluorescence intensity. For the *Sample solution* and *Standard solution*, plot the percentage of fluorescence intensity versus the concentration of the respective solution. By using the least squares method of regression analysis, compute the ED50 in ng/mL of the *Sample solution* and the *Standard solution*. The coefficient of determination for curve regression should be $\geq 0.98$. Calculate the potency in USP Interleukin 4 Units/mg:

$$\text{Result} = A \times E_S/E_U$$

A = activity of USP rHuman Interleukin 4 RS (USP units/mg)
$E_S$ = determined $ED_{50}$ of *Standard solution* (ng/mL)
$E_U$ = determined $ED_{50}$ of *Sample solution* (ng/mL)

**Acceptance criteria:** NLT $0.5 \times 10^7$ USP IL-4 Units/mg

- **STERILITY TESTS** ⟨71⟩: Meets the requirements
- **BACTERIAL ENDOTOXINS TEST** ⟨85⟩: It contains NMT 50 USP Endotoxin Units/mg.

## ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in tight containers, and store at –80°.
- **LABELING:** Material is of recombinant DNA origin.
- **USP REFERENCE STANDARDS** ⟨11⟩

# ⟨111⟩ DESIGN AND ANALYSIS OF BIOLOGICAL ASSAYS

## INTRODUCTION

The potency of several Pharmacopeial articles must be determined by bioassays. The aim of this chapter is to present a concise account of certain essential biometrical procedures for bioassays in chapters or monographs of *USP–NF*, namely outlier identification, confidence intervals for relative potency measurements, and combination of independent assays. For bioassays not in *USP–NF*, other methods may be appropriate. See general information chapter *Analysis of Biological Assays* ⟨1034⟩ which may be a helpful, but not mandatory, guidance.

## REJECTION OF OUTLYING OR ABERRANT OBSERVATIONS

A response that is questionable because of failure to comply with the procedure during the course of an assay is rejected. Other aberrant values may be discovered only after the responses have been tabulated, but can then be traced to assay irregularities that justify their omission. The arbitrary rejection or retention of an apparently aberrant response can be a serious source of bias. In general, the rejection of observations solely on the basis of their relative magnitudes, without investigation as to cause, is a procedure to be used sparingly. Should it be understood, either following an investigation into cause or based on practical assay experience, that an observation's discordance is unlikely to arise from a reasonable expectation of response to assay treatments, then a suspected aberrant response or outlier may be tested against one of two criteria, both of which assume that the data have an approximately normal distribution (which may be satisfied only after a suitable transformation of the original responses). Alternative statistically sound approaches to outlier detection may be used. The conditions under which outlier testing will be conducted and the criterion to be used should be specified a priori in the lab's procedures if not specified in the monograph or chapter.

### Criterion 1 (Dixon's Test)

The first criterion is based on the variation within a single group of supposedly equivalent responses, such as a group of animals given a common concentration of a sample. At a confidence level of 99%, a valid observation will be rejected once in 100 trials (when the suspected outlier can occur at only one end) or once in 50 trials (when the suspected outlier can occur at either end), provided that relatively few, if any, responses within the group are identical. Arrange the responses in order of magnitude from $y_1$ to $y_N$, where $N$ is the number of observations in the group. Compute the relative gap by using the formulas in *Table 1* below.

**Table 1**

| Sample Size ($N$) | Candidate Outlier is Smallest ($y_1$) | Candidate Outlier is Largest ($y_N$) |
|---|---|---|
| 3–7 | $G_1 = (y_2 - y_1)/(y_N - y_1)$ | $G_1 = (y_N - y_{N-1})/(y_N - y_1)$ |
| 8–10 | $G_2 = (y_2 - y_1)/(y_{N-1} - y_1)$ | $G_2 = (y_N - y_{N-1})/(y_N - y_2)$ |
| 11–13 | $G_3 = (y_3 - y_1)/(y_{N-1} - y_1)$ | $G_3 = (y_N - y_{N-2})/(y_N - y_2)$ |

If $G_1$, $G_2$, or $G_3$, as appropriate, exceeds the critical value in *Table 2*, for the observed $N$, there is a statistical basis for identifying the discordant measurement as an outlier and considering its removal. For $N$ larger than 13, use *Criterion 2*.

In samples from a normal population, at a confidence level of 99%, gaps equal to or larger than the following values of $G_1$, $G_2$, and $G_3$ occur with a probability $P = 0.01$, when outlier measurements can occur only at one end; or with $P = 0.02$, when they may occur at either end.

**Table 2. Test for Outlier Measurements**

| | | | | | |
|---|---|---|---|---|---|
| $N$ | 3 | 4 | 5 | 6 | 7 |
| $G_1$ | 0.988 | 0.889 | 0.780 | 0.698 | 0.637 |
| | | | | | |
| $N$ | 8 | 9 | 10 | — | — |
| $G_2$ | 0.683 | 0.635 | 0.597 | — | — |
| | | | | | |
| $N$ | 11 | 12 | 13 | — | — |
| $G_3$ | 0.679 | 0.642 | 0.615 | — | — |

### Criterion 2 (Grubbs, Extreme Studentized Deviate Test)

The second criterion may be used to examine for outlying values in groups of supposedly equivalent responses and may also be used in examining the set of residuals from a fitted model (linear or nonlinear) where there is constant variance. The final

@2024 USPC
DOI: https://doi.org/10.31003/USPNF_M98860_03_01

model (which yields the residuals for outlier detection) should include all important design variables. (For further discussion of design variables, see general information chapter *Design and Development of Biological Assays* ⟨1032⟩, which may be a helpful, but not mandatory, resource.) (Note that for application to residuals, the following is an approximation. If the statistical software provides studentized residuals, those values should be used instead of those from the following equation.) For the value, *R*, that is furthest from the sample mean, compute the standardized deviation *Z*:

$$Z = (R - \overline{R})/S$$

where $\overline{R}$ and *S* are the mean and standard deviation, respectively, of the set of values. For residuals from a least squares fit, such as for a parallel line assay, $\overline{R} = 0$, and *S* is the square root of the residual mean square from the analysis. If $|Z|$ is greater than *C* as determined below, then the value *R* is identified as a statistical outlier at the 1% level.

$$C = \frac{(N - 1)t_{df - 1,p}}{\sqrt{N(N - 2 + t^2_{df - 1,p})}}$$

where *N* is the sample size, *t* is the one-sided 100*p* percentage point from the *t* distribution with *df* the degrees of freedom associated with *S*:

$$p = 1 - \frac{0.01}{2N}$$

Alternative outlier methods are available that are intended for use on data sets that may contain multiple outliers and for detection of outliers associated with the bioassay design or model. For further discussion of outliers, see general information chapter *Analytical Data—Interpretation and Treatment* ⟨1010⟩, which may be a helpful, but not mandatory, resource.

## THE CONFIDENCE INTERVAL AND LIMITS OF POTENCY

The following method (Fieller's) is used to determine the confidence interval for an estimate of log relative potency from a parallel line assay or a slope ratio assay. Let $M = a/b$ be the ratio for which we need a confidence interval. For the estimates, *a* and *b*, we have their respective standard errors, $SE_a$ and $SE_b$, and a covariance between them, denoted *Cov*. The confidence interval, ($M_{Low}$, $M_{Up}$), for the estimated log relative potency then is as follows:

$$(M_{Low}, M_{Up}) = \left\{ \frac{M - \frac{gCov}{SE_b^2} \pm \frac{t}{b}\sqrt{\left(1 - g\right) SE_a^2 + M^2 SE_b^2 - 2MCov + \frac{gCov^2}{SE_b^2}}}{1 - g} \right\}$$

where:

$$g = \frac{t^2 SE_b^2}{b^2}$$

and $t = t_{df,\alpha/2}$ is the upper α/2 percentage point (or the two-sided α percentage point) with the residual degrees of freedom, *df*, from the statistical analysis and chosen confidence level, 100*(1–α), (usually 95%). If $g \geq 1$, it means that the denominator, *b*, is not statistically significantly different from 0 and the use of the ratio is not sensible for those data. The length, *L*, of this confidence interval is $M_{Up} - M_{Low}$.

For those cases in which the estimates of *a* and *b* are statistically uncorrelated (*Cov* = 0), the confidence interval formula simplifies to the following:

$$(M_{Low}, M_{Up}) = \left\{ \frac{M \pm \frac{t}{b}\sqrt{\left(1 - g\right) SE_a^2 + M^2 SE_b^2}}{1 - g} \right\}$$

For further discussion of confidence intervals for potency, see chapter ⟨1034⟩ which may be a helpful, but not mandatory, resource.

***Change to read:***

## COMBINATION OF INDEPENDENT ASSAYS

When the monograph or chapter permits, multiple independent assays may be performed until the combined results reduce the confidence interval width to within the limits specified in the pertinent monograph or chapter. Where two or more

Official

https://pharmacopeia.cn/v29240/

independent assays are required, each leading to a log-potency *M*, the *M*'s are combined using one of the following two methods.

## Method 1

Let $M_i$ denote the logarithm of the relative potency of the *i*th assay of *h* assay results to be combined. To combine the *h* results, the mean, standard deviation, and standard error of the $M_i$ are calculated in the usual way:

$$\text{Mean } \overline{M} = \sum_{i=1}^{h} M_i/h$$

$$\text{Standard Deviation } S = \sqrt{\frac{1}{h-1}\sum_{i=1}^{h}\left(M_i-\overline{M}\right)^2}$$

$$\text{Standard Error } SE = S/\sqrt{h}$$

A 100(1 – α)% confidence interval is then found as:

$$\overline{M} \pm t_{h-1,\alpha/2}SE$$

where $t_{h-1,\alpha/2}$ is the upper α/2 percentage point (or the two-sided α percentage point) of a *t*-distribution with *h* – 1 degrees of freedom. The width, *L*, of this interval is $2t_{h-1,\alpha/2}SE$.

## Method 2

It is assumed that the results of each of the *h* assays have been analyzed to give *h* values of log potency with associated confidence limits. For each assay, *i*, obtain the confidence interval for the log potency or log relative potency. Then compute value $L_i$ by subtracting the *i*th lower confidence limit from the *i*th upper confidence limit. A weight $w_i$ for each value of the log relative potency, $M_i$, is calculated as follows, where $t_i$ has the same *t*-distribution value as that used in the calculation of confidence limits in the *i*th assay and is based on $n_i$ degrees of freedom:

$$W_i = \frac{4t_i^2}{L_i^2}$$

The products $w_iM_i$ are formed for each assay, and their sum is divided by the total weight (*w*) for all assays to give the weighted mean log relative potency and its standard error as follows:

$$\left.\begin{aligned} \text{Mean, } \overline{M} &= \sum_{i=1}^{h} w_iM_i/w \\ \text{Approximate Standard Error, } SE &= 1/\sqrt{w} \\ \text{where } w &= \sum_{i=1}^{h} w_i \end{aligned}\right\} \quad (1)$$

Next compute an approximate chi-square:

$$\chi^2_M = \sum_{i=1}^{h} w_i\left(M_i-\overline{M}\right)^2 = \sum_{i=1}^{h} w_iM_i^2 - w\overline{M}^2$$

If the value of the approximate $\chi^2_M$ is *well under* the 5% value shown in *Table 3*, compute the confidence interval using the mean and approximate standard error equations in (1) above; otherwise use *Alternate weights* as described below. Labs need to specify in their procedures how to quantify "well under". Absent such a specification, the 20% values of *Table 3* are suggested.

A 100(1 – α)% confidence interval in the log scale is then found as:

$$\overline{M} \pm L/2$$

$$\text{where } L = \frac{2t_{df,\alpha/2}}{\sqrt{w}}\sqrt{1+\frac{4}{w^2}\times\sum_{i=1}^{h}\frac{w_i\left(w-w_i\right)}{n_i'}}$$

$$n_i' = n_i - 4\times\frac{h-2}{h-1}$$

$$\text{and } df = \left.w^2\middle/\sum_{i=1}^{h} w_i^2/n_i\right.$$

@2024 USPC
DOI: https://doi.org/10.31003/USPNF_M98860_03_01

where $t_{N,\alpha/2}$ is the upper $\alpha/2$ percentage point (or the two-sided $\alpha$ percentage point) of a *t*-distribution with degrees of freedom, *df*. The width of this interval is *L*.

**Table 3. Critical Values for Approximate Chi-Square Test**

| | Critical Values | |
|---|---|---|
| ***h*** | **5%** | **20%** |
| 2 | 3.841 | 1.642 |
| 3 | 5.991 | 3.219 |
| 4 | 7.815 | 4.642 |
| 5 | 9.488 | 5.989 |
| 6 | 11.070 | 7.289 |
| 7 | 12.592 | 8.558 |
| 8 | 14.067 | 9.803 |
| 9 | 15.507 | 11.030 |
| 10 | 16.919 | 12.242 |

**Alternate weights:** The observed variation among the estimated log potencies or relative potencies can be divided into two components:

- intra-assay variation for assay *i*:
  $V_i = 1/w_i$
- inter-assay component of variation:

$$S_B^2 = \max\left\{0, \frac{1}{h-1}\sum_{i=1}^{h}\left(M_i - \overline{M}\right)^2 - \frac{1}{h}\sum_{i=1}^{h} V_i\right\}$$

▲▲ (ERR 1-Aug-2020)

For each assay, a weighting coefficient is then calculated as:

$$W_i' = \frac{1}{V_i + S_B^2}$$

The confidence interval is then found as:

$$\overline{M} \pm t \times SE',$$
$$\text{where } SE' = 1\sqrt{w'} \text{ and } w' = \sum_{i=1}^{h} w_i'$$

and *t*, the *t-distribution value*, is often approximated by the value 2.

For further discussion of combination of assays, see ⟨1034⟩, which may be a helpful, but not mandatory, resource.

# ⟨115⟩ DEXPANTHENOL ASSAY

## INTRODUCTION

The following liquid chromatographic procedure is provided for the determination of dexpanthenol as a component in dietary supplements or pharmaceutical dosage forms.

While conducting this procedure, protect solutions containing and derived from the test specimen and the Reference Standards from the atmosphere and light, preferably with the use of low-actinic glassware. Use the appropriate USP Reference Standards.

## ASSAY

• **Chromatographic Methods, Procedure 1**

This procedure can be used to determine dexpanthenol in:

- *Oil- and Water-Soluble Vitamins Oral Solution*
- *Oil- and Water-Soluble Vitamins with Minerals Oral Solution*
- *Water-Soluble Vitamins with Minerals Oral Solution*

Unless specified in the monograph, the *Standard solution*, *System suitability solution*, and *Sample solution* are prepared as follows.

**Mobile phase:** 0.2 M monobasic sodium phosphate and methanol (97:3). Adjust with 1.7 M phosphoric acid to a pH of 3.2 ± 0.1.

**Standard solution:** 80 µg/mL of USP Dexpanthenol RS in *Mobile phase*

**System suitability solution:** 80 µg/mL of USP Calcium Pantothenate RS in *Mobile phase*. Mix the resulting solution and *Standard solution* (1:1).

**Sample solution:** Equivalent to 80 µg/mL of dexpanthenol from Oral Solution in *Mobile phase*

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 210 nm

**Column:** 4.0-mm × 10-cm; packing L1

**Flow rate:** 1 mL/min

**Injection volume:** 20 µL

**System suitability**

**Samples:** *Standard solution* and *System suitability solution*

**Suitability requirements**

**Resolution:** NLT 1.5 between dexpanthenol and calcium pantothenate, *System suitability solution*

**Tailing factor:** NMT 2.0 for the dexpanthenol peak, *Standard solution*

**Relative standard deviation:** NMT 2.0%, *Standard solution*

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of dexpanthenol ($C_9H_{19}NO_4$) in the portion of the sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of dexpanthenol from the *Sample solution*

$r_S$ = peak response of dexpanthenol from the *Standard solution*

$C_S$ = concentration of USP Dexpanthenol RS in the *Standard solution* (mg/mL)

$C_U$ = nominal concentration of dexpanthenol in the *Sample solution* (mg/mL)

# ⟨121.1⟩ PHYSICOCHEMICAL ANALYTICAL PROCEDURES FOR INSULINS

## INTRODUCTION

Several physicochemical procedures are used for the assessment of the quality attributes of Insulin Human, various insulin analogues, and animal derived insulins, hereafter called insulins. Of these procedures, peptide mapping and determination of high molecular weight proteins are similar for the various insulin drug substances and drug products. This chapter describes the tests for peptide mapping and for quantitative analysis of high molecular weight proteins that can be used for the various insulins.

Specific instructions that deviate from the general procedures outlined here are given in the respective drug substance or drug product monographs for the different insulins.

### PEPTIDE MAPPING

Insulin digestion is performed using *Staphylococcus aureus* strain V8 (*S. aureus* V8) protease (also referred to as Endoproteinase Glu-C), a serine endoproteinase that cleaves at the C-terminal side of glutamyl and aspartyl residues in phosphate buffer at pH 7.8. This protease is specific for Glu-C digestion in ammonium bicarbonate or other non-phosphate-containing buffers at pH 7.8. The presence of proline on the carboxy side of the peptide bond inhibits cleavage. The buffer system used should cleave all glutamyl bonds in insulin without cleavage of the aspartyl bonds. In general, insulin is digested into four peptides in the buffer system described in the *Sample solution* below.

The following show the amino acid differences of the insulin analogues compared to Insulin Human and the *in silico* differences in the fragments obtained upon digestion with *S. aureus* V8 protease.

*Figure 1* shows the four fragments of Insulin Human following digestion with *S. aureus* V8 protease.

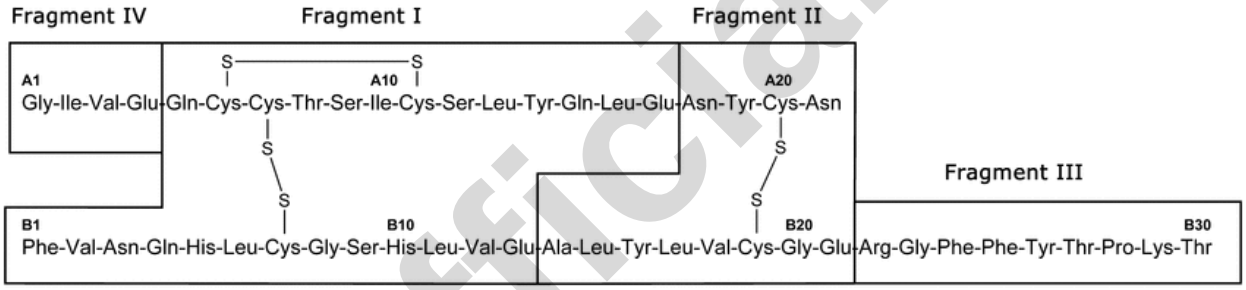

Figure 1. Insulin Human: *S. aureus* V8 protease digest fragments.

*Table 1* shows the amino acid differences between insulin analogues, animal derived insulins, and Insulin Human.

**Table 1. Amino Acid Differences between Insulin Analogues, Animal Derived Insulins, and Insulin Human**

| Insulin | Amino Acid Differences from Insulin Human |
|---|---|
| Insulin aspart | B28 Asp |
| Insulin glargine | A21 Gly, two Arg added to C-terminus of B chain |
| Insulin glulisine | B3 Lys, B29 Glu |
| Insulin lispro | B28 Lys, B29 Pro |
| Insulin porcine | B30 Ala |
| Insulin bovine | A8 Ala, A10 Val, B30 Ala |

*Table 2* shows specific *S. aureus* V8 protease digest fragments of insulin analogues and animal derived insulins. Amino acid differences compared to Insulin Human are highlighted.

**Table 2. Amino Acid Differences: Insulin Human, Insulin Analogues, and Animal Derived Insulins (Differences with Insulin Human Are Shown in Boldface)**

| Insulin | Amino Acid Differences Compared to Insulin Human[a] | |
|---|---|---|
| Insulin aspart | Fragment III | (B22) Arg-Gly-Phe-Phe-Tyr-Thr-**Asp**-Lys-Thr (B30) |
| Insulin glargine | Fragment II | (A18) Asn-Tyr-Cys-**Gly** (A21) |
| | Fragment III | (B22) Arg-Gly-Phe-Phe-Tyr-Thr-Pro-Lys-Thr-**Arg**-**Arg** (B32) |
| Insulin glulisine | Fragment I | (B1) Phe-Val-**Lys**-Gln-His-Leu-Cys-Gly-Ser-His-Leu (B11) |
| | Fragment III | (B22) Arg-Gly-Phe-Phe-Tyr-Thr-Pro-**Glu**-Thr (B30) |
| Insulin lispro | Fragment III | (B22) Arg-Gly-Phe-Phe-Tyr-Thr-**Lys**-**Pro**-Thr (B30) |
| Insulin porcine | Fragment III | (B22) Arg-Gly-Phe-Phe-Tyr-Thr-Pro-Lys-**Ala** (B30) |

**Table 2. Amino Acid Differences: Insulin Human, Insulin Analogues, and Animal Derived Insulins (Differences with Insulin Human Are Shown in Boldface)** *(continued)*

| Insulin | Amino Acid Differences Compared to Insulin Human[a] | |
|---|---|---|
| | Fragment I | (A5) Gln-Cys-Cys-**Ala**-Ser-**Val**-Cys-Ser-Leu-Tyr-Gln-Leu-Glu (A17) |
| Insulin bovine | Fragment III | (B22) Arg-Gly-Phe-Phe-Tyr-Thr-Pro-Lys-**Ala** (B30) |

[a] A and B denote the A and B chains of insulin, respectively; numbers denote amino acid position in the chain.

- **Peptide Mapping Procedure**

The following procedure is applicable for preparing peptide maps of Insulin Human, insulin analogues, and animal derived insulins.

**HEPES buffer:** Dissolve 2.38 g of HEPES (*N*-2-hydroxyethylpiperazine-*N*′-2-ethanesulfonic acid) in about 90 mL of water in a 100-mL volumetric flask. Adjust with 5 M sodium hydroxide to a pH of 7.5, dilute with water to volume, and mix.

**Sulfate buffer:** 2.0 M ammonium sulfate and 0.5 M sulfuric acid (1:1). Mix, and filter.

- **Insulin Digestion**

The following procedure provides efficient cleavage of the glutamyl bonds of insulin. [Note—Volumes up to 20-fold higher can be used as long as the ratio of the solutions remains the same. If interfering autolysis byproducts are observed in the chromatogram when a digest of the enzyme alone is run, the enzyme-to-insulin ratio must be decreased and digestion time must be increased.]

**Enzyme solution:** Prepare a 1-mg/mL solution of *S. aureus* V8 protease in water (approximately 500 units/mg using casein as the substrate).

**Sample solution:** Prepare a 2.0-mg/mL solution of the insulin to be examined in 0.01 N hydrochloric acid. To a clean vial add 25 µL of the 2.0-mg/mL insulin solution, 100 µL of *HEPES buffer*, and 20 µL of *Enzyme solution* (final ratio is 25:100:20). Cap the vial, and incubate at 25° for 6 h. Stop the reaction by adding an equal volume of *Sulfate buffer*. Longer incubation times may be needed for analogues with poor solubility at pH 7.5.

**Standard solution:** Prepare at the same time and in the same manner a solution of the appropriate USP Insulin Reference Standard as directed in the *Sample solution*.

- **Peptide Fragment Determination**

Determine the peptide fragments using the following peptide mapping procedure (see *Biotechnology-Derived Articles—Peptide Mapping* ⟨1055⟩).

**Solution A:** Acetonitrile, water, and *Sulfate buffer* (100:700:200). Filter, and degas.

**Solution B:** Acetonitrile, water, and *Sulfate buffer* (400:400:200). Filter, and degas.

**Mobile phase:** See *Table 3*.

**Table 3**

| Time (min) | Solution A (%) | Solution B (%) |
|---|---|---|
| 0 | 95 | 5 |
| 3 | 95 | 5 |
| 30 | 41 | 59 |
| 35 | 20 | 80 |
| 40 | 95 | 5 |
| 50 | 95 | 5 |

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 214 nm

**Column:** 4.6-mm × 10-cm; 5-µm packing L1

**Column temperature:** 40°

**Flow rate:** 1 mL/min

**Injection volume:** 50–100 µL

**System suitability**

**Sample:** *Standard solution*

**Suitability requirements**

**Chromatogram comparability:** In the chromatogram obtained from the *Standard solution*, identify the peaks due to digest fragments I, II, III, and IV. The chromatogram of the *Standard solution* corresponds to that of the typical chromatogram provided with the appropriate USP Insulin Reference Standard.

**Resolution:** There should be complete separation of the peaks due to fragments II and III. The resolution is defined in the applicable insulin monograph.

**Tailing factor:** NMT 1.5 for digest fragments II and III

**Analysis**

**Samples:** *Sample solution* and *Standard solution*

Official

https://pharmacopeia.com/

Condition the *Chromatographic system* by running at initial conditions, $t$ = 0 min, for at least 15 min. Carry out a blank gradient program before injecting the digests. Separately inject equal volumes of the *Standard solution* and the *Sample solution*, and record the responses of each peak.

**Acceptance criteria:** The chromatographic profile of the *Sample solution* corresponds to that of the *Standard solution*.

## LIMIT OF HIGH MOLECULAR WEIGHT PROTEINS

• **PROCEDURE**

**Solution A:** 1 mg/mL of L-arginine in water

**Mobile phase:** *Solution A*, acetonitrile, and glacial acetic acid (65:20:15). Filter, and degas.

**Resolution solution:** Store a suitable amount of insulin drug substance at room temperature for a sufficient period of time (5–10 days, or as needed) to obtain insulin with more than 0.4% high molecular weight proteins. Prepare a 4-mg/mL solution in 0.01 N hydrochloric acid. Store the solution in a refrigerator, and use within 7 days. Alternatively, dissolve about 4 mg of USP High Molecular Weight Insulin Human RS in 1 mL of 0.01 N hydrochloric acid.

**Sample solution:** In a small vial, prepare a 4-mg/mL solution of insulin in 0.01 N hydrochloric acid, and mix to dissolve. Store in a refrigerator, and use within 7 days.

**Chromatographic system**

(See *Chromatography* ⟨621⟩*, System Suitability*.)

**Mode:** LC

**Detector:** UV 276 nm

**Column:** 7.8-mm × 30-cm; 5- to 10-µm packing L20

**Temperatures**

**Autosampler:** It is advisable to use a refrigerated autosampler.

**Column:** Ambient

**Flow rate:** 0.5 mL/min

**Injection volume:** 100 µL

**System suitability**

**Sample:** *Resolution solution*

**Suitability requirements**

**Retention times:** Between 13 and 17 min for the polymeric insulin complexes, about 17.5 min for the covalent insulin dimer, and between 18 and 22 min for the insulin monomer, with salts eluting after the insulin monomer

**Peak-to-valley ratio:** The ratio of the height of the covalent insulin dimer peak to the height of the valley between the covalent insulin dimer peak and the insulin monomer peak is NLT 2.0.

**Analysis**

**Sample:** *Sample solution*

Disregard any peaks with retention times greater than that of the insulin monomer.

Calculate the percentage of high molecular weight proteins in the portion of Insulin taken:

$$\text{Result} = \Sigma r_H/(\Sigma r_H + r_M) \times 100$$

$\Sigma r_H$ = sum of the responses of all peaks with retention times less than that of the insulin monomer

$r_M$ = peak response of the insulin monomer

**Acceptance criteria:** As stated in the applicable insulin monograph

## ADDITIONAL REQUIREMENTS

# ⟨121⟩ INSULIN ASSAYS

***Change to read:***

## INTRODUCTION

The most prominent manifestation of insulin activity, an abrupt decrease in blood glucose, was the basis for biologic assay from the time of its first clinical use. The ▲bio▲ (USP 1-Dec-2020) assay, although relatively cumbersome, has the great merit of accurately reflecting the effect on the diabetic patient. The advent of practical yet sophisticated physicochemical methods (e.g., liquid chromatography) to measure insulin potency quantitatively has resulted in a more accurate and precise compendial test for insulin and insulin products. However, the bioidentity of insulin and insulin products cannot be assessed by these methods. Thus, a bioidentity test ▲▲ (USP 1-Dec-2020)is called for in the appropriate monographs.

▲Two options are provided: The *Rabbit Blood Sugar Method* can be used for any compendial insulin or insulin analog. The *In Vitro Cell-Based Bioidentity Test* can be used for Insulin glargine and Insulin lispro.▲ (USP 1-Dec-2020) The *Rabbit Blood Sugar Method—Quantitative* is used to determine the potency of Insulin Reference Standards, for the validation of the stability of new insulin preparations, and to determine the specific activities of insulin analogs.

## ASSAY

***Change to read:***

- **Rabbit Blood Sugar Method—Quantitative**

**Diluent:** Prepare an aqueous solution containing 0.1%–0.25% (w/v) of either cresol or phenol, 1.4%–1.8% (w/v) of glycerin, and sufficient hydrochloric acid to produce a pH between 2.5 and 3.5, unless otherwise directed in the individual monograph.

**Standard stock solution:** Prepare a solution containing 40 USP Insulin Units/mL of the USP Insulin Reference Standard of the appropriate species in *Diluent* and having a pH between 2.5 and 3.5, unless otherwise directed in the individual monograph. Store in a ▲refrigerator,▲ (USP 1-Dec-2020) protected from freezing, and use within 6 months.

**Standard solution 1:** Dilute a portion of the *Standard stock solution* with *Diluent* to contain 1.0 USP Insulin Unit/mL.

**Standard solution 2:** Dilute a portion of the *Standard stock solution* with *Diluent* to contain 2.0 USP Insulin Units/mL.

**Sample stock solution:** Prepare as directed in the *Standard stock solution*, except to use a suitable quantity of the preparation under test in place of the USP Insulin Reference Standard of the appropriate species. The *Sample stock solution* contains about 40 USP Insulin Units/mL.

**Sample solution 1:** Dilute a portion of the *Sample stock solution* with *Diluent* to make a dilution of the preparation under test. On the basis of the assumed potency, it is expected to contain 1.0 USP Insulin Unit/mL. In the case of neutral insulin injection, adjust to a pH of 2.5–3.5 before making the dilution.

**Sample solution 2:** Dilute a portion of the *Sample stock solution* with *Diluent* to make a dilution of the preparation under test. On the basis of the assumed potency, it is expected to contain 2.0 USP Insulin Units/mL. In the case of neutral insulin injection, adjust to a pH of 2.5–3.5 before making the dilution.

**Doses of the solutions to be injected:** Select, on the basis of trial or experience, the dose of the dilutions to be injected, the volume of which usually will be between 0.30 and 0.50 mL. For each animal, the volume of the *Standard solution* is the same as that of the *Sample solution*.

**Preparation of animal:** Select suitable, healthy rabbits, each weighing NLT 1.8 kg. Keep the rabbits in the laboratory for NLT 1 week before use in the assay, maintaining them on an adequate uniform diet, with water available at all times.

**Analysis:** Divide the rabbits into four equal groups of preferably NLT 6 rabbits each. On the preceding day, approximately 20 h before performing the assay, provide each rabbit with an amount of food that will be consumed within 6 h. Follow the same feeding schedule before each test day. During the assay, withhold all food until after the final blood specimen is taken. Handle the rabbits with care to avoid undue excitement, and inject subcutaneously the doses indicated in the following design (see *Table 1*), the second injection being made on the day after the first injection, or NMT 1 week later. The time between the first and second injections is the same for all rabbits.

**Table 1**

| Group | First Injection | Second Injection |
|---|---|---|
| 1 | *Standard solution 2* | *Sample solution 1* |
| 2 | *Standard solution 1* | *Sample solution 2* |
| 3 | *Sample solution 2* | *Standard solution 1* |
| 4 | *Sample solution 1* | *Standard solution 2* |

**Blood samples:** At 1 h ± 5 min and 2.5 h ± 5 min after the time of ▲each▲ (USP 1-Dec-2020) injection, obtain from each rabbit a suitable blood specimen from a marginal ear vein. Blood can also be collected effectively from the central auricular artery.

**Dextrose determination:** Determine the dextrose content of the blood specimens by a suitable procedure that is adapted to automated analysis. The following procedure may be used.

**Anticoagulant solution:** Dissolve 1 g of edetate sodium and 200 mg of sodium fluoride in 1 L of water, and mix.

**Dextrose standard preparations:** Transfer known concentrations of USP Dextrose RS to suitable vessels, and dilute quantitatively and stepwise with *Anticoagulant solution* (1:9) to obtain a range of *Dextrose standard preparations* containing 20–100 mg/100 mL, having known concentrations similar to the concentrations in the rabbit blood samples.

**Sample preparations:** Pipet into separate, suitable vessels 0.1 mL of each *Blood sample* and 0.9 mL of *Anticoagulant solution*.

**Analysis:** Subject the *Sample preparations* to dialysis across a semipermeable membrane for a sufficient time so that the dextrose passes through the membrane into a saline TS solution containing glucose oxidase, horseradish peroxidase, 3-methyl-2-benzothiazolinone hydrazone hydrochloride TS, and *N,N*-dimethylaniline. The absorbances of the *Sample preparations* are determined at 600 nm in a recording colorimeter. The absorbances of the *Dextrose standard preparations* are similarly determined at the start and the end of each run.

**Calculation:** Calculate the response of each rabbit to each injection from the sum of the two blood sugar values, and subtract its response, disregarding the chronological order in which the responses were observed, to obtain the individual differences, *y*, as shown in *Table 2*.

When the data for one or more rabbits are missing in an assay, do not use the confidence interval formulas given here, but seek statistical help. The data can still be analyzed with proper analysis of variance.

When the number of rabbits, *f*, carried through the assay is the same in each group, total the *y*'s in each group and compute:

$$T_a = -T_1 + T_2 + T_3 - T_4$$

and

$$T_b = T_1 + T_2 + T_3 + T_4$$

The logarithm of the relative potency of the test dilutions is $M' = 0.301 T_a/T_b$. The potency of the injection in USP Units/mg equals the antilog (log $R + M'$), where:

$$R = v_S/v_U$$

$v_S$ = number of USP Units/mL of insulin in the *Standard solution*
$v_U$ = number of mg/mL of insulin in the corresponding *Sample solution*

**Table 2**

| Group | Differences | Individual Response (*y*) | Total Response (*T*) | Standard Deviation of Differences (*S*) |
|---|---|---|---|---|
| 1 | *Standard solution 2 – Sample solution 1* | $y_1$ | $T_1$ | $S_1$ |
| 2 | *Sample solution 2 – Standard solution 1* | $y_2$ | $T_2$ | $S_2$ |
| 3 | *Sample solution 2 – Standard solution 1* | $y_3$ | $T_3$ | $S_3$ |
| 4 | *Standard solution 2 – Sample solution 1* | $y_4$ | $T_4$ | $S_4$ |

Determine the 95% confidence interval for the log-relative potency using *Fieller's Theorem for Determining the Confidence Interval for a Ratio* as shown below. ▲▲ (USP 1-Dec-2020) If the confidence interval ▲width $(U - L)$▲ (USP 1-Dec-2020) is more than 0.082, which corresponds at P = 0.95 to confidence limits of about ±10% of the computed potency, repeat the assay until the combined data of the two or more assays, redetermined as described in *Design and Analysis of Biological Assays* ⟨111⟩, *Combination of Independent Assays*, meet this acceptable limit.

***Change to read:***

▲▲ (USP 1-Dec-2020)**Fieller's Theorem for Determining the Confidence Interval for a Ratio**

This version of Fieller's Theorem is for the case where the numerator and denominator are uncorrelated. The equation assumes that the numerator and denominator are normally distributed and that the groups of rabbits are of equal sizes.

Then, the 95% confidence interval ▲($L$: lower, $U$: upper)▲ (USP 1-Dec-2020) for the ratio is:

$$(L,U) = \frac{M' \pm \frac{t}{T_b}\sqrt{\left(1-g\right)S_N^2 + (M')^2 S_D^2}}{1-g}$$

where $f$ (degrees of freedom in the standard errors) = $4(k - 1)$, where $k$ is the number of rabbits in a group, $t$ is the upper 97.5 percentile of the $t$-distribution with $f$ degrees of freedom, and

$$g = \frac{t^2 S_D^2}{T_b^2}$$

If $g \geq 1$, the denominator is not significantly different from 0 and the formula does not work.

$$S_N = 0.301\sqrt{k}\sqrt{S_1^2 + S_2^2 + S_3^2 + S_4^2}$$
$$S_D = \sqrt{k}\sqrt{S_1^2 + S_2^2 + S_3^2 + S_4^2}$$

• ▲**IN VIVO**▲ (USP 1-Dec-2020) **BIOIDENTITY TEST**

Proceed as directed in *Rabbit Blood Sugar Method—Quantitative* with the following modifications.

**Procedure:** Divide the rabbits into four equal groups of 2 rabbits each.

**Calculation:** Proceed as directed for *Calculation* in *Rabbit Blood Sugar Method—Quantitative*, but do not determine the confidence interval of the log-relative potency, *M*′.

**Interpretation:** If the potency value obtained is NLT 15 USP Units/mg, then the ▲*In Vivo*▲ (USP 1-Dec-2020) *Bioidentity Test* requirement is met. If the potency value is less than 15 USP Units/mg, then repeat the test using 8 more rabbits. If the average potency of the two sets of tests is NLT 15 USP Units/mg, then the requirement of the test is met.

***Add the following:***

▲• **IN VITRO CELL-BASED BIOIDENTITY TEST FOR INSULIN GLARGINE AND INSULIN LISPRO**

**Minimal medium:** Ham's F-12 Nutrient Mixture containing 1 mM L-alanyl-L-glutamine[1]

**Growth medium:** 90% (v/v) Ham's F-12 Nutrient Mixture with 1 mM L-alanyl-L-glutamine, 10% (v/v) fetal bovine serum (FBS),[2] and 0.03% (w/v) hygromycin B

**D-PBS solution:** Dulbecco's phosphate-buffered saline without calcium and magnesium[3] containing 0.2 g/L of potassium chloride, 0.2 g/L of monobasic potassium phosphate, 8 g/L of sodium chloride, and 2.16 g/L of dibasic sodium phosphate.

**Fixing solution:** Prepare 3.7% (v/v) formaldehyde solution by diluting a commercially available 37% (w/v) formaldehyde solution with *D-PBS solution*. Prepare freshly before use.

**Permeabilization solution:** 0.1% (v/v) Triton® X-100 in *D-PBS solution*

**Washing solution:** 0.1% (v/v) polysorbate 20 in *D-PBS solution*

**Blocking buffer:** 2% (w/v) bovine serum albumin (BSA)[4] in *D-PBS solution*. [NOTE—Filtration of solution can be helpful to remove particles.]

**Blocking buffer for primary antibody:** 0.1% (v/v) polysorbate 20 in *Blocking buffer*

**Primary antibody solution:** Dilute an anti-phosphotyrosine antibody recognizing phosphotyrosines of insulin receptors in *Blocking buffer for primary antibody*. [NOTE—For example, dilute the anti-phosphotyrosine mouse monoclonal antibody[5] in *Blocking buffer* for primary antibody at 1:2000 when the antibody is at a concentration of 1 mg/mL. Use within 15 min after preparation.]

**Blocking buffer for secondary antibody:** 0.2% (v/v) polysorbate 20 in *Blocking buffer*

**Secondary antibody solution:** Dilute a suitable secondary antibody conjugated with a suitable fluorescent dye,[6] a fluorescent dye for cell staining,[7] and/or a suitable fluorescent dye for DNA staining[8] in *Blocking buffer for secondary antibody*. Protect the solution from light. [NOTE—See example on preparing a *Secondary antibody solution*.[9]]

**Cell culture preparation:** Culture CHO INSR 1284 cells[10] in *Growth medium* at 37° and 5% carbon dioxide ($CO_2$) atmosphere in a humidified incubator. Cells should be transferred when the cultures are approximately 70%–95% confluent. For cell transfer, remove the flasks from the incubator and discard the media. Rinse the cells with *D-PBS solution*. Add an appropriate amount of Accutase[11] to the cells and place in an incubator for about 5 min at 37°. Tap repeatedly on the flask in order to remove all cells from the flask bottom. Add an appropriate amount of *Growth medium* to stop the Accutase activity. Determine cell concentration and viability. Calculate the desired amount of cells for seeding depending on planned cultivation days. Cells are transferred into a T75 $cm^2$ flask with approximately 18 mL of *Growth medium* at $0.25 \times 10^5$ to $9 \times 10^5$ cells per flask or a T175 $cm^2$ flask with approximately 45 mL of *Growth medium* at $0.1 \times 10^6$ to $2 \times 10^6$ cells per flask.

**Preparation of cells for analysis**

**Plates:** Sterile 96-well, clear bottom, black[12]

**System suitability requirements for the cells**

**Viability:** NLT 85%

**Average % of cell aggregates:** NMT 15% of cell clumps. [NOTE—The clump is defined as a cluster containing more than 3 cells.]

For bioidentity test, a total of two plates of cells are needed to assay two independent dilutions of the *Standard solution* and the *Sample solution*. The maximal number of cell passages to be used is determined individually. Following the procedure described in *Cell culture preparation*, prepare an appropriate volume of cell solution at $0.5 \times 10^5$ to $1 \times 10^5$ viable cells/mL in *Growth medium* (see *Table 3* for examples of seeding densities).

**Table 3**

| Initial Cell Concentration (cells/mL) | Number of Cells Seeded per Well | Time Needed for Growth Prior to Analysis (days) |
|---|---|---|
| 100,000 | 20,000 ± 20% | 2 |
| 70,000 | 14,000 ± 20% | 3 |
| 50,000 | 10,000 ± 20% | 4 |

To the sterile plates add 0.2 mL of cell solution per well under aseptic conditions. Mix the cell solution frequently during dispensing to prevent cells from settling and to ensure consistent density throughout the plate. Cover the plates. Let the plates seeded with cells stand at room temperature for 30 min before transferring them into an incubator. Arrange the plates side by side, and do not stack up the plates. Incubate plates at 37° with 5% carbon dioxide ($CO_2$) for the indicated time as shown in *Table 3*. Verify even growth and 90% or higher confluency via microscope before *Analysis*. Following the incubation, remove media from the cells and wash each well with 200 µL of sterile *D-PBS solution*. Add 160 µL of sterile *Minimal medium* to each well. Incubate plates for 3–5 h at 37° with 5% carbon dioxide ($CO_2$). This last step is for cell media starvation prior to *Analysis*.

**Preparation of solutions for insulin glargine and insulin lispro**

Up to three different insulin samples can be tested in one assay. For bioidentity test, independently prepare *Standard solutions* and *Sample solutions* in duplicate that are assayed in two separate plates to obtain two intermediate potency results per sample.

[NOTE—All described dilutions except for stock solutions are to be carried out just prior to their application to the cells. For each black plate seeded with cells as described in *Preparation of cells for analysis*, one separate 96-well polypropylene plate can be used for preparation of the serial dilutions from one of the *Standard solution* or *Sample solution* duplicates.]

Preparation of the *Standard solution* and *Sample solution* and delivery to the cells must occur within 15 min when using plasticware.

**Insulin glargine**

**Standard stock solution:** 17 USP Insulin Glargine Units/mL of USP Insulin Glargine RS in 0.01 N hydrochloric acid

**Standard solutions:** 0.34 USP Insulin Glargine Units/mL prepared by diluting the *Standard stock solution* with *D-PBS solution*. Prepare in duplicate.

**Sample solutions:** 0.34 USP Insulin Glargine Units/mL of insulin glargine in *D-PBS solution*. Prepare in duplicate.

**Diluted standard solutions and sample solutions:** For each assay plate, prepare three separate dilution sets from one of the *Standard solution* and *Sample solution* preparations. The range of the concentrations of insulin glargine solutions to be added to the cells needs to be determined during method verification. Successful testing was demonstrated for a range of $340 \times 10^{-3}$ to $0.16 \times 10^{-3}$ USP Insulin Glargine Units/mL. The dilution can be prepared as follows. Add 200 µL of *D-PBS solution* into each well of a 96-well polypropylene plate, except those wells in row A. Next, add 300 µL of *Standard solution* into wells A1, A5, and A9 of the dilution plate. Add 300 µL of the first *Sample solution* into wells A2, A6, and A10; the second *Sample solution* into wells A3, A7, and A11; the third *Sample solution* into wells A4, A8, and A12. Perform simultaneously serial three-fold dilutions on the plate by transferring 100 µL of solution from the first row (A1–A12) to the second row, and mix three times. Then transfer 100 µL of solution from the second row to the third row, and mix three times. Repeat this procedure across the whole plate up to row H. Repeat the above for the replicate preparation.

**Insulin lispro**

**Dilution buffer:** 0.1% (w/v) BSA[4] in *D-PBS solution*. Prepare freshly before use.

**Standard stock solution:** 10 USP Insulin Lispro Units/mL of USP Insulin Lispro RS in 0.01 N hydrochloric acid

**Standard solutions:** 0.3 USP Insulin Lispro Units/mL in duplicate prepared by diluting the *Standard stock solution* with *Dilution buffer*

**Sample solutions:** 0.3 USP Insulin Lispro Units/mL of insulin lispro in *Dilution buffer*. Prepare in duplicate.

**Diluted standard solutions and sample solutions:** For each assay plate, prepare three separate dilution sets from one of the *Standard solution* and *Sample solution* preparations. The range of the concentrations of insulin lispro solutions to be added to the cells needs to be determined during method verification. Successful testing was demonstrated for a range of $300 \times 10^{-3}$ to $0.004 \times 10^{-3}$ USP Insulin Lispro Units/mL. The dilution can be prepared as follows. Dispense 300 µL of *Dilution buffer* into each well of a 96-well polypropylene plate, except those wells in rows A, B, and C. Add 180 µL of *Dilution buffer* into the wells of row B and C. Next, add 300 µL of *Standard solution* into wells A1, A5, and A9. Add 300 µL of the first *Sample solution* into wells A2, A6, and A10; the second *Sample solution* into wells A3, A7, and A11; the third *Sample solution* into wells A4, A8, and A12. Perform simultaneously serial dilutions on the plate by transferring 120 µL of solution from the first row (A1–A12) to the second row, and mix three times. Then transfer 60 µL of solution from the second row to the third row, and mix three times. Next transfer 60 µL of solution from the third row to the fourth row, mix three times, and repeat this procedure across the whole plate up to row H. Repeat the above for the replicate preparation.

**Analysis:** All solutions are added by pipetting them into the plate wells carefully without touching the bottom. Following cell starvation, add 40 µL per well of each *Diluted standard solution* or *Diluted sample solution* into appropriate wells of the plate. Since each well has contained 160 µL of *Minimal medium*, the *Diluted standard solution* and *Diluted sample* solution are further diluted by a factor of 5.

[NOTE—See *Table 4* for an example of the plate layout, which can be changed column by column for randomization purposes. See *Design and Development of Biological Assays 1032, 5. Stages in the Bioassay Development Process, 5.1 Design: Assay Layout, Blocking, and Randomization* for helpful information on randomization of samples and plate layout.]

**Legend:**
St,#1–#8 = *Diluted standard solutions* prepared from the dilution series of *Standard solutions*.
S1, S2, S3, #1–#8 = *Diluted sample solutions* prepared from the dilution series of *Sample solutions* of insulin samples 1, 2, and 3.
BG = Background; *Diluted standard solutions* at the lowest concentration serve as background.

[NOTE—All the steps below are performed at room temperature, unless otherwise specified.]

Incubate the plates at 37° with 5% carbon dioxide ($CO_2$) for 20 min. Discard the media and replace with 150 µL of freshly prepared *Fixing solution* per well. Incubate the plates for 20 min with constant gentle shaking. Discard the *Fixing solution*, and add 200 µL of *Permeabilization solution* to each well. Incubate the plates for 10 min with constant gentle shaking. Repeat the permeabilization step once. Discard the *Permeabilization solution* and add 300 µL of *Blocking buffer* to each well. Cover the plates. Incubate the plates at 2°–8° overnight without shaking.

Remove *Blocking buffer* and add 50 µL of freshly prepared *Primary antibody solution* to each well. Cover the plates. Incubate the plates for about 2 h with constant gentle shaking. Alternatively, before removing the *Blocking buffer*, incubate the plates at room temperature for 1 h with constant gentle shaking. Then remove the *Blocking buffer*, add freshly prepared *Primary antibody solution*, and cover the plates. Incubate at 2°–8° overnight without shaking.

Discard the *Primary antibody solution*, wash each well 5 times using 200 µL of *Washing solution* per well each time. Perform each wash step under constant gentle shaking for about 5 min. Apply 50 µL of freshly prepared *Secondary antibody solution* to each well. Incubate the plates protected from light (use black lids) for about 1 h with constant gentle shaking. Discard the *Secondary antibody solution*. Wash each well 5 times using 200 µL of *Washing solution* per well each time. Perform each wash step under constant gentle shaking for about 5 min. Add 200 µL of *Washing solution* per well and leave the solution in until measurement. Protect the plates from light. [NOTE—The plates containing the *Washing solution* can be stored at 2°–8° for a maximum of 24 h and protected from light]

Read the plate in a suitable microplate reader or scanner with appropriate excitation and emission wavelengths.

**Instrumental conditions**

**Mode:** Fluorescence[13]

**Analytical wavelengths:** Appropriate excitation and emission wavelengths based on the fluorescent dyes used. Excitation wavelength for the secondary antibody signal needs to differ from the wavelength of the cell and/or DNA stain in order to enable parallel readout, for example, using about 800 nm to detect the secondary antibody and about 700 nm to detect DRAQ5™ DNA Dye and Sapphire700™.

**Calculations:** For each well of each assay plate, normalize (for number of cells per well) the assay signals detected from the secondary antibody that is bound to the primary antibody with the signals from the fluorescent dye for the cell staining and/or DNA fluorescent dye, which represent the total number of cells present for that well. The processed signal is derived from the normalized signal that is subtracted by the background signal. The background signal is the average of the normalized signals detected by the *Diluted standard solution* at the lowest concentration. If necessary, it can be multiplied with a factor smaller than 1.0 in order to avoid negative values at the lowest concentration after background subtraction.

Generate a dose-response curve by plotting the processed signal responses from each set of *Diluted standard solutions* or *Diluted sample solutions* from one assay plate against their concentrations on a logarithmic scale using a four parameter logistic (4-PL) constrained model. Therefore, three individual curves representing triplicate sets of *Diluted standard solutions* or *Diluted sample solutions* from each assay plate are generated. Determine the individual $EC_{50}$ value for the *Standard solution* or *Sample solution* from each of the curves of each assay plate.

[NOTE—The necessity of the responses to be weighted is to be determined during method verification. See *Design and Development of Biological Assays* ⟨1032⟩*, 4. Statistical Aspects of Bioassay Fundamentals, 4.8 Outliers* for helpful information on performing outlier detection and rejection, e.g., through a goodness-of-fit tool.]

Calculate the relative potency ($RP_{U,1\ or\ 2}$) percentage for each insulin sample from each assay plate:

$$RP_{U,x} = (EC_{50,S}/EC_{50,U}) \times 100$$

$EC_{50,S}$ = $EC_{50}$ value for the *Standard solution* from one assay plate
$EC_{50,U}$ = $EC_{50}$ value for the *Sample solution* from one assay plate

Calculate the geometric mean of the relative potency ($M_U$) of each insulin sample from both assay plates:

[13] Using a microplate reader with fluorescence detection, such as LI-COR Odyssey Infrared Imaging System or equivalent.

DocId: GUID-76345062-D120-4006-B133-AB1EA5CDAB75_6_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M98870_06_01
@2024 USPC

$$M_U = \sqrt{RP_{U,1} \times RP_{U,2}}$$

$RP_{U,1}$ = relative potency of an insulin sample from assay plate 1
$RP_{U,2}$ = relative potency of an insulin sample from assay plate 2

Calculate the potency of the insulin sample in USP Insulin Glargine Units/mg or USP Insulin Lispro Units/mg:

$$\text{Potency} = (C_S \times M_U)/(C_U \times 100)$$

$C_S$ = concentration of USP Insulin Glargine RS or USP Insulin Lispro RS in the *Standard stock solution* (USP Insulin Glargine Units/mL or USP Insulin Lispro Units/mL)
$M_U$ = geometric mean of the relative potency of each insulin sample from both assay plates
$C_U$ = initial concentration of insulin sample (mg/mL)

**Parallelism between standard and sample solution curves:** See *Design and Development of Biological Assays* ⟨1032⟩*, 4. Statistical Aspects of Bioassay Fundamentals, 4.7 Suitability Testing* for helpful information on determining the parallelism by assessing the slope ratio and the upper and lower asymptotes.
**Relative standard deviation for $EC_{50}$:** NMT 25% for three $EC_{50}$ values derived from the triplicate sets of *Diluted sample solutions* from the same assay plate using the 4-PL free model
**Relative bias for relative potency of each individual sample:** NMT 35%
Determine the relative bias (RB) for relative potency of each individual sample:

$$\text{RB} = [(RP_{U,1\text{ or }2}/M_U) - 1] \times 100$$

$RP_{U,1\text{ or }2}$ = relative potency of an insulin sample from assay plate 1 or 2
$M_U$ = average of the relative potency of each insulin sample from both assay plates

**System suitability**
Generate a dose-response curve by plotting the processed signal responses of all three sets of *Diluted standard solutions* or *Diluted sample solutions* from one assay plate against their concentrations on a logarithmic scale using a 4-PL free model. Therefore, one curve representing all three sets of *Diluted standard solutions* and one curve for all three sets of *Diluted sample solutions* from one assay plate are generated. Determine the $EC_{50}$ value for the *Standard solution* ($EC_{50,S}$) and *Sample solution* ($EC_{50,U}$) of each assay plate from the corresponding curve.
**Samples:** *Diluted standard solution* and *Diluted sample solution*
**Suitability requirements**
**Relative standard deviation for $EC_{50}$:** NMT 25% for three $EC_{50}$ values derived from the triplicate sets of *Diluted standard solutions* from the same assay plate using the 4-PL free model
**Signal-to-noise ratio:** The mean signal for the *Diluted standard solutions* at the highest concentration is NLT 1.5-fold of the mean signal for all *Diluted standard solutions* at the lowest concentration from the same assay plate.
**Acceptance criteria:** NLT 15 USP Insulin Units/mg on the as-is basis▲ (USP 1-Dec-2020)

# ⟨123⟩ GLUCAGON BIOIDENTITY TESTS

## INTRODUCTION

Glucagon is a peptide hormone that increases blood glucose levels via release of liver glycogen stores. A robust and precise physicochemical chromatographic procedure is used in the glucagon assay to assign potency on a mass basis. Bioidentity is still required in *Glucagon for Injection*, and two procedure options are presented here: an in vivo procedure based on release of glucose from freshly prepared rat liver cells (hepatocytes) stimulated with glucagon ex vivo or production of cyclic adenosine monophosphate (cAMP) in vitro in response to glucagon stimulation of the glucagon receptor cell line. To meet the acceptance criteria of the bioidentity test, only one of these bioidentity tests is required.

## PROCEDURE

***Change to read:***

• **A. Primary Liver Cell Bioidentity Test**

[Note—All buffers are oxygenated, prepared with either *Sterile Water for Injection* or *Sterile Water for Irrigation*, warmed to 37°, and adjusted to a final pH of 7.4 unless otherwise indicated. At least two independent assays (replicates) must be performed utilizing two rat livers for each lot of glucagon. *Figure 1* demonstrates the process used to generate one replicate value. A minimum of two replicates are combined according to the *Calculations* section. The concentration range of the *Standard preparations* and *Assay preparations* may be modified to fall within the linear range of the *Assay*, and the calculations can be adjusted accordingly. Alternatively, full curve analysis using validated nonlinear statistical methods can be used, provided that similarity is demonstrated when analysts compare the responses of the *Standard preparations* and *Assay preparations*.]

**Hepatocyte preparation**

**Calcium-free perfusion buffer with dextrose:** Prepare a solution containing 7.92 g/L of sodium chloride, 0.35 g/L of potassium chloride, 1.80 g/L of dextrose, 0.19 g/L of edetic acid (EDTA), and 2.38 g/L of 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid (HEPES). Oxygenate before use.

**Collagenase buffer:** Prepare a solution containing 3.62 g/L of sodium chloride, 23.83 g/L of HEPES, 0.35 g/L of potassium chloride, 0.52 g/L of calcium chloride, and 1.8 g/L of dextrose. Adjust to a pH of 7.6. Immediately before perfusion, dissolve a quantity of collagenase in this solution to obtain a concentration of 0.02%–0.05%. The exact concentration of collagenase is determined empirically for each new lot of enzyme and is the amount that can consistently dissociate the tissue within 10 min of buffer entry and produce a viable cell concentration of not less than $3 \times 10^6$ cells/mL.

**Wash buffer:** Prepare a solution containing 7.92 g/L of sodium chloride, 0.35 g/L of potassium chloride, 0.19 g/L of EDTA, 2.38 g/L of HEPES, 0.11 g/L of calcium chloride, and 0.06 g/L of magnesium sulfate.

**Incubation buffer:** Prepare a solution containing 6.19 g/L of sodium chloride, 0.35 g/L of potassium chloride, 0.22 g/L of calcium chloride, 0.12 g/L of magnesium sulfate, 0.16 g/L of monobasic potassium phosphate, 11.915 g/L of HEPES, and 10 g/L of bovine serum albumin (1% BSA). Adjust to a pH of 7.5.

**Test animals:** Male Sprague-Dawley rats are maintained on a standard rat chow diet, given water ad libitum, and allowed to adjust to their new housing before testing. On the morning of the test, select a healthy rat weighing approximately 300–400 g, and administer 100 units of Heparin Sodium subcutaneously.

**Procedure:** [NOTE—Conduct this procedure in the morning to ensure that the rat has optimal glycogen in its liver and so that the procedure can be completed in 1 day.] Anesthetize the rat with an appropriate anesthetic. Open the abdominal cavity and isolate the portal vein. Insert an angiocatheter and tie into the portal vein at the general location of the lienal branch and then connect to a perfusion pump. Start the perfusion (25 mL/min) in situ with the previously warmed, oxygenated, *Calcium-free perfusion buffer with dextrose*. As the liver enlarges, cut the inferior vena cava to allow pressure equilibrium. [NOTE—About 300 mL of the perfusate is needed to clear the liver of red blood cells at a flow rate of 25–60 mL/min.] Then circulate *Collagenase buffer* at an appropriate flow rate so that the liver leaks perfusate out of the lobes in approximately 10 min (typically 25–60 mL/min). When the liver significantly increases in size, changes color and consistency, and starts to leak perfusate out of the lobes, change the system to the oxygenated prewarmed *Wash buffer*. About 100 mL of *Wash buffer* is needed to wash the liver of collagenase at a flow rate of 25 mL/min. Surgically remove the liver from the animal, and place in a prewarmed Petri dish containing a small amount of oxygenated *Wash buffer* (37°). Gently comb the liver with a stainless steel, fine-toothed comb to free the hepatocytes. Filter and wash the hepatocytes with *Wash buffer*, through prewetted cheesecloth (three layers thick, or through a 150-µm mesh polyethylene net) into a beaker. Transfer the cells to 2 centrifuge tubes and spin for about 1 min at 600 rpm. Discard the supernatant fractions and resuspend the two pellets in *Incubation buffer*. Combine the two pellets in a suitable container and add sufficient *Incubation buffer* to make 150 mL.

**System suitability of cell preparation:** The cell yield may vary because of the collagenase activity and the viability of the hepatocytes. To check cell viability and to determine viable cell concentration, dilute a 100-µL aliquot of the cell suspension with 400 µL of *Wash buffer* and 500 µL of isotonic 0.4% trypan blue solution. Load aliquots of the cell suspension into both chambers of a hemocytometer and count the cells in all eight quadrants. To meet system suitability of the cell preparation method, a viable cell concentration of $3 \times 10^6$ cells/mL (acceptable range of $2.5 \times 10^6$ to $3.4 \times 10^6$ cells/mL) must be obtained to proceed with the bioassay. If the viable cell concentration exceeds the upper limit, additional *Incubation buffer* may be added to the cells to adjust the concentration to $3 \times 10^6$ cells/mL. In this case, the cells are counted again in a hemocytometer, as described above, to verify the concentration. [NOTE—Viable cells are those cells that exclude the trypan blue.]

**Glucose determination**

**Negative control solution:** Prepare a solution containing 0.5% BSA using *Sterile Water for Injection* or *Sterile Water for Irrigation*.

**Incubation flasks:** Use specially prepared 25-mL conical flasks, the bottoms of which have been heated and pushed inward to form a conically raised center, or similar flasks that allow sufficient mixing when swirling. Place the *Incubation flasks* in an orbital shaker water bath at 35°.

**Standard preparations:** On the day of the assay, dissolve 2 vials of ▲USP Glucagon (Human) RS▲ (USP 1-Aug-2022) in 0.01 N hydrochloric acid or other suitable diluent (volume based on the potency of the Reference Standard lot) to obtain two solutions each containing ▲1 USP Glucagon (Human) Unit/mL.▲ (USP 1-Aug-2022) All dilutions thereafter are made using *Negative control solution*. Accurately dilute measured volumes of each solution with *Negative control solution* to obtain an intermediate concentration of 400 µU/mL, and then dilute the intermediate to produce 5 concentrations: 200, 100, 50, 25, and 12.5 µU/mL (*Standard preparations*). Pipet 0.1 mL of each *Standard preparation* into separate *Incubation flasks*. Pipet 0.1 mL of *Negative control solution* into each of 2 flasks (*Negative control solutions 1* and *2*).

**Assay preparations:** Using accurately weighed quantities of glucagon samples, proceed as directed for *Standard preparations* or, if testing *Glucagon for Injection*, reconstitute 10 vials by slowly adding the contents of the accompanying prefilled syringes containing an appropriate glucagon diluent. Gently mix each vial until the glucagon is dissolved. Using the same syringes, withdraw the contents of 5 vials and place the solutions in a 25-mL volumetric flask. Repeat for the second set of 5 vials, transferring the contents to a second 25-mL volumetric flask. Dilute each flask with 0.01 N hydrochloric acid to volume. Dilute an accurate amount of each solution with 0.5% BSA to yield a concentration of 400 µU/mL, and dilute the intermediate to produce 5 *Assay preparation* concentrations: 200, 100, 50, 25, and 12.5 µU/mL. Then proceed as directed for the *Standard preparations*.

**Reference stock solution:** Dry USP Dextrose RS, and then transfer 1.0 g, accurately weighed, to a 100-mL volumetric flask. Dissolve in and dilute with saturated benzoic acid solution to volume.

**Reference solutions:** Transfer suitable quantities of *Reference stock solution* to 4 flasks, and dilute with saturated benzoic acid solution to obtain *Reference solutions* having concentrations of 100, 500, 1000, and 1500 mg/L.

**Potassium ferrocyanide solution:** Dissolve 1.25 g of trihydrate potassium ferrocyanide in 125 mL of *Sterile Water for Injection*, or use an appropriate commercial source.

https://pharmacopeia.cn/

**System suitability:** Analyze the *Potassium ferrocyanide solution*, the *Reference solutions*, and an additional 5 replicates of either the 500- or 1000-mg/L *Reference solution* in an appropriate glucose analyzer. [NOTE—*Potassium ferrocyanide solutions* are only appropriate standards for glucose analyzers that measure glucose oxidase activity. The procedure can also be performed using alternative platforms.] Prepare a standard curve using the *Reference solutions* as directed for the *Standard preparations*. The square root of the residual error mean square from the regression divided by the average of the response multiplied by 100% (line %RSD) must be not more than 2.0%. In addition, the response of the *Potassium ferrocyanide solution* must be not more than 30 mg/L, and the relative standard deviation must be not more than 2.0% for the replicate analyses of the middle *Reference solution*.

**Procedure:** Dispense 5 mL of *Hepatocyte preparation* into the *Incubation flasks* in sequence from high glucagon concentration to low glucagon concentration, alternating the *Standard preparations* with the *Assay preparations*. Swirl the flasks in an orbiting water bath at 125 rpm at 30°–35° for approximately 30 min. Following incubation, remove 1.0-mL aliquots from each *Incubation flask*, transfer to labeled microcentrifuge tubes, and centrifuge at 13,000 rpm for 15 s. Place each supernatant fraction in a labeled sampling tube for a glucose analyzer, and determine the glucose concentration (mg/L) of each *Standard preparation* and *Assay preparation*. Measure the background reading of *Negative control solution 1* and *Negative control solution 2*, and calculate the average of the two responses.

To conform to the linear range of the instrument being used, analysts may find it necessary to adjust by dilution each of the *Standard preparations* and *Assay preparations*. Use a glucose analyzer that has demonstrated appropriate specificity, accuracy, precision, and linear response over the range of concentrations being determined. Determine the increase in glucose concentration for each *Standard preparation* and *Assay preparation* compared to the average value of the *Negative control solution*.

**Calculations**

Calculate the relative potency of the glucagon samples using statistical methods for parallel-line assays, comparing the Reference Standard curve (from the *Standard preparations*) to the glucagon sample curve (from the *Assay preparations*). No dose–response reversals may occur within a run for the 25, 50, or 100 µU/mL *Standard preparations* and *Assay preparations*. [NOTE—Either the low- or high-dose level, but not both, may be excluded from the calculation in order to meet linearity requirements.] Because a minimum of two valid assays (rats) are required, the estimated potencies are combined using the procedures in *Design and Analysis of Biological Assays* ⟨111⟩*, Combination of Independent Assays*, and the width, *L*, of a 95% confidence interval for the estimated logarithm of the relative potency is calculated. If *L* is not more than 0.1938, the results are valid. If *L* is >0.1938, additional assays may be performed and combined until a valid *L* term results, and the relative potency is then calculated from all valid independent runs. Calculate the potency of the glucagon samples in ▲USP Glucagon (Human) Units/mg▲ (USP 1-Aug-2022) by multiplying the relative potency result by the potency of ▲USP Glucagon (Human) RS.▲ (USP 1-Aug-2022)

**Acceptance criteria:** Not less than ▲0.80 USP Glucagon (Human) Units/mg▲ (USP 1-Aug-2022)

***Change to read:***

- **B. IN VITRO CELL-BASED BIOIDENTITY TEST**

**Medium A:** Dulbecco's Modified Eagle Medium (DMEM) containing 4.5 mg/mL of D-glucose and sodium pyruvate, 4 mM L-alanine-L-glutamine[1] or L-glutamine, 10% (v/v) fetal bovine serum,[2] and 0.5 mg/mL of G418[3]

**Buffer A:** Hank's Balanced Salt Solution[4] containing 5.3 mM potassium chloride, 0.4 mM potassium phosphate monobasic, 4.2 mM sodium bicarbonate, 137.9 mM sodium chloride, 0.3 mM sodium phosphate dibasic anhydrous, and 5.6 mM dextrose

**Cell culture preparation:** Remove glucagon receptor cell line[5] from cryostorage and immediately thaw at 37° until the cell suspension has just thawed. Aseptically transfer the cell suspension from the cryotube into a sterile test tube containing 10 mL of warmed *Medium A*. Mix and then pellet the cells by centrifugation for 5 min at 125 × g. Remove the supernatant and resuspend the cells in fresh, warmed *Medium A*. Measure the quantity of cells contained in an aliquot of the suspension by suitable methods, and adjust the cell concentration with *Medium A* such that the cell suspension is 0.5–5 × $10^3$ cells/$cm^2$ of tissue culture flask surface. Inoculate tissue culture flasks[6] and store in a humidified incubator at 37° containing 5% carbon dioxide. Cells should be passaged two to three times per week when they are not more than 90% confluent but never trypsinized 2 days in a row. If cells are not ready for passaging after 3 days of culture, the medium should be replaced with fresh *Medium A*. Cells are passaged by first removing the medium from the cell flasks, followed by adding sufficient *Buffer A* prewarmed to room temperature to cover the surface of the flasks. The flasks are gently rocked to wash the cells. This wash fluid is discarded and then sufficient trypsin[7] is added to the cell flasks to cover the surface, followed by gentle rocking and placement back in the incubator. After 3–5 min, the trypsinized cells are aseptically collected from the flasks and transferred to a sterile centrifuge tube. Then, a volume of *Medium A* is added that is a minimum of 2 times the volume of trypsinized cells, and an aliquot is counted. The cell suspension is further diluted with fresh *Medium A* to a final cell concentration of 0.5–5 × $10^3$ cells/$cm^2$ of tissue culture flask surface. After a minimum of 8 passages post-thaw but not more than 25 passages, the cells can be used in the assay. The day before an assay, follow the cell passaging instructions above, but resuspend the cells in fresh, warmed *Medium A* to a final cell concentration of 4–5 × $10^4$ cells/mL. [NOTE—Three identical, independent 96-well white plates[8] are needed for measurement of two test samples ("A" and "B") analyzed on each. All wells must be loaded with cells within 40 min of resuspension following trypsinization and counting

in order to keep a homogeneous cell suspension.] Using constant, gentle mixing without foaming, each well is loaded with 0.1 mL of cell suspension and incubated overnight at 37° and 5% carbon dioxide (approximately 24 h ± 4 h) prior to starting the *Procedure*. [NOTE—All remaining solutions should be prepared on the day of the *Procedure*.]

**Medium B:** *Krebs salt solution* containing 0.3% (v/v) human serum albumin, 25 mM HEPES, 1.7 mM 3-isobutyl-1-methyl-xanthine, 0.2 mg/mL of glucose, 650 KIU/mL of aprotinin, and 0.0003% (v/v) polysorbate 80, pH 7.4

**Medium C:** *Krebs salt solution* containing 0.3% (v/v) human serum albumin and 25 mM HEPES, pH 7.4

**Standard stock solution:** Reconstitute ▲USP Glucagon (Human) RS▲ (USP 1-Aug-2022) in *Water for Injection* or another suitable diluent to a concentration of 4 mg/mL by gently mixing on a rotator for 10 min or until completely clear. Dilute this material 1:1000 with *Medium B* to a concentration of 4 µg/mL and then 1:200 with *Medium B* to 20 ng/mL.

**Standard solutions:** Within an hour of use, dilute the 20-ng/mL *Standard stock solution* with *Medium B* to make a 1:5 concentration series of 4 ng/mL (R8), 0.8 ng/mL (R7), 160 pg/mL (R6), 32 pg/mL (R5), 6.4 pg/mL (R4), and 1.3 pg/mL (R3). A final dilution is made from R3 in *Medium B* to make 65 fg/mL (R2). [NOTE—Alternative suitable concentrations can be similarly prepared if necessary and validated.] R1 is a blank solution of *Medium B*. [NOTE—For these *Standard solutions*, as well as the *Sample solutions* and *cAMP standard solutions* described below, it may be helpful to prepare these dilutions in a dilution microplate that mimics the assay plate layout to easily and quickly transfer the materials to the wells of the assay plate.]

**Sample solutions:** Reconstitute two independent preparations of glucagon from the same lot of material in *Water for Injection* or the same suitable diluent used to prepare the *Standard stock solution* to a concentration of 4 mg/mL. Prepare by diluting this material further with *Medium B* to prepare a concentration series similar to that suggested for the *Standard solutions*. One preparation series is *Sample solution* A8–A2 and the other preparation series is *Sample solution* B8–B2.

**cAMP standard solutions:** Prepare a 5 mM cAMP▲▲ (USP 1-Aug-2022) solution in water, and then prepare further solutions by dilution with *Medium B* as shown in *Table 1*. [NOTE—To conform to the linear range of the instrument being used, analysts may find it necessary to adjust by dilution each of the *Standard solutions*, *cAMP standard solutions*, and *Assay solutions*. Alternative suitable concentrations can be similarly prepared if necessary and validated.]

**Table 1. Preparation of cAMP Standard Solutions**

| Starting cAMP Solution | Fold Dilution with Medium B | Final cAMP Solution | Final cAMP Standard Solution Name |
|---|---|---|---|
| 5 mM | 1:10 | 0.5 mM | — |
| 0.5 mM | 1:20 | 25 µM | C1 |
| 25 µM | 1:3.3 | 7.5 µM | C2 |
| 25 µM | 1:10 | 2.5 µM | C3 |
| 7.5 µM | 1:10 | 0.75 µM | C4 |
| 2.5 µM | 1:10 | 250 nM | C5 |
| 0.75 µM | 1:10 | 75 nM | C6 |
| 250 nM | 1:10 | 25 nM | C7 |
| 75 nM | 1:10 | 7.5 nM | C8 |
| *Medium B* only | — | No cAMP | C9 |

**Donor biotin-cAMP beads:** Dissolve 10 nmol biotinylated cAMP in 0.5 mL of phosphate-buffered saline, pH 7.4. Add 80 µL of this biotinylated cAMP solution to 33.8 mL of a 5 mM HEPES lysis buffer containing 0.1% (w/v) BSA and 0.3% (v/v) polysorbate 20, pH 7.4. Add 270 µL of donor beads[9] and 2.4 mL of 120 mM magnesium chloride solution.

**Procedure:** Remove the plates seeded with cells the day before, and discard the *Medium A* in each well. Wash the cells with 350 µL of *Medium C* per well, then discard the wash solution. Rapidly add 20 µL of diluted 1 × anti-cAMP-acceptor beads per well. Add 30 µL each of *Standard solution*, *Sample solution*, *Medium B*, or *cAMP standard solution* per well as indicated in the plate layouts shown in *Table 2* and *Table 3*. [NOTE—The white plate for the *cAMP standard solutions* does not contain cells.] Cover the plate,[10] protecting it from light and evaporation, and incubate for 35–60 min in an incubator at 37° with gentle shaking. Next, dispense 60 µL of *Donor biotin-cAMP beads*[9] per well, mix thoroughly, then cover the plate again and wrap it with foil. [NOTE—The beads are light sensitive so plates should be kept in the dark or under green light conditions.] Gently rotate the plate on a shaker for at least 30 min at room temperature. Keep the plate in the dark at room temperature without shaking for 16–30 h before measuring the top luminescence from the plate wells on a suitable plate reader[11] and detection mode (excitation wavelength of about 680 nm; emission of 520–620 nm).

C1–C9 = Dilution series of cAMP standard controls starting with C1, which contains 25 µM cAMP, through C9, which does not contain cAMP.

**System suitability criteria:** The lower asymptote of the four-parameter logistic curves generated from *Sample solutions* A2–A8 and B2–B8 and *Standard solutions* R1–R8 must be above the lower limit (defined as C3) of the *cAMP standard solutions*. Not less than a three-fold difference between the signals obtained in the wells of cells treated without glucagon (R1) versus those with the maximal amount of glucagon (R8). Not more than 4 technical outliers may be omitted per standard curve. Any plate that fails one or more of these criteria is rejected and must be repeated. If either *Sample solution* A or B fails one of these criteria, then only the passing series can be used for the calculations. [NOTE—The upper asymptotes of the four-parameter logistic standard curves generated from *Sample solutions* A2–A8 and B2–B8 and *Standard solutions* R1–R8 should be approximately equal to or less than the C8 response of the *cAMP standard solutions* and within the linear range of the instrument used.]

**Calculations:** A series of two independent *Sample solution* preparations must be used for each test sample across 3 plates (assays). Outliers identified by Grubbs test (see ⟨111⟩; but not more than 4 per curve and not more than 1 data point from a replicate set) are omitted, and then the same number of *Standard solution* and *Sample solution* dose responses, including the 50% response ($EC_{50}$) of the standard/test sample within this range, are used to calculate the relative potency of the glucagon sample using statistical methods for parallel-curve analysis with a four-parameter logistic fit using all replicate values. For each individual *Sample solution* compared to the *Standard solution*, the statistical tests for slope and parallelism must pass at the 95% confidence level. Calculate the relative potency of the glucagon samples by comparing the Reference Standard curve (from the *Standard solutions*) to the glucagon sample curve (from the *Sample solutions*). Because a minimum of three valid assays are required, the estimated potencies are combined using the procedures in ⟨111⟩, *Combination of Independent Assays*, and the confidence interval is calculated using suitable statistical methods. If the confidence limits are between 64% and 156%, the results are valid. If not, up to 2 more assay plates may be performed and combined until a valid confidence interval results, and the relative potency is then calculated from all valid independent runs. Calculate the potency of the glucagon samples in ▲USP Glucagon (Human) Units/mg▲ (USP 1-Aug-2022) by multiplying the relative potency result by the potency of ▲USP Glucagon (Human) RS.▲ (USP 1-Aug-2022)

**Acceptance criteria:** Not less than ▲0.80 USP Glucagon (Human) Units/mg▲ (USP 1-Aug-2022)

# ⟨124⟩ ERYTHROPOIETIN BIOASSAYS

## INTRODUCTION

This chapter provides guidance about the use of bioassays to measure the biological activity of erythropoietin (EPO). Based on a relative potency approach described in general chapter *Design and Development of Biological Assays* ⟨1032⟩, the biological activity of an unknown EPO preparation typically is determined by comparison to the biological activity of a Reference Standard (RS). For this purpose, a USP Erythropoietin for Bioassays RS has been developed. The assays described in the chapter are not applicable to forms of EPO that have been engineered to prolong their half-life.

The USP Erythropoietin for Bioassays RS has been calibrated against the World Health Organization (WHO) International Standard for EPO using both the normocythemic mouse bioassay and the exhypoxic polycythemic mouse bioassay. Accordingly, the USP Erythropoietin for Bioassays RS has an assigned unitage in terms of International Units (IU) of EPO as defined by WHO. Of these two in vivo bioassays, the normocythemic mouse bioassay is less cumbersome and is more widely used for the determination of EPO potency. The assay is based on the measurement of EPO-stimulated reticulocyte maturation. Because the USP Erythropoietin for Bioassays RS has been calibrated against the WHO International Standard for EPO by in vivo bioassay, it can be used directly in the normocythemic mouse bioassay for the calibration of any process-specific EPO preparation.

However, if the intent is to use a validated in vitro bioassay to transfer the unitage from the USP Erythropoietin for Bioassays RS to a process-specific EPO preparation, then it is necessary to demonstrate that the USP Erythropoietin for Bioassays RS and the process-specific EPO preparation exhibit an equivalent ratio of in vitro to in vivo potency. This is because the biological activity of EPO shows a complex relationship between structure and function. In particular, the ratio of in vitro to in vivo activity is inversely correlated with type and degree of terminal sialylation. Highly sialylated products have a higher level of in vivo activity; thus, they have a relatively lower ratio of in vitro to in vivo activity. Because of differences in the manufacturing processes used in the preparation of EPO, the type and degree of terminal sialylation can be variable from one EPO preparation to another, including EPO preparations used as Reference Standards. As a result, the use of an in vitro assay to measure the biological activity of an EPO preparation requires a full understanding of the relationship between the EPO's in vivo and in vitro activity. This understanding is best achieved by comparing the test EPO preparation with the USP Erythropoietin for Bioassays RS in both the in vivo assay and in a specific in vitro assay.

The USP Erythropoietin for Bioassays RS is assigned a unitage that represents its activity in both in vivo assays and in vitro assays. If the ratios of in vitro to in vivo potency for the material being tested and the USP Erythropoietin for Bioassays RS are equivalent, then the USP Erythropoietin for Bioassays RS can be used directly in the in vitro assay to calibrate the material being tested. However, if the ratios are not equivalent, then the material being tested and the USP Erythropoietin for Bioassays RS have a different ratio of in vitro to in vivo potency, and the standard cannot be used with its assigned potency in the in vitro assay. Instead, this ratio determined for the material being tested should be used to assign a process-specific in vitro assay unitage to the USP Erythropoietin for Bioassays RS. The USP Erythropoietin for Bioassays RS, with its adjusted in vitro assay unitage, then can be used in the in vitro assay to transfer the unitage from the USP Erythropoietin for Bioassays RS to the material being tested.

## ASSAY

- **Normocythemic Mice Assay**

**Solution A:** Dissolve 10.75 g of disodium hydrogen phosphate dodecahydrate, 7.6 g of sodium chloride, and 10 g of bovine albumin in 1000 mL of water. Immediately before use adjust with sodium hydroxide solution or phosphoric acid to a pH of 7.2.

**Standard solution 1:** Dissolve USP Erythropoietin for Bioassays RS in *Solution A* to a concentration of 80 IU/mL.

**Standard solution 2:** Mix equal volumes of *Solution A* and *Standard solution 1*.

**Standard solution 3:** Mix equal volumes of *Solution A* and *Standard solution 2*.

**Sample solution 1:** Prepare the sample to be tested in *Solution A* to a concentration of 80 IU/mL.

**Sample solution 2:** Mix equal volumes of *Solution A* and *Sample solution 1*.

**Sample solution 3:** Mix equal volumes of *Solution A* and *Sample solution 2*.

The exact concentrations of each *Standard solution* and *Sample solution* may require adjustment based on the response range in the animals used.

**Preparation of animals:** At the beginning of the assay procedure, randomly distribute mice of a suitable age and strain (8-week-old B6D2F1 mice are suitable) into six cages. A minimum of eight mice per cage is recommended. Inject each animal subcutaneously with 0.5 mL of the appropriate treatment (one solution per cage), and put the animal in a new cage. Combine the mice in such a way that each cage housing the treated mice contains one mouse out of the six different treatments (each *Standard solution* and each *Sample solution*; six mice per cage).

**Analysis:** Four days after the injections, collect blood samples from the animals, and determine the number of reticulocytes by using a suitable procedure. The following method can be employed.

The volume of blood, dilution procedure, and fluorescent reagent may require modification to ensure maximum development and stability of fluorescence.

For concentrated colorant solution, use a solution of thiazole orange suitable for the determination of reticulocytes. Prepare at a concentration twice that necessary for the analysis.

Proceed with the following dilution steps. Dilute whole blood 500-fold in the buffer used to prepare the colorant solution. Dilute this solution two-fold in the concentrated colorant solution. After staining for 3–10 min, determine the reticulocyte count microfluorometrically in a flow cytometer. The percentage of reticulocytes is determined using a biparametric histogram: number of cells/red fluorescence (620 nm).

Calculate the potency by the usual statistical methods for a parallel-line assay. For additional information, see general chapter *Analysis of Biological Assays* ⟨1034⟩.

Official

https://pharmacopeia.cn/

**Acceptance criteria:** The activity of each *Sample solution* is compared with that of the USP Erythropoietin for Bioassays RS and is expressed in IU. The confidence limits of the estimated potency ($P = 0.95$) are NLT 64% and NMT 156% of potency as determined by the method given above. The estimated potency is NLT 80% and NMT 125% of the stated potency.

## ADDITIONAL REQUIREMENTS

***Change to read:***

# ⟨126⟩ SOMATROPIN BIOIDENTITY TEST▲ ▲ (USP 1-May-2023)

***Change to read:***

Somatropin is a protein hormone that contains the same amino acid sequence as the human growth hormone produced by the pituitary gland. A robust and precise physicochemical chromatographic procedure is used in the assay to assign potency on a mass basis. Bioidentity is still required,▲ so a▲ (USP 1-May-2023) rat-cell-line-based approach that measures production of ATP as a direct indicator of cell growth ▲is presented here.▲ (USP 1-May-2023) [NOTE—The bioidentity test may be performed either on the somatropin bulk drug substance or on the drug product.]

**PROCEDURE**

***Delete the following:***

▲• **IN VIVO BIOIDENTITY TEST**▲ (USP 1-May-2023)

• **IN VITRO CELL-BASED BIOIDENTITY TEST**

**Medium A:** Fischer's medium[1] containing 10% heat-inactivated fetal bovine serum,[2] 10% heat-inactivated horse serum,[3] 0.075% sodium bicarbonate, and 0.05 mM 2-mercaptoethanol. Filter sterilize. [NOTE—Store for up to 2 weeks at 2°–8°.]

**Medium B:** Fischer's medium containing 1% horse serum, 0.075% sodium bicarbonate, and 0.05 mM 2-mercaptoethanol. Filter sterilize. [NOTE—Store for up to 2 weeks at 2°–8°.]

**Phosphate buffered saline[4]:** Calcium- and magnesium-free phosphate buffered saline containing 1.5 mM monobasic potassium phosphate, 155 mM sodium chloride, and 3 mM dibasic sodium phosphate, pH 7.2–7.4

**Cell culture preparation:** Prepare cell suspension cultures of Nb2-11[5] cells in *Medium A* in a humidified incubator at 37° and containing 5% carbon dioxide. Cells should be passaged twice per week and reseeded at a density of $1 \times 10^5$ cells/mL for 2 days, $2 \times 10^4$ cells/mL for 3 days, and $1 \times 10^4$ cells/mL for 4 days in *Medium A*. [NOTE—Seeding densities may need adaptation when analysts qualify new lots of fetal bovine serum and horse serum.] On the day of an assay, cells are harvested from flasks and are pelleted by centrifugation for 7 min at about 218 × g. The supernatant is discarded, and the cells are washed twice with phosphate buffered saline followed by centrifugation. The cells are resuspended in *Medium B* and are counted, and the cell concentration is adjusted to $1 \times 10^5$ cells/mL with *Medium B*. Except for the wells of the first column, transfer 50 µL of cell suspension into each well of a 96-well black tissue culture plate with a clear bottom.[6] Pipet 50 µL of *Medium B* into each well of the first column of the plate. [NOTE—Cover the plate, and incubate at 37° for up to 1 h while preparing the *Standard solutions* and *Test solutions*.]

**Standard solutions:** Reconstitute USP Somatropin RS in 1 mL of phosphate buffered saline. From the reconstituted USP Somatropin RS, the *Standard solutions* and the *Positive control solution* are prepared for use in the *Procedure*. For the *Standard solutions*, the reconstituted USP Somatropin RS is further diluted with *Medium B* to a concentration of 2.0 ng/mL. [NOTE—Use polypropylene test tubes to make dilutions. For each plate approximately 1 mL of this solution is needed. Do not use single step dilutions of more than 1:100 or smaller transfer volumes than 40 µL.]

**Test solutions:** For each test solution, two results must be obtained by two independent preparations of somatropin. Reconstitute two independent preparations of somatropin in a suitable diluent (e.g., phosphate buffered saline or *Water for Injection*) to a concentration of not more than 5 mg/mL. Prepare *Test solutions* by diluting this material further with *Medium B* to a concentration of 2.0 ng/mL. [NOTE—Use polypropylene test tubes to make dilutions. For each plate approximately 1 mL of this solution is needed. Do not use single step dilutions of more than 1:100 or smaller transfer volumes than 40 µL.] One preparation is *Test solution A*, and the other preparation is *Test solution B*.

**Positive control solution:** Starting with the reconstituted stock preparation of USP Somatropin RS described in *Standard solutions*, dilute with *Medium B* to a concentration of 20 ng/mL. [NOTE—Use polypropylene test tubes to make dilutions. Do not use single step dilutions of more than 1:100 or smaller transfer volumes than 40 µL.]

**Procedure:** Dispense 100 µL of *Medium B* into each well of a U-bottom, clear 96-well plate,[7] except those wells in column 12 (wells A12–H12 = positive control) and wells A2–A10. [NOTE—For each black plate seeded with cells as described in *Cell culture preparation*, one separate U-bottom plate is used for preparation of the *Standard solutions* and *Test solutions* dilutions.] Next, dispense 200 µL of 2.0-ng/mL *Standard solutions* into wells A3, A6, and A9 of the dilution plate. Dispense 200 µL of 2.0-ng/mL *Test solution A* into wells A2, A5, and A8 of the dilution plate. Dispense 200 µL of 2.0-ng/mL *Test solution B* into wells A4, A7, and A10 of the dilution plate. Dispense 100 µL of 20-ng/mL *Positive control solution* into the last plate column (wells A12–H12) of the dilution plate. Using a 12-channel pipet, perform serial two-fold dilutions on the plate by aspirating 100 µL from the first row (A2–A10), transfer to the second row, and mix three times. Then aspirate 100 µL from the second row, transfer to the third row, and mix three times, etc. Repeat this procedure across the whole plate up to row H. Discard the 100 µL aspirated from the last row. [NOTE—The wells of column 11 (wells A11–H11) are negative controls containing 100 µL of *Medium B*; the wells of column 1 (wells A1–H1) are blanks.]

Starting with the lowest concentration and using a 12-channel pipet, transfer 50 µL of each solution in the dilution plate to the respective well of the black plate containing the cells. [NOTE—During the transfer, immerse the pipet tips into

**LEGEND:**
BL = *Blank*: no somatropin, no cells.
A = Dilution series of *Test solution A* (with 1.0 ng/mL as starting concentration).
St = Dilution series of *Standard solutions* (with 1.0 ng/mL as starting concentration).
B = Dilution series of *Test solution B* (with 1.0 ng/mL as starting concentration).
NEG = Negative control: no somatropin, but cells are present.
POS = *Positive control solution*: maximum somatropin concentration (10 ng/mL).

**Calculations:** A minimum of two independent *Test solutions* preparations must be used for each test sample. The *Test solutions* and *Standard solutions* are normalized by protein content before calculation of the relative potency. [NOTE—1 mg of anhydrous somatropin is equivalent to 3.0 USP Somatropin Units.] Technical outliers (but not more than 4 per curve) are omitted, and then the same number of *Standard solutions* and *Test solutions* dose responses, including the 50% response ($EC_{50}$) of the standard per test sample within this range, are used to calculate the relative potency of each somatropin sample using statistical methods for parallel-line analysis. For each of the individual *Test solutions* compared to the *Standard solutions*, the statistical tests for linearity, slope, and parallelism must pass at the 95% level. The confidence limit for each calculated relative potency must be within 75%–133%. The relative potency of each of the *Test solutions* must be within the validated assay range (50%–200% relative potency) of the *Standard solutions*. The unweighted mean log relative potency is calculated from valid individual samples, and the potency is then calculated in USP Somatropin Units/mg relative to the USP Somatropin RS.

**System suitability criteria:** The signal-to-noise ratio of the mean chemiluminescence signal of the *Positive control solution* to the mean chemiluminescence signal of the negative control wells must be not less than 3. Not more than 4 technical outliers may be omitted per standard curve. Any plate that fails one or more of these criteria is rejected and must be repeated.

**Acceptance criteria:** Not less than 2 USP Somatropin Units/mg

# ⟨127⟩ FLOW CYTOMETRIC ENUMERATION OF CD34+ CELLS

## INTRODUCTION

The CD34 antigen is expressed on the surface of almost all human hematopoietic stem and progenitor cells. The absolute number of CD34+ hematopoietic stem cells (HSCs) has been shown to correlate with in vitro colony-forming unit (CFU) assay activity and with clinical engraftment in hematopoietic grafts prepared from peripheral blood, bone marrow, and cord blood sources. The single-platform, flow cytometric CD34+ cell enumeration method described here is based on a clinical laboratory protocol,[1] established by the International Society of Hematotherapy and Graft Engineering (ISHAGE), now known as the International Society for Cellular Therapy (ISCT). This protocol can be used to enumerate CD34+ cells in samples of peripheral blood, leukapheresis products, bone marrow, and cord blood. CD34+ cell enumeration by flow cytometry is a rare event analysis, which requires specific gating instructions that are provided in this chapter. Furthermore, the USP CD34+ Cell Enumeration System Suitability RS has been developed to assess the reagents and ensure the correct gating during data acquisition and analysis.

## IDENTIFICATION OF CD34+ HEMATOPOIETIC STEM CELLS

CD34+ cell enumeration by flow cytometry is a rare event analysis. For the analysis of CD34+ HSCs, cell samples are stained with fluorescently labeled antibodies against both the HSC antigen CD34 and the pan-leukocyte antigen CD45. Five parameters —forward light scatter (FSC), side light scatter (SSC), CD34 staining, CD45 staining, and viability dye staining are combined in a sequential, or Boolean, gating strategy to identify viable CD34+ cells.

CD34+ HSCs have FSC and SSC characteristics similar to lymphocytes; expressing both CD45 and CD34, and exhibiting dim CD45 expression and low SSC characteristics. Viability dye does not stain live cells, allowing the exclusion of dead cells from the analysis of viable cell preparations. For analysis of nonviable, fixed (preserved) cell preparations such as the USP CD34+ Cell Enumeration System Suitability Reference Standard (RS), either the flow cytometer viable cell analysis gate is fully opened to include all cells, or the *Viability dye* is omitted from the analysis.

## ENUMERATION CONSIDERATIONS

The CD34+ cell enumeration method described here relies on the use of synthetic fluorescent microspheres (counting beads) as internal enumeration controls. Homogeneous counting beads are added to the cell sample at a known concentration and volume, or the counting beads may be procured, pre-aliquoted, and lyophilized in special sample tubes, in which all subsequent cell staining and processing steps are conducted. To avoid the loss of counting beads, the wash steps are omitted, and protein-containing sample buffers are used. An ammonium chloride-based, red blood cell (RBC)-lysing protocol is used for fresh cell preparations; no lysing is necessary for frozen, thawed, or fixed cell preparations.

After the cells are stained and processed, the counting beads and cells are simultaneously analyzed on a flow cytometer. The number of CD34+ cells/µL in the cell sample can be directly calculated by comparing the absolute number of target CD34+ cells and the number of counting beads detected in the same data file. The USP CD34+ Cell Enumeration System Suitability RS is used to verify that the correct reagents and flow cytometer gating parameters were used.

## EQUIPMENT SPECIFICATIONS

The following equipment is needed:

- A pipettor capable of accurately reverse-pipetting microliter volumes
- A flow cytometer with the following minimum specifications (see *Flow Cytometry* ⟨1027⟩):
  - Detection capabilities for FSC; SSC; "green" fluorescence emission (range, 510–550 nm); "yellow" fluorescence emission (range, 560–590 nm); and "red" fluorescence emission (>600 nm)
  - Light-scatter and fluorescence measurements that are correlated to time
  - Light-scatter resolution allowing for the identification of lymphocytes, monocytes, granulocytes, and fluorescent counting beads
  - Detection and data acquisition rates of at least 5000 cells/s
  - A 488-nm laser excitation source
  - Fluorescence intensity sensitivity allowing for the detection of cellular autofluorescence
  - Analysis software, including a data file structure in the Flow Cytometry Standard (FCS) or equivalent, with spectral overlap correction capability

## FLOW CYTOMETER INSTRUMENT SETUP AND CONSIDERATIONS

[NOTE—For general information, see ⟨1027⟩ and the flow cytometer manufacture's recommendations.]

@2024 USPC

Ensure that the sheath fluid receptacle is filled, the waste fluid receptacle is empty, and all caps are tightly closed. Verify that the laser power, system vacuum, and pressure are properly set.

Using fluorochrome-conjugated calibration microspheres, verify proper system alignment by measuring the average detection rate, mean fluorescence, mean FSC, mean SSC, and the respective calculated coefficient of variance (CV) values as measured by each detector. All values should fall within the ranges recommended by the manufacturer of the flow cytometer instrument. Adjust the detector threshold to ensure that all counting bead events are included.

Use either antibody-binding microspheres or preserved cells, such as the USP CD34+ Cell Enumeration System Suitability RS, to establish a matrix of detector values while adjusting for spectral overlap (compensation). Note that although either microspheres or cells can be stained with anti-CD34 phycoerythrin (PE) and anti-CD45 fluorescein isothiocyanate (FITC) antibodies, only fresh cells can be stained with *Viability dye*.

## REAGENTS

**Phosphate-buffered saline (PBS):** 138 mM sodium chloride, 2.7 mM potassium chloride, 8 mM dibasic sodium phosphate, and 1.47 mM monobasic potassium phosphate. [NOTE—pH 7.0–7.4. If needed, adjust pH with hydrochloric acid.]

**Dilution buffer:** 1% (w/v) bovine serum albumin or human serum albumin in *PBS*

**10X Stock ammonium chloride RBC lysis buffer:** 1.5 M ammonium chloride, 0.01 M sodium bicarbonate, and 0.01 M ethylenediaminetetraacetic acid (EDTA)[2]

**Diluted (1X) RBC lysis buffer:** *10X Stock ammonium chloride RBC lysis buffer* diluted 1:10 with water

**Anti-CD34 PE:** PE-conjugated mouse IgG1 anti-human CD34 antibody (clones QBEnd10, 8G12, 581, Birma K3, or equivalent class II or class III PE-conjugated anti-CD34 antibodies), appropriately titrated

**Anti-CD45 FITC:** FITC-conjugated mouse IgG1 anti-human CD45 antibody (clones J33, T29/33, or HLE-1 or equivalent FITC-conjugated anti-CD45 antibodies), appropriately titrated

**Viability dye:** 1 µg/mL of 7-aminoactinomycin D (7-AAD) or equivalent, freshly diluted from a stock solution of 100 µg/mL[3]

**Instrument calibration beads:** Fluorochrome-conjugated instrument calibration microspheres[4]

**Suspended counting beads:** Fluorochrome-conjugated counting beads, formulated in liquid suspension[5]

**Lyophilized counting bead tube:** Fluorochrome-conjugated counting beads, formulated and lyophilized in a counting tube[6]

**System suitability standard USP CD34+ Cell Enumeration System Suitability RS:** Reconstitute the entire vial of USP CD34+ Cell Enumeration System Suitability RS with 0.5 mL of distilled water.

**Cell samples:** Fresh, fixed, or cryopreserved and thawed cell suspensions containing CD34+ cells, with a minimum of 100,000 nucleated cells/sample. Cell samples may include peripheral blood, leukapheresis product, cord blood, or bone marrow.

## SAMPLE PREPARATION

Use reverse-pipetting techniques for all sample dilutions and transfers. Dilute *Cell samples* with *Dilution buffer* to obtain a total nucleated cell concentration of 10–30 × $10^6$ cells/mL. Add *Anti-CD45 FITC* and *Anti-CD34 PE* to a 12-mm × 75-mm polystyrene tube (or a *Lyophilized counting bead tube*), followed by *Viability dye* to a final concentration of 1 µg/mL. Add 100 µL of well-mixed *Cell samples* to the bottom of the tube, and mix. Incubate for 20 min protected from light. Add 2 mL of *Diluted (1X) RBC lysis buffer* to fresh samples or add 2 mL of *Dilution buffer* to a fixed or frozen and thawed sample; vortex to mix. For fresh *Cell samples*, incubate for 10 min protected from light; for fixed or frozen then thawed *Cell samples*, no incubation time is needed. Place samples on ice. Samples should be analyzed within 1 h of lysis.

Immediately before acquiring data on the flow cytometer, pipet 100 µL of well-mixed *Suspended counting beads* (if not using *Lyophilized counting bead tubes*) to the prepared *Cell samples* described above. Cap the tube, and gently mix by inversion. Do not add counting beads to *Cell samples* intended to be used for adjustment of the instrumentation compensation matrix.

Immediately proceed to flow acquisition to collect a minimum of 75,000 CD45+ events and a minimum of 100 CD34+ cells. Acquire and analyze data by creating regions and logical gates (manually, or by using software appropriate for the flow cytometer), as described in *Table 1*.

### System Suitability Requirements

Use the USP CD34+ Cell Enumeration System Suitability RS to verify that the gating strategy described below allows the detection and quantitation of CD34+ HSCs. Note that for fixed *Cell samples*, the viability gate (*R1* in *Table 1*) must be opened to include all events; alternatively, the *Viability dye* can be omitted. Calculate the number of CD34+ HSCs/µL in USP CD34+ Cell Enumeration System Suitability RS.

## Acceptance Criteria

The results should fall within the range provided in the USP CD34+ Cell Enumeration System Suitability RS certificate.

# DATA ACQUISITION AND ANALYSIS

For flow acquisition, collect a minimum of 75,000 CD45+ events and a minimum of 100 CD34+ cells. Acquire and analyze data by creating regions and logical gates (manually, or using software appropriate for the flow cytometer) as described in *Table 1*. The best results are obtained when cell and bead data (events) are displayed as bivariate dot plots. *Table 1* contains representative dot plots and gating strategies for fresh cell samples. Dot plot displays may vary depending on the cell sample, flow cytometer, and software used. Troubleshooting guidelines can be found in *Table 2*.

**Table 1. Dot Plot Descriptions and Gating Instructions**

| Step | Format | Purpose | Gating Instructions | Representative Dot Plots and Gating Strategies |
|---|---|---|---|---|
| 1 | SSC (linear) vs. *Viability dye* fluorescence (log) | Define viable cells | • Display all unselected events. Create region *R1* around events with little-to-no fluorescence.<br>• Included in the region *R1*: viable cells, debris.<br>• Excluded from the region *R1*: dead and dying cells, counting beads. |  |
| 2 | SSC (linear) vs. CD45 fluorescence (log) | Define viable CD45+ leukocytes and lymphocytes | • Display *R1*-selected events. Create region *R2* around events with CD45+ fluorescence, excluding debris (i.e., events with very low SSC). Within *R2*, create region *R3* around events with high CD45+ fluorescence and low SSC.<br>• Included in the region *R2*: viable CD45+ leukocytes.<br>• Included in the region *R3*: viable lymphocytes.<br>• Excluded from the region *R2*: cell debris, platelets, and unlysed RBCs.<br>• Excluded from the region *R3*: granulocytes, monocytes, and other non-lymphocytes. |  |

**Table 2. Troubleshooting Guidelines (see also ⟨1027⟩)**

| Problems | Possible Reasons | Solutions | Comments |
|---|---|---|---|
| Unable to clearly define the bead gate (*R7*) in *Table 1*, graph 7 due to fluorescent debris | Degraded fresh cell sample; fixed sample; too many platelets; incomplete RBC lysis; nucleated RBCs (e.g., in cord blood) | Use a far-red fluorescence channel (>600 nm), instead of FITC, to gate counting beads. | Counting beads are highly fluorescent in all channels. Autofluorescence interference decreases dramatically at longer wavelengths (>600 nm). |
| Unable to find CD34+ population in *Table 1*, graph 3 | Incorrect compensation settings for PE and *Viability dye* | Repeat the spectral compensation setup procedure, and adjust settings accordingly. | Make sure that counting beads are not in the compensation matrix sample, because they can interfere with compensation settings. |
| Unsure of gating for singlet or total beads | High levels of counting bead aggregates | Follow the counting bead manufacturer's recommendation for including or excluding aggregates. | Counting bead concentration calculations will vary by manufacturer. |
| Want to use a different CD34 antibody clone | Multi-parametric flow cytometry considerations | Alternative antibody clones must be carefully validated against the specified CD34 antibodies. Choose a class II or class III antibody that detects all CD34 isoforms and glycoforms. | Class I antibodies do not detect all CD34 glycoforms. |
| Want to use a different CD45 antibody clone | Multi-parametric flow cytometry considerations | Alternative antibody clones must be carefully validated against the specified CD45 antibodies. Choose an antibody that detects all isoforms and all glycoforms of CD45. | — |

## CALCULATION OF ABSOLUTE CD34 NUMBER

The absolute number of viable CD34+ cells/µL is calculated as follows:

$$\text{Viable CD34+ cells/µL} = (\text{number of CD34+ cells})/(\text{number of counting beads}) \times (\text{bead concentration} \times DF)$$

*DF* = sample dilution factor

The number of CD34+ cells is determined from the viable CD34+ cells (region *R5* from *Table 1*, Step 6). Depending on the recommendations of the counting bead manufacturer, the number of counting beads is determined from either the total counting beads (region *R7* from *Table 1*, graph 7) or the singlet counting beads (region *R8* from *Table 1*, graph 8). The bead concentration is specified by the counting bead manufacturer.

# ⟨129⟩ ANALYTICAL PROCEDURES FOR RECOMBINANT THERAPEUTIC MONOCLONAL ANTIBODIES

## INTRODUCTION

This chapter provides analytical procedures for murine, chimeric, and humanized IgG isotype monoclonal antibodies and subtypes (e.g., IgG1 and IgG2). Subclasses show differences in amino acid sequence and in the number of disulfide bonds, and in some cases they require subclass-specific analysis. This chapter applies to monoclonal antibodies for therapeutic and prophylactic use and for use as in vivo diagnostics. It does not apply to monoclonal antibodies used as reagents in the manufacture of medicinal products, for which applicable requirements are determined by the appropriate regulatory agency.

Naturally occurring polyclonal antibodies in serum or plasma can bind to many different targets as part of the immune system. In contrast, therapeutic monoclonal antibodies for human use are preparations of an immunoglobulin (or a fragment of an immunoglobulin) that have specificity for a target and are derived from a single clone of cells. Therapeutic monoclonal antibodies can bind to and neutralize soluble antigens, and their mechanism of action (MOA) often involves blocking of the ligand from binding to its cognate receptor. Alternatively, therapeutic monoclonal antibodies can recognize and bind to cell-bound antigens and in these cases may also engage the immune system through Fc (crystallizable fragment) mediated effector functions as part of their MOA. Monoclonal antibodies that have a single defined binding specificity are monospecific, whereas recombinantly engineered bispecific monoclonal antibodies can bind to two different targets (e.g., antigens). IgG-type monoclonal antibodies have a molecular weight of approximately 150 kD. Each molecule consists of two heavy and two light polypeptide chains that have a molecular weight of approximately 50 and 25 kD, respectively. Antibodies can be schematically represented as a Y joined by disulfide bridges, where each arm of the Y is called the Fab domain, and the stem of the Y is called the Fc domain. Monoclonal antibodies are glycoproteins that have a glycosylation site in the Fc portion located on each of the heavy chains and have possible additional glycosylation sites in the Fab domain, depending on the molecule.

The specificity of a monoclonal antibody is based on its antigen binding site, which is located in the Fab part of the molecule. The Fc domain contains receptor binding sites that are associated with antibody effector functions that have subclass-specific applications such as antibody-dependent cellular cytotoxicity and complement-dependent cytotoxicity. Pharmacokinetic effects via binding to the neonatal Fc receptor also are present in this domain.

Monoclonal antibodies are produced in cell culture using a seed lot system with master and working cell banks. After harvest, purification steps ensure that product- and process-related impurities are reduced to an acceptable level.

Currently licensed monoclonal antibody therapeutics include those involved in the activation of effector cells, cell killing, cross-linked induced apoptosis, antagonism against several targets, and agonist antibodies.

This chapter includes purity assessments by size-exclusion chromatography (SE-HPLC), capillary electrophoresis, and analysis of oligosaccharides, and it provides validated procedures for each of these.

Although this chapter is focused on IgG-type monoclonal antibodies, the principles of the tests included can apply to other related molecules, such as IgM or other isotype antibodies, antibody fragments, and Fc-fusion proteins. When the active substance is a conjugated antibody, such tests can be performed on the purified antibody before modification or conjugation.

Alternative methods and/or procedures may be used if they provide advantages in terms of accuracy, sensitivity, precision, selectivity, or adaptability to automation or computerized data reduction, or in other special circumstances. Such alternative procedures and methods shall be validated as described in *Validation of Compendial Procedures* ⟨1225⟩ and must be shown to give equivalent or better results.

### • Size-Exclusion Chromatography

Although SE-HPLC is robust for measuring monomer and high-molecular-weight species (HMWS, aggregates), the quantitation of low-molecular-weight species (LMWS, fragments) can be highly variable depending on the mAb studied. The measurement of LMWS is better quantitated by capillary electrophoresis sodium dodecyl sulfate (CE-SDS).

**Mobile phase:** Prepare by mixing 10.5 g of dibasic potassium phosphate, 19.1 g of monobasic potassium phosphate, and 18.6 g of potassium chloride per L of water. Verify that the pH is 6.2 ± 0.1. Pass through a membrane filter of ≤ 0.45-µm or smaller pore size.

**System suitability solution:** Prepare a 10-mg/mL USP Monoclonal IgG System Suitability RS solution in *Mobile phase* by reconstituting the contents of one vial with 200 µL of *Mobile phase*. Reconstituted *System suitability solution* should be used within 24 h after reconstitution, and should be stored at 2°–8° if not used immediately.

**System suitability blank:** Use *Mobile phase*.

**Sample solution:** Dilute the sample to 10 mg/mL in *Mobile phase* if dilution is required. Similarly, a blank should be prepared using an equivalent dilution of formulation buffer in *Mobile phase*.

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 280 nm

**Column:** 7.8-mm × 30-cm; 5-µm packing L59

**Temperatures**

**Column:** Ambient

**Autosampler:** Maintain at 2°–8°

**Flow rate:** 0.5 mL/min

**Injection volume:** 20 µL

**Run time:** 30 min

**System suitability**

**Sample:** *System suitability solution*

[Note—Approximate retention times for polymer, dimer, monomer, and LMWS are 12, 15, 18, and 22 min, respectively.]

**Suitability requirements**

**Chromatogram:** The chromatogram of the *System suitability solution* is consistent with the typical chromatogram as illustrated in the USP Certificate for USP Monoclonal IgG System Suitability RS.

**Chromatogram similarity:** The chromatographic profiles of *System suitability solution* injections that bracket injections of *Sample solutions* in a sample set are consistent with each other and with the typical chromatographic profile as illustrated in the USP Certificate for USP Monoclonal IgG System Suitability RS. All named peaks in the typical chromatogram must be present, be well-resolved, and in the same elution order as that in the *System suitability solution* chromatograms.

**Quantitative criteria:** Bracketing *System suitability solution* injections must meet the following quantitative criteria:
The percent peak area of the HMWS in the *System suitability solution* must be 0.4%–0.67%.
The percent peak area of the main peak in the *System suitability solution* must be 99.1%–99.6%.
The percent peak area of the LMWS in the *System suitability solution* must be NMT 0.2%.

**Analysis**

**Samples:** *Blank, System suitability solution*, and *Sample solution*

Injections of the *Sample solution* should be bracketed minimally with single injections of the *System suitability solution*. An injection of a *Blank* should be included as the final injection before the final *System suitability solution* injection.

**Calculations:** Using a suitable electronic integrator or computer system, analyze the bracketing *System suitability solution* injections. Exclude from integration any peaks that are present in the *Blank*. Protein-related peaks that elute before the main peak are classified as HMWS; those that elute after the main peak are classified as LMWS. Report the percentage of peak areas for the HMWS, main peak, and LMWS.

- **Capillary SDS Electrophoresis (Reduced and Nonreduced)**

Capillary sodium dodecyl sulfate (CE-SDS) electrophoresis is a sensitive, analytical method for quantitative estimation of product-related impurities such as nonglycosylated molecules, half antibodies, and fragments, and thus is also useful as a stability-indicating assay. After denaturation with SDS, the method allows the analysis of the complete antibody under nonreducing conditions, and the analysis of light and heavy chains (LC and HC, respectively) under reducing conditions.

[Note—Slight variations in sample preparation may be necessary depending on the stability of the individual antibody. If 15 min incubation at 70° leads to fragmentation or cleavage of disulfide bonds for a particular antibody sample, adjust the incubation time accordingly.]

**SDS sample buffer:** Prepare a solution containing 100 mM tris-hydrochloride (tris-HCl), a pH of 8.95 ± 0.05, and 1% (w/w) SDS.

**SDS gel buffer:** Buffer at a pH of 8.0 containing 0.2% (w/w) SDS and an appropriate hydrophilic polymer acting as a molecular sieve[1]

**Alkylation solution:** 250 mM iodoacetamide in water prepared immediately before use

**System suitability solution:** Reconstitute 1 vial of USP Monoclonal IgG System Suitability RS with 0.5 mL of *Water for Injection* (WFI) to a final concentration of 4 mg/mL.

**Internal standard solution:** 5 mg/mL of 10 kDa internal standard[2] in water containing 0.5% (w/w) SDS and 0.2% (w/v) sodium azide

**Nonreduced system suitability solution:** Mix 25 µL of the *System suitability solution* with 4 µL of *Internal standard solution*. Mix 66 µL of *SDS sample buffer* with 5 µL of the *Alkylation solution*. Add the *SDS sample buffer* and *Alkylation solution* mixture to the *System suitability solution* and *Internal standard solution* mixture. Mix thoroughly, and heat the mixture at 70° for 15 min. Allow to cool for 3 min at room temperature, centrifuge at 300 × g for 1 min, and transfer 100 µL into autosampler vials.

**Reduced system suitability solution:** Mix 25 µL of the *System suitability solution* with 66 µL of *SDS sample buffer*. Add 4 µL of *Internal standard solution* and 5 µL of neat β-mercaptoethanol. Mix thoroughly, and heat the mixture at 70° for 15 min. Allow to cool for 3 min at room temperature, centrifuge at 300 × g for 1 min, and transfer 100 µL into autosampler vials.

**Blank solution:** Mix 45 µL of water with 50 µL of *SDS sample buffer*. Add 4 µL of *Internal standard solution* and 5 µL of neat β-mercaptoethanol for the reduced conditions or 5 µL of *Alkylation solution* for the nonreducing conditions. Mix thoroughly, and heat the mixture at 70° for 15 min. Allow to cool for 3 min at room temperature, centrifuge at 300 × g for 1 min, and transfer 100 µL into autosampler vials.

**Nonreduced sample solution:** Dilute 100 µg of the sample to be tested with 50–95 µL of *SDS sample buffer* to give a final volume of 95 µL. Add 4 µL of *Internal standard solution* and 5 µL of the *Alkylation solution*. Mix thoroughly, and heat the mixture at 70° for 15 min. Allow to cool for 3 min at room temperature, centrifuge at 300 × g for 1 min, and transfer 100 µL into autosampler vials.

**Reduced sample solution:** Dilute 100 µg of the sample to be tested with 50–95 µL of *SDS sample buffer* to give a final volume of 95 µL. Add 4 µL of *Internal standard solution* and 5 µL of neat β-mercaptoethanol. Mix thoroughly, and heat the mixture at 70° for 15 min. Allow to cool for 3 min at room temperature, centrifuge at 300 × g for 1 min, and transfer 100 µL into autosampler vials.

**Instrumental conditions**

**Mode:** CE-SDS

**Detector:** UV or diode array 220 nm

**Capillary:** Fused-silica capillary (i.d. 50 µm) cut to a total length of 30 cm with an effective length of 20 cm.[3] The following preconditioning and prefilling steps are required between each run.

**Preconditioning of the capillary:** Rinse for 3 min at 70 psi with 0.1 N sodium hydroxide followed by 0.1 N hydrochloric acid for 1 min at 70 psi, and water for 1 min at 70 psi.

**Prefilling of capillary:** Rinse for 10 min at 70 psi with *SDS gel buffer*.

[1] Available from Beckman Coulter as a component of test kit, catalog number A10663, or a suitable equivalent.
[2] Available from Beckman Coulter as a component of test kit, catalog number A10663, or a suitable equivalent.
[3] Beckman Coulter catalog number 338472 or equivalent.

Official

**Sample injection:** Electrokinetic injection, 5.0 kV reversed polarity for 20 s
**Voltage separation**
**Nonreduced conditions:** Run time 40 min at 15 kV, reversed polarity
**Reduced conditions:** Run time 40 min at 15 kV, reversed polarity
**Temperatures**
**Sample storage:** Approximately 25°
**Capillary:** Approximately 25°

**System suitability**

**Suitability requirements for reducing conditions**

**Sample:** *Reduced system suitability solution*

**Electropherogram:** The electropherogram of the *Reduced system suitability solution* is consistent with the typical electropherogram illustrated in the USP Certificate for USP Monoclonal IgG System Suitability RS.

**Resolution:** The main peak of the heavy chain and the peak of the nonglycosylated heavy chain can be clearly identified. The resolution between the nonglycosylated heavy chain and the intact heavy chain is NLT 1.2.

**Ratio of nonglycosylated to total heavy chain:** Use time-corrected peak areas (see *Capillary Electrophoresis* ⟨1053⟩, *Quantification*, which may be a helpful, but not mandatory resource) for calculation. Calculate the ratio of nonglycosylated to total heavy chain by dividing the relative amount of nonglycosylated heavy chain by the sum of all heavy chains, and multiply by 100. The ratio of nonglycosylated to total heavy chain in the *System suitability solution* should be within the limits of 0.75%–1.34%.

**Suitability requirements for nonreducing conditions**

**Sample:** *Nonreduced system suitability solution*

**Electropherogram:** The electropherogram of the *Nonreduced system suitability solution* is consistent with the typical electropherogram illustrated in the USP Certificate for USP Monoclonal IgG System Suitability RS.

**Resolution:** The IgG main peak can be clearly identified. The resolution between the IgG main peak and Fragment 1 (F1) is NLT 1.3.

**Amount of main peak:** Calculate the relative amount of the main peak by dividing the sum of the time-corrected peak area of the main IgG peaks by the sum of all time-corrected peak areas excluding internal standard peaks and all system peaks, and multiply by 100. The relative amount of the main IgG peak of the *System suitability solution* should be within the limits of 61.4%–86.4%.

**Relative standard deviation:** NMT 2% for the migration of the internal standard in the bracketing *Blank solution*. No other peaks migrating after the internal standard are detectable.

**Analysis**

**Samples:** *Blank solution, System suitability solution*, and *Sample solution*

[NOTE—Based on instrument requirements, the field applied across the capillary and the conditions for the sample injection may be adjusted to achieve *System suitability*.] Apply a field strength of 500 V/cm (reversed polarity) for 40 min, using the *SDS gel buffer* as the electrolyte in both buffer reservoirs. Electrophorese the samples, using a 20-s reversed polarity and electrokinetic injection at 5.0 kV, into the anodic end of the capillary, and record the electropherograms at 220 nm. Rinse for 3 min at 70 psi with 0.1 N sodium hydroxide followed by 0.1 N hydrochloric acid for 1 min at 70 psi, and water for 1 min at 70 psi. Inject at least in duplicate.

Calculate the time-corrected peak areas of all peaks migrating after the internal standard peak.

**Reduced conditions:** Calculate the relative amount of product peak by dividing the sum of the time-corrected peak areas of heavy chain, nonglycosylated heavy chain, and light chain by the sum of all time-corrected peak areas for peaks appearing after the internal standard, and multiply by 100.

**Nonreduced conditions:** Calculate the relative amount of product peak by dividing the sum of the time-corrected peak area of the main IgG peak by the sum of all time-corrected peak areas for peaks appearing after the internal standard, and multiply by 100.

- **OLIGOSACCHARIDE ANALYSIS—ANALYSIS OF *N*-LINKED OLIGOSACCHARIDES OF MONOCLONAL ANTIBODIES**

The inclusion of oligosaccharide analysis in a specification for a monoclonal antibody drug substance should be assessed using science- and risk-based approaches and should be defined on a product-specific basis. If applicable, one or more of the following analytical approaches can be employed for oligosaccharide profiling or quantitation of individual structures. Other validated methods that are suitable for determination of *N*-linked glycosylation utilizing different modes of separation, labeling, or detection can be used. [NOTE—For monoclonal antibodies with both Fc and Fab *N*-linked oligosaccharides, additional sample preparation procedures (e.g., treatment with the enzyme papain) can be employed to separate the domains before analyses so that information at individual glycosylation sites can be obtained. All additional sample preparation steps for the method require validation.]

[NOTE—Numerical acceptance criteria may be defined for individual glycan structures. If applicable, acceptance criteria must be derived from product-specific information taking into consideration a suitable range of historical batch data.]

**Method A: Capillary electrophoresis with laser-induced fluorescence detection**

**Run buffer:** Prepare 100 mM triethanolamine (TEA) and 10% glycerol at pH 7.5 by dissolving 1.492 g of TEA and 10 g of glycerol in 80 mL of water. Adjust with 1 N hydrochloric acid to a pH of 7.5, and dilute with water to a final volume of 100 mL.

**Sample buffer:** Dilute 1 mL of *Run buffer* with 9 mL of water.

**Enzyme reaction buffer:** Prepare 50 mM sodium phosphate, pH 7.5.

**APTS labeling reagent:** Dissolve 5 mg of 8-aminopyrene-1,3,6-trisulfonate (APTS) in 48 µL of 15% acetic acid, and mix.

**Sample solution:** Add 2 µL of peptide *N*-glycosidase F (PNGase F) (5 units/mL) to 50 µg of sample, and adjust with *Enzyme reaction buffer* to a volume of 50 µL. [NOTE—The unit definition for PNGase F may differ among commercial sources. It may be necessary to experimentally determine the appropriate quantity of PNGase F required for the complete release of *N*-linked oligosaccharides in the sample.] Incubate at 37° for 18 h. Separate released oligosaccharides by centrifugation using a 10,000 molecular-weight-cut-off (MWCO) centrifugal filter. Dry the released

oligosaccharides in a centrifugal vacuum evaporator to dryness. Add 2 µL of *APTS labeling reagent* and 2 µL of 1 M sodium cyanoborohydride to the dried oligosaccharides. Incubate at 55° for 90 min. Add 46 µL of water to quench the reaction and mixture. Add 5 µL of APTS-labeled sample to 95 µL of *Sample buffer*.

**System suitability solution:** Resuspend each of the suitable glycan standards (10 µg) in 50 µL of water, and mix on a vortex mixer. Add 5 µL of a suitable glycan standard (1 µg) to a microcentrifuge tube. Dry the glycan standard using centrifugal vacuum evaporation at ambient temperature. Add 2 µL of sodium cyanoborohydride to each standard. Add 2 µL of the *APTS labeling reagent* to each standard. Mix the standards on a vortex mixer, and centrifuge briefly to settle the liquid before incubation at 55° for 90 min. Quench the reaction by the addition of 46 µL of water to each standard. Standards can be stored at –20° up to 5 weeks.

**Instrumental conditions**

**Mode:** CE

**Detector:** Laser-induced fluorescence detector (488-nm excitation wavelength; 520-nm emission wavelength)

**Capillary:** 50-µm inner diameter bare fused-silica capillary with 50-cm total length and 40-cm separation length

**Sample injection:** 10-s hydrodynamic injection

**Separation voltage:** 22kV for 50 min

**Samples:** *Sample solution* and *System suitability solution*

**Analysis:** Integrate peaks in the resultant electropherogram, and report relative percentage time-corrected peak areas of major glycan structures relevant to the product. Comparison to suitable product-specific reference standard can be performed.

**Method B: Liquid chromatography with fluorescence detection**

**Enzyme reaction buffer:** Prepare 100 mM sodium phosphate, a pH of 7.5.

**Labeling buffer:** Prepare 8% (w/v) sodium acetate trihydrate and 4% (w/v) boric acid solutions in methanol by dissolving 800 mg of sodium acetate trihydrate and 400 mg of boric acid in 10 mL of methanol.

**Labeling reagent solution:** Prepare a 100-mg/mL stock solution of anthranilic acid (2-AA) in *Labeling buffer.* Mix with an equal volume of 1 M sodium cyanoborohydride in methanol for a final *Labeling reagent solution* containing 50 mg/mL of 2-AA and 0.5 M sodium cyanoborohydride. [NOTE—Keep the labeling reagent protected from light.]

**Solution A:** Prepare 50 mM ammonium formate, pH 4.4.

**Solution B:** Acetonitrile

**Mobile phase:** See *Table 1*.

**Table 1**

| Time (min) | Solution A (%) | Solution B (%) |
|---|---|---|
| 0.0 | 32.5 | 67.5 |
| 48.0 | 42.5 | 57.5 |
| 49.0 | 100 | 0 |
| 53.0 | 100 | 0 |
| 54.0 | 32.5 | 67.5 |
| 60.0 | 32.5 | 67.5 |

**Sample preparation:** Transfer 80 µg of test sample to a microcentrifuge tube. Add 3 µL of PNGase F (2.5 units/mL). [NOTE—The unit definition for PNGase F may differ among commercial sources. It may be necessary to experimentally determine the appropriate quantity of PNGase F required for complete release of *N*-linked oligosaccharides in the sample.] Add 14 µL of *Enzyme reaction buffer.* Add water to 70 µL of total volume, and incubate at 37° for 18 h. Add 70 µL of freshly prepared *Labeling reagent solution*, and incubate at 70° for 2 h in a fume hood. Allow to cool, and add 60 µL of 50% methanol to each sample. Mix, then centrifuge. Remove 140 µL of the supernatant, and transfer to a microcentrifuge tube. Add 500 µL of acetonitrile to the supernatant-containing tube. Load the sample onto a hydrophilic-interaction solid-phase extraction cartridge to remove excess labeling reagent. Wash the cartridge with 95% acetonitrile (approximately 10 mL). Elute the labeled glycans from the cartridge with 0.5 mL of 20% acetonitrile. Dilute the eluate 1:1 with acetonitrile.

**Chromatographic system**

(See *Chromatography* ⟨621⟩*, System Suitability*.)

**Mode:** LC

**Column:** 4.6-mm × 15-cm; 3-µm packing L68

**Detector:** Fluorescence (360-nm excitation wavelength; 420-nm emission wavelength)

**Column temperature:** Maintain column at 30°.

**Flow rate:** 0.8 mL/min

**Injection volume:** 50 µL

**Analysis**

**Sample:** *Sample preparation*

Integrate peaks in the resulting chromatogram, and report relative percentage peak areas of major glycan structures relevant to the product. Comparison to a suitable product-specific reference standard can be performed.

- **OLIGOSACCHARIDE ANALYSIS—SIALIC ACID ANALYSIS**

[NOTE—The range of the standard curve or the mass of test sample may require modification depending on the sialic acid content of the monoclonal antibody.]

**Analysis**

**Samples:** *Standard solutions*, *System suitability solution*, and *Sample solution*

Integrate the NeuAc, NeuGc, and *Internal standard stock solution* peaks in each chromatogram. For the *Standard solutions*, evaluate the NeuAc and NeuGc peak areas relative to the peak area of the *Internal standard stock solution* as follows.

Area of NeuAc peak/area of *Internal standard stock solution* peak × 100

Area of NeuGc peak/area of *Internal standard stock solution* peak × 100

Generate NeuAc and NeuGc standard curves. Quantify NeuAc and NeuGc in the *Sample solution* by comparison of the relative percent of NeuAc of the *Internal standard stock solution* and the relative percent of NeuGc of the *Internal standard stock solution*, using the standard curves.

Divide the determined NeuAc and NeuGc concentrations by the test sample concentration, and report as molar ratio (i.e., numbers of NeuAc and NeuGc per molecule of test sample).

# ⟨151⟩ PYROGEN TEST

## INTRODUCTION

The pyrogen test is designed to limit to an acceptable level the risks of febrile reaction in the patient to the administration, by injection, of the product concerned. The test involves measuring the rise in temperature of rabbits following the intravenous injection of a test solution and is designed for products that can be tolerated by the test rabbit in a dose not to exceed 10 mL/kg injected intravenously within a period of NMT 10 min. For products that require preliminary preparation or are subject to special conditions of administration, follow the additional directions given in the individual monograph or, in the case of antibiotics or biologics, the additional directions given in the federal regulations (see *Biologics* ⟨1041⟩). A validated, equivalent in vitro pyrogen or bacterial endotoxin test may be used in place of the in vivo rabbit pyrogen test,[1] where appropriate.

## APPARATUS AND DILUENTS

Render the syringes, needles, and glassware free from pyrogens by heating at 250° for NLT 30 min or by any other suitable method. Treat all diluents and solutions for washing and rinsing of devices or parenteral injection assemblies in a manner that will assure that they are sterile and pyrogen-free. Periodically perform control pyrogen tests on representative portions of the diluents and solutions for washing or rinsing of the apparatus. Where *Sodium Chloride Injection* is specified as a diluent, use Injection containing 0.9% of sodium chloride (NaCl).

## TEMPERATURE RECORDING

Use an accurate temperature-sensing device such as a clinical thermometer, or thermistor probes or similar probes that have been calibrated to assure an accuracy of ±0.1° and have been tested to determine that a maximum reading is reached in less than 5 min. Insert the temperature-sensing probe into the rectum of the test rabbit to a depth of NLT 7.5 cm, and, after a period of time NLT that previously determined as sufficient, record the rabbit's body temperature.

## TEST ANIMALS

Use healthy, mature rabbits. House the rabbits individually in an area of uniform temperature between 20° and 23° and free from disturbances likely to excite them. The temperature varies NMT ±3° from the selected temperature. Before using a rabbit for the first time in a pyrogen test, condition it NMT 7 days before use by a sham test that includes all of the steps as directed in *Procedure* except injection. Do not use a rabbit for pyrogen testing more frequently than once every 48 h, nor prior to 2 weeks following a maximum rise of its temperature of 0.6° or more while being subjected to the pyrogen test, or following its having been given a test specimen that was adjudged pyrogenic.

## PROCEDURE

Perform the test in a separate area designated solely for pyrogen testing and under environmental conditions similar to those under which the animals are housed and free from disturbances likely to excite them. Withhold all food from the rabbits used during the period of the test. Access to water is allowed at all times, but may be restricted during the test. If rectal temperature-measuring probes remain inserted throughout the testing period, restrain the rabbits with light-fitting neck stocks that allow the rabbits to assume a natural resting posture. NMT 30 min prior to the injection of the test dose, determine the "control temperature" of each rabbit: this is the base for the determination of any temperature increase resulting from the injection of a test solution. In any one group of test rabbits, use only those rabbits whose control temperatures do not vary by more than 1° from each other, and do not use any rabbit with a temperature exceeding 39.8°.

Unless otherwise specified in the individual monograph, inject into an ear vein of each of three rabbits 10 mL of the test solution per kg of body weight, completing each injection within 10 min after start of administration. The test solution is *either* the product, constituted if necessary as directed in the labeling, *or* the material under test treated as directed in the individual monograph and injected in the dose specified therein. For pyrogen testing of devices or injection assemblies, use washings or rinsings of the surfaces that come in contact with the parenterally administered material or with the injection site or internal tissues of the patient. Assure that all test solutions are protected from contamination. Perform the injection after warming the test solution to a temperature of 37 ± 2°. Record the temperature at 30-min intervals between 1 and 3 h subsequent to the injection.

## TEST INTERPRETATION AND CONTINUATION

Consider any temperature decreases as zero rise. If no rabbit shows an individual rise in temperature of 0.5° or more above its respective control temperature, the product meets the requirements for the absence of pyrogens. If any rabbit shows an individual temperature rise of 0.5° or more, continue the test using five other rabbits. If NMT three of the eight rabbits show

individual rises in temperature of 0.5° or more and if the sum of the eight individual maximum temperature rises does not exceed 3.3°, the material under examination meets the requirements for the absence of pyrogens.

# RADIOACTIVE PHARMACEUTICALS

## Test Dose for Preformulated, Ready-to-Use Products Labeled with Radioactivity

### AGGREGATED ALBUMIN AND OTHER PARTICLE-CONTAINING PRODUCTS

For the rabbit pyrogen test, dilute the product with *Sodium Chloride Injection* to NLT 100 µCi/mL, and inject a dose of 3 mL/kg of body weight into each rabbit.

### OTHER PRODUCTS

**Where physical half-life of radionuclide is greater than 1 day:** Calculate the maximum volume of the product that might be injected into a human subject. This calculation takes into account the maximum recommended radioactive dose of the product, in µCi, and the radioactive assay, in µCi/mL, of the product at its expiration date or time. Using this information, calculate the maximum volume dose per kg to a 70-kg human subject.

For the rabbit pyrogen test, inject a minimum of 10 times this dose per kg of body weight into each rabbit. If necessary, dilute with *Sodium Chloride Injection*. The total injected volume per rabbit is NLT 1 mL and NMT 10 mL of solution.

**Where physical half-life of radionuclide is less than 1 day:** For products labeled with radionuclides with a half-life of less than 1 day, the dosage calculations are identical to those described in the first paragraph in *Other Products*. These products may be released for distribution prior to completion of the rabbit pyrogen test, but such test must be initiated at NMT 36 h after release.

## Test Dose for Pharmaceutical Constituents or Reagents to Be Labeled

The following test dose requirements pertain to reagents that are to be labeled or constituted prior to use by the direct addition of radioactive solutions such as *Sodium Pertechnetate Tc 99m Injection*, i.e., "cold kits".

Assume that the entire contents of the vial of nonradioactive reagent will be injected into a 70-kg human subject, or that $^{1}/_{70}$ of the total contents per kg will be injected. If the contents are dry, constitute with a measured volume of *Sodium Chloride Injection*.

For the rabbit pyrogen test, inject ($^{1}/_{7}$) of the vial contents per kg of body weight into each rabbit. The maximum dose per rabbit is the entire contents of a single vial. The total injected volume per rabbit is NLT 1 mL and NMT 10 mL of solution.

# ⟨161⟩ MEDICAL DEVICES—BACTERIAL ENDOTOXIN AND PYROGEN TESTS

## INTRODUCTION

The methods and requirements in this chapter apply to assemblies or devices labeled sterile and nonpyrogenic that are in contact directly or indirectly with the cardiovascular system, lymphatic system, or cerebrospinal fluid. This includes, but may not be limited to, the following:

- Fluid pathways of catheters and administration sets such as solution administration sets, extension sets, transfer sets, blood administration sets, intravenous catheters, implants, extracorporeal oxygenator tubing, dialysis tubing, intramuscular drug delivery catheters, and transfusion and infusion assemblies
- Liquid medical devices such as dialysate
- Implantable medical devices such as heart valves and vascular grafts, and other medical devices with a nonpyrogenic claim that may come into contact with blood or cerebrospinal fluid
- Gels with a nonpyrogenic claim including demineralized bone matrices and drug delivery systems

## BACTERIAL ENDOTOXINS

For the bacterial endotoxins test (BET) assay parameters, procedures, standards, and controls for the gel-clot and kinetic and endpoint assays, proceed as directed in *Bacterial Endotoxins Test* ⟨85⟩, substituting the medical device eluate for the product sample.

## DEFINITIONS

### Endotoxin limit

- The endotoxin limit for the finished device is NMT 20 USP Endotoxin Units per device and NMT 2.15 USP Endotoxin Units for devices in contact with cerebrospinal fluid.
- For devices that directly or indirectly contact the intraocular environment, a lower endotoxin limit may apply (*1*).
- The endotoxin limit for the device extract in Endotoxin Units/mL is calculated as:

$$\text{Result} = (K \times N)/V$$

$K$ = limit for each device
$N$ = number of devices tested
$V$ = total volume of the extract

**Kit:** A kit is defined as a collection of individual devices in its primary package, or a variety of related devices. Each individual type of device may have its own product endotoxin limit and should be tested and evaluated on an individual basis; see *Table 1. Selection of Product Units for Testing* [refer to ANSI/AAMI ST72 (*2*)].

**Table 1. Selection of Product Units for Testing**

| Product Unit | Item for Testing |
|---|---|
| Individual medical device in a primary package where each medical device is used individually in clinical practice | Individual medical device |
| Set of components in a primary package where components are assembled as a product and are used together in clinical practice | Combination of components |
| A number of identical medical devices in one primary package where each medical device is used independently in clinical practice | Single medical device taken from the primary package |
| Kit of procedure-related medical devices where each medical device is used independently in clinical practice and where each medical device may have a different endotoxin limit | Each type of medical device that has a nonpyrogenic claim, or all items together |

**Lambda (λ):** λ is the test method sensitivity for gel-clot methods. For turbidometric or chromogenic technique, λ is equal to the lowest endotoxin concentration on the referenced standard curve.

**Product families:** Product families for the purposes of BET may be defined on the basis of common materials of construction and/or common components. The choice of family members should be justified and documented. If a product family contains devices of many sizes, the device with the largest surface area claimed to be nonpyrogenic is chosen as the representative member of the family to be used in suitability testing.

**Extracting or rinsing solution:** *Water for BET* [see *Bacterial Endotoxins Test* ⟨85⟩*, Reagents and Test Solutions, Water for Bacterial Endotoxins Test (BET)*] or other suitable solvent demonstrated to be noninterfering with the BET assay is used to extract or rinse the medical device.

Official

https://pharmacopeia.cn/v29240/

### Sampling

1. *Sample*: A sample for end-product testing must be in its final configuration and packaging, including all component parts that make up the final medical device.
2. *Representative sampling*: A representative sample is a sample plan that is created and justified based on the assumption that the manufacturing process is validated and in a state of control.
3. *Sample size*: The number of devices chosen for routine testing is dependent on the size of the lot, level of control, statistical considerations, and historical performance. In most cases, each lot of product must be tested using an appropriate number of samples, NMT 10, taken at random to represent the quality of the lot. Alternate sampling plans that utilize small sample sizes or do not test each lot of product must be clearly defined and must be supported/justified by a robust risk assessment.
4. *Pre-post sterilization samples*: When qualifying a BET assay for pre-sterilization samples, equivalency in test results must be shown with post-sterilization samples to ensure that sterilization and post-sterilization handling have no adverse impact on the accuracy of the test result. Pre-sterilization testing is inappropriate for products that support microbial growth.

**Suitability testing (also known as test for interfering factors):** Suitability studies of device extracts are designed to ensure that the device extract under test does not adversely impact the accuracy of the test result by either a) causing the assay to underestimate endotoxin (inhibition) or b) contributing to overestimation of endotoxin (enhancement).

## REAGENTS AND TEST SOLUTIONS

See ⟨85⟩.

## PREREQUISITES TO TESTING

### Apparatus

All equipment used in the extraction or testing process must be properly qualified and/or calibrated as appropriate. This equipment includes but is not limited to water baths, heat blocks, mechanical pipetters (fixed, adjustable, and repeating pipetters), thermometers, and plate/tube/cartridge readers.

Depyrogenate all glassware and other heat-stable materials in a hot air oven using a validated process. If employing plastic apparatus such as microplates and pipet tips for automatic pipetters, use apparatus that is shown to be free of detectable endotoxin and does not interfere with the test.

Analysts must be properly trained to perform the assay.

The assay sensitivity must be confirmed as described in *Bacterial Endotoxins Test* ⟨85⟩, *Gel-Clot Technique, Preparatory Testing, Test for Confirmation of Labeled Lysate Sensitivity* for gel-clot reagents and *Bacterial Endotoxins Test* ⟨85⟩, *Photometric Quantitative Techniques, Preparatory Testing, Assurance of Criteria for the Standard Curve* for quantitative methods. Assay sensitivity confirmation must be carried out when a new batch of reagent (lysate or endotoxin) is used or when there is any change in the test conditions that could affect the outcome of the test.

## PREPARATION OF DEVICES: STANDARD METHODS

### Endotoxin Limit

The endotoxin limit for the extracting or rinsing solution is:

$$\text{Result} = (K \times N)/V$$

$K$ = amount of endotoxin allowed per device (20 Endotoxin Units per device; 2.15 for intrathecal devices)
$N$ = number of devices tested
$V$ = total volume of the extract or rinse

[NOTE—The volume of the rinse or extract may be adjusted for the size and configuration of the device.]

The standard extracting fluid for extracting, rinsing, or soaking medical devices is *Water for BET*. If necessary, other solvents may be used after it has been demonstrated that they do not interfere with the performance of the assay. Extraction is not required for liquid medical devices. Either the entire device if claimed to be nonpyrogenic or all components of the device that are claimed to be nonpyrogenic, including fluid pathways, must come in contact with the extraction fluid for the entire course of the extraction.

The standard extraction method is to soak or immerse the device or flush the fluid pathway with extracting fluid that has been heated to 37 ± 1.0°, keeping the extracting fluid in contact with the relevant surface(s) for NLT 1 h at controlled room temperature. Alternate extraction or rinsing methods may be used, but must be demonstrated to be equivalent to or better than the standard method. Extracts from individual medical devices are typically pooled for testing.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M98910_01_01

### Suitability

Suitability of the BET assay must be demonstrated for each product or product family. The number of batches of product chosen for the suitability study is reflective of the level of control of the process and must be justified.

For the suitability test, medical device extracts or liquid medical devices are considered to be the sample solutions under test and are tested as outlined for the chosen technique in *Bacterial Endotoxins Test* ⟨85⟩, *Gel-Clot Technique, Preparatory Testing, Test for Interfering Factors*.

If necessary, adjust the pH of the solution to be examined (or dilution thereof) so that the pH of the mixture of the lysate and sample solution falls within the pH range specified by the lysate manufacturer, usually pH 6.0–8.0. The pH may be adjusted by use of an acid, base, or suitable buffer as recommended by the lysate manufacturer. Acids and bases may be prepared from concentrates or solids with *Water for BET* in containers free of detectable endotoxin. Buffers must be shown to be free of detectable endotoxin and interfering factors.

If the undiluted rinsing or extracting solution or liquid medical device is determined to be unsuitable for ⟨85⟩, the test for interfering factors may be repeated utilizing dilution or a method that will neutralize or eliminate the interfering substance.

If glucan interference is suspected, the use of a glucan-blocking agent or endotoxin-specific lysate is permissible.

Dilution in *Water for BET* or other validated solvent by a factor not to exceed the maximum valid dilution (MVD) is permissible. The MVD for medical devices is the following:

$$\text{MVD} = \text{Endotoxin limit (of the rinsing, extracting, or diluting solution in Endotoxin Units/mL)}/\lambda$$

$\lambda$ = sensitivity of the test method in Endotoxin Units/mL

Interference may be overcome by suitable treatment of the device extract. Methods for overcoming interference and the qualification of such treatments are described in ⟨85⟩. To establish that the chosen treatment effectively eliminates interference without loss of endotoxins, perform the assay described in ⟨85⟩ using the preparation to be examined to which standard endotoxin has been added and which has then been submitted to the chosen treatment.

## DEMONSTRATION OF CONTINUED SUITABILITY

The continued suitability of the assay should be re-assessed when significant changes are made to the product, process, raw material supply, manufacturing and/or testing site, BET reagent source, or any other change that could adversely affect the accuracy of the BET result. The results of this re-assessment should be documented, and suitability studies re-executed as necessary.

Changes to extraction techniques require a new suitability study. Because of possible changes in interference patterns between standard BET methods, a change in BET methodology (e.g., from gel-clot limits test to kinetic chromogenic) requires a re-execution of the suitability study.

### Routine Testing

Routine testing of the finished medical devices must utilize the same extraction techniques that were documented in the successful suitability study.

Routine testing is to be performed as outlined in ⟨85⟩, following instructions for incubation and controls listed under the chosen assay technique.

### Interpretation of Test Results

See ⟨85⟩. The preparation under test complies with the test if the mean endotoxin concentration of the replicates of *Solution A*, after correction for dilution and concentration, is less than 20 Endotoxin Units per medical device (2.15 Endotoxin Units per medical device for those devices that come in contact with the cerebrospinal fluid.) For liquid medical devices, the limit meets the requirements set forth in *Bacterial Endotoxins Test* ⟨85⟩, *Determination of Maximum Valid Dilution (MVD), Endotoxin Limit, footnote 2*.

If a device fails to meet this requirement, an investigation may be initiated per documented procedures. A failed, valid BET assay may not be repeated using *Pyrogen Test* ⟨151⟩ in its place.

## PYROGENS

For samples that cannot be tested by BET because of nonremovable inhibition or enhancement of the test, ⟨151⟩ is applied. Select an appropriate number of devices, NMT 10, and obtain a pooled extract utilizing preparation methods appropriate to the device as directed for bacterial endotoxins, but with volumes of rinse or extraction fluid not to exceed 40 mL of sterile saline test solution per device. The requirements of ⟨151⟩ must be met.

# ⟨162⟩ DIPHTHERIA ANTITOXIN POTENCY TESTING FOR HUMAN IMMUNE GLOBULINS

An in vitro method is provided that is suitable for determining the potency of diphtheria antitoxin (antibodies against the diphtheria toxin) in preparations of plasma-derived human immune globulins. Diphtheria toxin is produced by *Corynebacterium diphtheriae* and has the ability to produce a cytopathogenic effect on susceptible epithelial cell lines. The test is based on the ability of diphtheria antitoxin to neutralize the diphtheria toxin, decreasing its cytotoxic effect. Specifically, the test determines the potency of the diphtheria antitoxin based on its ability to inhibit the cytotoxic effect of diphtheria toxin on cultured Vero cells (African green monkey kidney epithelial cells) relative to a reference standard. The mitochondrial dehydrogenases of live Vero cells can reduce the dye 3-(4,5-dimethylthiazol-2-yl)-2,5 diphenyltetrazolium bromide (MTT) to a blue–black product that is then measured by absorbance at 540 nm. If little or no diphtheria antitoxin is present, then diphtheria toxin induces cell death and the inability of cells to reduce MTT, resulting in the presence of white or colorless wells. Acceptance criteria are defined by the appropriate regulatory agencies.

**DMEM-2 solution:** Dulbecco's Modified Eagle's Medium,[1] supplemented to contain 2% FBS ▲or a suitable chemically defined alternative,▲ (USP 1-May-2022) 2 mM L-glutamine, 50 µg/mL of gentamicin, and 2.5 µg/mL of fungizone. [NOTE—Alternatively, a combination of 0.1 mg/mL of kanamycin sulfate, 0.1 units/mL of penicillin, and 0.1 mg/mL of streptomycin can be used in place of gentamicin.]

**MTT solution:** 5 mg/mL of MTT in phosphate-buffered saline.[2] Prepare just before use and minimize exposure to room light.

**Extraction solution:** 0.4 N hydrochloric acid in isopropanol

**Toxin test solution:** Obtain a liquid preparation of toxin from a culture of *C. diphtheriae*.[3] It may have been rendered sterile by filtration, and sterility may be maintained by the inclusion of a suitable antimicrobial preservative. ▲If using fresh, noncommercially available toxin,▲ (USP 1-May-2022) store the filtrate in the dark at 2°–8° for several weeks until the activity is considered to be constant, as determined by testing. Dilute the toxin in *DMEM-5 solution* to obtain a suitable *Toxin test solution* that provides a working equivalence with the *Standard solution*. [NOTE—An appropriate *Toxin test solution* may be empirically determined as follows. ▲The example described here is for an assay performed using a toxin dose level of LCD/40 (where "LCD" stands for limit of cytotoxic dose, and "/40" refers to 1/40 units/mL [or 0.025 units/mL]).▲ (USP 1-May-2022) Titrate the toxin against a fixed concentration of antitoxin (e.g., ▲0.025▲ (USP 1-May-2022) units/mL) using volumes and media as defined below. Determine the lowest concentration of toxin that causes Vero cell toxicity in the presence of the ▲fixed▲ (USP 1-May-2022) antitoxin concentration. ▲▲ (USP 1-May-2022) This is ▲the toxin▲ (USP 1-May-2022) concentration that should be used in the *Assay*.]

**Trypsin–EDTA solution:** Dissolve 0.4 g of trypsin, 0.2 g of ethylenediaminetetraacetic acid (EDTA), and 0.85 g of sodium chloride in 100 mL of sterile water. Use cell culture grade and sterile reagents to prepare. Alternatively, a premade sterile preparation may be used.

**Cell culture preparation:** Prepare Vero cells[4] by culturing in 75-cm$^2$ tissue culture flasks in *DMEM-5 solution* at 36 ± 1°, 5% carbon dioxide in a humidified environment. [NOTE—Alternative flask sizes may be used by adjusting the volumes used below.] After 2–3 days of growth, the medium may be replaced by *DMEM-2 solution* and growth allowed to continue. When the cells have reached a confluent monolayer, discard the culture media. Wash the cell layer by pipetting 5 mL of *Trypsin–EDTA solution* into the flask and gently rocking the flask back and forth for approximately 30 s. Remove and discard the *Trypsin–EDTA solution*. Add an additional 5 mL of *Trypsin–EDTA solution*, and gently rock back and forth for ▲approximately▲ (USP 1-May-2022) 1 min. Remove and discard all but 1 mL. Incubate at 36 ± 1°, 5% carbon dioxide, in a humidified environment for approximately 10 min or until the cell sheet begins to slough from the flask, and tap the flask to release the cells. Add 10 mL of *DMEM-5 solution* to the trypsinized cells, count the cells, and adjust the cell suspension to 1 × 10$^5$ cells/mL in the same medium.

**Standard solutions:** In sterile tubes, prepare 4 concentrations of the standard by diluting ▲an appropriate diphtheria antitoxin standard suitable for the Vero cell assay▲ (USP 1-May-2022)[5] with *DMEM-2 solution* to 1 unit/mL, followed by serial dilutions in the same media that result in the additional concentrations of 0.5, 0.25, and 0.1 units/mL.

**Sample solutions:** ▲In sterile tubes, use *DMEM-2 solution* to dilute each human immune globulin test sample to 1.25% protein.▲ (USP 1-May-2022)Further dilute the samples with *DMEM-2 solution* to achieve an expected diphtheria antitoxin concentration that is within the range of the *Standard solutions* (i.e., 1–0.1 units/mL).

**Analysis**

**Samples:** *Toxin test solution*, *Standard solutions*, and *Sample solutions*

https://pharmacopeia.cn/

Test each *Standard solution* or *Sample solution* in duplicate. Label 96 well culture plates by marking off the 8-well columns in groups of two; all 4 *Standard solutions* and 1 *Sample solution* can be tested per plate. As described below, columns 11 and 12 can be used for the untreated cell control and the toxin control, respectively. [NOTE—Alternative plate layouts maintaining the dilutions can be used.] Add 112.5 µL of *DMEM-2 solution* to each well in row A, columns 1–10 only (these are standard- or sample-nonspecific toxicity controls). Add 75 µL of *DMEM-2 solution* to each well in rows B–H, columns 1–10 only.

Add 37.5 µL of a *Standard solution* dilution or a *Sample solution* to wells A1–A2, and add 75 µL of the same solution to wells B1–B2. Add 37.5 µL of a second *Standard solution* dilution or *Sample solution* to wells A3–A4, and add 75 µL of the same solution to wells B3–B4. Continue to make similar additions of *Standard solution* dilutions or *Sample solutions* to each group of two columns in columns 1–10. Make two-fold serial dilutions by transferring 75 µL from each well in row B to each well in row C of the same column. Mix and then continue transferring 75 µL in the same manner down each column. Discard the last 75 µL after mixing row H. Add 75 µL of the *Toxin test solution* to rows B–H in columns 1–10. Add 150 µL of *DMEM-2 solution* to all wells in column 11 (cell control), and add 75 µL of *DMEM-2 solution* plus 75 µL of *Toxin test solution* to all wells in column 12 (toxin control).

Cover the plates, and incubate them for 1 h at 36 ± 1°, at 5% carbon dioxide in a humidified environment. Add 150 µL of cell suspension to all wells, cover the plates, and incubate them at 36 ± 1°, at 5% carbon dioxide in a humidified environment. Incubate for 4–5 days, checking periodically for microbial contamination by microscopic examination. Once toxicity control wells in row A containing the lowest concentration of a *Standard solution* are nearly confluent, add 15 µL of *MTT solution* to each well. Cover the plates, and incubate them in the carbon dioxide incubator at 37° for 3 h. Discard the medium, and add 150 µL of *Extraction solution* to each well. Cover the plates, and place aluminum foil over them to minimize light exposure. Shake gently to solubilize the blue formazan formed by viable cells. Using a suitable plate reader, read the absorbance of each well at a wavelength of 540 nm.

**Calculation:** The cutoff dilution is the highest dilution in which there are still viable cells in the well but beyond which there are no viable cells. Cutoff dilution is defined by a corresponding absorbance (Abs). [NOTE—The average absorbance value can be calculated for the cell control wells in column 11 and divided by 2 to obtain a 50% control Abs value. This value can be used to determine cutoff dilutions. The cutoff dilution for each *Standard solution* and *Sample solution* can therefore be defined as the highest dilution where the Abs value is greater than the 50% control Abs value.] Determine the cutoff dilutions for each *Standard solution* and *Sample solution*. Plot the cutoff dilutions obtained for all *Standard solutions* (expressed as the reciprocal of the cutoff dilution) versus ▲the appropriate diphtheria antitoxin standard▲ (USP 1-May-2022) units. Calculate a linear regression line from the data. Calculate the geometric mean for the four cutoff dilutions associated with each *Sample solution*. Compare the mean cutoff dilution to the linear regression of the *Standard solution* data to determine a titer, in units per milliliter, for each *Sample solution*. To obtain the final potency value for the *Sample solution*, multiply the titer by any dilution that was made to the *Sample solution* prior to the *Assay*.

**System suitability:** The correlation coefficient of the standard curve must be >0.995. The slope of the standard curve must be between 26 and 38. The test is valid if the cells in wells of row A, columns 1–10, appear normal and similar to the cell control wells in column 11. In addition, the cutoff dilution values for *Standard solution* and *Sample solution* replicates should be within one serial dilution of each other, and the cutoff dilution must be within the range of the *Sample solution* serial dilutions.

# ⟨165⟩ PREKALLIKREIN ACTIVATOR

## DEFINITION

Prekallikrein activator (PKA), also known as Factor XIIa, activates prekallikrein to kallikrein. Activated kallikrein cleaves kininogens into kinins (e.g., bradykinin) that can result in a loss of blood pressure. PKA is assayed by its ability to activate prekallikrein, which once activated cleaves a synthetic peptide substrate and releases a chromophore that can be measured spectrophotometrically. The amount of PKA is determined by comparison with reference standard material. The procedure presented in this chapter traditionally has been used to determine the amount of PKA in human plasma derivatives such as albumin and immunoglobulin preparations.

Some immunoglobulin preparations may contain kallikrein or kallikrein-like activity in the absence of the added prekallikrein substrate, resulting in turnover of the synthetic peptide substrate. If present, this kallikrein or kallikrein-like activity requires consideration when analysts verify the assay for suitability under the conditions of use. Some questions to consider when verifying the assay for suitability under the conditions of use include:

- Are sample matrix effects observed?
- Is the appropriate statistical model used for data analysis?
- Is an endpoint analysis sufficient, or is a kinetic analysis needed?

(For informational purposes only, refer to sections 2, 4, and 5 of *Design and Development of Biological Assays* ⟨1032⟩ when considering assay fitness for use.)

## ASSAY

• **PREKALLIKREIN ASSAY**

**Buffer A:** Prepare a solution of 0.05 M tris(hydroxymethyl)aminomethane and 0.15 M sodium chloride. Adjust with 2 N hydrochloric acid to a pH of 7.95–8.05.

**Buffer B:** Prepare a solution of 1.0 M tris(hydroxymethyl)aminomethane. Adjust with 2 N hydrochloric acid to a pH of 7.95–8.05.

**Solution A:** Prepare a solution of 0.33 N hydrochloric acid.

**Solution B:** Prepare a solution of 0.33 N sodium hydroxide.

**Solution C:** Prepare a solution of 50% acetic acid.

**Chromogenic substrate solution:** Prepare a solution of a suitable chromogenic substrate for amidolytic test specific for kallikrein in *Buffer A* to obtain a solution having a concentration of about 1.2 mM.

**Prekallikrein substrate:** Use a suitable *Prekallikrein substrate*. Test the *Prekallikrein substrate* for the absence of kallikrein activity by mixing 1 part with 20 parts of the *Chromogenic substrate solution* prewarmed at 37°, and incubate at 37° for 2 min. The substrate is suitable if the increase in absorbance at 405 nm is less than 0.001/min. [NOTE—To remove proteinase inhibitor contamination from the *Prekallikrein substrate*, acid treatment of the prekallikrein should be performed individually on each sample before use.] If frozen, thaw *Prekallikrein substrate* at 35°–39°. Add 2.0 mL of *Solution A* to 4 mL of *Prekallikrein substrate*, and incubate for 15 min at 23°–25°. Bring pH back to neutrality with 2.0 mL of *Solution B*. Add 200 µL of *Buffer B*, and store at room temperature for NMT 4 h.

**Standard solutions:** Dissolve the contents of a vial of USP Prekallikrein Activator RS in 0.5 mL of water. Dilute USP Prekallikrein Activator RS with *Buffer A* (1:5). Make five evenly spaced *Standard solutions* between 0 and 8.5 IU/mL.

**Sample solution:** Dilute sample appropriately to fall within the range of the standard dilutions with *Buffer A* performing at minimum (1:1).

**System suitability**

**Samples:** *Buffer A* and *Standard solutions*

**Suitability requirements**

**Assay range:** If the absorbance value of a sample is higher than the highest value of the standard curve, dilute the sample with *Buffer A* and repeat the *Assay*. If the absorbance of a sample is lower than the *Assay* limit of detection, the activity should be reported as less than the limit of detection.

**Correlation coefficient:** NLT 0.99

**Analysis**

**Samples:** *Buffer A*, *Standard solutions*, and *Sample solution*

[NOTE—This procedure also can be performed using alternative platforms. Care must be taken to minimize the time between the addition of *Prekallikrein substrate* to the *Standard solutions* and the *Sample solution* because some degradation of the *Prekallikrein substrate* can occur with time when thawed.]

To four separate individual wells of a suitable microtiter plate transfer 25 µL of either the *Standard solutions* or the *Sample solution*. Incubate the microtiter plate for 2–3 min at 35°–39°. Start to prewarm *Buffer A*, the *Prekallikrein substrate*, and the *Chromogenic substrate solution* at 35°–39°. For each *Standard solution* and *Sample solution*, in two of the four wells add 100-µL *Buffer A* and to the other two wells add 100-µL prewarmed *Prekallikrein substrate*; incubate at 35°–39° for 10 min. Add 125 µL of prewarmed *Chromogenic substrate solution* to all wells in the same order as the *Buffer A* and *Prekallikrein substrate* additions, and incubate at 35°–39° for 20 min. Stop the reactions with 50 µL of *Solution C*, and mix well. Read absorbance of each well of the plate at 405 nm within 2 h. Subtract the average $A_{405}$ of the two wells containing *Buffer A* for each *Standard solution* and *Sample solution* to give the corrected $A_{405}$ values. Using the least-squares method of linear regression, generate a standard curve from the activities of the *Standard solutions* (IU/mL) and their corresponding corrected absorbance values. Calculate prekallikrein activities of samples from the calibration curve of the standards. To obtain the corrected activity in IU/mL, multiply each activity by the sample's dilution factor.

# ⟨171⟩ VITAMIN $B_{12}$ ACTIVITY ASSAY

## ASSAY

• **PROCEDURE**

**Assay preparation:** Place a suitable quantity of the material to be assayed, previously reduced to a fine powder if necessary and accurately measured or weighed, in an appropriate vessel containing, for each g or mL of material taken, 25 mL of an aqueous extracting solution prepared just prior to use to contain, in each 100 mL, 1.29 g of disodium phosphate, 1.1 g of anhydrous citric acid, and 1.0 g of sodium metabisulfite. Autoclave the mixture at 121° for 10 minutes. Allow any undissolved particles of the extract to settle, and filter or centrifuge, if necessary. Dilute an aliquot of the clear solution with water so that the final test solution contains vitamin $B_{12}$ activity approximately equivalent to that of the *Standard cyanocobalamin solution* which is added to the assay tubes.

**Standard cyanocobalamin stock solution:** To a suitable quantity of USP Cyanocobalamin (Crystalline) RS, accurately weighed, add sufficient 25 percent alcohol to make a solution having a known concentration of 1.0 µg of cyanocobalamin per mL. Store in a refrigerator.

**Standard cyanocobalamin solution:** Dilute a suitable volume of *Standard cyanocobalamin stock solution* with water to a measured volume such that after the incubation period as described for *Procedure*, the difference in transmittance between the inoculated blank and the 5.0-mL level of the *Standard cyanocobalamin solution* is not less than that which corresponds to a difference of 1.25 mg in dried cell weight. This concentration usually falls between 0.01 ng and 0.04 ng per mL of *Standard cyanocobalamin solution.* Prepare a fresh standard solution for each assay.

**Basal medium stock solution:** Prepare the medium according to the following formula and directions. A dehydrated mixture containing the same ingredients may be used provided that, when constituted as directed in the labeling, it yields a medium comparable to that obtained from the formula given herein.

Add the ingredients in the order listed, carefully dissolving the cystine and tryptophane in the hydrochloric acid before adding the next eight solutions in the resulting solution. Add 100 mL of water, mix, and dissolve the dextrose, sodium acetate, and ascorbic acid. Filter, if necessary, add the polysorbate 80 solution, adjust the solution to a pH between 5.5 and 6.0 with 1 N sodium hydroxide, and add purified water to make 250 mL.

| | |
|---|---|
| L-Cystine | 0.1 g |
| L-Tryptophane | 0.05 g |
| 1 *N* Hydrochloric Acid | 10 mL |
| Adenine–Guanine–Uracil Solution | 5 mL |
| Xanthine Solution | 5 mL |
| Vitamin Solution I | 10 mL |
| Vitamin Solution II | 10 mL |
| Salt Solution A | 5 mL |
| Salt Solution B | 5 mL |
| Asparagine Solution | 5 mL |
| Acid-hydrolyzed Casein Solution | 25 mL |
| Dextrose, Anhydrous | 10 g |
| Sodium Acetate, Anhydrous | 5 g |
| Ascorbic Acid | 1 g |
| Polysorbate 80 Solution | 5 mL |

**Acid-hydrolyzed casein solution:** Prepare as directed under *Calcium Pantothenate Assay* ⟨91⟩.

**Asparagine solution:** Dissolve 2.0 g of L-asparagine in water to make 200 mL. Store under toluene in a refrigerator.

**Adenine–guanine–uracil solution:** Prepare as directed under *Calcium Pantothenate Assay* ⟨91⟩.

**Xanthine solution:** Suspend 0.20 g of xanthine in 30 mL to 40 mL of water, heat to about 70°, add 6.0 mL of 6 N ammonium hydroxide, and stir until the solid is dissolved. Cool, and add water to make 200 mL. Store under toluene in a refrigerator.

**Salt solution A:** Dissolve 10 g of monobasic potassium phosphate and 10 g of dibasic potassium phosphate in water to make 200 mL. Add 2 drops of hydrochloric acid, and store under toluene.

**Salt solution B:** Dissolve 4.0 g of magnesium sulfate, 0.20 g of sodium chloride, 0.20 g of ferrous sulfate, and 0.20 g of manganese sulfate in water to make 200 mL. Add 2 drops of hydrochloric acid, and store under toluene.

**Polysorbate 80 solution:** Dissolve 20 g of polysorbate 80 in alcohol to make 200 mL. Store in a refrigerator.

**Vitamin solution I:** Dissolve 10 mg of riboflavin, 10 mg of thiamine hydrochloride, 100 µg of biotin, and 20 mg of niacin in 0.02 N glacial acetic acid to make 400 mL. Store, protected from light, under toluene in a refrigerator.

**Vitamin solution II:** Dissolve 20 mg of para-aminobenzoic acid, 10 mg of calcium pantothenate, 40 mg of pyridoxine hydrochloride, 40 mg of pyridoxal hydrochloride, 8 mg of pyridoxamine dihydrochloride, and 2 mg of folic acid in dilute neutralized alcohol (1 in 4) to make 400 mL. Store, protected from light, in a refrigerator.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M98920_01_01
@2024 USPC

**Tomato juice preparation:** Centrifuge commercially canned tomato juice so that most of the pulp is removed. Suspend about 5 g per L of analytical filter-aid in the supernatant, and filter, with the aid of reduced pressure, through a layer of the filter-aid. Repeat, if necessary, until a clear, straw-colored filtrate is obtained. Store under toluene in a refrigerator.

**Culture medium:** [NOTE—A dehydrated mixture containing the same ingredients may be used provided that, when constituted as directed in the labeling, it yields a medium equivalent to that obtained from the formula given herein.] Dissolve 0.75 g of water-soluble yeast extract, 0.75 g of dried peptone, 1.0 g of anhydrous dextrose, and 0.20 g of potassium biphosphate in 60 mL to 70 mL of water. Add 10 mL of *Tomato juice preparation* and 1 mL of *Polysorbate 80 solution.* Adjust the solution with 1 N sodium hydroxide to a pH of 6.8, and add water to make 100 mL. Place 10-mL portions of the solution in test tubes, and plug with cotton. Sterilize the tubes and contents in an autoclave at 121° for 15 minutes. Cool as rapidly as possible to avoid color formation resulting from overheating the medium.

**Suspension medium:** Dilute a measured volume of *Basal medium stock solution* with an equal volume of water. Place 10-mL portions of the diluted medium in test tubes. Sterilize, and cool as directed above for the *Culture medium*.

**Stock culture of *Lactobacillus leichmannii*:** To 100 mL of *Culture medium* add 1.0 g to 1.5 g of agar, and heat the mixture, with stirring, on a steam bath, until the agar dissolves. Place approximately 10-mL portions of the hot solution in test tubes, cover the tubes suitably, sterilize at 121° for 15 minutes in an autoclave (exhaust line temperature), and allow the tubes to cool in an upright position. Inoculate three or more of the tubes, by stab transfer of a pure culture of *Lactobacillus leichmannii*.[*] (Before first using a fresh culture in this assay, make not fewer than 10 successive transfers of the culture in a 2-week period.) Incubate 16 to 24 hours at any selected temperature between 30° and 40° but held constant to within ±0.5°, and finally store in a refrigerator.

Prepare fresh stab cultures at least three times each week, and do not use them for preparing the inoculum if more than 4 days old. The activity of the microorganism can be increased by daily or twice-daily transfer of the stab culture, to the point where definite turbidity in the liquid inoculum can be observed 2 to 4 hours after inoculation. A slow-growing culture seldom gives a suitable response curve, and may lead to erratic results.

**Inoculum:** [NOTE—A frozen suspension of *Lactobacillus leichmannii* may be used as the stock culture, provided it yields an inoculum comparable to a fresh culture.] Make a transfer of cells from the *Stock culture of Lactobacillus leichmannii* to 2 sterile tubes containing 10 mL of the *Culture medium* each. Incubate these cultures for 16 to 24 hours at any selected temperature between 30° and 40° but held constant to within ±0.5°. Under aseptic conditions, centrifuge the cultures, and decant the supernatant. Suspend the cells from the culture in 5 mL of sterile *Suspension medium*, and combine. Using sterile *Suspension medium*, adjust the volume so that a 1 in 20 dilution in saline TS produces 70% transmittance when read on a suitable spectrophotometer that has been set at a wavelength of 530 nm, equipped with a 10-mm cell, and read against saline TS set at 100% transmittance. Prepare a 1 in 400 dilution of the adjusted suspension using *Basal medium stock solution*, and use it for the test inoculum. (This dilution may be altered, when necessary, to obtain the desired test response.)

**Calibration of spectrophotometer:** Check the wavelength of the spectrophotometer periodically, using a standard wavelength cell or other suitable device. Before reading any tests, calibrate the spectrophotometer for 0% and 100% transmittance, using water and with the wavelength set at 530 nm.

**Procedure:** Cleanse meticulously by suitable means, followed preferably by heating at 250° for 2 hours, hard-glass test tubes, about 20 mm × 150 mm in size, and other necessary glassware because of the high sensitivity of the test organism to minute amounts of vitamin $B_{12}$ activity and to traces of many cleansing agents.

To test tubes add, in duplicate, 1.0 mL, 1.5 mL, 2.0 mL, 3.0 mL, 4.0 mL, and 5.0 mL, respectively, of the *Standard cyanocobalamin solution.* To each of these tubes and to four similar empty tubes add 5.0 mL of *Basal medium stock solution* and water to make 10 mL.

To similar test tubes add, in duplicate, respectively, 1.0 mL, 1.5 mL, 2.0 mL, 3.0 mL, and 4.0 mL of the *Assay preparation.* To each tube add 5.0 mL of *Basal medium stock solution* and water to make 10 mL. Place one complete set of standard and assay tubes together in one tube rack and the duplicate set in a second rack or section of a rack, preferably in random order.

Cover the tubes suitably to prevent bacterial contamination, and sterilize the tubes and contents in an autoclave at 121° for 5 minutes, arranging to reach this temperature in not more than 10 minutes by preheating the autoclave, if necessary. Cool as rapidly as practicable to avoid color formation resulting from overheating the medium. Take precautions to maintain uniformity of sterilizing and cooling conditions throughout the assay, since packing tubes too closely in the autoclave, or overloading it, may cause variation in the heating rate.

Aseptically add 0.5 mL of *Inoculum* to each tube so prepared, except two of the four containing no *Standard cyanocobalamin solution* (the uninoculated blanks). Incubate the tubes at a temperature between 30° and 40° held constant to within ±0.5°, for 16 to 24 hours.

Terminate growth by heating to a temperature not lower than 80° for 5 minutes. Cool to room temperature. After agitating its contents, place the container in a spectrophotometer that has been set at a wavelength of 530 nm, and read the transmittance when a steady state is reached. This steady state is observed a few seconds after agitation when the reading remains constant for 30 seconds or more. Allow approximately the same time interval for the reading on each tube.

With the transmittance set at 100% for the uninoculated blank, read the transmittance of the inoculated blank. If the difference is greater than 5% or if there is evidence of contamination with a foreign microorganism, disregard the results of the assay.

With the transmittance set at 100% for the uninoculated blank, read the transmittance of each of the remaining tubes. Disregard the results of the assay if the slope of the standard curve indicates a problem with sensitivity.

**Calculation:** Prepare a standard concentration-response curve by the following procedure. Test for and replace any aberrant individual transmittances. For each level of the standard, calculate the response from the sum of the duplicate values of

[*] Pure cultures of *Lactobacillus leichmannii* may be obtained as No. 7830 from the American Type Culture Collection, 10801 University Blvd., Manassas, VA 20110.

https://pharmacopeia.com/

the transmittances (Σ) as the difference, y = 2.00 – Σ. Plot this response on the ordinate of cross-section paper against the logarithm of the mL of *Standard cyanocobalamin solution* per tube on the abscissa, using for the ordinate either an arithmetic or a logarithmic scale, whichever gives the better approximation to a straight line. Draw the straight line or smooth curve that best fits the plotted points.

Calculate the response, y, adding together the two transmittances for each level of the *Assay preparation.* Read from the standard curve the logarithm of the volume of the *Standard preparation* corresponding to each of those values of y that falls within the range of the lowest and highest points plotted for the standard. Subtract from each logarithm so obtained the logarithm of the volume, in mL, of the *Assay preparation* to obtain the difference, x, for each dosage level. Average the values of x for each of three or more dosage levels to obtain x = M′, the log-relative potency of the *Assay preparation.* Determine the quantity, in µg, of USP Cyanocobalamin (Crystalline) RS corresponding to the cyanocobalamin in the portion of material taken for assay by the equation:

$$\text{antilog } M = \text{antilog } (M' + \log R)$$

R = number of µg of cyanocobalamin that was assumed to be present in each mg (or capsule or tablet) of the material taken for assay

**Replication:** Repeat the entire determination at least once, using separately prepared *Assay preparations.* If the difference between the two log potencies M is not greater than 0.08, their mean, M, is the assayed log-potency of the test material (see *Vitamin $B_{12}$ Activity Assay* under *Design and Analysis of Biological Assays* ⟨111⟩). If the two determinations differ by more than 0.08, conduct one or more additional determinations. From the mean of two or more values of *M* that do not differ by more than 0.15, compute the mean potency of the preparation under assay.

## ADDITIONAL REQUIREMENTS

# ⟨181⟩ IDENTIFICATION—ORGANIC NITROGENOUS BASES

## INTRODUCTION

The purpose of this test is the identification of tertiary amine compounds. This spectroscopic test has a limited degree of specificity and, therefore, the conformance with all additional identification tests listed in a particular monograph is necessary to ensure the identity of the specimen under examination.

## ASSAY

• **PROCEDURE**

**Standard solution:** In a separator dissolve 50 mg of the corresponding USP Reference Standard in 25 mL of 0.01 N hydrochloric acid.

**Sample solution:** Depending upon the nature of the sample, dissolve 50 mg of the bulk substance under test in 25 mL of 0.01 N hydrochloric acid, or shake a quantity of powdered tablets or the contents of capsules, equivalent to 50 mg of the substance, with 25 mL of 0.01 N hydrochloric acid for 10 min. Transfer the liquid to a separator, filtering if necessary, and washing the filter and the residue with several small portions of water.

**Instrumental conditions**

(See *Mid-Infrared Spectroscopy* ⟨854⟩.)

**Mode:** IR

**Wavelength range:** 7–15 µm (1430 $cm^{-1}$ to 650 $cm^{-1}$)

**Cell:** 1-mm

**Blank:** Carbon disulfide

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Treat each solution as follows: Add 2 mL of 1 N sodium hydroxide and 4 mL of carbon disulfide, and shake for 2 min. Centrifuge if necessary to clarify the lower phase, and pass it through a dry filter, collecting the filtrate in a small flask provided with a glass stopper. Determine the absorption spectra of the filtered *Standard solution* and *Sample solution* without delay.

**Acceptance criteria:** The spectrum of the *Sample solution* must show all of the significant absorption bands present in the spectrum of the *Standard solution*.

# ⟨191⟩ IDENTIFICATION TESTS—GENERAL

## INTRODUCTION

Procedures in this chapter are referenced in monographs for the identification of official articles and their components. Any acids, bases, or other reagents used in these procedures should not interfere with the results. Volumes may be scaled proportionally unless otherwise indicated. All of the tests include approximate amounts, except where specified.

Instrumental techniques described in this chapter may be used in lieu of chemical identification tests. Those instrumental techniques are not exhaustive and other techniques, such as nuclear magnetic resonance, ion-selective electrodes, and near-infrared, may be used in lieu of a chemical identification test provided that they are suitable and validated.

Unless otherwise specified in the monograph, if a chemical identification test is selected for an ion, then all chemical test procedures listed for the ion shall be met. If an instrumental identification test is selected, then only one instrumental technique is required for the ion(s).

## CHEMICAL IDENTIFICATION TESTS

**Acetate**

- **A.** Dissolve about 30 mg of the substance to be examined in 3 mL of water, or use 3 mL of the prescribed solution. Adjust the pH of the solution with sodium hydroxide to be slightly alkaline. Add 0.25 mL of lanthanum nitrate test solution (TS). If a white precipitate is formed, filter the solution. Add successively 0.1 mL of iodine and potassium iodide TS 3, and 0.1 mL of ammonia TS 2 to the solution. If no blue color is observed, heat carefully to boiling. In the presence of acetates, a dark color develops or a blue precipitate is formed.
- **B.** With neutral solutions of acetates, ferric chloride TS produces a red color that is destroyed by the addition of mineral acids.

**Aluminum**

- **A.** By using 6 N ammonium hydroxide, solutions of aluminum salts yield a gelatinous, white precipitate that is insoluble in an excess of 6 N ammonium hydroxide.
- **B.** 1 N sodium hydroxide or sodium sulfide TS with solutions of aluminum salts produces a similar gelatinous, white precipitate, which dissolves in an excess of either of the same reagents.

**Ammonium**

- **A.** Add 0.2 g of magnesium oxide to the solution under test. Pass a current of air through the mixture, and direct the gas that escapes to just beneath the surface of the indicator solution prepared previously by mixing 1 mL of 0.1 M hydrochloric acid and 0.05 mL of methyl red TS 2. In the presence of ammonium, the color of the indicator solution is changed to yellow. After directing the gas into the indicator solution for a sufficient period of time, add 1 mL of freshly prepared sodium cobaltinitrite TS to the indicator solution. Upon the addition of the sodium cobaltinitrite TS, a yellow precipitate is formed when ammonium is present.

**Antimony**

- **A.** With hydrogen sulfide, solutions of antimony (III) compounds, strongly acidified with hydrochloric acid, yield an orange precipitate of antimony sulfide that is insoluble in 6 N ammonium hydroxide but is soluble in ammonium sulfide TS.

**Barium**

- **A.** Solutions of barium salts yield a white precipitate with the addition of 2 N sulfuric acid. This precipitate is insoluble in hydrochloric acid and in nitric acid.

**Benzoate**

- **A.** In neutral solutions, benzoates yield a salmon-colored precipitate with ferric chloride TS.
- **B.** In moderately concentrated solutions, benzoates yield a precipitate of benzoic acid upon acidification when 2 N sulfuric acid is added. This precipitate is readily soluble in ethyl ether.

**Bicarbonate**

- **A.** Bicarbonates effervesce with acids, evolving a colorless gas that, when passed into calcium hydroxide TS, produces a white precipitate immediately.
- **B.** A cold solution (1 in 20) of a soluble bicarbonate or the solution prescribed in the specific monograph remains unchanged or is only slightly colored by phenolphthalein TS.

**Bismuth**

- **A.** When dissolved in a slight excess of nitric acid or hydrochloric acid, bismuth salts yield a white precipitate upon dilution with water. This precipitate is colored brown by hydrogen sulfide, and the resulting compound dissolves in a warm mixture of equal parts of nitric acid and water.

**Bisulfite** See *Sulfite*.

**Borate**

- **A.** To 1 mL of a borate solution acidified with hydrochloric acid, add 3 or 4 drops of iodine TS and 3 or 4 drops of polyvinyl alcohol solution (1 in 50): an intense blue color is produced.

**Bromide**

- **A.** Solutions of bromides, upon the addition of chlorine TS dropwise, liberate bromine, which is dissolved by shaking with chloroform, coloring the chloroform red-to-reddish brown.
- **B.** Silver nitrate TS produces, in solutions of bromides, a yellowish-white precipitate that is insoluble in nitric acid and is slightly soluble when 6 N ammonium hydroxide is added.

**Calcium**

- **A.** Solutions of calcium salts form insoluble oxalates when treated as follows. To a solution of the calcium salt (1 in 20) or the solution prescribed in the specific monograph, add 2 drops of methyl red TS and neutralize with 6 N ammonium hydroxide. Add 3 N hydrochloric acid dropwise, until the solution is acid to the indicator. Upon the addition of ammonium oxalate TS, a white precipitate is formed. This precipitate is insoluble when 6 N acetic acid is added but dissolves in hydrochloric acid.

Official

https://pharmacopeia.cn/

**Carbonate**
- **A.** Carbonates effervesce with acids, evolving a colorless gas that, when passed into calcium hydroxide TS, produces a white precipitate immediately.
- **B.** A cold solution (1 in 20) of a soluble carbonate or the solution prescribed in the specific monograph is colored red by phenolphthalein TS, whereas a similar solution of a bicarbonate remains unchanged or is only slightly colored.

**Chlorate**
- **A.** Solutions of chlorates yield no precipitate with silver nitrate TS. The addition of sulfurous acid to this mixture produces a white precipitate that is insoluble in nitric acid but is soluble in 6 N ammonium hydroxide.
- **B.** Upon ignition, chlorates yield chlorides, recognizable by appropriate tests.
- **C.** When sulfuric acid is added to a dry chlorate, decrepitation occurs and a greenish-yellow gas is evolved. [**CAUTION**—Use only a small amount of chlorate for this test, and exercise extreme caution in performing it.]

***Change to read:***

**Chloride**
- **A.** With silver nitrate TS, solutions of chlorides yield a white, curdy precipitate that is insoluble in nitric acid but is soluble in a slight excess of 6 N ammonium hydroxide. ▲When testing amine (including alkaloidal) hydrochlorides that do not respond to the previous test, add 1 drop of diluted nitric acid and 0.5 mL of silver nitrate TS to a solution of the substance being examined containing, unless otherwise directed in the monograph, about 2 mg of chloride ion in 2 mL: a white, curdy precipitate is formed. Centrifuge the mixture without delay, and decant the supernatant layer. Wash the precipitate with three 1-mL portions of nitric acid solution (1 in 100), and discard the washings. Add ammonia TS dropwise to this precipitate. It dissolves readily.▲ (USP 1-May-2021)

**Citrate**
- **A.** To 15 mL of pyridine add a solution or suspension of a few milligrams of a citrate salt in 1 mL of water or the solution prescribed in the specific monograph, and shake. To this mixture add 5 mL of acetic anhydride, and shake: a light red color is produced.

**Cobalt**
- **A.** Solutions of cobalt salts (1 in 20) in 3 N hydrochloric acid or the solution prescribed in the specific monograph yield a red precipitate when heated on a steam bath with an equal volume of a hot, freshly prepared solution of 1-nitroso-2-naphthol (1 in 10) in 9 N acetic acid.
- **B.** Solutions of cobalt salts, when saturated with potassium chloride and treated with potassium nitrite and acetic acid, yield a yellow precipitate.

**Copper**
- **A.** Cupric compounds, acidified with hydrochloric acid, deposit a red film of metallic copper upon a bright, untarnished surface of metallic iron.
- **B.** An excess of 6 N ammonium hydroxide, when added to a solution of a cupric salt, produces first a bluish precipitate and then a deep blue-colored solution.
- **C.** With potassium ferrocyanide TS, solutions of cupric salts yield a reddish-brown precipitate, insoluble in diluted acids.

**Hypophosphite**
- **A.** Hypophosphites in solution yield a white precipitate with mercuric chloride TS. This precipitate becomes gray when an excess of hypophosphite is present.
- **B.** Solutions of hypophosphites, acidified with sulfuric acid and warmed with cupric sulfate TS, yield a red precipitate.

**Iodide**
- **A.** Solutions of iodides, upon the addition of chlorine TS dropwise, liberate iodine, which colors the solution from yellow to red. When the solution is shaken with chloroform, the solution is colored violet. The iodine thus liberated gives a blue color with starch TS.
- **B.** Silver nitrate TS produces, in solutions of iodides, a yellow, curdy precipitate that is insoluble in nitric acid and insoluble in 6 N ammonium hydroxide.

**Iron**
- **A.** Ferrous and ferric compounds in solution yield a black precipitate with ammonium sulfide TS. This precipitate dissolves in cold 3 N hydrochloric acid and evolves hydrogen sulfide.

  **Ferric salts**
  - **A.** Acid solutions of ferric salts yield a dark blue precipitate with potassium ferrocyanide TS.
  - **B.** With an excess of 1 N sodium hydroxide added to the ferric salts solutions, a reddish-brown precipitate is formed.
  - **C.** With ammonium thiocyanate TS, solutions of ferric salts produce a deep red color that is not destroyed by dilute mineral acids.

  **Ferrous salts**
  - **A.** Solutions of ferrous salts yield a dark blue precipitate with potassium ferricyanide TS. This precipitate is insoluble in 3 N hydrochloric acid but is decomposed by 1 N sodium hydroxide.
  - **B.** With 1 N sodium hydroxide, solutions of ferrous salts yield a greenish-white precipitate; when shaken, the color changes rapidly to green and then to brown.

**Lactate**
- **A.** When solutions of lactates are acidified with sulfuric acid, potassium permanganate TS is added; the mixture is heated, and acetaldehyde evolves. Acetaldehyde can be detected by allowing the vapor to come into contact with a filter paper that has been moistened with a freshly prepared mixture of equal volumes of 20% aqueous morpholine and sodium nitroferricyanide TS: a blue color is produced.

**Lead**
- **A.** With 2 N sulfuric acid, solutions of lead salts yield a white precipitate that is insoluble in 3 N hydrochloric or 2 N nitric acid but is soluble in warm 1 N sodium hydroxide and in ammonium acetate TS.

Official

https://pharmacopeia.cn/v29240/

- **B.** With potassium chromate TS, solutions of lead salts, free or nearly free from mineral acids, yield a yellow precipitate that is insoluble in 6 N acetic acid but is soluble in 1 N sodium hydroxide.

**Lithium**

- **A.** With sodium carbonate TS, moderately concentrated solutions of lithium salts, made alkaline with sodium hydroxide, yield a white precipitate on boiling. The precipitate is soluble in ammonium chloride TS.
- **B.** Solutions of lithium salts are not precipitated by 2 N sulfuric acid or soluble sulfates (distinction from strontium).

**Magnesium**

- **A.** Solutions of magnesium salts in the presence of ammonium chloride yield NMT a slightly hazy precipitate when neutralized with ammonium carbonate TS, but on the subsequent addition of dibasic sodium phosphate TS, a white, crystalline precipitate, which is insoluble in 6 N ammonium hydroxide, is formed.

**Manganese**

- **A.** With ammonium sulfide TS, solutions of manganous salts yield a salmon-colored precipitate that dissolves in acetic acid.

**Mercury**

- **A.** When applied to bright copper foil, solutions of mercury salts, free from an excess of nitric acid, yield a deposit that, upon rubbing, becomes bright and silvery in appearance.
- **B.** With hydrogen sulfide, solutions of mercury compounds yield a black precipitate that is insoluble in ammonium sulfide TS and in boiling 2 N nitric acid.

**Mercuric salts**

- **A.** Solutions of mercuric salts yield a yellow precipitate with 1 N sodium hydroxide.
- **B.** Solutions of mercuric salts yield, in neutral solutions with potassium iodide TS, a scarlet precipitate that is very soluble in an excess of the reagent.

**Mercurous salts**

- **A.** Mercurous compounds are decomposed by 1 N sodium hydroxide, producing a black color.
- **B.** With hydrochloric acid, solutions of mercurous salts yield a white precipitate that is blackened by the addition of 6 N ammonium hydroxide.
- **C.** With potassium iodide TS, a yellow precipitate, which may become green upon standing, is formed.

**Nitrate**

- **A.** When a solution of a nitrate is mixed with an equal volume of sulfuric acid, the mixture is cooled, and a solution of ferrous sulfate is superimposed; a brown color is produced at the junction of the two liquids.
- **B.** When a nitrate is heated with sulfuric acid and metallic copper, brownish-red fumes evolve.
- **C.** Nitrates do not decolorize acidified potassium permanganate TS (distinction from nitrites).

**Nitrite**

- **A.** When treated with dilute mineral acids or with 6 N acetic acid, nitrites evolve brownish-red fumes. The solution colors starch–iodide paper blue.

**Oxalate**

- **A.** Neutral and alkaline solutions of oxalates yield a white precipitate with calcium chloride TS. This precipitate is insoluble in 6 N acetic acid but is dissolved by hydrochloric acid.
- **B.** Hot acidified solutions of oxalates decolorize potassium permanganate TS.

**Permanganate**

- **A.** Solutions of permanganates acidified with sulfuric acid are decolorized by hydrogen peroxide TS and by sodium bisulfite TS, in the cold, and by oxalic acid TS in a hot solution.

**Peroxide**

- **A.** Solutions of peroxides slightly acidified with sulfuric acid yield a deep blue color upon the addition of potassium dichromate TS. On shaking the mixture with an equal volume of ethyl ether and allowing the liquids to separate, the blue color is found in the ethyl ether layer.

**Phosphate**

[NOTE—Where the monograph specifies the identification test for *Phosphate*, use the tests for orthophosphates, unless the instructions specify the use of the pyrophosphate tests or indicate that the product is to be ignited before performing the test.]

**Orthophosphates**

- **A.** With silver nitrate TS, neutral solutions of orthophosphates yield a yellow precipitate that is soluble in 2 N nitric acid and in 6 N ammonium hydroxide.
- **B.** With ammonium molybdate TS, acidified solutions of orthophosphates yield a yellow precipitate that is soluble in 6 N ammonium hydroxide. This precipitate may be slow to form.

**Pyrophosphates**

- **A.** With silver nitrate TS, pyrophosphates obtained by ignition yield a white precipitate that is soluble in 2 N nitric acid and soluble in 6 N ammonium hydroxide.
- **B.** With ammonium molybdate TS, pyrophosphates obtained by ignition yield a yellow precipitate that is soluble in 6 N ammonium hydroxide.

**Potassium**

- **A.** In neutral, concentrated, or moderately concentrated solutions of potassium salts (depending upon the solubility and the potassium content), sodium bitartrate TS produces a white crystalline precipitate that is soluble in 6 N ammonium hydroxide and in solutions of alkali hydroxides and carbonates. The formation of the precipitate, which is usually slow, is accelerated by stirring or rubbing the inside of the test tube with a glass rod. The addition of a small amount of glacial acetic acid or alcohol also promotes the precipitation.

**Salicylate**

- **A.** In moderately concentrated solutions of salicylates, ferric chloride TS produces a violet color.
- **B.** Addition of acids to moderately concentrated solutions of salicylates produces a white, crystalline precipitate of salicylic acid that melts between 158° and 161°.

**Silver**
- **A.** With hydrochloric acid, solutions of silver salts yield a white, curdy precipitate that is insoluble in nitric acid but is readily soluble in 6 N ammonium hydroxide.
- **B.** A solution of a silver salt, to which 6 N ammonium hydroxide and a small quantity of formaldehyde TS are added, deposits, upon warming, a mirror of metallic silver upon the sides of the container.

**Sodium**
- **A.** Unless otherwise specified in an individual monograph, prepare a solution to contain 0.1 g of the sodium compound in 2 mL of water. Add 2 mL of 15% potassium carbonate, and heat to boiling. No precipitate is formed. Add 4 mL of potassium pyroantimonate TS, and heat to boiling. Allow to cool in ice water and, if necessary, rub the inside of the test tube with a glass rod. A dense precipitate is formed.

**Sulfate**
- **A.** With barium chloride TS, solutions of sulfates yield a white precipitate that is insoluble in hydrochloric acid and in nitric acid.
- **B.** With lead acetate TS, neutral solutions of sulfates yield a white precipitate that is soluble in ammonium acetate TS.
- **C.** Hydrochloric acid produces no precipitate when added to solutions of sulfates (distinction from thiosulfates).

**Sulfite**
- **A.** When treated with 3 N hydrochloric acid, sulfites and bisulfites yield sulfur dioxide, which blackens filter paper moistened with mercurous nitrate TS.

**Tartrate**
- **A.** Dissolve a few mg of a tartrate salt in 2 drops of sodium metaperiodate solution (1 in 20). Add 1 drop of 1 N sulfuric acid and after 5 min add a few drops of sulfurous acid, followed by a few drops of fuchsin-sulfurous acid TS: a reddish-pink color is produced within 15 min.

**Thiocyanate**
- **A.** With ferric chloride TS, solutions of thiocyanates yield a red color that is not destroyed by moderately concentrated mineral acids.

**Thiosulfate**
- **A.** With hydrochloric acid, solutions of thiosulfates yield a white precipitate that soon turns yellow, and evolve sulfur dioxide, which blackens filter paper moistened with mercurous nitrate TS.
- **B.** The addition of ferric chloride TS to solutions of thiosulfates produces a dark violet color that disappears quickly.

**Zinc**
- **A.** In the presence of sodium acetate, solutions of zinc salts yield a white precipitate with hydrogen sulfide. This precipitate is insoluble in acetic acid but is dissolved by 3 N hydrochloric acid.
- **B.** Ammonium sulfide TS produces a similar precipitate in neutral and in alkaline solutions.
- **C.** With potassium ferrocyanide TS, zinc salts in solution yield a white precipitate that is insoluble in 3 N hydrochloric acid.

## INSTRUMENTAL IDENTIFICATION TESTS

Instrumental techniques described in this section may be used in lieu of procedures described in *Chemical Identification Tests*. Instrumental techniques provide flexibility in the choice of identification tests. All instrumental techniques shall follow method validation procedures for identification tests (see *Validation of Compendial Procedures* ⟨1225⟩, *Validation, Data Elements Required for Validation, Category IV*). *Instrumental Identification Tests* must demonstrate specificity. In addition, other suitable, validated instrumental techniques may be used.

The selection of the appropriate sample preparation depends on the material under test and must be appropriate for the technique being used. The analyst may use any of the following preparation procedures, with the appropriate verification. An electronic library spectrum of the Reference Standard may be used in comparison to the test sample provided adequate specificity is maintained. When using solvents, the solvent must be free of interfering species. Use *USP Reference Standards* where available (see *General Notices, 5.80 USP Reference Standards*).

### • Identification Using X-Ray Fluorescence Spectrometry

X-ray fluorescence spectrometry (XRF) can typically be used for identification of elements with atomic numbers from magnesium through uranium. The actual range of elements for which the instrument is capable is dependent on the instrument design. Guidance regarding the use of XRF may be found in *X-Ray Fluorescence Spectrometry* ⟨735⟩.

**Sample preparation**

**Powders/solids:** Powders and solids can be used without further manipulation, or material can be made into pellets as described in ⟨735⟩.

**Neat liquids:** Liquids can be used without further manipulation, provided the liquid is a single phase, is compatible with the sample holder, and has sufficiently low volatility.

**Samples in solution:** Samples may be dissolved in an appropriate solvent.

**Procedure**

**Blank:** For *Powders/solids* and *Neat liquids*, prepare a blank sample holder. For *Samples in solution*, use the solvent as a blank.

**Reference standard** and **Sample:** Prepare each *Reference standard* and *Sample* by using sufficient material as required for the specific manufacturer's instrumentation.

**Analysis:** Analyze the *Blank*, *Reference standard*, and *Sample* according to the manufacturer's suggestions for the specific instrument. If there is any interference, use the *Blank* to make the correction. The spectrum of the *Reference standard* exhibits radiation characteristic of the element(s) under investigation. The energy bands of the *Sample* exhibit radiation characteristic of the element(s) under investigation and compare qualitatively with that of the *Reference standard*.

### • Identification Using Atomic Spectroscopy Techniques: Atomic Absorption Spectroscopy, Inductively Coupled Plasma–Optical Emission Spectroscopy, Inductively Coupled Plasma–Mass Spectrometry

Atomic absorption (AA) spectroscopy techniques can be used for the identification of many elements. Guidance regarding the use of AA spectroscopy may be found in *Atomic Absorption Spectroscopy* ⟨852⟩ . Guidance regarding the use of

Official

https://pharmacopeia.com/

inductively coupled plasma–optical emission spectroscopy (ICP–OES) or inductively coupled plasma–mass spectrometry (ICP–MS) may be found in *Plasma Spectrochemistry* ⟨730⟩.

**Sample preparation:** Samples should be dissolved in an appropriate solvent. If dissolving the sample is not possible, digestion may be necessary.

**Procedure**

**Blank:** Prepare an appropriate solution that does not contain the analyte(s) of interest and is compatible with the technique being used.

**Standard solution:** Standards must contain the analyte of interest. All solutions should be matrix-matched where possible.

**Sample solution:** Prepare the sample in the same solvent as the standard.

**Analysis:** Analyze the *Blank*, *Standard solution*, and *Sample solution* according to the manufacturer's suggestions for the specific instrument. When a wavelength-based technique is used, wherever possible select at least two wavelengths characteristic of the analyte(s) of interest. When a mass-based technique is used, wherever possible select at least two isotopes characteristic of the analyte(s) of interest. If two isotopes are unavailable, or if an element is monoisotopic, it may be possible to monitor the oxide of the analyte(s) ($m + 16$), if one is formed. If no oxide is formed, or if multiple isotopes cannot be evaluated because of interferences or because of a limited number of isotopes, then a different technique may be required. If interfering elements are present in the sample solution, wavelengths or masses examined must be selected to unequivocally identify the analyte(s) of interest.

- **Identification Using Ion Chromatography**

Ion chromatography (IC) can be used to identify a number of anions and cations found in drug substances (for additional information, see *Ion Chromatography* ⟨1065⟩).

**Apparatus:** Analyte detection will typically utilize suppressed conductivity, although other detection methods are possible, depending on the analyte (see ⟨1065⟩). The ion-exchange column must be capable of separating the analyte from any other ions of the same charge known to be in the sample at a concentration ≥5% of the analyte.

**Procedure**

**Blank:** Use the sample solvent as a blank.

**Standard** and **Sample solutions:** Dissolve or dilute the sample in water. Other solvents can be used if compatible with the IC column.

**Analysis:** Analyze an equal volume of the *Blank*, Reference Standard, and sample (according to the manufacturer's suggestions for the specific instrument and column dimensions). The counterion is identified if a peak in the sample has the same retention time as the peak in the Reference Standard, and there is not a peak of ≥5% of its size at the same retention time in the *Blank*.

- **Identification by Other Liquid Chromatography Techniques in Chromatography** ⟨621⟩

Some of the ions suitable for IC identification can also be identified by other forms of liquid chromatography. Sample and Reference Standard concentrations, as well as injection volumes, need to be adjusted, depending on the detection technique used. All high-concentration components in the test substance should be analyzed to judge whether there is interference with the analyte of interest.

- **Identification Using Raman Spectroscopy**

Raman spectroscopy can be used for identification of counterions. Guidance regarding the use of Raman spectroscopy may be found in *Raman Spectroscopy—Theory and Practice* ⟨1858⟩.

**Apparatus:** Prepare the spectrometer for operation according to the instrument instruction manual and the instrument manufacturer's recommendations. An instrument performance check and the quality of spectra collected should be evaluated at time of use or following manufacturer's instructions.

**Procedure**

**Reference standard** and **Sample:** All reference material and sample spectra should be collected using identical instrumental parameters. These instrumental parameters may be determined by the analyst based on the nature of the sample and the type of analysis and should be selected based on the quality of spectra needed. Use the appropriate sample container and/or sample holding apparatus, depending on the type of reference material and sample (powder, liquid, paste, film, or other) being analyzed. Transfer the sample or reference material into the appropriate sample container and/or holder, as needed, and acquire the spectrum for each.

**Analysis:** Qualitatively compare the Raman spectra obtained from the reference material and the *Sample*. The *Sample* complies with the identity test if the spectrum exhibits maxima only at the same wavelengths as that of a similar preparation of the corresponding USP Reference Standard, where available.

- **Identification Using Mid-Infrared Spectroscopy**

Mid-infrared spectroscopy techniques can be used for identification of counterions. Guidance regarding the use of mid-infrared spectroscopy may be found in *Mid-Infrared Spectroscopy* ⟨854⟩ and *Spectroscopic Identification Tests* ⟨197⟩. If the monograph contains an identification test by IR (e.g., ⟨197⟩) and a reference to ⟨191⟩, then mid-infrared cannot be used as an instrumental replacement for the chemical identification tests prescribed in this chapter.

**Procedure**

**Standard** and **Sample solutions:** Sample preparation may be conducted using any of the procedures described in ⟨854⟩ that are appropriate for the sample of concern. The standard preparation should be conducted in the same way but using the USP Reference Standard of the substance under test, where available.

**Analysis:** Record the spectra of the test specimen and the corresponding Reference Standard over the range from about 3800 to 650 $cm^{-1}$ (2.6–15 µm). The IR absorption spectrum of the preparation of the test specimen, previously dried under conditions specified for the corresponding Reference Standard, unless the Reference Standard is to be used without drying, exhibits maxima only at the same wavelengths as that of a similar preparation of the corresponding USP Reference Standard, where available.

Official

https://pharmacopeia.com/

# ⟨193⟩ IDENTIFICATION—TETRACYCLINES

The following chromatographic procedures are provided to confirm the identity of Pharmacopeial drug substances that are of the tetracycline type, such as doxycycline, oxytetracycline, and tetracycline, and to confirm the identity of such compounds in their respective Pharmacopeial dosage forms. Two procedures are provided, one based on paper chromatography (*Method I*) and the other on thin-layer chromatography (*Method II*). *Method I* is to be used unless otherwise directed in the individual monograph.

## PROCEDURES

**Standard solution:** Unless otherwise directed in the individual monograph, dissolve the USP Reference Standard for the drug substance being identified in the same solvent and at the same concentration as for the *Test solution*.

**Test solution:** Prepare as directed in the individual monograph.

• **METHOD I**

**pH 3.5 Buffer:** Dissolve 13.4 g of anhydrous citric acid and 16.3 g of dibasic sodium phosphate in 1000 mL of water, and mix.

**Developing solvent:** On the day of use, mix 10 volumes of chloroform, 20 volumes of nitromethane, and 3 volumes of pyridine.

**Mixed test solution:** Mix equal volumes of the *Standard solution* and the *Test solution*.

**Chromatographic sheet:** Draw a spotting line 2.5 cm from one edge of a 20-cm × 20-cm sheet of filter paper (Whatman No. 1, or equivalent). Impregnate the sheet with *pH 3.5 Buffer* by passing it through a trough filled with *pH 3.5 Buffer*, and remove the excess solvent by firmly pressing the sheet between nonfluorescent blotting papers.

**Procedure:** To a suitable chromatographic chamber, prepared for ascending chromatography (see *Chromatography* ⟨621⟩) add *Developing solvent* to a depth of 0.6 cm. Apply at 1.5-cm intervals 2 µL each of the *Standard solution*, the *Test solution*, and the *Mixed test solution* to the spotting line of the *Chromatographic sheet*. Allow the sheet to dry partially, and while still damp place it in the chromatographic chamber with the bottom edge touching the *Developing solvent*. When the solvent front has risen about 10 cm, remove the sheet from the chamber, and expose the sheet to ammonia vapor. Examine the chromatogram under long-wavelength UV light. Record the positions of the major yellow fluorescent spots: the $R_F$ value of the principal spot obtained from the *Test solution* and from the *Mixed test solution* corresponds to that obtained from the *Standard solution*.

• **METHOD II**

**Resolution solution:** Unless otherwise directed in the individual monograph, prepare a solution in methanol containing 0.5 mg each of USP Chlortetracycline Hydrochloride RS, USP Doxycycline Hyclate RS, USP Oxytetracycline RS, and USP Tetracycline Hydrochloride RS per mL.

**Developing solvent:** Prepare a mixture of 0.5 M oxalic acid, previously adjusted with ammonium hydroxide to a pH of 2.0, acetonitrile, and methanol (80:20:20).

**Chromatographic plate:** Use a suitable thin-layer chromatographic plate (see *Thin-Layer Chromatography* under *Chromatography* ⟨621⟩) coated with a 0.25-mm layer of octylsilanized chromatographic silica gel mixture. Activate the plate by heating it at 130° for 20 minutes, allow to cool, and use while still warm.

**Procedure:** Separately apply 1 µL each of the *Standard solution*, the *Test solution*, and the *Resolution solution* to the *Chromatographic plate*. Allow the spots to dry, and develop the chromatogram in the *Developing solvent* until the solvent front has moved about three-fourths of the length of the plate. Remove the plate from the developing chamber, mark the solvent front, and allow to air-dry. Expose the plate to ammonia vapors for 5 minutes, and promptly locate the spots on the plate by viewing under long-wavelength UV light: the chromatogram of the *Resolution solution* shows clearly separated spots, and the principal spot obtained from the *Test solution* corresponds in $R_F$ value, intensity, and appearance to that obtained from the *Standard solution*.

# ⟨197⟩ SPECTROSCOPIC IDENTIFICATION TESTS

***Change to read:***

## INTRODUCTION AND SCOPE

This chapter provides several tests and procedures that are used to confirm the chemical identity of a specific material in its respective monograph. When one of the tests listed in this chapter is referenced in a monograph, it must be used to confirm the identity of the material. Alternative identification procedures may be used, provided they are demonstrated to be equivalent to or better than the specified procedure and if they meet the requirements specified in the *Equivalent/Alternative Tests* section.

Spectroscopic tests contribute meaningfully toward the identification of many official articles. The test procedures that follow are applicable to substances that absorb, transmit, reflect, or scatter electromagnetic radiation in the near-infrared (NIR), infrared (IR), visible or near-infrared (Raman), ultraviolet (UV), visible (Vis), or X-ray ranges (see *Mid-Infrared Spectroscopy* ⟨854⟩, ▲*Near-Infrared Spectroscopy* ⟨856⟩,▲ (ERR 1-Sep-2021)*Ultraviolet-Visible Spectroscopy* ⟨857⟩, ▲▲ (ERR 1-Sep-2021)*Raman Spectroscopy* ⟨858⟩, and *X-Ray Powder Diffraction* ⟨941⟩). The NIR, IR, and Raman spectra, or X-ray diffraction pattern of a substance, compared with the spectrum or diffraction pattern obtained with the corresponding USP Reference Standard, provides perhaps the most conclusive evidence of the identity of the substance that can be realized from any single test. The UV or Vis absorption spectrum of a substance, on the other hand, does not exhibit a high degree of specificity in most cases. To provide unambiguous confirmation of the identity of a substance, it may be necessary to execute two (or more) identity tests, as specified in a large proportion of compendial monographs.

## IDENTIFICATION METHODOLOGY

Suitable identification methodology must be used for the chemical identification of materials through comparison with the appropriate compendial standards. Where alternative techniques are used, it must be demonstrated that the alternative identification methodology is suitable for the intended application (see *Validation of Compendial Procedures* ⟨1225⟩). Identification procedures should be able to discriminate between materials similar in molecular structure. The lack of specificity of a single technique may be compensated by other supporting analytical procedure(s) or an application of an additional identification technique.

The IR spectrum of a substance, compared with that obtained using equivalent instruments and conditions for the corresponding USP Reference Standard, is the most widely used methodology for chemical identification in compendial monographs. In general practice, the analysis of the sample and the USP Reference Standard are completed at the same time; however, if the USP Reference Standard spectrum was obtained previously using equivalent instruments and conditions, it is appropriate to compare the sample spectrum with the stored USP Reference Standard spectrum.

Under conditions where the IR spectrum lacks specificity for definitive chemical identification, additional spectroscopic information can be used to supplement chemical identification. For example, conformance with both IR and UV test specifications, as specified in a large proportion of compendial monographs, provides complementary information for the definitive identity of the sample under examination. In these instances, the combined spectroscopic information enables discrimination between compounds similar in structure that would not be possible from either IR spectrum or UV spectrum alone.

For preparing the standards used in the applications of this chapter, unless the directions for preparing the USP Reference Standard are explicitly specified in the monograph procedure, the USP Reference Standard must be used in accordance with instructions on its label. For preparation of the test sample, the sample must be prepared in accordance with the directions in the individual monograph procedure. Where no specific instructions are provided for sample preparation, handle the sample in the same manner as described by the USP Reference Standard label. For example, dry the sample as per drying conditions on the label of the corresponding USP Reference Standard.

## INFRARED SPECTROSCOPY

Several methods are indicated for the preparation of test samples and USP Reference Standards for analysis by infrared spectroscopy (see *Table 1* and ⟨854⟩). The approaches for the techniques used in IR identity testing are summarized in *Table 1*.

**Table 1. Infrared Spectroscopy Sample Preparation Techniques[a]**

| Method Reference | Sample Preparation |
|---|---|
| ⟨197A⟩ | The substance under examination is intimately in contact with an internal reflection element for attenuated total reflection (ATR) analysis. |
| ⟨197D⟩ | The substance under examination is mixed intimately with potassium bromide and transferred to a sample container for diffuse reflection (DR) analysis. |
| ⟨197E⟩ | The substance under examination is pressed as a thin sample against a suitable plate for IR microscopic analysis. |
| ⟨197F⟩ | The substance under examination is a thin film of a neat liquid or semisolid between suitable (e.g., sodium chloride or potassium bromide) plates, or a thin microcrystalline or glassy film deposited from a solution or cooled from a melt. |
| ⟨197K⟩ | The substance under examination is mixed intimately with potassium bromide and compressed into a transparent pellet. |

DOI: https://doi.org/10.31003/USPNF_M98947_05_01
@2024 USPC

**Table 1. Infrared Spectroscopy Sample Preparation Techniques[a]** *(continued)*

| Method Reference | Sample Preparation |
|---|---|
| ⟨197M⟩ | The substance under examination (10–20 mg) is finely ground and dispersed in a drop of mulling agent (unless otherwise directed in the monograph, mineral oil is to be used). |
| ⟨197S⟩ | A solution of designated concentration is prepared in the solvent specified in the individual monograph. The solution is examined in 0.1-mm cells, unless a different cell path length is specified. |

[a] Each of the techniques in the table can be used as alternative methods when any other technique from the table is required in the monograph (see *General Notices, 6.30 Alternative and Harmonized Methods and Procedures*).

In each instance, infrared spectra of both the sample and corresponding USP Reference Standard are obtained using the same sample preparation technique and measurement parameters. Record and compare the spectra of the sample and the corresponding USP Reference Standard over the range from 3800 to 650 $cm^{-1}$, unless otherwise specified in the individual monograph. The comparison must establish that the IR spectrum of the preparation of the sample exhibits maxima only at the same wavenumbers as that of the appropriately prepared corresponding USP Reference Standard. If there are differences between the spectra, and the sample spectrum was compared with a previously obtained and electronically stored spectrum of the USP Reference Standard, the comparison must be repeated concomitantly with a freshly prepared USP Reference Standard.

Differences between the USP Reference Standard spectrum and sample spectrum that may be observed are sometimes attributable to differences in the solid-state form of the materials, if a solid-state technique is used (e.g., ⟨197A⟩, ⟨197K⟩, or ⟨197M⟩). If a specific crystal form is not specified in the monograph, where spectral differences between the sample and USP Reference Standard are observed, recrystallize both the sample and USP Reference Standard under identical conditions to produce the same solid-state form, unless specific procedures are provided in the individual monographs. Dissolve equal portions of the sample and the USP Reference Standard in equal volumes of a suitable solvent, evaporate the solutions to dryness in similar containers under identical conditions, and repeat the identification test on the residues. Other techniques for recrystallizing the sample and USP Reference Standard based on known scientific principles may be used with appropriate scientific justification.

***Change to read:***

## NEAR-INFRARED AND RAMAN SPECTROSCOPY

The reference ⟨197NIR⟩ in a monograph signifies that a test sample and a standard sample are examined by the NIR spectroscopic technique (see ▲⟨856⟩▲ (ERR 1-Sep-2021)), and the reference ⟨197R⟩ in a monograph signifies that a test sample and a standard sample are examined by the Raman spectroscopic technique (see ⟨858⟩). NIR and Raman spectroscopic procedures may be used to confirm the identity of materials. The approach is similar to that of IR identity testing but is often augmented through the use of spectral libraries and chemometrics. A sample can thus be analyzed by NIR or Raman techniques, with the resulting spectrum compared with stored spectra in the spectral library through the use of multivariate analysis. In general, a visual comparison or simple overlay of the spectra alone may not be sufficient and additional evaluation may be needed.

In both techniques, samples can be directly interrogated with minimal or no sample preparation. Measurement is nondestructive and noninvasive, and data collection can often be made through glass or plastic containers.

A description of these techniques, and the strategy for procedure and chemometrics model development and validation can be found in the appropriate associated chapters when available (see *Chemometrics* ⟨1039⟩, *Near-Infrared Spectroscopy—Theory and Practice* ⟨1856⟩, and *Raman Spectroscopy—Theory and Practice* ⟨1858⟩▲▲ (ERR 1-Sep-2021)).

## ULTRAVIOLET-VISIBLE SPECTROSCOPY

The reference ⟨197U⟩ in a monograph signifies that a sample solution and a Standard solution are examined spectroscopically, in 1-cm cells, over the spectral range from 200 to 400 nm, unless otherwise specified in the individual monograph (see ⟨857⟩). Dissolve a portion of the substance under examination in the designated medium to obtain a sample solution having the concentration specified in the monograph. Record and compare the spectra obtained for the sample solution and the Standard solution. Review or calculate the absorptivities and/or absorbance ratios and compare the results, and where appropriate, compare to criteria specified in an individual monograph.

The comparison must establish that the UV spectrum of the preparation of the sample exhibits absorption maxima and minima only at the same wavelengths as those of the appropriately prepared corresponding USP Reference Standard, and that the absorptivities and/or absorbance ratios are within the specified limits. If there are differences in the spectra, and the sample spectrum was compared with a previously obtained and electronically stored spectrum of the USP Reference Standard, the comparison must be concomitantly repeated with a freshly prepared USP Reference Standard.

Unless otherwise specified in the monograph, absorbances indicated for the calculations of the absorptivities and/or absorbance ratios are those measured at the maximum absorbance wavelength (within ±2 nm) specified in the individual monograph. Where the absorbance is to be measured at about the specified wavelength other than that of maximum absorbance, the abbreviations for minimum (min) and shoulder (sh) are used, respectively, in an absorption spectrum.

The reference ⟨197U-LC⟩ in a monograph signifies that, when a diode array detector is used in tandem with an LC procedure test in the monograph, the spectra of the major chromatographic peak(s) of the sample solution and Standard solution are examined spectroscopically.

The requirements are met if the UV spectra of the sample solution and of the Standard solution exhibit maxima and minima at the same wavelengths, and, if applicable, the absorptivities and/or absorbance ratios are within specified limits.

Official

https://pharmacopeia.cn/

## X-RAY POWDER DIFFRACTION

The reference ⟨197XR⟩ in a monograph signifies that a test sample and a standard sample are examined according to ⟨941⟩.

Prepare and mount the specimen as directed in ⟨941⟩. Unless otherwise indicated in the monograph, record the diffraction pattern in a 2θ-range from as near to 0° as possible to at least 32°. Unless otherwise specified in the monograph, the requirements are met if the X-ray diffraction pattern of the test specimen conforms to that of the corresponding USP Reference Standard obtained using equivalent instruments and conditions. Differences in the diffraction line intensities (but not line positions) between the sample and the Standard are acceptable.

The comparison must establish that the diffraction pattern of the preparation of the test specimen conforms to the diffraction pattern of the corresponding USP Reference Standard. If there are differences in the diffraction pattern and the sample diffraction pattern was compared with a previously obtained and electronically stored diffraction pattern of the USP Reference Standard, the comparison must be repeated concomitantly with a freshly prepared USP Reference Standard.

***Change to read:***

## EQUIVALENT/ALTERNATIVE TESTS

In addition to IR, NIR, Raman, X-ray, and UV absorption, several other spectroscopic methodologies can be utilized for the identification of the specimen under examination. The methods cited in this chapter may be used for identification of materials as an alternative method to the method referenced in the monograph, provided that the alternative technique has been determined to be suitable for identification. Suitable identification tests must be able to discriminate between compounds similar in molecular structure that are likely to be present. The choice of such potentially interfering materials must be based on sound scientific judgment, with consideration of interferences that could occur. It is not always possible to demonstrate that an analytical procedure is specific for a particular analyte (complete discrimination).

For information regarding sample preparation and measurement parameters associated with an alternative identification method, refer to the appropriate general chapter (see *Mass Spectrometry* ⟨736⟩, *Nuclear Magnetic Resonance Spectroscopy* ⟨761⟩, ⟨854⟩, ▲ ⟨856⟩,▲ (ERR 1-Sep-2021) ⟨857⟩, ▲▲ (ERR 1-Sep-2021) ⟨858⟩, and ⟨941⟩).

# ▲⟨198⟩ NUCLEAR MAGNETIC RESONANCE SPECTROSCOPY IDENTITY TESTING OF BACTERIAL POLYSACCHARIDES USED IN VACCINE MANUFACTURE

## 1. INTRODUCTION AND SCOPE

This chapter describes the application of nuclear magnetic resonance (NMR) spectroscopy to the identity testing of bacterial polysaccharides used in vaccine manufacture. The identity of the saccharide component in polysaccharide and glycoconjugate vaccines should be confirmed at various stages of the manufacturing process, including bulk monovalent polysaccharide, blended polysaccharide bulk, activated polysaccharide (if isolated), bulk monovalent conjugate, blended conjugate bulks, and final fills. NMR is an appropriate method to confirm the identity of polysaccharides, although it is most useful for bulk monovalent polysaccharides and activated polysaccharides (if isolated). This chapter describes the use of NMR spectroscopy for this purpose, but alternative validated approaches may also be suitable.

For additional information on NMR, including its general principles and applications, see *Applications of Nuclear Magnetic Resonance Spectroscopy* ⟨1761⟩. More specific information on instrument qualification, procedure validation, and reference standards are included in *Nuclear Magnetic Resonance Spectroscopy* ⟨761⟩.

### 1.1 NMR Spectra

NMR spectra for identity testing are typically collected for samples dissolved in deuterated water ($D_2O$) or a combination of deuterated water and small amounts of one or more internal standards for chemical shift calibration, quantification, or other purposes. The chemical shift of the resonance from residual water in deuterated solvent (HOD) is more temperature sensitive than other solvent resonances. The spectral separation and resolution of the HOD resonance may be optimized by the choice of temperature at which the spectrum is obtained.

### 1.2 *O*-Acetylated Polysaccharides

For those polysaccharides that are *O*-acetylated, the consistency of the degree of *O*-acetylation is considered part of the identity test. This could be evaluated through the use of the spectrum of a reference polysaccharide with an acceptable degree of *O*-acetylation, quantification of resonances characteristic of the *O*-acetylation in the spectrum of the intact polysaccharide, or chemical de-*O*-acetylation and relative quantification of the resulting acetate anion compared to the polysaccharide (see *2.4 Experimental Procedures*). The implementation of any given approach is likely to be product specific.

For some polysaccharides, a quantitative specification for the minimum degree of *O*-acetylation may exist; the approaches described in this chapter, appropriately validated, can be used to perform that assay. Requirements for the *O*-acetyl content of polysaccharides are typically quoted as a minimum quantity of "*O*-acetyl residues" (measured by a Hestrin assay) in millimoles per gram of dry weight of polysaccharide. This NMR assay method described in this chapter reports a value based on the average number of *O*-acetyl groups per repeat unit. A method to calibrate between the two approaches should be developed during method validation.

***Change to read:***

## 2. PROCEDURE

### 2.1 Equipment Requirements

A description of a typical NMR spectrometer is given in ⟨1761⟩, and approaches to installation, performance, and operational qualification are given in ⟨761⟩. This section, and the rest of the chapter, refers to specific requirements for the identity testing of bacterial polysaccharides.

NMR SPECTROMETER

An NMR spectrometer with a minimal nominal field strength corresponding to a proton resonance frequency of NLT 400 MHz and with control of the sample temperature should be used. Temperature calibration within ±3° of the desired temperature is sufficient, provided a consistent sample temperature between the test and reference samples is achieved (or demonstrated in method validation), with temperature stability within a run of NMT 0.5°. NMR probes optimized for proton detection and suitable for 5-mm (outside diameter) NMR tubes should be used. Other probe options are possible but should be proven suitable before use.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M10157_05_01
@2024 USPC

PROCESSING PARAMETERS

A weighting function may be applied to the free induction decay (FID) before Fourier transform: a suitable line broadening function may be applied, and in some cases 0.3 Hz has been found suitable. After transform of the FID, the phase is adjusted to pure ▲absorption▲ (ERR 1-Jul-2018) phase. Baseline correction should be applied consistently.

NMR TUBES

These should be of a quality suitable for use in high-field spectrometers and qualified for use in the assay.

## 2.2 Reagents for Vaccine Polysaccharide Sample Solutions

SOLVENTS

Deuterated solvents subject to proton exchange with the polysaccharide [e.g., deuterated water ($D_2O$)] must be selected with the highest deuterium proportion (e.g., >99.9 atom % D).

CHEMICAL SHIFT REFERENCE COMPOUNDS

Sodium 2,2-dimethyl-2-silapentane-5-sulfonate (DSS; preferred), sodium trimethylsilylpropionate (TSP), or a deuterated analogue (TSP–$d_4$) are classically used and set to 0 ppm for the methyl signals. The reference material is usually added at low amounts [0.1%–0.01% (w/v) has been found to be appropriate] to the deuterated water used to dissolve the final sample.
[NOTE—Deuterated water >99.96% $^2H$ containing 0.01% DSS (w/v) is commercially available.]

SODIUM DEUTEROXIDE

Forty percent w/v (10 M) sodium deuteroxide (NaOD) in deuterated water (>99 atom % D) is commonly used to induce the de-*O*-acetylation of polysaccharides.

## 2.3 Sample Requirements

An aliquot of bulk purified polysaccharide or appropriate process intermediates in solid or liquid state containing 0.5–20 mg of saccharide content is suitable for preparation of NMR analytical samples. To obtain a solid aliquot, the relevant amount of material in liquid solution is dried under vacuum (using a freeze-drier, lyophilizer, or other solvent evaporator).

REFERENCE SPECTRA FOR ANTICIPATED IMPURITIES

Reference spectra for anticipated process-related impurities (e.g., ethanol, antifoaming agents, phenol, cetyl trimethylammonium bromide) should be obtained under the same experimental conditions as those used to analyze the test sample and at concentrations found similar to those in routine test samples. These spectra provide evidence for those resonances that may be excluded from further consideration when assigning the identity of the samples.

REFERENCE SPECTRA FOR POLYSACCHARIDES

Reference spectra for the polysaccharides samples being tested should be obtained by collecting spectra of authentic samples under identical sample preparation and spectrometer acquisition and data processing conditions to those used for test samples. Comparison of the spectra of test samples with these reference spectra allows the identity of the test samples to be confirmed.

## 2.4 Experimental Procedures

Two experimental protocols are described below. The first protocol is suitable for samples in which a single one-dimensional $^1H$ NMR spectrum will produce all of the required information. The second protocol includes in situ base-catalyzed de-*O*-acetylation of the polysaccharide to release *O*-acetyl groups as acetate anions, both simplifying the spectrum of the polysaccharide and allowing quantification of the degree of *O*-acetylation. A second one-dimensional $^1H$ NMR spectrum is collected after the de-*O*-acetylation step. The choice of which protocol to adopt will depend upon the product being tested and the information required; many stages in these two protocols are similar (e.g., sample preparation).

SAMPLE PREPARATION

NMR analytical samples of polysaccharide and its derivatives can be prepared as either solid- or liquid-state aliquots. NMR analytical samples are usually prepared by dissolving the solid aliquot in about 0.7 mL of deuterated solvent or, more rarely, by adding at least 10% (v/v) of deuterated solvent to the liquid aliquot. The solution is mixed to obtain a uniform concentration and is subsequently transferred to a 5-mm NMR tube.
[NOTE—NMR instrument design may allow or require the use of smaller volumes; users should confirm this for their instrument configuration.]

Official

https://pharmacopeia.cn/

DEUTERIUM EXCHANGE

With suitable method validation, lyophilization from deuterium oxide ("deuterium exchange") may be used to reduce the intensity of the resonance from residual water ($H_2O$)/HOD.

pH

Under some circumstances, control of the pH of the sample may be appropriate.

## 2.5 Procedure 1a

This procedure uses visual comparison with a reference spectra and/or comparison of test chemical shifts with reference chemical shift values.

SCOPE

This approach is compatible with polysaccharides that lack *O*-acetylation, such as *Haemophilus influenzae* type b or many pneumococcal polysaccharides, or with *O*-acetylated polysaccharides, such as *Neisseria meningitidis* or many pneumococcal polysaccharides where the product and spectral consistency allow identity to be established through direct comparison of test and reference spectra.

NMR SPECTRUM OF THE TEST SAMPLE

The NMR spectrum of the test sample is acquired under the same instrument operational and data processing parameters to those used to obtain the reference spectrum. Confirmation of identity can be based on visual comparison of the test and product-specific reference spectra, comparing resonance position, line width, relative intensity, and multiplicity. The complete spectrum, distinctive regions of the spectrum, or a series of at least five resonances (or three distinctive resonances in polysaccharides with monosaccharide or disaccharide repeat units) can be used in this comparison (as long as these are shown to be diagnostic).

RESONANCES

In a well-understood assay, resonances assigned as deriving from process-related impurities that are known to be removed at a later stage in the manufacturing process or otherwise proven not to impact product quality can be excluded from determination of identity.

## 2.6 Procedure 1b

This procedure uses analytical samples in deuterated water ($D_2O$) and a comparison with a reference spectrum by calculation of a correlation coefficient.

SCOPE

This approach is compatible with *Streptococcus pneumoniae* polysaccharides where the consistency of the product and the spectrum allow identity to be established through direct mathematical comparison of test and reference spectra.

With mathematical comparisons, a distinctive region of each spectrum (e.g., 4.64–5.89 ppm) is compared to spectra generated for designated reference samples for each polysaccharide of interest. The similarity of two spectral profiles for a test and reference sample acquired under identical conditions and in the same matrix is evaluated using a correlation coefficient ($\rho$). A positive identification of the sample polysaccharide is achieved when $\rho$ is NLT 0.95 (or another validated value) between the sample and reference spectra.

## 2.7 Procedure 2

The procedure is in-tube base-catalyzed de-*O*-acetylation and quantification of the acetate content.

SCOPE

In some cases, the degree of *O*-acetylation and their position, accompanied by spontaneous *O*-acetyl migration in solution, can complicate the NMR profile. Base-catalyzed de-*O*-acetylation of the polysaccharide in the NMR tube has proven useful for the *Salmonella typhi* Vi and the meningococcal Groups A, C, W135, and Y polysaccharides. Adding a base may also reduce line widths.

SAMPLE HANDLING

The sample is prepared as in *Sample Preparation* in *2.4 Experimental Procedures* and a one-dimensional $^1$H NMR spectrum is acquired as in *2.5 Procedure 1a*. This spectrum provides information on the presence/amount of acetate anion in the native sample. Sodium deuteroxide (NaOD) in deuterated water ($D_2O$) is added to the sample in the NMR tube to a final concentration of approximately 200 mM [equivalent to adding 14 µL of 10 M sodium deuteroxide (NaOD) in deuterated water ($D_2O$) to a

Official

@2024 USPC

0.7-mL sample]. De-*O*-acetylation is very rapid for almost all polysaccharides, but appropriate conditions should be evaluated in method development and validation. The NMR spectrum of the sample is reacquired after de-*O*-acetylation using acquisition conditions appropriate for quantitative spectroscopy. The spectrum of the de-*O*-acetylated material is characteristic of the polysaccharide backbone, and the degree of *O*-acetylation in the original sample is calculated from the integrals of the acetate anion and an appropriate resonance arising from the saccharide backbone. If the amount of acetate anion in the native sample is low, for example <5%, correction of the intensity of the acetate anion resonance in the de-*O*-acetylated sample is not necessary.

## 2.8 Assay Criteria

### TEMPERATURE

The temperature of the sample should be the same, within limits established during method validation, as that of the reference standard, and the sample temperature can be determined by the chemical shift difference between the HOD resonance and the internal chemical shift reference standard. For example, when using TSP-$d_4$ as the reference standard, calculate the actual temperature using the following equation based on the chemical shift of the HOD signal:

$$\delta = 5.051 - 0.0111(T)$$

where $\delta$ is the chemical shift of the HOD peak, and $T$ is the temperature in Celsius (°).

Other equations apply when different chemical shift reference standards are used. Consistency in the chemical shift difference between the HOD and chemical shift reference standard is a surrogate for sample temperature.

### CHEMICAL SHIFT REFERENCE STANDARD

The full width half-height (*fwhh*) line width of a defined resonance from a small molecule (e.g., the chemical shift reference standard) in the test sample should be within limits set during method validation to indicate both acceptable shimming of the magnet and sample temperature stability during the analysis. The signal-to-noise ratio of a defined signal within the spectrum of the polysaccharide material should exceed the specification established during method validation.

## 2.9 System Suitability

### SYSTEM SUITABILITY SOLUTION

Dissolve 1 vial of USP PS NMR System Suitability RS in deuterated water (>99.9% D, 1 mL) containing 0.01% DSS with brief mixing.

[NOTE—For example, for 10 s using a rotary mixer.]

Transfer 0.7 mL of this solution into an NMR tube (5-mm outside diameter).

[NOTE—NMR instrument design may allow or require the use of smaller volumes; users should confirm this for their instrument configuration.]

### SYSTEM SUITABILITY: PROCEDURE

Using an NMR spectrometer operating at NLT 400 MHz nominal frequency for $^1$H, acquire an FID using NLT 64 scans with a 90° pulse, a spectral width of 12 ppm, a recycle delay of NLT 30 s, a number of data points NLT 64,000, and with the spectral window centered at 4 ppm. Record the $^1$H NMR spectra of the *System suitability solution* at a stable temperature of 25 ± 3°. Obtain the spectrum using the above parameters. Transform the data after exponential multiplication (0.3 Hz line broadening). The DSS methyl signal should be set to 0.00 ppm.

### ACCEPTANCE CRITERIA

- The chemical shifts for the *N*-acetyl, GlcA H-2, and GlcNAc H-1 anomeric resonances in the *System suitability solution* should be observed at 2.01 ± 0.05, 3.33 ± 0.05, and 5.15 ± 0.05 ppm, respectively.
- The line width (*fwhh*) of the *N*-acetyl resonance at 2.01 ppm should be NMT 3.5 Hz.

# ⟨201⟩ THIN-LAYER CHROMATOGRAPHIC IDENTIFICATION TEST

## PROCEDURES

- **General Procedure**

The following procedure is applicable as an aid in verifying the identities of many compendial drug substances as such and in their respective dosage forms.

Prepare a test solution as directed in the individual monograph. On a line parallel to and about 2 cm from the edge of a suitable thin-layer chromatographic plate, coated with a 0.25-mm layer of chromatographic silica gel mixture (see *Chromatography* ⟨621⟩) apply 10 µL of this solution and 10 µL of a *Standard solution* prepared from the USP Reference Standard for the drug substance being identified, in the same solvent and at the same concentration as the test solution, unless otherwise directed in the individual monograph. Allow the spots to dry, and develop the chromatogram in a solvent system consisting of a mixture of chloroform, methanol, and water (180:15:1), unless otherwise directed in the individual monograph, until the solvent front has moved about three-fourths of the length of the plate. Remove the plate from the developing chamber, mark the solvent front, and allow the solvent to evaporate. Unless otherwise directed in the individual monograph, locate the spots on the plate by examination under short-wavelength UV light. The $R_F$ value of the principal spot obtained from the test solution corresponds to that obtained from the Standard solution.

- **Procedure for Bacitracin, Neomycin, and Polymyxin B**

The following thin-layer chromatographic procedure is applicable as an aid in verifying the identities of bacitracin, neomycin, and polymyxin B active ingredients and in dosage forms when present singly and in two- and three-component mixtures. The reference ⟨201BNP⟩ in a monograph signifies that this procedure is intended.

Prepare a *Test solution* as follows, unless otherwise directed in the individual monograph.

**Test solution**

**For drug substances:** Dissolve a portion of Bacitracin, Bacitracin Zinc, Neomycin Sulfate, or Polymyxin B Sulfate in 0.1 N hydrochloric acid to obtain a solution containing about 500 USP Bacitracin Units per mL, 3.5 mg of neomycin (base) per mL, or 10,000 USP Polymyxin B Units per mL.

**For solutions:** Where the solution contains neomycin and polymyxin B, dilute a portion of it with 0.1 N hydrochloric acid to obtain a solution containing the equivalent of about 3.5 mg of neomycin (base) per mL. Where the Solution contains polymyxin B but not neomycin, dilute a portion of it with 0.1 N hydrochloric acid to obtain a solution containing about 10,000 USP Polymyxin B Units per mL.

**For creams, lotions, and ointments:** Where the Cream, Lotion, or Ointment contains Bacitracin or Bacitracin Zinc, transfer a portion of it equivalent to about 500 USP Bacitracin Units, to a 15-mL centrifuge tube. Where the Cream, Lotion, or Ointment contains neomycin, but not Bacitracin or Bacitracin Zinc, transfer a portion of it equivalent to about 3.5 mg of neomycin (base) per mL to a 15-mL centrifuge tube. Add 4 mL of chloroform to the centrifuge tube, and shake well to disperse the Cream, Lotion, or Ointment. Add 1 mL of 0.1 N hydrochloric acid, vortex for 4 minutes, centrifuge, and use the clear supernatant.

[Note—The *Modified test solution* as described below in the *Modified procedure* may be used in lieu of the *Test solution*.]

**Standard bacitracin solution:** Dissolve a portion of USP Bacitracin Zinc RS in 0.1 N hydrochloric acid to obtain a solution containing 500 USP Bacitracin Units per mL.

**Standard neomycin solution:** Dissolve a portion of USP Neomycin Sulfate RS in 0.1 N hydrochloric acid to obtain a solution containing the equivalent of 3.5 mg of neomycin (base) per mL.

**Standard polymyxin B solution:** Dissolve a portion of USP Polymyxin B Sulfate RS in 0.1 N hydrochloric acid to obtain a solution containing 10,000 USP Polymyxin B Units per mL. Where the article under test also contains Bacitracin or Bacitracin Zinc, dissolve a portion of USP Polymyxin B Sulfate RS in 0.1 N hydrochloric acid to obtain a solution containing 500*J* USP Polymyxin B Units per mL, *J* being the ratio of the labeled amount of USP Polymyxin B Units to the labeled amount of USP Bacitracin Units in each g of Cream, Lotion, or Ointment.

**Developing solvent solution:** Prepare a mixture of methanol, isopropyl alcohol, methylene chloride, ammonium hydroxide, and water (4: 2: 2: 2: 1.5).

**Procedure:** Apply 10 µL of the *Test solution* and each of the relevant *Standard solutions* to a suitable thin-layer chromatographic plate (see *Chromatography* ⟨621⟩) coated with a 0.25-mm layer of chromatographic silica gel. Place the plate in a presaturated chromatographic chamber, and develop the chromatogram with the *Developing solvent system* until the solvent front has moved about three-fourths of the length of the plate. Remove the plate from the chamber, and dry at 105° for 10 minutes. Spray the plate with a 0.2% solution of ninhydrin in butyl alcohol, and heat at 105° for 5 minutes. The $R_F$ value of each principal spot in the chromatogram of the *Test solution* corresponds to that of the principal spot in the chromatogram obtained from each relevant *Standard solution* as appropriate for the labeled active ingredient or ingredients specified on the label. If the chromatogram of the *Test solution* yields excessive streaking, proceed as directed for *Modified procedure*.

**Modified procedure:** Transfer the *Test solution* to a 15-mL centrifuge tube, add 10 mL of saturated aqueous picric acid solution (1.2%, w/v), vortex for 1 minute, centrifuge for 10 minutes, and discard the supernatant. Wash the residue with 1-mL portions of water until no yellow color is observed in the washing. Discard the washings, and dry the residue under a stream of nitrogen at 50°. Dissolve the residue in 1 mL of acetone, add 1 mL of a freshly prepared solution of sulfuric acid in acetone (1 in 100), shake, centrifuge for 5 minutes, and discard the supernatant. Rinse the residue with 1 mL of acetone, centrifuge briefly, and discard the washing. Repeat the washing until no yellow color is observed. Dry the residue under a stream of nitrogen at 50°. Dissolve the residue in 0.5 mL of 0.1 N hydrochloric acid (*Modified test solution*). Repeat the *Procedure* using this *Modified test solution* instead of the *Test solution*. The $R_F$ value of each principal spot in the chromatogram of the *Modified test solution* corresponds to that of the principal spot in the chromatogram obtained from each relevant *Standard solution* as appropriate for the active ingredient or ingredients specified on the label.

# ⟨202⟩ IDENTIFICATION OF FIXED OILS BY THIN-LAYER CHROMATOGRAPHY

## INTRODUCTION

The following procedure for the USP *Identification* test is used to identify fixed oils using high-performance thin-layer chromatography (HPTLC), with a suitable octadecylsilyl silica gel as the coating substance.

## IDENTIFICATION

• **METHOD I**

**Mobile phase 1:** Ethyl ether

**Mobile phase 2:** Methylene chloride, glacial acetic acid, and acetone (20:40:50)

**System suitability solution 1:** Dissolve about 20 mg (1 drop) of USP Corn Oil RS in 3 mL of methylene chloride.

**System suitability solution 2:** Dissolve about 20 mg (1 drop) of USP Olive Oil RS in 3 mL of methylene chloride.

**Standard solution:** Dissolve about 20 mg (1 drop) of the appropriate USP Reference Standard in 3 mL of methylene chloride.

**Sample solution:** Dissolve about 20 mg (1 drop) of a fixed oil sample in 3 mL of methylene chloride.

**Chromatographic system**

(See *Chromatography* ⟨621⟩*, Thin-Layer Chromatography*.)

**Mode:** HPTLC

**Plate:** 20 cm × 10 cm, silica gel 60 RP-18, 0.15–0.2 mm layer, 4–8 µm particle size[1]

**Application volume:** 1 µL, manually spot

**Spray reagent:** 100 mg/mL of phosphomolybdic acid in 96% alcohol

**System suitability**

**Samples:** *System suitability solution 1* and *System suitability solution 2*

**Suitability requirements**

**Resolution:** The four principal spots from corn oil are clearly identified and separated, and the two principal spots from olive oil are clearly identified and separated.

[NOTE—Retardation factors ($R_F$) are provided for informational purposes only to aid in spot identification. The $R_F$ values for the four principal spots for USP Corn Oil RS are 0.39, 0.45, 0.51, and 0.56, and the $R_F$ values for the two principal spots for USP Olive Oil RS are 0.39 and 0.45.]

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Apply the *Samples* in separate bands to the previously marked starting point on an HPTLC plate, and develop the plate in the following order:

1. Ensure that the spots are at least 3 mm above the surface of the mobile phase. Develop two times over a path of 0.5 cm using *Mobile phase 1*. Remove the plate from the chamber after each run, and allow the plate to dry in air.
2. Develop two times over a path of 8 cm using *Mobile phase 2*. Allow the plate to dry for about 5 min after each development and before spraying with a spray reagent.

Spray the plate with the *Spray reagent*.

Heat the plate at 120° for about 1 min, and examine in daylight.

**Acceptance criteria:** The $R_F$ values of the principal spots of the *Sample solution* correspond to those of the *Standard solution*.

• **METHOD II**

**Mobile phase:** Methylene chloride, glacial acetic acid, and acetone (20:40:50)

**System suitability solution 1:** Dissolve 25 µL of USP Corn Oil RS in 3 mL of methylene chloride.

**System suitability solution 2:** Dissolve 25 µL of USP Olive Oil RS in 3 mL of methylene chloride.

**Standard solution:** Dissolve 25 µL of the appropriate USP Reference Standard in 3 mL of methylene chloride.

**Sample solution:** Dissolve 25 µL of a fixed oil sample in 3 mL of methylene chloride.

**Chromatographic system**

(See *Chromatography* ⟨621⟩*, Thin-Layer Chromatography*.)

**Mode:** HPTLC

**Plate:** 20 cm × 10 cm, silica gel 60 RP-18 (or RP-18 $F_{254}$), 0.15–0.2 mm layer, 4–8 µm particle size

**Conditioning of plate:** Condition the plate to a relative humidity of about 33%.

**Application volume:** 2 µL as bands of 8 mm. A suitable automated apparatus is used.

**Spray reagent:** 25 mg/mL of phosphomolybdic acid in 96% alcohol

**System suitability**

**Samples:** *System suitability solution 1* and *System suitability solution 2*

**Suitability requirements**

**Resolution:** The four principal bands from corn oil are clearly identified and separated, and the two principal bands from olive oil are clearly identified and separated.

[NOTE—Retardation factors ($R_F$) are provided for informational purposes only to aid in band identification. The $R_F$ values for the four principal bands for USP Corn Oil RS are 0.20, 0.26, 0.30, and 0.34, and the $R_F$ values for the two principal bands for USP Olive Oil RS are 0.20 and 0.26.]

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Predevelop the plate with methylene chloride to the upper edge. Dry the plate at 120° for 10 min.

[1] HPTLC Silica Gel 60 RP-18 plate from Merck EMD, or equivalent.

Official

https://pharmacopeia.cn/v-about/

Apply the *Samples* in separate bands to the previously marked starting point on an HPTLC plate.
Ensure that the bands are at least 3 mm above the surface of the mobile phase.
Develop over a path of 7 cm using *Mobile phase*. Allow the plate to dry in air.
Treat the plate with the *Spray reagent*.
Heat the plate at 120° for 3 min, and examine in daylight.

**Acceptance criteria:** The $R_F$ values of the principal bands of the *Sample solution* correspond to those of the *Standard solution*.

# ⟨203⟩ HIGH-PERFORMANCE THIN-LAYER CHROMATOGRAPHY PROCEDURE FOR IDENTIFICATION OF ARTICLES OF BOTANICAL ORIGIN

***Change to read:***

## INTRODUCTION

This chapter describes a procedure for use in a USP Identification test that ▲employs▲ (USP 1-May-2020) the technique of high-performance thin-layer chromatography (HPTLC). ▲Precise▲ (USP 1-May-2020) control of the ▲experimental▲ (USP 1-May-2020) variables ▲is essential for reproducible analysis. [NOTE—For additional information,▲ (USP 1-May-2020) see *Identification of Articles of Botanical Origin by High-Performance Thin-Layer Chromatography Procedure* ⟨1064⟩.]

***Change to read:***

## ▲▲ (USP 1-MAY-2020)EQUIPMENT

The equipment used for HPTLC ▲analysis typically includes:▲ (USP 1-May-2020)

- Plates: Unless otherwise specified in the individual monograph, use 20 × 10 cm plates coated with a uniform 200-µm layer of porous (60-Å pore size) silica gel having irregular particles of 2–10 µm and an average particle size of 5 µm, a polymeric binder, and a fluorescence indicator ($F_{254}$). [NOTE—▲▲ (USP 1-May-2020)Glass plates are preferred over aluminum-backed sheets.▲▲ (USP 1-May-2020)]
- A device suitable for ▲application of indicated volumes as bands of▲ (USP 1-May-2020) specified length at the ▲designated▲ (USP 1-May-2020) positions.
- A device suitable for controlling the activity of the stationary phase ▲by preconditioning the plate to a prescribed▲ (USP 1-May-2020) relative humidity.
- A suitable chromatographic chamber ▲to maintain reproducible vapor phase composition and to allow for control of developing distance▲ (USP 1-May-2020) (for example, a twin-trough chamber).
- A device suitable for reproducible drying of the developed plate.
- A device suitable for treatment of the plate with derivatization reagent, if required.
- A device suitable for ▲controlled plate▲ (USP 1-May-2020) heating as part of the derivatization procedure, if required.
- A ▲device▲ (USP 1-May-2020) suitable for ▲illumination under prescribed observation conditions, typically, short-wave UV (nominally 254 nm), long-wave UV (nominally 365 or 366 nm),▲ (USP 1-May-2020) and white light. ▲ [NOTE—Light sources used for chromatogram visualization typically produce broad-band emission; therefore, the maxima quoted above carry only nominal significance.]
- A photographic system for documentation of chromatograms under the prescribed visualization conditions.▲ (USP 1-May-2020)

***Change to read:***

## PROCEDURE

### Preparation of the Test Solution

Unless otherwise stated in an individual monograph, 100 mg of a powdered botanical ingredient, 10 mg of a dry extract, ▲▲ (USP 1-May-2020) or the amount of a dosage form containing the equivalent of the aforementioned quantities of the botanical ingredient is sonicated for 15 min with 1 mL of methanol. After ▲filtration or▲ (USP 1-May-2020) centrifugation, the filtrate or supernatant is used as the *Sample solution*. ▲For essential oils, 50 µL/mL solution in toluene is▲ (USP 1-May-2020) used as the *Sample solution*.

### Preparation of the Standard Solutions

Unless otherwise stated in an individual monograph, Reference Standards of individual marker compounds are dissolved ▲in methanol▲ (USP 1-May-2020) at a concentration of 1 mg/mL. The Reference Standard extracts are shaken and sonicated in methanol at a concentration of 10 mg/mL or, for essential oils, ▲in toluene at 50 µL/mL.▲ (USP 1-May-2020)

### Sample Application and Plate Layout

Samples are applied as narrow bands of ▲8-mm▲ (USP 1-May-2020) length at a distance of ▲8 mm▲ (USP 1-May-2020) from the lower edge of the plate ▲ [NOTE—Refer to ⟨1064⟩ for additional information.]▲ (USP 1-May-2020) The system suitability standards are applied to the ▲track▲ (USP 1-May-2020) nearest to the ▲lateral▲ (USP 1-May-2020) edge at NLT 20 mm from the ▲lateral▲ (USP 1-May-2020) edge of the plate. The distance between tracks, center-to-center, is NLT ▲11 mm.▲ (USP 1-May-2020) All application volumes are specified

Official

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Nov-2020
DOI Ref: 5l8bm
DocId: GUID-AC55337F-C4CA-4792-9D64-59C649957B03_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M9134_02_01
@2024 USPC

in the individual monographs, ▲and▲ (USP 1-May-2020) usually range from 2–10 µL. The developing distance is marked with a pencil close to one of the ▲lateral▲ (USP 1-May-2020) edges of the plate before the development; ▲alternatively,▲ (USP 1-May-2020) an electronic solvent front detection device ▲is used.▲ (USP 1-May-2020)

## Preconditioning of the Plate

Following sample application and unless otherwise stated in an individual monograph, the plate is conditioned at a relative humidity of 33% ▲by exposure to the atmosphere generated by vapors in equilibrium with saturated magnesium chloride solution in a sealed chamber▲ (USP 1-May-2020) for a minimum of 10 min. ▲Other frequently used saturated salt solutions of potassium thiocyanate and sodium chloride establish equilibrium relative humidity of 47% and 75%, respectively, at 25°.▲ (USP 1-May-2020)

## Preparation of the Developing Chamber and Development of the Plate

Where a twin-trough chamber is used, the rear trough is fitted with filter paper. The chamber is charged with a sufficient volume of developing solvent to wet the filter paper completely and achieve a level of developing solvent of exactly 5 mm in both troughs. With the lid closed, the chamber is ▲allowed to achieve saturation for▲ (USP 1-May-2020) 20 min. ▲▲ (USP 1-May-2020) The plate is introduced ▲vertically▲ (USP 1-May-2020) into the front trough of the chamber ▲with the chromatographic layer facing▲ (USP 1-May-2020) the filter paper. ▲Once the solvent front▲ (USP 1-May-2020) has ▲ascended 6 cm from the application line,▲ (USP 1-May-2020) the plate is removed from the chamber and dried in a vertical position in a current of cold air that does not affect the integrity of the separated zones. ▲Alternative▲ (USP 1-May-2020) chamber configurations and developing distances may be specified in an individual monograph. [NOTE—Other development chambers may be employed if the results obtained fulfill all of the system suitability criteria.]

## Derivatization Procedure

Where derivatization reagents are used, ▲appropriate▲ (USP 1-May-2020) volumes of reagents ▲▲ (USP 1-May-2020) (typically 1–2 mL) are ▲uniformly▲ (USP 1-May-2020) sprayed onto the plate or the plate is immersed into the reagent solution at a defined speed and for a defined dwell time. [NOTE—Immersion speed of 50 mm/s and the dwell time of 1 s ▲are recommended▲ (USP 1-May-2020) for most nonaqueous reagents.]

## Visualization

Chromatograms on the plate are visualized as directed in an individual monograph, ▲typically under short-wave UV, long-wave UV,▲ (USP 1-May-2020) or white light prior to and after derivatization.

## System Suitability

▲A general system suitability requirement is that the solvent front and the chromatographic bands are strictly parallel to the horizontal sides of the chromatographic plate. Specific suitability parameters are detailed in the monographs. Typically, to assess▲ (USP 1-May-2020) suitability of the chromatographic system for resolution, position, and color of the bands, ▲▲ (USP 1-May-2020) two or more reference substances are selected that have similar but just separable $R_F$ values under the chromatographic conditions to be used; for example, chlorogenic acid (blue) and hyperoside (yellow-orange) ▲are commonly▲ (USP 1-May-2020) used for flavonoids ▲methods. System suitability is required every time the analysis is performed; it is conducted on the same plate alongside the test articles. Failure to meet the system suitability requirements invalidates the analysis. In the event of failure, its cause needs to be identified and corrected (see ⟨1064⟩ for potential sources of failure), and the analysis repeated until the suitability requirements have been met. Individual▲ (USP 1-May-2020) Reference Standards, ▲or their▲ (USP 1-May-2020) mixtures, ▲are typically employed▲ (USP 1-May-2020) for system suitability ▲monitoring, and the use of▲ (USP 1-May-2020) the USP Reference Standard extracts ▲is common. The▲ (USP 1-May-2020) resolution, position, and colors of the key bands of the ▲Reference Standard chromatogram▲ (USP 1-May-2020) should match the description in the monograph within a specified tolerance. ▲▲ (USP 1-May-2020)

## Evaluation and Acceptance Criteria

Chromatograms of the *Sample solution* and *Standard solution* are compared against the descriptions in the *Acceptance criteria* section of the monograph with respect to ▲band▲ (USP 1-May-2020) position, ▲▲ (USP 1-May-2020)separation, color, and relative intensity.

## Documentation

▲Test results are required to be documented▲ (USP 1-May-2020) in an auditable manner to comply with the current good manufacturing practices. Proper documentation tools should be employed; for example, a ▲digital▲ (USP 1-May-2020) camera ▲capable of capturing images▲ (USP 1-May-2020) under ▲prescribed illumination, or a scanning densitometer along with the▲ (USP 1-May-2020) imaging software suitable for archival, retrieval, and analysis of the results.

## ▲INTRODUCTION

These procedures are▲ (Official 1-Jun-2023) provided to demonstrate that the content of aluminum (Al) does not exceed the limit given in the individual monograph of a substance labeled as intended for use in hemodialysis. ▲Use *Procedure 1*, *Procedure 2*, or *Procedure 3* as indicated in the individual monograph. *Procedure 2* or *Procedure 3* can be used in all circumstances, provided that suitability is demonstrated by meeting the *Requirements for Procedure Validation*.▲ (Official 1-Jun-2023)

***Change to read:***

## ▲PROCEDURES

- **Procedure 1: Atomic Absorption Spectroscopy**▲ (Official 1-Jun-2023)

[Note—The *Standard preparations* and the *Test preparation* may be modified, if necessary, to obtain solutions of suitable concentrations adaptable to the linear or working range of the instrument.]

**Nitric acid diluent:** Transfer 40 mL of nitric acid to a 1000-mL volumetric flask, and dilute with water to volume.

**Standard preparations:** Treat some aluminum wire with 6 N hydrochloric acid at 80° for a few minutes. Dissolve about 100 mg of the treated wire, accurately weighed, in a mixture of 10 mL of hydrochloric acid and 2 mL of nitric acid by heating at about 80° for approximately 30 min. Continue heating until the volume is reduced to about 4 mL. Cool to room temperature, and add 4 mL of water. Evaporate to about 2 mL by heating. Cool, and transfer this solution, with the aid of water, to a 100-mL volumetric flask, dilute with water to volume, and mix. Transfer 10.0 mL of this solution to a second 100-mL volumetric flask, dilute with water to volume, and mix. Transfer 1.0 mL of this solution to a third 100-mL volumetric flask, dilute with water to volume, and mix. The concentration of aluminum in this *Standard preparation* is about 1.0 µg/mL. If a more diluted *Standard preparation* is required, transfer 1.0-, 2.0-, and 4.0-mL portions of this solution to separate 100-mL volumetric flasks, dilute with *Nitric acid diluent* to volume, and mix. These solutions contain 0.01, 0.02, and 0.04 µg of aluminum per milliliter, respectively.

**Test preparation:** Unless otherwise directed in the individual monograph, prepare as follows. Transfer an accurately weighed amount, in grams, of the test substance, as specified in the monograph, to a 100-mL plastic volumetric flask, add 50 mL of water, and sonicate for 30 min. Add 4 mL of nitric acid, dilute with water to volume, and mix.

**▲Analysis:▲** (Official 1-Jun-2023) Determine the absorbances of the *Standard preparations* and the *Test preparation* at the aluminum emission line at 309.3 nm with a suitable atomic absorption spectrophotometer (see *Atomic Absorption Spectroscopy* ⟨852⟩) equipped with an aluminum hollow-cathode lamp and a flameless electrically heated furnace, using the *Nitric acid diluent* as the blank. Plot the absorbances of the *Standard preparations* versus the content of aluminum, in micrograms per milliliter, drawing a straight line best fitting the three points. From the graph, determine the quantity, in micrograms, of aluminum in each milliliter of the *Test preparation*. Calculate the amount of aluminum in the specimen taken, in micrograms per gram, by multiplying this value by 100/*W*, where *W* is the weight, in grams, of the substance taken to prepare the *Test preparation*.

- **▲Procedure 2 and Procedure 3**

Both *Procedure 2* and *Procedure 3* are ICP-based procedures and can be used for the determination of aluminum. *Procedure 2* can be used for the determination of aluminum by inductively coupled plasma atomic (or optical) emission spectroscopy (ICP–AES or ICP–OES). *Procedure 3* can be used for the determination of aluminum by ICP–MS.

Before initial use, the analyst should verify that the procedure is appropriate for the instrument and sample used (procedural verification) by meeting the *Requirements for Procedure Validation*.

Where a monograph specifies a limit for aluminum concentration, the value listed in the monograph should be used as the *J* value for the purposes of this test.

System standardization and suitability evaluation using applicable reference materials should be performed on the day of analysis.

**Sample preparation:** Forms of sample preparation include neat, direct aqueous solution, direct organic solution, and indirect solution. The selection of the appropriate sample preparation depends on the material under test and is the responsibility of the analyst. When a sample preparation is not indicated in the monograph, an analyst may use any appropriately validated preparation procedure. In cases where spiking of a material under test is necessary to provide an acceptable signal intensity, the blank should be spiked with aluminum using, where possible, the same spiking solution. [Note—All liquid samples should be weighed.]

**Closed vessel digestion:** This sample preparation procedure is designed for samples that must be digested in a concentrated acid using a closed vessel digestion apparatus. Closed vessel digestion minimizes the loss of volatile impurities. The choice of a concentrated acid depends on the sample matrix. The use of any of the concentrated acids may be appropriate, but each introduces inherent safety risks. Therefore, appropriate safety precautions should be used at all times. [Note—Weights and volumes provided may be adjusted to meet the requirements of the digestion apparatus used.]

An example procedure that has been shown to have broad applicability is as follows. Dehydrate and predigest 0.5 g of the primary sample in 5 mL of freshly prepared concentrated acid. Allow to sit loosely covered for 30 min in a fume hood. Add an additional 10 mL of concentrated acid, and digest using a closed vessel technique until the digestion or extraction is complete. Repeat, if necessary, by adding an additional 5 mL of concentrated acid. [Note—Follow the manufacturer's recommended procedures to ensure safe use.]

**Reagents:** All reagents used for the preparation of sample and standard solutions should be free of elemental impurities, in accordance with *Plasma Spectrochemistry* ⟨730⟩.

https://pharmacopeia.cn/v-cn/

**Procedure 2: ICP–OES**
**Standardization solution 1:** 1.5*J* of aluminum in a matched matrix
**Standardization solution 2:** 0.5*J* of aluminum in a matched matrix
**Sample stock solution:** Prepare as directed in *Sample preparation*. Allow the sample to cool, if necessary.
**Sample solution:** Dilute the *Sample stock solution* with an appropriate solvent to obtain a final aluminum concentration of not more than 1.5*J*.
**Blank:** Matched matrix
**Elemental spectrometric system**
(See ⟨730⟩.)
**Rinse:** Use diluent.
**Standardization:** *Standardization solution 1*, *Standardization solution 2*, and *Blank*
**System suitability**
**Sample:** *Standardization solution 1*
**Suitability requirements**
**Drift:** Compare results obtained from *Standardization solution 1* before and after the analysis of the *Sample solution*.
**Suitability criteria:** Not more than 20% for aluminum. [NOTE—If samples are high in mineral content, rinse the system well before introducing the *Sample* in order to minimize carryover.]
**Analysis:** Analyze according to the manufacturer's suggestions for program and wavelength. Calculate and report results on the basis of the original sample size. [NOTE—Appropriate measures must be taken to correct for matrix-induced interferences (e.g., wavelength overlaps).]
**Procedure 3: ICP–MS**
Follow *Procedure 2* except for *Detector* and *Analysis*.
[NOTE—An instrument with a cooled spray chamber is recommended. (A collision cell or reaction cell may also be beneficial.)]
**Detector:** Mass spectrometer
**Analysis:** Analyze according to the manufacturer's suggestions for program and mass-to-charge ratio. Calculate and report results based on the original sample size. [NOTE—Appropriate measures must be taken to correct for matrix-induced interferences.]▲ (Official 1-Jun-2023)

***Add the following:***

## ▲REQUIREMENTS FOR PROCEDURE VALIDATION

The following section defines the validation parameters and the acceptance criteria for performance-based procedures. Meeting these requirements must be demonstrated experimentally using an appropriate system suitability procedure and reference materials. Any alternative procedure (e.g., an atomic-absorption-based procedure) that has been validated and meets the acceptance criteria that follow is considered to be suitable for use.

Meeting these validation acceptance criteria is sufficient to demonstrate that the procedure will produce comparable results to those obtained using the procedure prescribed in the monograph.

- **ACCURACY**
  **Standard solutions:** Prepare solutions containing aluminum at concentrations ranging from 50% to 150% of *J* using appropriate reference materials.
  **Test samples:** Spike the material under test with the appropriate reference materials before any sample preparation steps (digestion or solubilization). Prepare three replicate samples at concentrations ranging from 50% to 150% of *J* for aluminum.
  **Acceptance criteria**
  **Spike recovery:** 70%–150% for the mean of three replicate preparations at each concentration
- **PRECISION**
  **Repeatability**
  **Test samples:** Six independent samples of material under test (taken from the same lot), spiked with appropriate reference materials for aluminum, at the indicated concentration
  **Acceptance criteria**
  **Relative standard deviation:** Not more than 20% ($N = 6$) for aluminum
  **Intermediate precision (ruggedness)**
  **Analysis:** Perform the *Repeatability* analysis again on a different day, with different instrumentation, with a different analyst, or a combination thereof. Combine the results of this analysis with the *Repeatability* analysis so the total number of analyses is 12.
  **Acceptance criteria**
  **Relative standard deviation:** Not more than 25% ($N = 12$) for aluminum
- **SPECIFICITY:** The procedure must be able to unequivocally assess (see *Validation of Compendial Procedures* ⟨1225⟩) aluminum in the presence of components that may be expected to be present, including matrix components.
- **LIMIT OF QUANTITATION, RANGE, AND LINEARITY:** Demonstrated by meeting the *Accuracy* requirement.▲ (Official 1-Jun-2023)

***Add the following:***

## ▲GLOSSARY

**Concentrated acid:** Concentrated ultra-pure nitric, sulfuric, hydrochloric, or hydrofluoric acid or aqua regia.
**Aqua regia:** Aqua regia is a mixture of concentrated hydrochloric and nitric acids, typically at ratios of 3:1 or 4:1.
**Matched matrix:** Solutions having the same solvent composition as the *Sample solution*. In the case of an aqueous solution, a matched matrix would indicate that the same acids and acid concentrations are used in both preparations.

Official

https://pharmacopeia.cn/v-download/

**Target limit or target concentration:** The acceptance value for the elemental impurity being evaluated, in this case aluminum. Where a monograph specifies a threshold limit, this shall become the target limit or target concentration of aluminum for the material. Exceeding the target limit indicates that a material under test exceeds the acceptable value. The determination of compliance is addressed in other chapters.

***J*:** The concentration (w/w) of the element of interest, in this case aluminum, at the target limit, appropriately diluted to the working range of the instrument.

**Appropriate reference materials:** Where "appropriate reference materials" are specified in the chapter, certified reference materials (CRMs) from a national metrology institute (NMI), or reference materials that are traceable to the CRM of an NMI should be used. An example of an NMI in the United States is the National Institute of Standards and Technology (NIST).▲ (Official 1-Jun-2023)

# ⟨207⟩ TEST FOR 1,6-ANHYDRO DERIVATIVE FOR ENOXAPARIN SODIUM

The following procedure is used to determine the levels of 1, 6-anhydro forms in enoxaparin sodium. [NOTE—The test for the 1,6-anhydro derivative is conducted only where specified in the individual monograph.]

## INTRODUCTION

The disaccharides specified in this general chapter are listed by name and structure in *Appendix 1*; the oligosaccharides are listed in *Appendix 2*.

Depolymerization of heparin into enoxaparin sodium produces a partial but characteristic conversion of glucosamines at the reducing termini of oligosaccharide chains with terminal glucosamine 6-*O* sulfate, yielding 1,6-anhydro derivatives (see *Figure 1*).

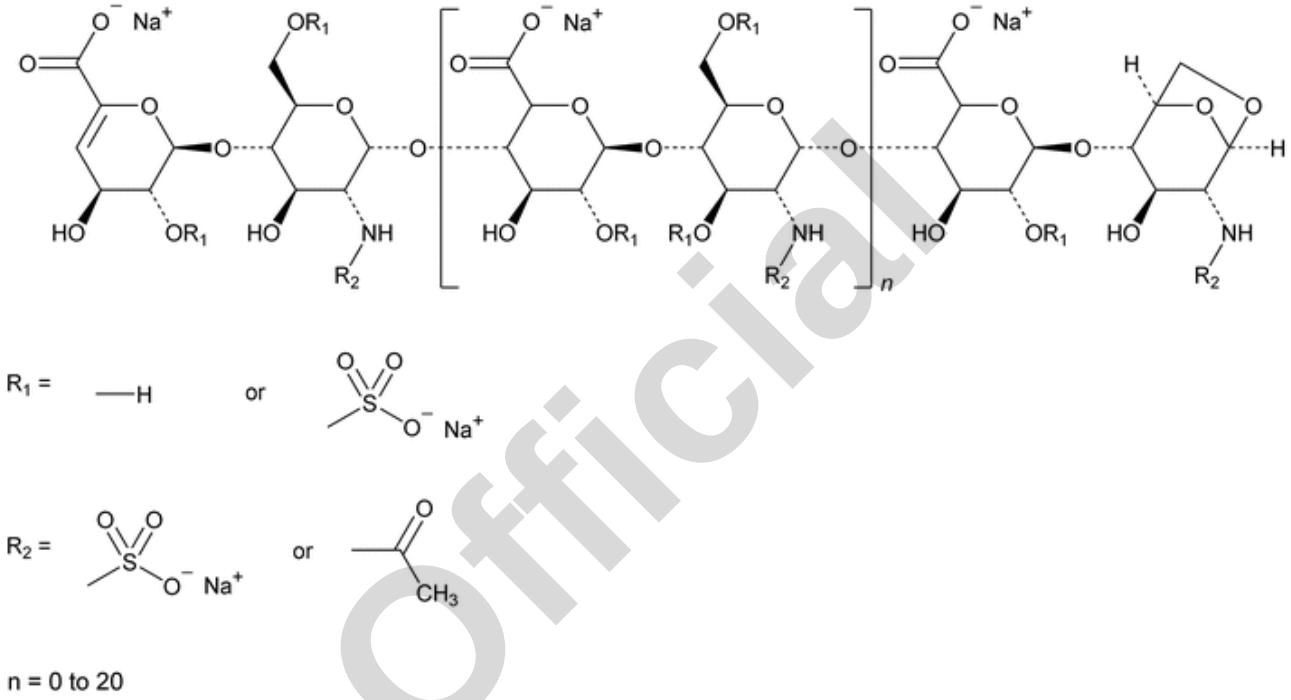

Figure 1. Structure of enoxaparin sodium containing a 1,6-anhydro derivative on the reducing end of the chain.

The percentage of oligosaccharide chains that are cyclized in a 1,6-anhydro ring is a characteristic of enoxaparin sodium.

## PROCEDURES

- **DEPOLYMERIZATION OF ENOXAPARIN SODIUM BY HEPARINASES AND RESULTING OLIGOSACCHARIDES**

The assay involves HPLC analysis of a depolymerized enoxaparin sodium solution by a mixture of heparinases. After enzymatic depolymerization, the main 1,6-anhydro residues of enoxaparin sodium observed are 1,6-anhydro ΔIIS and 1,6-anhydro $\Delta IIS^{epi}$, and 1,6-anhydro ΔIS and 1,6-anhydro $\Delta IS–IS^{epi}$ (see *Appendix 2*.).

The 1,6-anhydro $\Delta IS–IS^{epi}$ tetrasaccharide (2-*O*-sulfated mannosamine form) is not completely cleaved by the heparinases. The two disaccharides (1,6-anhydro ΔIIS and 1,6-anhydro $\Delta IIS^{epi}$), which generally co-elute, are poorly resolved with respect to ΔIIA (see *Appendix 1*), especially because the latter occurs as two anomers: α and β. To allow quantitation of 1,6-anhydro ΔIIS and 1,6-anhydro $\Delta IIS^{epi}$, the enoxaparin sodium sample already depolymerized by heparinases is then reduced by sodium borohydride (see *Figure 2*).

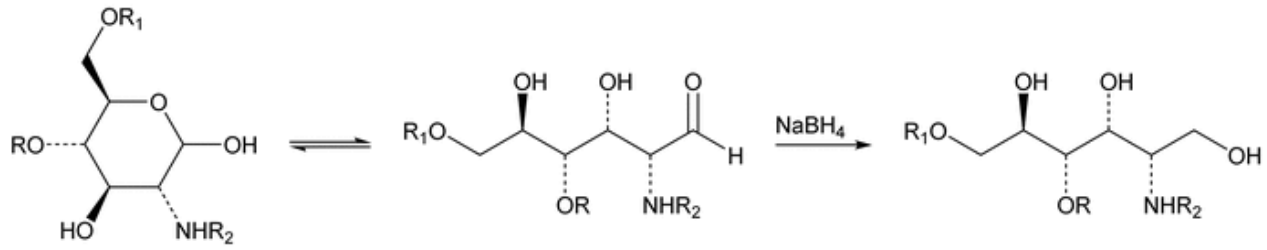

Figure 2. Reduction of oligosaccharides by sodium borohydride

DOI Ref: 0bq93
DocId: GUID-61D4B1FB-E10B-40E7-ACEA-137347D77E52_4_en-US
@2024 USPC
DOI: https://doi.org/10.31003/USPNF_M2740_04_01

The sodium borohydride reduction eliminates the $\alpha \leftrightarrow \beta$ anomeric effect by opening the terminal oligosaccharide ring. The four 1,6-anhydro derivatives (see *Appendix 2*.) are not reduced by sodium borohydride because the ring opening is blocked by the 1,6-anhydro bridge. The reduction of the oligosaccharides decreases their retention time, whereas the retention time of the 1,6-anhydro derivatives remains unchanged. Thus, it is possible to separate the two compounds—1,6-anhydro ΔIIS and 1,6-anhydro $\Delta IIS^{epi}$—from the reduced ΔIIA disaccharide peak.

[NOTE—1,6-Anhydro ΔIIS and 1,6-anhydro $\Delta IIS^{epi}$ are eluted as two nonresolved peaks and are quantitated together as a single compound, 1,6-anhydro ΔIIS. Therefore, for the purpose of simplification, the epimeric form is not referred to in the remaining text.]

- **PROCEDURE**

**Solutions**

**Solution A:** Dissolve 0.280 g of monobasic sodium phosphate in 950 mL of water, adjust with phosphoric acid to a pH of 3.0, and dilute with water to 1000 mL.

**Solution B:** Dissolve 140 g of sodium perchlorate in 950 mL of *Solution A,* adjust with phosphoric acid to a pH of 3.0, and dilute with *Solution A* to 1000 mL.

**Mobile phase:** Use variable mixtures of filtered and degassed *Solution A* and *Solution B* as directed in *Chromatographic system*.

**Sodium/Calcium acetate pH 7.0 solution:** Dissolve 10 mg of bovine serum albumin and 32 mg of calcium acetate in 60 mL of water. Add 580 µL of glacial acetic acid, and adjust with 2 M sodium hydroxide to a pH of 7.0. Transfer to a 100-mL volumetric flask, and dilute with water to volume. Pass the solution through a filter having a porosity of 0.45 or 0.22 µm.

**Potassium phosphate pH 7.0 buffer:** Dissolve 68 mg of monobasic potassium phosphate and 10 mg of bovine serum albumin in 30 mL of water in a 50-mL volumetric flask. Adjust with potassium hydroxide, if necessary, to a pH of 7.0, and dilute with water to volume. Pass the solution through a filter having a porosity of 0.45 or 0.22 µm.

**Sodium borohydride solution:** Dissolve 12 mg of sodium borohydride in 400 µL of water, and mix on a vortex mixer. [NOTE—Prepare fresh *immediately* before use.]

**Heparinase 1 solution:** Dissolve heparinase 1 (see *Reagent Specifications* under *Reagents, Indicators,* and *Solutions*) [reference: heparin lyase I, EC 4.2.2.7] in *Potassium phosphate pH 7.0 buffer* to obtain a solution having an activity of 0.4 IU per mL. Store the solution at –20° until ready to use. [NOTE—Heparinase solutions can be stored for 3 months at –20°.]

**Heparinase 2 solution:** Dissolve heparinase 2 (see *Reagent Specifications* under *Reagents, Indicators,* and *Solutions* [no EC number] in *Potassium phosphate pH 7.0 buffer* to obtain a solution having an activity of 0.4 IU per mL. Store the solution at –20° until ready to use.

**Heparinase 3 solution:** Dissolve heparinase 3 (see *Reagent Specifications* under *Reagents, Indicators,* and *Solutions* [reference: heparitinase I, EC 4.2.2.8] in *Potassium phosphate pH 7.0 buffer* to obtain a solution having an activity of 0.4 IU per mL. Store the solution at –20° until ready to use.

**Heparinases 1, 2, 3, solution:** Prepare a 1:1:1 (v:v:v) mixture of *Heparinase 1 solution, Heparinase 2 solution,* and *Heparinase 3 solution.*

**Peak identification solutions**

[NOTE—The depolymerized test solutions and Standard solutions must be prepared at the same time. Depolymerized test solutions are stable for 1 month at –20°. Also, the reduced test solutions and Standard solutions must be prepared at the same time. Reduced solutions are also stable for 1 month at –20°.]

**Disaccharide solutions:** Separately prepare a 0.25 mg per mL solution of each disaccharide[1] ΔIA, ΔIIA, ΔIIIA, ΔIVA, ΔIS, ΔIIS, ΔIIIS, ΔIVS (see *Appendix 1*). Chromatograph each disaccharide solution, and record the peak responses.

**Reduced disaccharide solutions:** To 60 µL of each *Disaccharide solution,* add 10 µL of freshly prepared *Sodium borohydride solution.* Mix on a vortex mixer, and allow to stand at room temperature for at least 4 hours. Chromatograph each solution, and record the peak response.

**Blank solution:** Prepare a mixture of 20 µL of water, 70 µL of *Sodium/Calcium acetate pH 7.0 solution,* and 100 µL of the *Heparinases 1, 2, 3 solution*. Mix gently by inversion, and allow to stand for at least 48 hours in a 25° water bath. Prepare a mixture of 60 µL of this depolymerized solution with 10 µL of freshly prepared *Sodium borohydride solution*. Homogenize, and allow to stand at room temperature for at least 4 hours. Chromatograph the resulting solution, and record the peak responses.

**Test solution 1:** Prepare two solutions, each containing 20 mg of enoxaparin sodium in 1 mL of water.

**Standard solution 1:** Prepare one solution containing 20 mg of USP Enoxaparin Sodium RS in 1 mL of water.

**Test solution 2:** For each solution, prepare a mixture of 20 µL of *Test solution 1,* 70 µL of *Sodium/Calcium acetate pH 7 solution,* and 100 µL of *Heparinases 1, 2, 3 solution.* Mix gently by inversion, and allow to stand for at least 48 hours in a 25° water bath. After 48 hours of depolymerization, chromatograph the solution, and record the peak responses.

**Standard solution 2:** Prepare a mixture of 20 µL of *Standard solution 1,* 70 µL of *Sodium/Calcium acetate pH 7 solution,* and 100 µL of *Heparinases 1, 2, 3 solution.* Mix gently, and allow to stand for at least 48 hours in a 25° water bath. After 48 hours of depolymerization, chromatograph the solution, and record the peak responses.

**Test solution 3:** For each depolymerized test solution, prepare a mixture of 60 µL of *Test solution 2* and 10 µL of freshly prepared *Sodium borohydride solution*. Homogenize, and allow to stand loosely capped at room temperature for at least 4 hours before injecting into the chromatograph. *Test Solution 3* is stable for 48 hours at room temperature.

**Standard solution 3:** Prepare a mixture of 60 µL of *Standard solution 2* and 10 µL of freshly prepared *Sodium borohydride solution*. Homogenize and mix on a vortex mixer, and allow to stand loosely capped at room temperature for at least 4 hours before injecting into the chromatograph. *Standard solution 3* is stable for 48 hours at room temperature.

**Chromatographic system**

(See *Chromatography* ⟨621⟩.)

The liquid chromatograph is equipped with a 234-nm detector and a 3-mm × 25-cm column that contains 5-µm packing L14. A guard column packed with the same material should also be used. The flow rate is 0.45 mL per minute, the column temperature is maintained at 50°, and the injection volume is 10 µL. The chromatograph is programmed as follows.

| Time (min) | Solution A (%) | Solution B (%) | Elution |
|---|---|---|---|
| 0–20 | 97→65 | 3→35 | Linear gradient |
| 20–50 | 65→0 | 35→100 | Linear gradient |
| 50–60 | 0 | 100 | Isocratic |
| 60–61 | 0→97 | 100→3 | Linear gradient for re-equilibration |
| 61–79 | 97 | 3 | Isocratic for re-equilibration |

Chromatograph the reduced *Test solution 3* and the reduced *Standard solution 3,* and record the peak responses as directed for *Procedure.*

**Depolymerization suitability test:** The ratio of the peak area of 1,6-anhydro-ΔIS-IS to that of 1,6-anhydro ΔIS is not more than 1.15 for the depolymerized *Standard solution 2*.

**Column performance suitability test:** Identify the peaks corresponding to reduced ΔIA and 1,6-anhydro-ΔIS for the *Standard solution 3:* the retention time of reduced ΔIS is between 27 and 33 minutes for the depolymerized and reduced *Standard solution 3;* and the resolution, *R,* between reduced ΔIA and 1,6-anhydro-ΔIS is not less than 1.5.

**Reduction suitability test:** The ratio of the peak area of ΔIS disaccharide to that of reduced ΔIS in the depolymerized and reduced *Standard solution 3* and *Test solution 3* is not more than ▲0.02.▲ (ERR 1-Oct-2018)

**Procedure/Calculation:** Separately inject equal volumes of the reduced *Test solutions 3* and the reduced *Standard solution 3* into the chromatograph. Use the normalized area percentage method for calculation. Each peak is integrated from the dwell volume peak to the last detected peak. Measure the area of each analyte peak after excluding solvent peaks at the beginning of the chromatogram and in the *Blank solution*. Using the previously obtained chromatograms of the *Reduced disaccharide solutions,* identify peaks belonging to the eight reduced disaccharides in the chromatograms for *Test solution 3* and *Standard solution 3*. The peaks belonging to 1,6-Anhydro ΔIS, 1,6-Anhydro ΔIIS, and 1,6-Anhydro ΔIS-IS$^{epi}$ are identified from the relative retention times provided in *Table 1* and the Reference chromatogram provided with USP Enoxaparin Sodium RS. Once the peaks have been identified, use the values in *Table 1* to calculate the (w/w) percentage of the three main 1,6-anhydro derivatives obtained after depolymerization of enoxaparin sodium using the following formula:

$$\%\ 1,6\text{-anhydro i (w/w)} = (100 \times MW_i \times A_i)/\ \Sigma(MW_x \times A_x)$$

$MW_i$ = molecular weight of the 1,6-anhydro peak i
$A_i$ = area of the 1,6-anhydro peak i
$MW_x$ = molecular weight of either the peak X or the zone X specified by its retention time
$A_x$ = area of either the peak X or the zone X specified by its retention time

[NOTE—Once the method is established, the peaks belonging to the different di- and tetrasaccharides can be easily identified using the USP Enoxaparin Sodium RS chromatogram. Thus, the use of the disaccharide Standards is only needed during the method-implementation stage.]

Calculate the molar percentage of components containing a 1,6-anhydro structure at the reducing end of their chain in the enoxaparin sodium test sample according to the following formula:

$$\%\ 1.6anhydro = 100 \times \frac{\text{MW}}{\Sigma \text{MW}_\text{X} \times \text{Area}_\text{x}} \times \left(\text{Area}\Delta\text{I}s1.6anydro + \text{Area}\Delta\text{II}s1.6anhydro + \text{Area}\Delta\text{I}s - \text{I}s1.6anhydro\right)$$

in which MW is the mass-average molecular mass (see *Identification* test *D* under *Enoxaparin Sodium*); $MW_x$ and $Area_x$ are the molecular weight and the area, respectively, of either the peak X or the range X specified by its retention time. The molar percentage of components having a 1,6-anhydro structure at the reducing end of their chain is between 15% and 25%. Typical retention times and molecular masses attributed to different oligosaccharide structures are provided in *Table 1*.

# ⟨208⟩ ANTI-FACTOR Xa AND ANTI-FACTOR IIa ASSAYS FOR UNFRACTIONATED AND LOW MOLECULAR WEIGHT HEPARINS

This chapter provides information and procedures to determine factor Xa inhibitory activity and factor IIa (thrombin) inhibitory activity for unfractionated heparin (UFH) and low molecular weight heparins (LMWH).

## INTRODUCTION

Unfractionated heparin and LMWH exert their anticoagulant effect by potentiating the activity of plasma coagulation inhibitors. Of all the commonly known glycosaminoglycans, only UFH, LMWH, and heparan sulfate (hereafter referred to generally as heparin) contain a specific pentasaccharide sequence that can bind to the plasma coagulation inhibitor, antithrombin (AT). AT-dependent assays, therefore, are developed to ensure the specificity of the methods for measuring the anticoagulant activity of heparin. Binding of heparin to AT induces a conformational change, thereby increasing AT's binding to and subsequent inactivation of activated blood coagulation factors. The major coagulation targets for the AT–heparin complex are factor IIa (thrombin) and coagulation factor Xa. Once AT is activated by the pentasaccharide sequence of heparin, it interacts with factors Xa and IIa via its reactive center loop. For efficient inhibition of thrombin, the heparin molecule also must bind to both AT and IIa. This interaction requires an extra length of approximately 13 monosaccharides attached at the nonreducing end of the AT-binding heparin pentasaccharide sequence. This minimum heparin motif for AT inhibition of thrombin, known as the C-domain, has an approximate molecular weight of 5400 Da. Although the potentiation of AT inactivation of factor Xa also depends on molecular weight, the additional saccharide units of the C-domain are not essential, and heparin with a molecular weight less than 5400 Da can potentiate AT to inactivate factor Xa. By convention, the potency ratio of anti-factor Xa to anti-factor IIa for UFH is 1. Unfractionated heparin is heterogenous and polydisperse but contains little or no material of molecular weight less than 5400 Da. The mean molecular weights of LMWH products are lower than those of UFH, and they contain a higher proportion of material that weighs less than 5400 Da. The potency ratio of anti-factor Xa to anti-factor IIa for LMWH products is greater than 1.5. This chapter describes assay procedures for the measurement of anti-factor Xa and anti-factor IIa activity of LMWH heparin in the presence of AT.

In the test system, heparin is bound to AT, and factor IIa or factor Xa added to the mixture binds to the heparin–AT complex. The residual factor IIa or factor Xa not inhibited by the heparin–AT complex is quantified by a chromogenic substrate that is specific for either factor IIa or factor Xa and is added in the final step. Analysts note an inverse relationship wherein more color is produced by more residual enzyme, which equates to less heparin activity.

As for any enzymatic assay, temperature and timing of the reaction, proper handling of the reagents, and the order in which the reagents are added are critical to the optimal performance of the assay.

### Anti-Factor Xa and Anti-Factor IIa Assays for Unfractionated Heparin

- **ANTI-FACTOR Xa ACTIVITY FOR UFH**

The following procedure is used where specified in the individual monographs. This assay can be performed manually in plastic tubes utilizing heated block stations or water bath. Microtiter plate equipment with a reader and automated coagulometer can improve reproducibility and throughput.

**pH 8.4 buffer:** Dissolve amounts of tris(hydroxymethyl)aminomethane, edetic acid or edetate sodium, and sodium chloride in water containing 0.1% of polyethylene glycol 6000 to obtain solutions having concentrations of 0.050 M, 0.0075 M, and 0.175 M, respectively. Adjust, if necessary, with hydrochloric acid or sodium hydroxide solution to a pH of 8.4.

**Antithrombin solution:** Reconstitute a vial of antithrombin (see *Reagents, Indicators, and Solutions—Reagent Specifications*) as directed by the manufacturer, and further dilute with *pH 8.4 buffer* to obtain a solution having a concentration of 1.0 Antithrombin IU/mL.

**Factor Xa solution:** Reconstitute bovine factor Xa as directed by the manufacturer (see *Factor Xa* in *Reagents, Indicators, and Solutions—Reagent Specifications*), and further dilute in *pH 8.4 buffer* to obtain a solution that gives an absorbance value of 0.65–1.25 at 405 nm when assayed as described below but using 30 µL of *pH 8.4 buffer* instead of 30 µL of the *Standard solutions* or the *Sample solutions*. [NOTE—*Factor Xa solution* contains about 3 nanokatalytic units/mL but can vary depending on the manufacturer of factor Xa or the substrate used.]

**Chromogenic substrate solution:** Prepare a solution of a suitable chromogenic substrate for amidolytic test (see *Reagents, Indicators, and Solutions—Reagent Specifications*) specific for factor Xa in water to obtain a concentration of 1 mM.

**Stopping solution:** 20% (v/v) solution of acetic acid

**Standard solutions:** Reconstitute the entire contents of an ampule of USP Heparin Sodium for Assays RS with water, and dilute with *pH 8.4 buffer* to obtain at least 5 dilutions in the concentration range of 0.03–0.375 USP Heparin Units/mL.

**Sample solutions:** Dissolve or dilute an accurately measured quantity of Heparin Sodium in *pH 8.4 buffer*, and dilute with the same buffer to obtain solutions having activities approximately equal to those of the *Standard solutions*.

**Analysis:** [NOTE—The procedure also can be performed using alternative platforms. Perform the test with each *Standard solution* and *Sample solution* in duplicate.]

To each of a series of suitable plastic tubes placed in a water bath set at 37°, transfer 120 µL of *pH 8.4 buffer*. Then separately transfer 30 µL of the different dilutions of the *Standard solutions* or the *Sample solutions* to the tubes. Add 150 µL of *Antithrombin solution*, prewarmed at 37° for 15 min, to each tube, mix, and incubate for 2 min. Add 300 µL of *Factor Xa solution*, prewarmed at 37° for 15 min, to each tube, mix, and incubate for 2 min. Add 300 µL of *Chromogenic substrate solution*, prewarmed at 37° for 15 min, to each tube, mix, and incubate for exactly 2 min. Add 150 µL of *Stopping solution* to each tube, and mix. Prepare a blank for zeroing the spectrophotometer by adding the reagents in reverse order, starting with the *Stopping solution* and ending with the addition of 150 µL of *pH 8.4 buffer*, and excluding the *Standard solutions* or the *Sample solutions*. Record the absorbance at 405 nm against the blank. The volume of the reactants can be increased or decreased to suit the assay format provided that the proportions of the reference sample or the test sample and the reagents are kept the same.

**Calculations:** Plot the log of the absorbance values of the *Standard solutions* and the *Sample solutions* vs. heparin concentrations in USP Units. Calculate the activity of heparin sodium in USP Units/mg using statistical methods for slope ratio assays. Calculate the anti-factor Xa activity of heparin sodium:

$$\text{Result} = A \times (S_T/S_S)$$

$A$ = the potency of USP Heparin Sodium for Assays RS
$S_T$ = slope of the line for the *Sample solutions*
$S_S$ = slope of the line for the *Standard solutions*

Express the anti-factor Xa activity of the *Sample solution* as USP Heparin Units/mg, calculated on the dried basis. Calculate the ratio of anti-factor Xa activity against anti-factor IIa potency (see *Assay* below):

anti-factor Xa activity/anti-factor IIa potency

**Acceptance criteria:** 0.9–1.1

• **ANTI-FACTOR IIa ACTIVITY FOR UNFRACTIONATED HEPARIN**

**pH 8.4 buffer:** Dissolve 6.10 g of tris(hydroxymethyl)aminomethane, 10.20 g of sodium chloride, 2.80 g of edetate sodium, and, if suitable, 0–10.00 g of polyethylene glycol 6000 and/or 2.00 g of bovine serum albumin in 800 mL of water. [NOTE—2.00 g of human albumin may be substituted for 2.00 g of bovine serum albumin.] Adjust with hydrochloric acid to a pH of 8.4, and dilute with water to 1000 mL.

**Antithrombin solution:** Reconstitute a vial of antithrombin (see *Reagents, Indicators, and Solutions—Reagent Specifications*) in water to obtain a solution of 5 Antithrombin IU/mL. Dilute this solution with *pH 8.4 buffer* to obtain a solution having a concentration of 0.125 Antithrombin IU/mL.

**Thrombin human solution:** Reconstitute thrombin human (factor IIa) (see *Reagents, Indicators, and Solutions—Reagent Specifications*) in water to obtain a solution of 20 Thrombin IU/mL, and dilute with *pH 8.4 buffer* to obtain a solution having a concentration of 5 Thrombin IU/mL. [NOTE—The thrombin should have a specific activity of NLT 750 IU/mg.]

**Chromogenic substrate solution:** Prepare a solution of a suitable chromogenic thrombin substrate for amidolytic test (see *Reagents, Indicators, and Solutions—Reagent Specifications*) in water to obtain a concentration of 1.25 mM.

**Stopping solution:** 20% (v/v) solution of acetic acid

**Standard solutions:** Reconstitute the entire contents of an ampule of USP Heparin Sodium for Assays RS with water, and dilute with *pH 8.4 buffer* to obtain at least four dilutions in the concentration range of 0.005–0.03 USP Heparin Unit/mL.

**Sample solutions:** Proceed as directed for *Standard solutions* to obtain concentrations of Heparin Sodium similar to those obtained for the *Standard solutions*.

**Analysis:** [NOTE—The procedure also can be performed using alternative platforms.] For each dilution of the *Standard solutions* and the *Sample solutions*, at least duplicate samples should be tested. Label a suitable number of tubes depending on the number of replicates that will be tested. For example, if five blanks will be used: B1, B2, B3, B4, and B5 for the blanks; T1, T2, T3, and T4 each at least in duplicate for the dilutions of the *Sample solutions*; and S1, S2, S3, and S4 each at least in duplicate for the dilutions of the *Standard solutions*. Distribute the blanks over the series in such a way that they accurately represent the behavior of the reagents during the experiments. [NOTE—Treat the tubes in the order B1, S1, S2, S3, S4, B2, T1, T2, T3, T4, B3, T1, T2, T3, T4, B4, S1, S2, S3, S4, B5.] Note that after each addition of a reagent, the incubation mixture should be mixed without allowing bubbles to form. Add twice the volume (100–200 µL) of *Antithrombin solution* to each tube containing one volume (50–100 µL) of either the *pH 8.4 buffer* or an appropriate dilution of the *Sample solutions* or the *Standard solutions*. Mix, but do not allow bubbles to form. Incubate at 37° for at least 1 min. Add to each tube 25–50 µL of *Thrombin human solution*, and incubate for at least 1 min. Add 50–100 µL of *Chromogenic substrate solution*. Note that all reagents, *Standard solutions*, and *Sample solutions* should be prewarmed to 37° just before use. The volume of the reactants can be increased or decreased to suit the assay format provided that the proportions of the reference sample or the test sample and the reagents are kept the same.

Two different types of measurements can be recorded:

1. Endpoint Measurement: Stop the reaction after at least 1 min with 50–100 µL of *Stopping solution*. Measure the absorbance of each solution at 405 nm using a suitable spectrophotometer (see *Ultraviolet-Visible Spectroscopy* ⟨857⟩). The RSD over the blank readings is less than 10%.
2. Kinetic Measurement: Follow the change in absorbance for each solution over 1 min at 405 nm using a suitable spectrophotometer (see ⟨857⟩). Calculate the change in absorbance/min (ΔOD/min). The blanks for kinetic measurement are also expressed as ΔOD/min and should give the highest values because they are carried out in the absence of heparin. The RSD over the blank readings is less than 10%.

**Calculations:** The statistical models for *Slope ratio assay* or *Parallel-line assay* can be used depending on which model best describes the correlation between concentration and response.

**Slope ratio assay:** For each series, calculate the regression of the log absorbance or the log change in absorbance/min against concentrations of the *Sample solutions* and of the *Standard solutions*, and calculate the potency of heparin sodium in USP Units/mL using statistical methods for slope ratio assays. Express the potency of heparin sodium/mg, calculated on the dried basis.

**Parallel-line assay:** For each series, calculate the regression of the absorbance or change in absorbance/min against log concentrations of the *Sample solutions* and the *Standard solutions*, and calculate the potency of heparin sodium in USP Units/mL using statistical methods for parallel-line assays. Express the potency of heparin sodium/mg, calculated on the dried basis.

**Acceptance criteria:** The potency of heparin sodium, calculated on the dried basis, is NLT 180 USP Heparin Units in each mg.

## Anti-Factor Xa and Anti-Factor IIa Assays for Low Molecular Weight Heparins

▲The following procedure is used where specified in the individual monographs. This assay can be performed manually in plastic tubes utilizing heated block stations or water bath. Microtiter plate equipment with a reader and automated coagulometer can improve reproducibility and throughput. Acetic acid solution (stopping solution) is used for manual and microtiter plate assay. Automated coagulometers measure initial kinetic rate, and because of that, stopping of the reaction is not needed.▲ (ERR 1-Aug-2020)

• **Anti-Factor Xa Activity for Low Molecular Weight Heparin**

**Acetic acid solution:** Glacial acetic acid and water (42:58)

**pH 7.4 polyethylene glycol 6000 buffer:** Dissolve 6.08 g of tris(hydroxymethyl)aminomethane and 8.77 g of sodium chloride in 500 mL of water. Add 1.0 g of polyethylene glycol 6000 or 10.0 g of bovine serum albumin, adjust with hydrochloric acid to pH 7.4, and dilute with water to 1000 mL.

**pH 7.4 buffer:** Dissolve 6.08 g of tris(hydroxymethyl)aminomethane and 8.77 g of sodium chloride in 500 mL of water. Adjust with hydrochloric acid to pH 7.4, and dilute with water to 1000 mL.

**pH 8.4 buffer:** Dissolve 3.03 g of tris(hydroxymethyl)aminomethane, 5.12 g of sodium chloride, and 1.40 g of edetate sodium in 250 mL of water. Adjust with hydrochloric acid to a pH of 8.4, and dilute with water to 500 mL.

**Human antithrombin solution:** Reconstitute a vial of human antithrombin (see *Reagents, Indicators, and Solutions—Reagent Specifications*) in water to obtain a solution containing 5 Antithrombin Units per mL. Dilute this solution with *pH 7.4 polyethylene glycol 6000 buffer* to obtain a solution having a concentration of 1.0 Antithrombin Unit/mL.

**Factor Xa solution:** Reconstitute an accurately weighed quantity of bovine factor Xa (see *Reagents, Indicators, and Solutions—Reagent Specifications*) as directed by the manufacturer's instructions. Further dilute the stock solution with *pH 7.4 polyethylene glycol 6000 buffer* to obtain a solution that gives an increase in absorbance value at 405 nm of NMT 0.20 absorbance units/min or 0.8 absorbance units after 4 min of incubation with the chromogenic substrate when assayed as described below but using as an appropriate volume, *V*, the volume in µL of *pH 7.4 buffer* instead of *V* µL of the standard or the sample solution.

**Chromogenic substrate solution:** Prepare a solution of a suitable chromogenic substrate for amidolytic test (see *Reagents, Indicators, and Solutions—Reagent Specifications*) for factor Xa in water to obtain a concentration of about 3 mM. Dilute with substrate *pH 8.4 buffer* to obtain a solution having a concentration of 0.5 mM. [Note—Preheat reagents to 37 ± 1° 15 min before use.]

**Standard solutions:** Reconstitute and dilute the entire contents of an ampule of USP Low Molecular Weight Heparin for Bioassays RS with distilled water and then further dilute with *pH 7.4 buffer* to obtain at least four dilutions in the concentration range of 0.025–0.2 USP anti-factor Xa Units/mL.

**Sample solutions:** Proceed as directed for *Standard solutions* to obtain concentrations of LMWH similar to those obtained for the *Standard solutions.*

**Analysis**

**Samples:** *Standard solutions, Sample solutions, Human antithrombin solution, pH 7.4 buffer, Factor Xa solution, Chromogenic substrate solution,* and *Acetic acid solution*

Label 18 suitable tubes: B1 and B2 for blanks; T1, T2, T3, and T4 each in duplicate for the dilutions of the *Sample solutions;* and S1, S2, S3, and S4 each in duplicate for the dilutions of the *Standard solutions.* [Note—Treat the tubes in the order B1, S1, S2, S3, S4, T1, T2, T3, T4, T1, T2, T3, T4, S1, S2, S3, S4, B2.] To each tube add 50 µL of *Human antithrombin solution* and an equal volume, *V,* of either the blank, *pH 7.4 buffer*, or an appropriate dilution of the *Sample solutions* or the *Standard solutions.* Mix, but do not allow bubbles to form. Incubate at 37° for 1.0 min. Add to each tube 100 µL of *Factor Xa solution,* and incubate for 1.0 min. Add 250 µL of *Chromogenic substrate solution.* Stop the reaction after about 4.0 min with 250 µL of *Acetic acid solution.* Measure the absorbance of each solution at 405 nm using a suitable spectrophotometer (see ⟨857⟩). Use quartz or disposable polystyrene cuvettes. The volume of the reactants can be increased or decreased to suit the assay format provided that the proportions of the reference sample or the test sample and the reagents are kept the same.

**System suitability:** The assay is valid if the following requirements are met:

1. A blank solution gives an increase in absorbance value at 405 nm of NMT 0.20 absorbance units/min (or 0.8 absorbance units in total) when assayed using an appropriate volume (50 µL) of *pH 7.4 buffer* instead of 50 µL of the *Standard solution* or the *Sample solution*.
2. The reading of the blank B2 is not more than ±0.05 absorbance units against blank B1.

**Calculations:** For this bioassay, parallel-line or slope ratio analysis can be applied.

Calculate the potency of the test sample in USP anti-factor Xa Unit/mL, using a statistical model for parallel assays, plotting absorbance against log concentrations of the *Sample solutions* and of the *Standard solutions.* In some cases, log transformation of absorbance may be needed to obtain linearity for the dose–response curves. The assay is valid when the data fulfill the acceptance criteria for regression, linearity, and parallelism as required for parallel line assay. For slope ratio analysis, plot absorbance against concentrations of *Sample solutions* and of the *Standard solutions.* In some cases, log transformation of absorbance may be needed to obtain linearity for the dose–response curves. The assay is valid when the data fulfill the acceptance criteria for regression, linearity, and common intercept as required for slope ratio assay (see *Design and Analysis of Biological Assays* ⟨111⟩ and *Analysis of Biological Assays* ⟨1034⟩).

Express the anti-factor Xa activity of sample/mg, calculated on the dried basis:

$$\text{Anti-factor Xa USP Unit/mg} = [\text{standard potency (USP Unit/mL)} \times \text{potency ratio}]/[\text{sample concentration (mg/mL)}]$$

• **ANTI-FACTOR IIa ACTIVITY FOR LOW MOLECULAR WEIGHT HEPARIN**

**Acetic acid solution, pH 7.4 polyethylene glycol 6000 buffer, pH 7.4 buffer, pH 8.4 buffer,** and **Human antithrombin solution:** Proceed as directed in the *Anti-Factor Xa Activity*, except that the concentration of the *Human antithrombin solution* is 0.5 Antithrombin Unit/mL.

**Thrombin human solution:** Reconstitute thrombin (see *Reagents, Indicators, and Solutions—Reagent Specifications*) in water, and dilute in *pH 7.4 polyethylene glycol 6000 buffer* to obtain a solution having a concentration of 5 Thrombin Units/mL. Use the *Thrombin human solution* immediately after preparation.

**Chromogenic substrate solution:** Prepare a solution of a suitable chromogenic substrate for the amidolytic test (see *Reagents, Indicators, and Solutions—Reagent Specifications*) for thrombin in water to obtain a concentration of about 3 mM. Dilute immediately before use with *pH 8.4 buffer* to 0.5 mM.

**Standard solutions:** Reconstitute and dilute the entire contents of an ampule of USP Low Molecular Weight Heparin for Bioassays RS with distilled water, and further dilute with *pH 7.4 buffer* to obtain at least four dilutions having concentrations in the range of 0.015–0.075 USP Unit of anti-factor IIa activity/mL.

**Sample solutions:** Proceed as directed for *Standard solutions* to obtain concentrations of LMWH similar to those obtained for the *Standard solutions*.

**Procedure:** Proceed as directed under *Anti-Factor Xa activity*, but use *Thrombin human solution* instead of *Factor Xa solution* and use the *Human antithrombin solution* as described above.

**System suitability:** The assay is valid if the following requirement is met:

1. The reading of blank B2 is NMT ±0.05 absorbance units against blank B1.

**Calculations:** Proceed as directed for calculation of *Anti-Factor Xa Activity*.

# ⟨209⟩ LOW MOLECULAR WEIGHT HEPARIN MOLECULAR WEIGHT DETERMINATIONS

This chapter provides procedures used to determine molecular weight (MW) distribution and weight-average molecular weight for low molecular weight heparins (LMWH).

## INTRODUCTION

Low molecular weight heparins are prepared from Heparin Sodium, USP, by partial depolymerization. LMWHs are polydisperse, i.e., they are made up of polysaccharide chains with a range of molecular weights. The MW distribution is a defining characteristic for each LMWH product. The *USP* contains specific monographs for LMWH products, including limits on molecular weight distribution parameters.

Most techniques for determination of the MW distribution of LMWHs make use of gel permeation chromatography (GPC), sometimes referred to as size exclusion chromatography (SEC). In order to derive molecular weight distribution from a chromatogram, it is necessary to know the relationship between retention time and MW. This chapter describes a GPC method that is calibrated using the USP Low Molecular Weight Heparin Molecular Weight Calibrant RS. This preparation is a single polydisperse standard for which the distribution of molecular weights is described in the form of a Broad Standard Table (see the USP Certificate for USP Low Molecular Weight Heparin Molecular Weight Calibrant RS) that lists the log of the molecular weight (log MW) of a number of reference points and the matching percent fractions by weight of the calibrant above or below these reference points. The Broad Standard Table is used together with a chromatogram of the calibrant to fit a suitable function, in this case a third degree polynomial, to the relationship between log MW and retention time, thus generating a calibration curve for the chromatographic system. With this calibration curve, the analyst calculates the weight-average molecular weight and distribution parameters from the chromatogram of a sample of LMWH.

All the calculations described in this chapter may be performed using a spreadsheet program, but this method is not recommended as it is laborious and open to human error. Proprietary software capable of automating the calibration and molecular weight calculations can be obtained from a number of chromatography systems manufacturers.

## PROCEDURE

***Change to read:***

- **Molecular Weight Measurements of Low Molecular Weight Heparins by Gel Permeation Chromatography**

The following procedure, with any necessary variations, is used where specified in the individual monographs.

**Ammonium acetate stock solution:** 1 M ammonium acetate in water

**Sodium azide solution:** 1% (w/v) sodium azide in water

**Mobile phase:** Transfer 100 mL of *Ammonium acetate stock solution* to a 1-L volumetric flask, add 20 mL of *Sodium azide solution*, and dilute with water to volume. Pass through a nylon membrane of 0.45-µm pore size prior to use.

**Calibration solution:** Add 2 mL of *Mobile phase* to a vial containing USP Low Molecular Weight Heparin Molecular Weight Calibrant RS. Filter using a nylon membrane of 0.45-µm pore size prior to use.

**Sample solution:** 5 mg/mL of low molecular weight heparin sample in *Mobile phase*. Pass through a nylon membrane of 0.45-µm pore size.

**System suitability solution:** As indicated in the product monograph. [Note—In the cases where no product monograph is available, 5 mg/mL of USP Dalteparin Sodium RS, in *Mobile phase* and filtered using a nylon membrane of 0.45-µm pore size, can be applied as the system suitability solution.]

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

[Note—The temperature of the refractive index detector must be set at the same temperature as that of the *Column temperature*.]

**Mode:** LC

**Detector:** Refractive index

**Columns**

**Analytical:** 7.8-mm × 30-cm; 5-µm packing L59 in series with a 7.8-mm × 30-cm; 5-µm packing L59[1]

**Guard:** 6-mm × 4-cm; 7-µm packing L59

**Column temperature:** 30°

**Flow rate:** 0.5 mL/min

**Column equilibration:** 0.5 mL/min for at least 2 h

**Injection volume:** 20 µL

**System suitability**

**Sample:** *System suitability solution*

**Suitability requirements**

**Resolution:** There is baseline resolution between the last peak of the USP Low Molecular Weight Heparin Molecular Weight Calibrant RS and the salt peak, or negative exchange peaks.

**Calibration curve:** The coefficient of determination of the calibration curve fitted to the Broad Standard Table values must be NLT 0.990, using a third-order polynomial equation.

**Weight-average molecular weight ($M_w$):** As indicated in the product monograph. [Note—In the cases where no product monograph is available and 5 mg/mL of USP Dalteparin Sodium RS is applied as the *System suitability solution*, take the mean of the calculated $M_w$ from the duplicate injections of the *System suitability solution*, and round

[1] The method was validated using a guard column TSK SWXL 6-mm × ▲4-cm▲ (ERR 1-Apr-2023); 7-µm in series with two analytical columns: TSK G3000 SWXL 7.8-mm × 30-cm; 5-µm in series with a TSK G2000 SWXL 7.8-mm × 30-cm; 5-µm.

https://pharmacopeia.cn/v29240/

to the nearest 50 Da. The chromatographic system is suitable if the $M_w$ of the USP Dalteparin Sodium RS is within 150 Da of the labeled value as stated in the USP Certificate for USP Dalteparin Sodium RS.]

**Analysis**

**Samples:** Inject 20 µL of the *Calibration solution* (single injection), *System suitability solution* (duplicate injections), and *Sample solution* (duplicate injections), and record the chromatograms for a length of time to ensure complete elution, including salt and solvent peaks (about 50 min).

[NOTE—The *Calibration solution*, *System suitability solution*, or *Sample solution* will give a broad peak between about 25 and 45 min, followed by a later eluting narrow salt peak, as illustrated in the USP Certificate for USP Low Molecular Weight Heparin Molecular Weight Calibrant RS.]

**Calculations:** Calculate the total area under the low molecular weight heparin peak from the *Calibration solution* and the cumulative area at each point under the peak as a percent of the total. Do not include the salt peak. Using the Broad Standard Table provided in the USP Certificate for USP Low Molecular Weight Heparin Molecular Weight Calibrant RS, identify those points in the chromatogram for which the percent cumulative area is closest to the percent fractions listed in the Broad Standard Table, and assign the MW in this Table to the corresponding retention time (RT) in the chromatogram. For the set of retention times and molecular weights identified, fit log(MW) vs. RT to a third-order polynomial function using suitable GPC software, or find values of $a$, $b$, $c$, and $d$ such that $\log MW = a + (b \times RT) + [c \times (RT)^2] + [d \times (RT)^3]$.

Using the same GPC software, for each of the duplicate chromatograms of the *System suitability solution* and the *Sample solution*, with the calibration function derived as described above, calculate $M_w$:

$$M_w = \Sigma(RI_i \times M_i)/\Sigma RI_i$$

$RI_i$ = detector response at each point
$M_i$ = MW at each point

Round the mean value of $M_w$ to the nearest 50 Da. Using the same GPC software, determine for each of the duplicate *Sample solution* chromatograms the percentage of product with molecular weight as indicated in the product monograph.

**Acceptance criteria:** As indicated in the product monograph

# ⟨210⟩ MONOSACCHARIDE ANALYSIS

## INTRODUCTION

The glycan composition of therapeutic glycoproteins may impact the biological activity, stability, pharmacokinetics, pharmacodynamics, efficacy, and immunogenicity of the molecule. The glycosylation pattern, or specific aspects of it such as the degree of sialylation, may form part of the product characterization and release specifications. One approach to ensuring the consistency of glycosylation and compliance of the product with specifications is to quantify specific monosaccharides present in the product. Monosaccharides are released by degradation of the product and quantified by chromatographic approaches. The most commonly determined sugars are *N*-acetylneuraminic acid (Neu5Ac) and its variant *N*-glycolylneuraminic acid (Neu5Gc). These monosaccharides can be selectively released from the protein either by dilute acid hydrolysis or by enzymatic methods, whereas increasingly aggressive hydrolysis conditions release neutral monosaccharides including mannose, galactose, and fucose, and then glucosamine and galactosamine. Separation and quantification of released monosaccharides by high-performance liquid chromatography (HPLC) can be achieved with or without fluorophore labeling.

## SAMPLE HANDLING PRIOR TO MONOSACCHARIDE RELEASE

The glycoprotein sample should be as free of salts, excipients, and other carrier materials as possible. This is typically achieved by: 1) dialysis against water or a volatile buffer using an appropriate membrane, or ultrafiltration through an appropriate membrane; 2) HPLC on an appropriate gel-permeation column eluted with water or a volatile buffer, monitored by UV absorbance or refractive index; 3) sample trapping on a solid-phase extraction (SPE) cartridge, followed by washing away salts and excipients and elution of the required sample. Where residual components are known to be present, their lack of interference in saccharide analysis should be confirmed during validation to verify either no bias or an acceptable level of bias due to matrix components. Sample concentration may be required.

***Change to read:***

## SIALIC ACID QUANTIFICATION

Sialic acids can be analyzed and quantified through the use of high-performance anion exchange chromatography with pulsed amperometric detection (HPAEC-PAD) without modification, or by the use of 1,2-diamino-4,5-methylenoxybenzene (DMB) labeling and reversed-phase HPLC (RP-HPLC) analysis equipped with a fluorescence detector. The combination of DMB labeling and RP-HPLC with fluorescence detection is significantly more sensitive than HPAEC-PAD analysis.

[NOTE—Under some circumstances, the presence of large amounts of protein may diminish the PAD response. For analysis by HPAEC-PAD, the use of 3-deoxy-D-glycero-D-galacto-2-nonulosonic acid (KDN), as an internal standard, can be an option to compensate for this effect. An example is to prepare an internal standard solution: 0.1 mM of ▲KDN▲ (USP 1-May-2021) in water. In the final dilution step, add 15 µL of the internal standard solution into each standard or sample solution, and reduce the amount of water added by 15 µL to keep the final volume of solution unchanged. Integrate the Neu5Ac, Neu5Gc, and KDN peaks in each chromatogram, and use the ratio of the Neu5Ac or Neu5Gc peak areas relative to the peak area of KDN for system suitability and sample analysis calculation.]

Sialic acids may be *O*-acetylated, and depending on the protein sample and the analytical procedure selected, it may be necessary to de-*O*-acetylate before sialic acid is released. Normally, dilute acid hydrolysis and anion exchange chromatography analysis lead to de-*O*-acetylation. Enzymatic methods of release can preserve *O*-acetyl groups, and the combined use of DMB labeling and RP-HPLC analysis (as in *Procedure 3*) retains the *O*-acetyl groups during the analytical steps.

A typical de-*O*-acetylation can be achieved by adding 10% of the sample's volume of 1 M sodium hydroxide to the sample, incubating at room temperature for 30 min, and then adding 10% of the sample's volume of 1 M hydrochloric acid to neutralize the reaction (e.g., to 20 µL of sample add 2 µL of 1 M sodium hydroxide, incubate at room temperature for 30 min, and then add 2 µL of 1 M hydrochloric acid to neutralize).

## PROCEDURES

***Change to read:***

- **PROCEDURE 1: ENZYMATIC RELEASE AND ANALYSIS BY HPAEC-PAD OF UNLABELED SIALIC ACIDS**

  **Sample buffer:** 20 mM sodium acetate prepared as follows. Dissolve 164 mg of sodium acetate anhydrous in 80 mL of water. Adjust with glacial acetic acid to a pH of 5.2, and dilute with water to 100 mL.

  **Standard stock solution:** 50 µmol/L (µM) of USP *N*-Acetylneuraminic Acid RS and 2 µM of USP *N*-Glycolylneuraminic Acid RS in water

  **Standard solutions:** See *Table 1* for typical five-level calibration *Standard solutions*.

**Table 1**

| Standard Solutions | Standard Stock Solution (µL) | Sample Buffer (µL) | Water (µL) | Concentration of Neu5Ac (µM) | Concentration of Neu5Gc (µM) |
|---|---|---|---|---|---|
| 5 | 50 | 200 | 250 | 5 | 0.2 |

[NOTE—1 µM = 1 nmol/mL = 1 × $10^{-3}$ nmol/µL = 1 pmol/µL.]

**Sample solution:** To 50 µL of 6–60 µg/mL of protein sample (equivalent to about 1.5 nmol of sialic acid) in *Sample buffer* add 4 µL of 0.5 milliunit/µL (2 milliunits) of neuraminidase[1] in water and make up to a total volume of 200 µL with *Sample buffer*. Incubate for 5 h at 37°. [NOTE—Or use validated sample preparation and time/temperature ranges.] Add 300 µL of water, and mix.

**HPAEC analysis**

[NOTE—Use either *Chromatographic system 1* or *Chromatographic system 2*.]

**Solution A:** 0.1 M sodium hydroxide prepared as follows. Dilute 5.28 mL of 50%–52% sodium hydroxide solution with water to 1000 mL. [NOTE—The solution must be sealed well to avoid absorbing carbon dioxide.]

**Solution B:** 1 M sodium acetate in 0.1 M sodium hydroxide prepared as follows. Dissolve 82.0 g of anhydrous sodium acetate in 800 mL of water. Pass through a nylon filter of 0.2-µm pore size. Add 5.28 mL of 50%–52% sodium hydroxide solution, and dilute with water to 1000 mL.

**Chromatographic system 1**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mobile phase:** See *Table 2*.

**Table 2**

| Time (min) | Solution A (%) | Solution B (%) |
|---|---|---|
| 0 | 98 | 2 |
| 2 | 98 | 2 |
| 9.5 | 82 | 18 |
| 11 | 82 | 18 |
| 11.5 | 98 | 2 |
| 17 | 98 | 2 |

**Mode:** LC

**Detector:** Integrated amperometric detector with gold electrode (for an example of a waveform, see *Table 4*)

**Columns**

**System suitability**
**Samples:** *Blank* and *Standard solutions*
**Suitability requirements**
**Chromatogram of the blank:** No peaks at the same retention time as Neu5Ac or Neu5Gc, *Blank*
**▲Coefficient of determination ($R^2$)▲ (USP 1-May-2021) calculated for the standard curve:** NLT ▲0.98▲ (USP 1-May-2021), *Standard solutions*
**Relative standard deviation:** NMT 5%, *Standard solution 3*

**Analysis**
**Samples:** *Standard solutions* and *Sample solution*
For the *Standard solutions*, generate a Neu5Ac and Neu5Gc standard curve of peak response versus concentrations using least square regression. From the standard curve, determine the concentration of Neu5Ac and Neu5Gc in the *Sample solution*. Divide the determined Neu5Ac and Neu5Gc concentrations by the protein concentration in the *Sample solution*, and report as molar ratio (nmol:nmol). [NOTE—Convert the protein concentration from mg/mL to µM (1 µM = 1 nmol/mL).]

• **PROCEDURE 2: ACID HYDROLYSIS AND ANALYSIS BY HPAEC-PAD OF UNLABELED SIALIC ACIDS**
**Sample buffer, HPAEC analysis, System suitability,** and **Analysis:** Proceed as directed in *Procedure 1*.
[NOTE—*Standard solutions* and *Sample solution* are to be prepared at the same time and subjected to the same hydrolysis and drying procedures. Using vacuum centrifuge for drying is described in the procedures; other suitable drying methods may also be used.]
[NOTE—Sialic standards subjected to the hydrolysis procedure may degrade to a different extent than sialic acids released from a glycoprotein during the procedure. A validated method in which the standard is not subjected to the hydrolysis conditions may be used.]
**Standard stock solution:** 50 µM of USP *N*-Acetylneuraminic Acid RS and 2 µM of USP *N*-Glycolylneuraminic Acid RS in water
**Standard solutions:** Add the amount of *Standard stock solution* to each microcentrifuge tube as indicated in *Table 5*.

**Table 5**

| Standard Solutions | Standard Stock Solution (µL) | Neu5Ac (nmol) | Neu5Gc (nmol) |
|---|---|---|---|
| Blank | 0 | 0 | 0 |
| 1 | 10 | 0.5 | 0.02 |
| 2 | 20 | 1 | 0.04 |
| 3 | 30 | 1.5 | 0.06 |
| 4 | 40 | 2 | 0.08 |
| 5 | 50 | 2.5 | 0.1 |

Dry each standard in a vacuum centrifuge without heat. Add 100 µL of 2 M acetic acid to each microcentrifuge tube, and hydrolyze all the standards series at approximately 80° for 2 h ± 15 min in a heating block. [NOTE—Or use validated time/temperature ranges.] Allow the tubes to cool to room temperature for approximately 10 min, and briefly centrifuge to ensure the entire sample is in the well of the tube. Dry the solutions in a vacuum centrifuge without heat, and resuspend in 300 µL of water. Before analysis, add 200 µL of *Sample buffer*. The final concentrations are summarized in *Table 6*.

- **PROCEDURE 3: ENZYMATIC HYDROLYSIS AND ANALYSIS BY RP-HPLC OF DMB-LABELED SIALIC ACIDS**

**Labeling reagent:** Aqueous solution of DMB, acetic acid, 2-mercaptoethanol, and sodium hydrosulfite[3]

**Standard stock solution:** 200 μM of USP *N*-Acetylneuraminic Acid RS and 10 μM of USP *N*-Glycolylneuraminic Acid RS in water

**Standard solutions:** See *Table 7* for the typical dilutions. Then label each solution as directed by *Labeling*.

**Table 7**

| Standard Solutions | Standard Stock Solution (μL) | Water (μL) | Concentration of Neu5Ac before Labeling (μM) | Concentration of Neu5Gc before Labeling (μM) |
|---|---|---|---|---|
| Blank | 0 | 400 | 0 | 0 |
| 1 | 4 | 396 | 2 | 0.1 |
| 2 | 8 | 392 | 4 | 0.2 |
| 3 | 20 | 380 | 10 | 0.5 |
| 4 | 40 | 360 | 20 | 1 |
| 5 | 80 | 320 | 40 | 2 |

The concentrations of the resulting labeled *Standard solutions* are listed in *Table 8*.

**Table 8**

| Standard Solutions | Concentration of Neu5Ac after Labeling (μM) | Concentration of Neu5Gc after Labeling (μM) |
|---|---|---|
| Blank | 0 | 0 |
| 1 | 0.02 | 0.001 |
| 2 | 0.04 | 0.002 |
| 3 | 0.1 | 0.005 |
| 4 | 0.2 | 0.01 |
| 5 | 0.4 | 0.02 |

**Labeling:** Transfer 5 μL of the to-be-labeled *Standard solution* or *Sample solution* into a microcentrifuge tube, add 20 μL of *Labeling reagent*, cap the tube, mix by vortexing, and incubate for 3 h at 50° in the dark. Terminate the reaction by adding 475 μL of water, cap, and vortex thoroughly. This solution should be kept at 2°–8° and analyzed within 24 h. [NOTE—The *Standard solution* and *Sample solution* are to be labeled simultaneously.]

[3] Available from Ludger as LudgerTag Sialic Acid DMB Labeling Kit, catalog #LT-KDMB-A1, or a suitable equivalent. [Note—For example, prepare the DMB reagent in the order that follows. Add 1.5 mL of water to a glass vial. To this solution add 172 μL of glacial acetic acid, and mix well. Add 112 μL of 2-mercaptoethanol, and mix well. Add 4.9 mg of sodium hydrosulfite to the solution, and mix well. The solution may then become cloudy in appearance. Lastly, add 3.5 mg of DMB hydrochloride and 200 μL of water, and mix the solution well. This solution is aliquoted into 200-μL aliquots and can be stored in the dark at –20° for up to 12 months.]

# ⟨211⟩ ARSENIC

***Add the following:***

## ▲INTRODUCTION

This chapter describes four analytical procedures for the evaluation of the levels of arsenic (As). Use *Procedure 1*, *Procedure 2*, *Procedure 3*, or *Procedure 4* as indicated in the individual monograph. *Procedure 3* or *Procedure 4* can be used in all circumstances, provided that suitability is demonstrated by meeting the *Requirements for Procedure Validation*.▲ (Official 1-Jun-2023)

***Change to read:***

## PROCEDURES

- **▲PROCEDURE 1 AND PROCEDURE 2**

  Both *Procedure 1* and *Procedure 2* are▲ (Official 1-Jun-2023) designed to determine the presence of trace amounts of arsenic by converting the arsenic in a substance under test to arsine, which is then passed through a solution of silver diethyldithiocarbamate to form a red complex. The red color so produced is compared, either visually or spectrophotometrically, to the color produced similarly in a control containing an amount of arsenic equivalent to the limit given in the individual monograph. Limits are stated in terms of arsenic. The content of arsenic does not exceed the limit given in the individual monograph.

  ▲These procedures differ▲ (Official 1-Jun-2023) only in the preliminary treatment of the test substance and the standard. Generally, ▲*Procedure 1*▲ (Official 1-Jun-2023) is used for inorganic materials, ▲and *Procedure 2*▲ (Official 1-Jun-2023) is used for organic materials.

  **Apparatus**

  The apparatus (see *Figure 1*) consists of an arsine generator (*a*) fitted with a scrubber unit (*c*) and an absorber tube (*e*) with standard-taper or ground glass ball-and-socket joints (*b* and *d*) between the units. However, any other suitable apparatus embodying the principle of the assembly described and illustrated may be used.

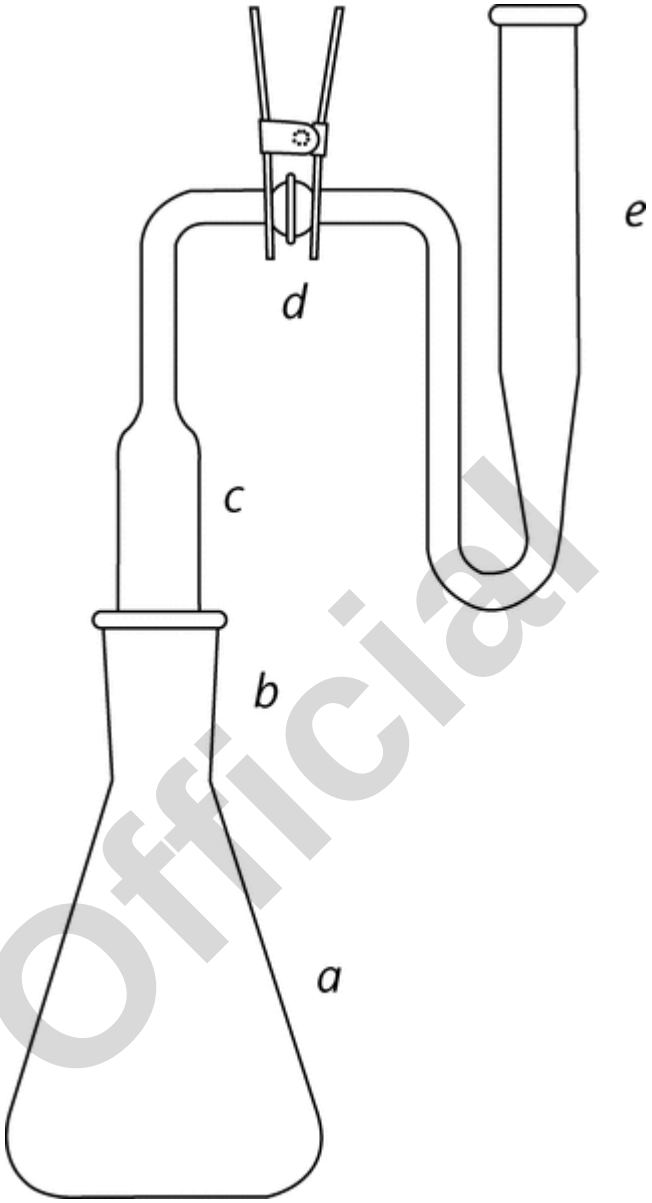

Figure 1. Arsenic test apparatus.

**Arsenic trioxide stock solution:** Dissolve 132.0 mg of arsenic trioxide, previously dried at 105° for 1 h and accurately weighed, in 5 mL of sodium hydroxide solution (1 in 5) in a 1000-mL volumetric flask. Neutralize the solution with 2 N sulfuric acid, add 10 mL more of 2 N sulfuric acid, then add recently boiled and cooled water to volume, and mix.

**Standard arsenic solution:** Transfer 10.0 mL of *Arsenic trioxide stock solution* to a 1000-mL volumetric flask, add 10 mL of 2 N sulfuric acid, then add recently boiled and cooled water to volume, and mix. Each milliliter of *Standard arsenic solution* contains the equivalent of 1 µg of arsenic. Keep this solution in an all-glass container, and use within 3 days.

▲**Procedure 1: Colorimetry**▲ (Official 1-Jun-2023)

**Standard preparation:** Pipet 3.0 mL of *Standard arsenic solution* into a generator flask, and dilute with water to 35 mL.

**Test preparation:** Unless otherwise directed in the individual monograph, prepare as follows. Transfer to the generator flask the quantity, in grams, of the test substance calculated as follows:

$$\text{Result} = 3.0/L$$

$L$ = limit of arsenic (ppm)

Dissolve in water and dilute with water to 35 mL.

▲**Analysis:**▲ (Official 1-Jun-2023) Treat the *Standard preparation* and the *Test preparation* similarly as follows. Add 20 mL of 7 N sulfuric acid, 2 mL of potassium iodide TS, 0.5 mL of stronger acid stannous chloride TS, and 1 mL of isopropyl alcohol, and mix. Allow to stand at room temperature for 30 min. Pack the scrubber tube (*c*) with two pledgets of cotton that have been soaked in saturated lead acetate solution, freed from excess solution by expression, and dried in vacuum at

https://pharmacopeia.cn/

room temperature, leaving a 2-mm space between the two pledgets. Lubricate the joints (*b* and *d*) with a suitable stopcock grease designed for use with organic solvents, and connect the scrubber unit to the absorber tube (*e*). Transfer 3.0 mL of silver diethyldithiocarbamate TS to the absorber tube. Add 3.0 g of granular zinc (#20 mesh) to the mixture in the flask, immediately connect the assembled scrubber unit, and allow the evolution of hydrogen and the color development to proceed at room temperature for 45 min, swirling the flask gently at 10-min intervals. Disconnect the absorber tube from the generator and scrubber units, and transfer the absorbing solution to a 1-cm absorption cell. Any red color produced by the *Test preparation* does not exceed that produced by the *Standard preparation*. If necessary or desirable, determine the absorbance at the wavelength of maximum absorbance between 535 and 540 nm, with a suitable spectrophotometer or colorimeter, using silver diethyldithiocarbamate TS as the blank.

**Interfering chemicals:** Metals or salts of metals, such as chromium, cobalt, copper, mercury, molybdenum, nickel, palladium, and silver, may interfere with the evolution of arsine. Antimony, which forms stibine, produces a positive interference in the color development with silver diethyldithiocarbamate TS; when the presence of antimony is suspected, the red colors produced in the two silver diethyldithiocarbamate solutions may be compared at the wavelength of maximum absorbance between 535 and 540 nm, with a suitable colorimeter, since at this wavelength the interference due to stibine is negligible.

**▲Procedure 2: Colorimetry▲** (Official 1-Jun-2023)

[**CAUTION**—Some substances may react with explosive violence when digested with hydrogen peroxide. Exercise safety precautions at all times.]

[NOTE—If halogen-containing compounds are present, use a lower temperature while heating the test specimen with sulfuric acid, avoid boiling the mixture, and add the hydrogen peroxide with caution, before charring begins, to prevent loss of trivalent arsenic.]

[NOTE—If the test substance reacts too rapidly and begins charring with 5 mL of sulfuric acid before heating, use instead 10 mL of cooled dilute sulfuric acid (1 in 2), and add a few drops of the hydrogen peroxide before heating.]

**Standard preparation:** Pipet 3.0 mL of *Standard arsenic solution* into a generator flask, add 2 mL of sulfuric acid, mix, and add the total amount of 30 percent hydrogen peroxide used in preparing the *Test preparation*. Heat the mixture to strong fuming, cool, cautiously add 10 mL of water, and again heat to strong fumes. Repeat this procedure with another 10 mL of water to remove any traces of hydrogen peroxide. Cool, and dilute with water to 35 mL.

**Test preparation:** Unless otherwise directed in the individual monograph, transfer to a generator flask the quantity, in grams, of the test substance calculated as follows:

$$\text{Result} = 3.0/L$$

$L$ = limit of arsenic (ppm)

Add 5 mL of sulfuric acid and a few glass beads, and digest in a fume hood, preferably on a hot plate and at a temperature not exceeding 120°, until charring begins. (Additional sulfuric acid may be necessary to wet some specimens completely, but the total volume added should not exceed 10 mL.) Cautiously add, dropwise, 30 percent hydrogen peroxide, allowing the reaction to subside and again heating between drops. Add the first few drops very slowly with sufficient mixing, in order to prevent a rapid reaction. Discontinue heating if foaming becomes excessive. When the reaction has abated, heat cautiously, rotating the flask occasionally to prevent the specimen from caking on glass exposed to the heating unit. *Maintain oxidizing conditions at all times during the digestion by adding small quantities of the hydrogen peroxide solution whenever the mixture turns brown or darkens.* Continue the digestion until the organic matter is destroyed, gradually raising the temperature of the hot plate until fumes of sulfur trioxide are copiously evolved, and the solution becomes colorless or retains only a light straw color. Cool, add cautiously 10 mL of water, mix, and again evaporate to strong fuming, repeating this procedure to remove any trace of hydrogen peroxide. Cool, cautiously add 10 mL of water, wash the sides of the flask with a few milliliters of water, and dilute with water to 35 mL.

**▲Analysis:▲** (Official 1-Jun-2023) Proceed as directed for ▲*Analysis* in *Procedure 1*.▲ (Official 1-Jun-2023)

**Interfering chemicals:** See *Interfering chemicals* in ▲*Procedure 1*.

- **PROCEDURE 3 AND PROCEDURE 4**

Both *Procedure 3* and *Procedure 4* are ICP-based procedures and can be used for the determination of arsenic. *Procedure 3* can be used for the determination of arsenic by inductively coupled plasma atomic (or optical) emission spectroscopy (ICP–AES or ICP–OES). *Procedure 4* can be used for the determination of arsenic by ICP–MS.

Before initial use, the analyst should verify that the procedure is appropriate for the instrument and sample used (procedural verification) by meeting the *Requirements for Procedure Validation*.

Where a monograph specifies a limit for arsenic concentration, the value listed in the monograph should be used as the *J* value for the purposes of this test.

System standardization and suitability evaluation using applicable reference materials should be performed on the day of analysis.

**Sample preparation:** Forms of sample preparation include neat, direct aqueous solution, direct organic solution, and indirect solution. The selection of the appropriate sample preparation depends on the material under test and is the responsibility of the analyst. When a sample preparation is not indicated in the monograph, an analyst may use any appropriately validated preparation procedure. In cases where spiking of a material under test is necessary to provide an acceptable signal intensity, the blank should be spiked with arsenic using, where possible, the same spiking solution. [NOTE—All liquid samples should be weighed.]

**Closed vessel digestion:** This sample preparation procedure is designed for samples that must be digested in a concentrated acid using a closed vessel digestion apparatus. Closed vessel digestion minimizes the loss of volatile impurities. The choice of a concentrated acid depends on the sample matrix. The use of any of the concentrated acids may be appropriate, but each introduces inherent safety risks. Therefore, appropriate safety precautions should be used

at all times. [NOTE—Weights and volumes provided may be adjusted to meet the requirements of the digestion apparatus used.]

An example procedure that has been shown to have broad applicability is as follows. Dehydrate and predigest 0.5 g of the primary sample in 5 mL of freshly prepared concentrated acid. Allow to sit loosely covered for 30 min in a fume hood. Add an additional 10 mL of concentrated acid, and digest using a closed vessel technique until digestion or extraction is complete. Repeat, if necessary, by adding an additional 5 mL of concentrated acid. [NOTE—Follow the manufacturer's recommended procedures to ensure safe use.]

**Reagents:** All reagents used for the preparation of sample and standard solutions should be free of elemental impurities, in accordance with *Plasma Spectrochemistry* ⟨730⟩.

**Procedure 3: ICP–OES**

**Standardization solution 1:** 1.5*J* of arsenic in a matched matrix

**Standardization solution 2:** 0.5*J* of arsenic in a matched matrix

**Sample stock solution:** Prepare as directed in *Sample preparation*. Allow the sample to cool, if necessary.

**Sample solution:** Dilute the *Sample stock solution* with an appropriate solvent to obtain a final arsenic concentration of not more than 1.5*J*.

**Blank:** Matched matrix

**Elemental spectrometric system**

(See ⟨730⟩.)

**Rinse:** Use diluent.

**Standardization:** *Standardization solution 1*, *Standardization solution 2*, and *Blank*

**System suitability**

**Sample:** *Standardization solution 1*

**Suitability requirements**

**Drift:** Compare results obtained from *Standardization solution 1* before and after the analysis of the *Sample solution*.

**Suitability criteria:** Not more than 20% for arsenic. [NOTE—If samples are high in mineral content, rinse the system well before introducing the *Sample* in order to minimize carryover.]

**Analysis:** Analyze according to the manufacturer's suggestions for program and wavelength. Calculate and report results on the basis of the original sample size. [NOTE—Appropriate measures must be taken to correct for matrix-induced interferences (e.g., wavelength overlaps).]

**Procedure 4: ICP–MS**

Follow *Procedure 3* except for *Detector* and *Analysis*.

[NOTE—An instrument with a cooled spray chamber is recommended. (A collision cell or reaction cell may also be beneficial.)]

**Detector:** Mass spectrometer

**Analysis:** Analyze according to the manufacturer's suggestions for program and mass-to-charge ratio. Calculate and report results based on the original sample size. [NOTE—Appropriate measures must be taken to correct for matrix-induced interferences (e.g., argon chloride interference with arsenic determinations).]▲ (Official 1-Jun-2023)

***Add the following:***

**▲REQUIREMENTS FOR PROCEDURE VALIDATION**

The following section defines the validation parameters and the acceptance criteria for performance-based procedures. Meeting these requirements must be demonstrated experimentally using an appropriate system suitability procedure and reference materials. Any alternative procedure (e.g., an atomic-absorption-based procedure) that has been validated and meets the acceptance criteria that follow is considered to be suitable for use.

Meeting these validation acceptance criteria is sufficient to demonstrate that the procedure will produce comparable results to those obtained using the procedure prescribed in the monograph.

- **ACCURACY**

**Standard solutions:** Prepare solutions containing arsenic at concentrations ranging from 50% to 150% of *J* using appropriate reference materials.

**Test samples:** Spike the material under test with the appropriate reference materials before any sample preparation steps (digestion or solubilization). Prepare three replicate samples at concentrations ranging from 50% to 150% of *J* for arsenic.

**Acceptance criteria**

**Spike recovery:** 70%–150% for the mean of three replicate preparations at each concentration

- **PRECISION**

**Repeatability**

**Test samples:** Six independent samples of material under test (taken from the same lot) spiked with appropriate reference materials for arsenic at the indicated concentration

**Acceptance criteria**

**Relative standard deviation:** Not more than 20% ($N = 6$) for arsenic

**Intermediate Precision (Ruggedness)**

**Analysis:** Perform the *Repeatability* analysis again on a different day, with different instrumentation, with a different analyst, or a combination thereof. Combine the results of this analysis with the *Repeatability* analysis so the total number of analyses is 12.

**Acceptance criteria**

**Relative standard deviation:** Not more than 25% ($N = 12$) for arsenic

- **SPECIFICITY:** The procedure must be able to unequivocally assess (see *Validation of Compendial Procedures* ⟨1225⟩) arsenic in the presence of components that may be expected to be present, including matrix components.
- **LIMIT OF QUANTITATION, RANGE, AND LINEARITY:** Demonstrated by meeting the *Accuracy* requirement.▲ (Official 1-Jun-2023)

Official

https://pharmacopeia.com/

***Add the following:***

## ▲GLOSSARY

**Concentrated acid:** Concentrated ultra-pure nitric, sulfuric, hydrochloric, or hydrofluoric acid or aqua regia.

**Aqua regia:** Aqua regia is a mixture of concentrated hydrochloric and nitric acids, typically at ratios of 3:1 or 4:1.

**Matched matrix:** Solutions having the same solvent composition as the *Sample solution*. In the case of an aqueous solution, a matched matrix would indicate that the same acids and acid concentrations are used in both preparations.

**Target limit or target concentration:** The acceptance value for the elemental impurity being evaluated, in this case arsenic. Where a monograph specifies a threshold limit, this shall become the target limit or target concentration of arsenic for the material. Exceeding the target limit indicates that a material under test exceeds the acceptable value. The determination of compliance is addressed in other chapters.

***J*:** The concentration (w/w) of the element of interest, in this case arsenic, at the target limit, appropriately diluted to the working range of the instrument.

**Appropriate reference materials:** Where "appropriate reference materials" are specified in the chapter, certified reference materials (CRMs) from a national metrology institute (NMI), or reference materials that are traceable to the CRM of an NMI should be used. An example of an NMI in the United States is the National Institute of Standards and Technology (NIST).▲ (Official 1-Jun-2023)

# ⟨212⟩ OLIGOSACCHARIDE ANALYSIS

## INTRODUCTION

Analysis of the asparagine (Asn-) linked oligosaccharide (also known as the *N*-linked oligosaccharide or *N*-glycan) composition of selected recombinant therapeutic proteins has become necessary for product characterization or release specifications of these proteins. For information on the characterization and assessment of protein glycosylation, see *Glycoprotein and Glycan Analysis—General Considerations* ⟨1084⟩. Chapter ⟨1084⟩ covers general analytical strategies and also highlights criteria for selecting appropriate methods for specific analytical challenges, thereby providing the context for this chapter. This chapter focuses on the analysis of *N*-linked oligosaccharides that are released from glycosylated recombinant therapeutic proteins. Therefore, the chapter provides 1) a generic procedure for enzymatic release of *N*-glycans using peptide *N*-glycosidase F (PNGase F), 2) two different approaches for fluorophore labeling of the released *N*-linked oligosaccharides, and 3) five analytical procedures based on chromatographic and electrophoretic separation, as well as performance criteria for the separation. Alternative analytical strategies are discussed in ⟨1084⟩. Although the procedures in this chapter are validated, the procedures must be verified with the individual specific product (see *Verification of Compendial Procedures* ⟨1226⟩). Furthermore, validation is required when the procedure is optimized for a specific product [e.g., outside the allowed parameter limits defined in *Chromatography* ⟨621⟩*, System Suitability* (see *Validation of Compendial Procedures* ⟨1225⟩)]. Data analysis, quantitation, and lot release specifications, which are expected to be product specific, will be found in individual product monographs; therefore, these aspects are not covered in this chapter.

Labeling oligosaccharides with a fluorophore before analysis provides an important advantage of enhanced detection of oligosaccharides during separation, because oligosaccharides have no or low absorptivity of either ultraviolet (UV) or visible light and no significant fluorophore groups. This chapter describes two different methods for fluorophore labeling of oligosaccharides: derivatization of oligosaccharides using 2-aminobenzamide (2-AB) for liquid chromatographic separation, and labeling of oligosaccharides with 8-aminopyrene-1,3,6-trisulfonic acid (APTS) for capillary electrophoresis (CE) separation. Although electrochemical detection (pulsed amperometric detection or pulsed electrochemical detection) is also used in oligosaccharide analysis by using a strong base elution, the electrochemical detection method is less sensitive and has a higher noise-to-signal ratio. Therefore, this detection method is not addressed in this chapter.

Many different chromatography and electrophoresis methods have been developed to analyze oligosaccharides, and the procedures described in this chapter have been used successfully for this purpose. The choice of procedures discussed is meant to reflect the most commonly and broadly used approaches for supporting current recombinant glycosylated biological medicines in commerce. These analytical procedures include normal phase or hydrophilic interaction liquid chromatography (HILIC), high-performance anion exchange liquid chromatography (HPAEC), and CE. Several other chromatographic modes that separate oligosaccharides by size, shape, and polarity are also commonly used for oligosaccharide separation, but those other chromatographic modes are not discussed in this chapter. The general principles of chromatography are covered in ⟨621⟩, and therefore ⟨621⟩ should be considered within that context.

USP Reference Standards (RS) have been developed to assess system suitability for these analytical procedures:

- USP Oligosaccharide System Suitability Mixture A RS consists of a mixture of partially sialylated, partially galactosylated, and partially fucosylated biantennary *N*-linked oligosaccharides that were released from human polyclonal immunoglobulin G (IgG) by PNGase F.
- USP Oligosaccharide System Suitability Mixture B RS consists of a mixture of high-mannose *N*-linked oligosaccharides with traces of hybrid chains that were released from bovine ribonuclease B (RNase B) by PNGase F.
- USP Oligosaccharide System Suitability Mixture C RS is a mixture of bi-, tri-, and tetra-antennary *N*-linked oligosaccharides with variable sialylation with or without fucose (Fuc; also containing $Le^x$-type structures); the mixture was released from human α1 acid-glycoprotein by PNGase F.
- USP Oligosaccharide System Suitability Mixture D RS is a mixture of sialylated bi- and tri-antennary complex type structures with an additional sialic acid on one of the tri-antennary structures; the mixture was released from bovine fetuin by PNGase F.

### ANALYTICAL PROCEDURES OVERVIEW

*Table 1* outlines the applications and separation principles of the analytical procedures included in this chapter. The choice of the appropriate RS will depend on the expected glycan content of the product being analyzed.

**Table 1**

| Analytical Procedures | Type of *N*-linked Oligosaccharides to Be Separated | Applicable USP Reference Standards |
|---|---|---|
| *Normal phase liquid chromatography/HILIC procedure 1*:<br>• Column: 2.0-mm × 15-cm; 3-µm packing L68<br>• More oligosaccharide peaks compared to *HILIC procedure 2*<br>• Longer mobile phase with shallow gradient compared to *HILIC procedure 2*<br>• Enhanced sensitivity for smaller sample size | Relatively simple biantennary chains with no or low levels of sialylated structures, after 2-AB labeling | USP Oligosaccharide System Suitability Mixture A RS |
| | High-mannose chains, after 2-AB labeling | USP Oligosaccharide System Suitability Mixture B RS |

**Table 1** *(continued)*

| Analytical Procedures | Type of *N*-linked Oligosaccharides to Be Separated | Applicable USP Reference Standards |
|---|---|---|
| *Normal phase liquid chromatography/HILIC procedure 2*:<br>• Column: 4.6-mm × 25-cm; 5-µm packing L68<br>• Fewer oligosaccharide peaks observed compared to *HILIC procedure 1*<br>• Shorter mobile phase with less shallow gradient compared to *HILIC procedure 1* | Relatively simple biantennary chains with no or low levels of sialylated structures, after 2-AB labeling | USP Oligosaccharide System Suitability Mixture A RS |
| | High-mannose chains, after 2-AB labeling | USP Oligosaccharide System Suitability Mixture B RS |
| *HPAEC procedure 1*<br>• Guard column: 4.0-mm × 5-cm; 10-µm packing L46<br>• Column: 4.0-mm × 25-cm; 10-µm packing L46<br>• Mobile phase: 0–75 mM sodium acetate in isocratic 0.15 N sodium hydroxide<br>• Selectivity is different from *HILIC procedures 1* and *2* with respect to the size and composition of oligosaccharide | Relatively simple biantennary chains with no or low levels of sialylated structures, after 2-AB labeling | USP Oligosaccharide System Suitability Mixture A RS |
| | High-mannose chains, after 2-AB labeling | USP Oligosaccharide System Suitability Mixture B RS |
| *HPAEC procedure 2*<br>• Guard column: 4.0-mm × 5-cm; 10-µm packing L46<br>• Column: 4.0-mm × 25-cm; 10-µm packing L46<br>• Mobile phase: 150–450 mM sodium acetate in isocratic 0.15 N sodium hydroxide<br>• Suitable for separation of charged *N*-linked oligosaccharides | Bi-, tri-, and tetra-antennary *N*-linked oligosaccharides with variable sialylation, after 2-AB labeling | USP Oligosaccharide System Suitability Mixture C RS |
| | Sialylated bi- and tri-antennary complex type structures with an additional sialic acid on one of the tri-antennary structure, after 2-AB labeling | USP Oligosaccharide System Suitability Mixture D RS |
| Capillary electrophoresis<br>• Appropriate for APTS- oligosaccharides<br>• Capillary: 50-µm inner diameter with 50 cm of total length and 40 cm of separation length | Relatively simple biantennary chains with no or low levels of sialylated structures, after APTS labeling | USP Oligosaccharide System Suitability Mixture A RS |
| | High-mannose chains, after APTS labeling | USP Oligosaccharide System Suitability Mixture B RS |

## SAMPLE PREPARATION

See *Appendix* (*Table 17*) for abbreviations and structures of glycans. The sample preparation is for all of the procedures that follow.

Ideally, the samples should be free of salts, excipients, and other carrier materials that may interfere with the analysis. This can be achieved by either 1) dialysis against water, a suitable buffer, or a volatile buffer using an appropriate membrane, 2) sample trapping on a solid-phase extraction (SPE) cartridge followed by washing away of salts and excipients and elution of the required sample, or 3) ultrafiltration using an appropriate membrane.

[NOTE—In addition to RS, a control sample with a known glycan profile should be included in the overall procedure to confirm correct performance of the analysis. A reaction blank control only containing the buffer matrix of the glycoprotein sample can also be included in the overall procedure.]

### • ENZYMATIC RELEASE OF *N*-GLYCANS

[NOTE—The following is a generic method that should be optimized for individual products depending on the amount of glycoprotein to be digested and the glycan structures, especially on the basis of the protein-to-glycan ratio in the molecule and the accessibility of the sugars.]

**Procedure 1 for chromatographic separation**

**Enzyme reaction buffer:** 50 mM sodium phosphate pH 7.5 or 15 mM tris(hydroxymethyl)-aminomethane, and adjust with hydrochloric acid to a pH of 7.0.

**Digestion with PNGase F:** Transfer 0.1–2.25 mg of glycoprotein to a vial, and adjust with *Enzyme reaction buffer* to a final volume of 30–100 µL. Add PNGase F to the glycoprotein sample in a ratio of 0.5–15 units of PNGase F to 0.1 mg of glycoprotein. Incubate at 37° for 12–24 h. Cool at room temperature for about 5 min. Vortex gently and centrifuge briefly. [NOTE—One unit of PNGase F is defined as the amount of enzyme required to catalyze the release of *N*-linked oligosaccharides from 1.0 nmol of denatured ribonuclease B per min at a pH of 7.5 at 37°, and is equal to 1 IUB milliunit. Complete digestion by PNGase F can be assessed by observing a mobility shift of the deglycosylated proteins on sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE), followed by Coomassie Blue staining or on SDS-capillary gel electrophoresis (SDS-CGE), as shown by reduction in mass of approximately 2 kDa per glycan chain cleaved.]

Two methods are described below for performing the separation of released glycans from glycoprotein.

**Method 1, using an ultrafiltration membrane with a molecular weight cutoff of 30 kDa:**[1,2] [NOTE—Ultrafiltration membranes with a lower molecular weight cutoff may be used for proteins < 150 kDa.]

Remove trace amounts of glycerin by centrifuging at 11,000 × *g* and rinsing the membrane with 0.5 mL of water. Discard the permeate. Add 0.1 mL of water into the sample reservoir and then add the digested glycoprotein

[1] A suitable ultrafiltration membrane is YM-30 microcon centrifugal filter device from Millipore (catalog numbers 42422, 42409, and 42410) or an equivalent.
[2] A suitable ultrafiltration membrane is EMD Millipore Ultra-0.5 Centrifugal Filter Unit (catalog number UFC501096) or an equivalent.

Official

https://pharmacopeia.cn/v29240/

sample to the reservoir. Rinse the reaction vial with 0.1 mL of water and add to the sample reservoir. Centrifuge at 11,000 × *g* and collect the permeate. Rinse the sample reservoir twice using 0.1 mL of water for each wash and collect the permeate. Combine the permeates (approximately 0.5 mL) and bring the samples to complete dryness using a centrifugal evaporator without heat.

**Method 2, using a reversed-phase SPE cartridge:**[3] Add 2.0 mL of methanol into a syringe, attach the syringe to the cartridge, and use the syringe plunger to pass methanol through to waste. Add into a syringe 6.0 mL of 5% (v/v) acetic acid prepared in water. Attach the syringe to the cartridge and use the syringe plunger to pass the acetic acid solution through to waste. Gently apply the digested sample onto an individual cartridge. Into a 1-mL syringe add 0.5 mL of 5% (v/v) acetic acid, attach the syringe to the cartridge, and use the syringe plunger to pass the acetic acid through to waste. To a 2- to 3-mL syringe add 1.5 mL of 5% (v/v) acetic acid. Attach the syringe to the cartridge, and use the syringe plunger to pass the acetic acid solution through, collecting the eluting solution into a 1.5-mL tube. Bring the samples to complete dryness using a centrifugal evaporator without heat.

**Procedure 2 for capillary electrophoresis separation**

**Enzyme reaction buffer:** 50 mM sodium phosphate, pH 7.5

**Digestion with PNGase F:** Add 2 µL of PNGase F (5 units/µL) to 50 µg of glycoprotein sample, and adjust with *Enzyme reaction buffer* to a final volume of 50 µL. Incubate at 37° for 18 h. Separate released oligosaccharides by centrifugation using a centrifugal filter with a 10,000 molecular weight cut-off.[2] In a centrifugal vacuum evaporator, dry the released oligosaccharides to dryness.

[NOTE—Follow the guidelines listed in *Table 1* to select the appropriate USP RS and label.]

- **2-AB LABELING[4] FOR LIQUID CHROMATOGRAPHIC SEPARATION**

**Solution A:** Mix glacial acetic acid and dimethyl sulfoxide (3:7, v/v).

**Solution B:** Add 1.5 mL of *Solution A* to 75 mg of 2-AB. Mix well by gentle vortexing to completely dissolve 2-AB.

**Labeling solution:** Add 1 mL of *Solution B* to 63 mg of sodium cyanoborohydride. Mix well by gentle vortexing. Cap the mixture tightly and incubate at 70° for 1–2 min for complete dissolution. Cool at room temperature for 10 min. Use this *Labeling solution* within 1 h of its preparation, and protect the solution from light.

**2-AB labeled standard solution:** Add 5–15 µL of *Labeling solution* to 1 vial of USP Oligosaccharide System Suitability Mixture A RS, USP Oligosaccharide System Suitability Mixture B RS, USP Oligosaccharide System Suitability Mixture C RS, or USP Oligosaccharide System Suitability Mixture D RS, and mix well.

**2-AB labeled sample solution:** Add 5–15 µL of *Labeling solution* to the dried glycan sample after enzymatic release and separation steps, and mix well.

**Procedure:** Immediately incubate the *2-AB labeled standard solution* and the *2-AB labeled sample solution* at 37° for 16–18 h or at 65° for 2 h. Allow to cool at room temperature for 10 min. Centrifuge briefly.

**Dried 2-AB labeled standard or Dried 2-AB labeled sample:** Two methods for the removal of free 2-AB are described below.

**Method 1, using a gel filtration spin column:** Prepare suitable G-10 microcentrifuge spin columns[5] by tapping the column gently to ensure that the dry resin is settled at the bottom. Remove the caps, and place the column in a 2-mL collection tube. Add 0.5 mL of water to the resin, and let it swell for at least 15 min. A longer swelling time (up to 24 h) is acceptable if maintained at 2°–8°. Centrifuge the column at maximum speed for 5–10 s. Remove the water from the collection tube. Wash the resin by adding 0.5 mL of water, and centrifuge the column. Repeat the washing step one more time. After removing the water from the final wash step, spin at maximum speed for 10 s to remove residual water from the resin. Residual water is sufficiently removed if the resin appears white. Place the column in a new, labeled collection tube. Add 100 µL of water to the *2-AB labeled standard solution* and the *2-AB labeled sample solution,* and then apply the entire solution to the center of each washed G-10 column, respectively. Place the G-10 columns in the microcentrifuge and spin at approximately 200 × *g* for 1 min. Apply the flow-through (approximately 90–120 µL) to the center of the second unused but previously washed G-10 column and spin at approximately 200 × *g* for 1 min. Transfer the repeat flow-through (approximately 60–100 µL) to a 0.5-mL microcentrifuge tube. Dry the eluates by centrifugal evaporation with no heat.

**Method 2, using an SPE cartridge:** Prepare suitable SPE cartridges[6] by washing with 1.0 mL of water, followed by 5 × 1.0 mL of 30% (v/v) acetic acid, and then 1.0 mL of acetonitrile. Apply the *2-AB labeled standard solution* and the *2-AB labeled sample solution* to the center surface of the cartridge discs, and allow the solution to incubate on the disc for 15–20 min. Wash each disc with 1 mL of acetonitrile, followed by 6 × 1.0 mL of 96% (v/v) acetonitrile, allowing each aliquot to drain before the next is applied. Elute the *2-AB labeled standard solution* and the *2-AB labeled sample solution* with 3 × 0.5 mL of water, allowing each aliquot to drain before the next is applied. Dry the eluates by centrifugal evaporation with no heat. [NOTE—Very small hydrophobic glycans may be lost during this procedure. During method verification, it should be confirmed that no oligosaccharide species are lost during the 2-AB removal step by comparing the chromatographic profiles of an unextracted reaction blank, an unextracted sample, and an extracted sample.]

- **APTS LABELING FOR CAPILLARY ELECTROPHORESIS SEPARATION**

**APTS labeling reagent:** Dissolve 5 mg of trisodium APTS in 48 µL of 15% (v/v) acetic acid.

**1 M sodium cyanoborohydride:** 1 M sodium cyanoborohydride in tetrahydrofuran

**Run buffer:** Dissolve 1.492 g of triethanolamine (TEA) and 10 g of glycerol, accurately weighed, in 80 mL of water. Adjust with 1 N hydrochloric acid to a pH of 7.5, and dilute with water to a final volume of 100 mL.

**Sample buffer:** Dilute 1.0 mL of *Run buffer* with 9.0 mL of water.

---

[3] A suitable SPE cartridge is Glyko GlycoClean R Cartridge from Prozyme (catalog number GKI-4756) or an equivalent.

[4] A suitable 2-AB labeling kit is Glyko Signal 2-AB Labeling Kit from Prozyme (catalog number GKK-404), LudgerTage 2-AB labeling kit from QA Bio (catalog number LT-KAB-A2), or an equivalent.

[5] A suitable prepacked Sephadex G-10 column is Macro Spin G-10 mini SEC column from Harvard Apparatus (catalog number 743900) or The Nest Group (catalog number SMM S010), or an equivalent.

[6] A suitable cartridge to remove free 2-AB is Glyko GlycoClean S Cartridge from Prozyme (catalog number GKI-4726) or an equivalent.

**APTS-labeled standard solution:** Add 2 µL of the *APTS labeling reagent* and 2 µL of *1 M sodium cyanoborohydride* to a vial of USP Oligosaccharide System Suitability Mixture A RS or USP Oligosaccharide System Suitability Mixture B RS. Incubate at 55° for 90 min. Add 46 µL of water to quench the reaction and mix. Transfer 5 µL of the APTS-labeled USP RS to 1.995 mL of *Sample buffer* before separation. [NOTE—The volume of *Sample buffer* may need to be adjusted so that the fluorescence signals of the oligosaccharides are similar to those from the *APTS-labeled sample solution*.]

**APTS-labeled sample solution:** Add 2 µL of *APTS labeling reagent* and 2 µL of *1 M sodium cyanoborohydride* to the dried glycan sample after enzymatic release and separation steps. Incubate at 55° for 90 min. Add 46 µL of water to quench the reaction and mix. Transfer 5 µL of the APTS-labeled glycan solution to 95 µL of *Sample buffer* before separation.

[NOTE—Follow the guidelines listed in *Table 1* to select the appropriate USP RS and label.]

## SEPARATION AND IDENTIFICATION OF OLIGOSACCHARIDES

- **NORMAL PHASE CHROMATOGRAPHY/HILIC**

**Procedure 1**

**1.4 M formic acid solution:** Mix 273 mL of water with 15 mL of 98%–100% formic acid.

**1.4 M ammonia solution:** Mix 155 mL of water with 40 mL of 26% ammonia solution.

**Ammonium formate buffer:** Add *1.4 M ammonia solution* to *1.4 M formic acid solution* until a pH of 4.4 is obtained.

**Solution A:** Acetonitrile, *Ammonium formate buffer*, and water (75: 4.3: 20.7)

**Solution B:** Acetonitrile, *Ammonium formate buffer*, and water (54: 8.3: 37.7)

**Mobile phase:** See *Table 2*.

**Table 2**

| Time (min) | Solution A (%) | Solution B (%) |
|---|---|---|
| 0.0 | 79 | 21 |
| 80.0 | 47 | 53 |
| 81.0 | 0 | 100 |
| 92.0 | 0 | 100 |
| 93.0 | 79 | 21 |
| 113.0 | 79 | 21 |

**Standard solution:** Reconstitute the *Dried 2-AB labeled standard* with NMT 500 µL of water. [NOTE—The volume of water may need to be adjusted so that the fluorescence signals from the *Standard solution* are similar to those from the *Sample solution*.]

**Sample solution:** Reconstitute the *Dried 2-AB labeled sample* with an appropriate volume of water. [NOTE—Use a ratio of 30 µL of water per 100 µg of glycoprotein used in the *Enzymatic Release of N-Glycans* test as a starting point.]

**Blank solution:** Buffer matrix of glycoprotein sample carried through the *Sample Preparation* procedure

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** Fluorescence (250-nm excitation wavelength and 428-nm emission wavelength)

**Column:** 2.0-mm × 15-cm; 3-µm packing L68

**Temperatures**

**Column:** 45°

**Autosampler:** 2°–8°

**Flow rate:** 0.2 mL/min

**Injection volume:** 2 µL

**System suitability**

**Samples:** *Standard solution* and *Blank solution*

**Suitability requirements**

**Blank:** No peak in the chromatogram of the *Blank solution* within the retention time window at 5–113 min

**Chromatogram similarity:** The chromatogram obtained from the *Standard solution* corresponds to that of the reference chromatogram provided with the Certificate for either USP Oligosaccharide System Suitability Mixture A RS or USP Oligosaccharide System Suitability Mixture B RS.

**Presence of *N*-glycan species:** If USP Oligosaccharide System Suitability Mixture A RS is used, identify peaks corresponding to *G0, G0F, G1Fa, G1Fb, G2F, A1F,* and *A2F* (see *Table 3*; see also *Appendix*) in the chromatogram obtained from the *Standard solution* by comparing the reference chromatogram provided with the USP Certificate for USP Oligosaccharide System Suitability Mixture A RS. If USP Oligosaccharide System Suitability Mixture B RS is used, identify peaks corresponding to oligomannose (MAN) *MAN-5, MAN-6, MAN-7, MAN-8,* and *MAN-9* (see *Table 4*; see also *Appendix*) in the chromatogram obtained from the *Standard solution* by comparing the reference chromatogram provided with the USP Certificate for USP Oligosaccharide System Suitability Mixture B RS.

**Relative retention times:** Corresponding to the relative retention times of *N*-glycans listed in *Table 3* or *Table 4*

**Table 3. Standard Solution Using USP Oligosaccharide System Suitability Mixture A RS**

| *N*-Glycan | Approximate Relative Retention Time |
|---|---|
| G0 (NGA2) | 0.47 |
| G0F (NGA2F) | 0.57 |
| G1Fa (NA1F, FA2G1, or NA2G1F) | 0.75 |
| G1Fb (NA1F, FA2G1, or NA2G1F) | 0.78 |
| G2F (NA2F) | 1.00 |
| A1F (G2fS1) | 1.39 |
| A2F (G2fS2) | 1.76 |

**Table 4. Standard Solution Using USP Oligosaccharide System Suitability Mixture B RS**

| *N*-Glycan | Approximate Relative Retention Time |
|---|---|
| MAN-5 | 0.74 |
| MAN-6 | 1.00 |
| MAN-7 | 1.29 |
| MAN-8 | 1.60 |
| MAN-9 | 1.85 |

**Analysis:** Equilibrate the *Chromatographic system* for at least 1 h with starting conditions described in *Table 2*. Inject the *Blank solution* until the baseline is stable (1–3 injections).

**Sample:** *Sample solution*

Integrate peaks in the resulting chromatogram, and report the relative peak areas of glycan structures relevant to the product. A baseline is drawn from the first to the last peak. For general information on chromatographic peak integration, see ⟨621⟩.

**Procedure 2**

**Solution A:** 250 mM ammonium formate, pH 4.0, prepared as follows. Mix 500 mL of water with 9.8 mL of 96% formic acid. Adjust with 30% ammonium hydroxide to a pH of 4.0 ± 0.1. Dilute with water to a final volume of 1000 mL. Pass the solution through a 0.22-µm pore size filter composed of cellulose acetate membrane.

**Solution B:** Acetonitrile

**Mobile phase:** See *Table 5*.

**Table 5**

| Time (min) | Solution A (%) | Solution B (%) |
|---|---|---|
| 0.0 | 20 | 80 |
| 2.0 | 30 | 70 |
| 67.0 | 52 | 48 |
| 67.1 | 80 | 20 |
| 73.0 | 80 | 20 |
| 73.1 | 20 | 80 |
| 85.0 | 20 | 80 |

**Standard solution:** Reconstitute the *Dried 2-AB labeled standard* with NLT 500 µL of water. [NOTE—The volume of water may need to be adjusted so that the fluorescence signals from the *Standard solution* are similar to those from the *Sample solution*.]

**Sample solution:** Reconstitute the *Dried 2-AB labeled sample* with an appropriate volume of water. [NOTE—Use a ratio of 50 µL of water per 100 µg of glycoprotein used in the *Enzymatic Release of N-Glycans* test as a starting point.]

**Blank solution:** Buffer matrix of glycoprotein sample carried through the *Sample Preparation* procedure

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** Fluorescence; set the excitation and emission wavelengths as listed in *Table 6*.

**Suitability requirements**

**Blank:** The chromatogram with *Blank solution* must not have any interfering components in the regions of *N*-glycan elution.

**Chromatogram similarity:** The chromatogram obtained from the *Standard solution* corresponds to that of the reference chromatogram provided with the Certificate for either USP Oligosaccharide System Suitability Mixture C RS or USP Oligosaccharide System Suitability Mixture D RS.

**Presence of *N*-glycan species:** If USP Oligosaccharide System Suitability Mixture C RS is used, identify peaks corresponding to *A1* (peak 1 and peak 2), *A2*, and *A3* (see *Table 13*; see also *Appendix*) in the chromatogram obtained from the *Standard solution* by comparing the reference chromatogram provided with the Certificate. If USP Oligosaccharide System Suitability Mixture D RS is used, identify peaks corresponding to *A1* (peak 1), *A2*, *A3*, and *A3G3S4* (see *Table 14*; see also *Appendix*) in the chromatogram obtained from the *Standard solution* by comparing the reference chromatogram provided with the Certificate.

**Relative retention times:** Corresponding to the relative retention times of *N*-glycans listed in *Table 13* or *Table 14*

**Table 13. Standard Solution Using USP Oligosaccharide System Suitability Mixture C RS**

| *N*-Glycan | Approximate Relative Retention Time |
|---|---|
| A1 (G1S1), peak 1 | 0.31 |
| A1 (G1S1), peak 2 | 0.32 |
| A2 (G2S2) | 0.73 |
| A3 (G3S3) | 1.00 |

**Table 14. Standard Solution Using USP Oligosaccharide System Suitability Mixture D RS**

| *N*-Glycan | Approximate Relative Retention Time |
|---|---|
| A1 (G1S1), peak 1 | 0.23 |
| A2 (G2S2) | 0.57 |
| A3 (G3S3) | 0.78 |
| A3G3S4 (S4NA3, or A3 + Sa) | 1.00 |

**Analysis:** [NOTE—Equilibrate the column with initial mobile phase conditions for a minimum of 15 min.]

**Sample:** *Sample solution*

Inject 25 µL of water, and run the gradient program at least once to equilibrate the column and system. Integrate peaks in the resulting chromatogram, and report the relative peak areas of glycan structures relevant to the product. For general information on chromatographic peak integration, see ⟨621⟩.

- **CAPILLARY ELECTROPHORESIS**

**Run buffer:** Dissolve 1.492 g of TEA and 10 g of glycerol in 80 mL of water. Adjust with 1 N hydrochloric acid to a pH of 7.5 and dilute with water to a final volume of 100 mL.

**Standard solution:** *APTS-labeled standard solution* prepared as directed in the test for *APTS Labeling for CE Separation*

**Sample solution:** *APTS-labeled sample solution* prepared as directed in the test for *APTS Labeling for CE Separation*

**Blank solution:** Buffer matrix of glycoprotein sample carried through the *Sample Preparation* procedure

**Instrumental conditions**

**Mode:** CE

**Detector:** Laser-induced fluorescence (488-nm excitation wavelength and 520-nm emission wavelength)

**Capillary:** 50-µm inner diameter bare fused-silica with 50 cm total length and 40 cm separation length

**Preconditioning of the capillary:** Between each run, rinse for 5 min at 40 psi with 0.5 N sodium hydroxide, followed by water for 1 min at 40 psi. [NOTE—Precondition a new capillary or as needed: Rinse for 5 min at 20 psi with methanol, followed by water for 1 min at 50 psi, 1 N hydrochloric acid for 5 min at 20 psi, water for 1 min at 50 psi, 0.5 N sodium hydroxide for 25 min at 20 psi, and water for 5 min at 50 psi.]

**Prefilling of the capillary:** Rinse for 5 min at 40 psi with *Run buffer.*

**Sample injection:** 10 s hydrodynamic (pressure) injection

**Voltage:** 22 kV for 60 min

**Temperatures**

**Capillary cartridge:** 18°

**Sample storage:** 20°

**System suitability**

**Sample:** *Standard solution*

**Suitability requirements**

**Electropherogram similarity:** The electropherogram obtained from the *Standard solution* corresponds to that of the reference electropherogram provided with the Certificate for either USP Oligosaccharide System Suitability Mixture A RS or USP Oligosaccharide System Suitability Mixture B RS.

**Presence of *N*-glycan species:** If USP Oligosaccharide System Suitability Mixture A RS is used, identify peaks corresponding to *G2F*, *G2*, *G1Fa*, *G1Fb*, *G0F*, *MAN-5*, *G0*, and *A1F* (see *Table 15*; see also *Appendix*) in the electropherogram obtained from the *Standard solution* by comparing the reference electropherogram provided with the USP Certificate for USP Oligosaccharide System Suitability Mixture A RS. If USP Oligosaccharide System Suitability Mixture B RS is used, identify peaks corresponding to *MAN-5*, *MAN-6*, *MAN-7*, *MAN-8*, and *MAN-9* (see

# ⟨221⟩ CHLORIDE AND SULFATE

***Change to read:***

The following limit tests are provided as general procedures for use where limits for chloride and sulfate are specified in the individual monographs.

Perform the tests and the controls in glass cylinders of the same diameter and matched as closely as practicable in other respects (see ▲*Visual Comparison* ⟨630⟩▲ (CN 1-May-2019)). Use the same quantities of the same reagents for both the solution under test and the control solution containing the specified volume of chloride or sulfate. If, after acidification, the solution is not perfectly clear, pass it through a filter paper that gives negative tests for chloride and sulfate. Add the precipitant, silver nitrate TS or barium chloride TS as required, to both the test solution and the control solution in immediate sequence.

Where the individual monograph calls for applying the test to a specific volume of a solution of the substance, and the limit for chloride or sulfate corresponds to 0.20 mL or less of 0.020 N hydrochloric acid or sulfuric acid, respectively, apply the test to the solution without further dilution. In such cases maintain the same volume relationships for the control solution as specified for the solution under test. In applying the test to the salts of heavy metals, which normally show an acid reaction, omit the acidification and do not neutralize the solution. Dissolve bismuth salts in a few mL of water and 2 mL of nitric acid before treating with the precipitant.

**CHLORIDE—**Dissolve the specified quantity of the substance under test in 30 to 40 mL of water, or, where the substance is already in solution, add water to make a total volume of 30 to 40 mL, and, if necessary, neutralize the solution with nitric acid to litmus. Add 1 mL each of nitric acid and of silver nitrate TS and sufficient water to make 50 mL. Mix, and allow to stand for 5 minutes protected from direct sunlight. Unless otherwise specified in the monograph, compare the turbidity, if any, with that produced in a solution containing the volume of 0.020 N hydrochloric acid specified in the monograph.

**SULFATE—**Dissolve the specified quantity of the substance under test in 30 to 40 mL of water, or, where the substance is already in solution, add water to make a total volume of 30 to 40 mL, and, if necessary, neutralize the solution with hydrochloric acid to litmus. Add 1 mL of 3 N hydrochloric acid, 3 mL of barium chloride TS, and sufficient water to make 50 mL. Mix, and allow to stand for 10 minutes. Unless otherwise specified in the monograph, compare the turbidity, if any, with that produced in a solution containing the volume of 0.020 N sulfuric acid specified in the monograph.

# ⟨223⟩ DIMETHYLANILINE

The following limit test is provided as a general procedure, when specified in the individual monographs for the gas chromatographic determination in compendial articles of traces of dimethylaniline, a hydrochloric acid scavenger that may have been carried over during processing.

**PROCEDURE**

**Internal standard solution:** Unless otherwise specified in the individual monograph, prepare a solution of naphthalene in cyclohexane containing about 50 µg per mL.

**Standard preparation:** Unless otherwise specified in the individual monograph, transfer 50.0 mg of *N*,*N*-dimethylaniline to a 50-mL volumetric flask, add 25 mL of 1 N hydrochloric acid, swirl to dissolve, dilute with water to volume, and mix. Transfer 5.0 mL of the resulting solution to a 250-mL volumetric flask, dilute with water to volume, and mix. To a suitable centrifuge tube add 1.0 mL of this solution, 5.0 mL of 1 N sodium hydroxide, and 1.0 mL of *Internal standard solution*, shake vigorously for 1 minute, and centrifuge. Use the clear supernatant as the *Standard preparation.*

**Test preparation:** Unless otherwise specified in the individual monograph, transfer 1.0 g of the substance to be tested to a suitable centrifuge tube, add 5 mL of 1 N sodium hydroxide, swirl to dissolve the specimen, add 1.0 mL of *Internal standard solution*, shake vigorously for 1 minute, and centrifuge. Use the clear supernatant as the *Test preparation.*

**Chromatographic system**

(See *Chromatography* ⟨621⟩.)

The gas chromatograph is equipped with a flame-ionization detector, maintained at about 250°, and a 0.53-mm × 30-m fused silica capillary column bonded with a 1.0-µm film of phase G42. The carrier gas is helium, with a linear velocity of about 30 cm per second and a split ratio of 10:1. The column temperature is maintained at 110° for the first 4 minutes after an injection is made, then increased from 110° to 200° at 8° per minute, and then held at 200° for 5 minutes. The injection port temperature is maintained at 250°. Chromatograph the *Standard preparation*, and record the responses as directed for *Procedure* identify the dimethylaniline and naphthalene peaks by their relative retention times, which are 1.0 and 1.3, respectively. The signal-to-noise ratio for the dimethylaniline peak is not less than 10.

**Procedure:** Inject equal volumes (about 1 µL) of the *Standard preparation* and the *Test preparation* into the chromatograph, record the chromatograms, and measure the areas for the major peaks. The ratio of the response of any dimethylaniline peak to the response of the naphthalene peak obtained from the *Test preparation* is not greater than that obtained from the *Standard preparation* (0.002%).

# ⟨226⟩ 4-EPIANHYDROTETRACYCLINE

This chromatographic procedure is provided to demonstrate that the content of 4-epianhydrotetracycline, a degradation product of tetracycline, does not exceed the limit given in the individual monograph.

**PROCEDURE**

**EDTA buffer:** Dissolve 37.2 g of edetate disodium in 800 mL of water, adjust with ammonium hydroxide to a pH of 7.8, dilute with water to 1000 mL, and mix.

**Support phase:** Add 5 mL of *EDTA buffer* to 10 g of acid-washed chromatographic siliceous earth for column chromatography, and mix until the siliceous earth is uniformly moistened.

**Test solution:** Prepare as directed in the individual monograph.

**Procedure:** Prepare a 15-mm × 170-mm chromatographic tube with a 4-mm × 50-mm outlet by packing it, in increments, with *Support phase*, firmly tamping down each increment, until the tube is filled to a height of about 10 cm. In a beaker, prepare a mixture of 1 g of acid-washed chromatographic siliceous earth for column chromatography and 1 mL of *Test solution.* Transfer the mixture to the top of the column. Dry-wash the beaker with *Support phase*, and transfer to the column to provide an additional 1-cm layer on top of the mixture containing the *Test solution.* Within 30 minutes, pass chloroform through the column, and collect successive fractions of 5.0 mL, 5.0 mL, 10.0 mL, 10.0 mL, and 5.0 mL. Observe the column during elution, and note the appearance of two separate yellow bands. The fraction or fractions containing the first yellow band contain the anhydrotetracyclines. Discard these fractions. The fractions after the first yellow band contain the 4-epianhydrotetracycline. Determine the absorbance of each 4-epianhydrotetracycline fraction at the wavelength of maximum absorbance at about 438 nm, with a suitable spectrophotometer, diluting each fraction, if necessary, with chloroform, and using chloroform as the blank. Calculate the quantity, in mg, of 4-epianhydrotetracycline in each fraction by the formula:

$$\text{Result} = A_U VD/A_S$$

$A_U$ = absorbance of the fraction taken
$V$ = volume of the fraction taken (mL)
$D$ = dilution factor, if the fraction was diluted
$A_S$ = absorptivity of 4-epianhydrotetracycline at 438 nm, 20.08

From the sum of the quantities of 4-epianhydrotetracycline found in the fractions, calculate the percentage of 4-epianhydrotetracycline in relation to the tetracycline hydrochloride equivalent contained in the *Test solution.*

# ⟨227⟩ 4-AMINOPHENOL IN ACETAMINOPHEN-CONTAINING DRUG PRODUCTS

## INTRODUCTION

This chapter provides a procedure and acceptance criterion (limit) to control the principal degradation product of acetaminophen, 4-aminophenol, an impurity that can form by hydrolysis of acetaminophen.

### SOLUTION PREPARATIONS

All solution preparations that contain acetaminophen or 4-aminophenol should be protected from light and should be stored only for as long as can be supported by solution stability data acquired during verification under actual conditions of use.

**Buffer:** 4.0 g/L of sodium citrate dihydrate and 1.5 g/L of anhydrous citric acid, in water

**Diluent:** Acetonitrile and *Buffer* (10:90)

**Solution A:** 10 mM phosphate buffer prepared as follows. Add 0.60 g of monobasic potassium phosphate and 0.82 g of anhydrous dibasic sodium phosphate to a 1-L volumetric flask. Dissolve and dilute with water to volume to a pH of 7.0.

**Solution B:** Water

**Solution C:** Acetonitrile

**Mobile phase:** See *Table 1*.

**Table 1**

| Time (min) | Solution A (%) | Solution B (%) | Solution C (%) |
|---|---|---|---|
| 0 | 90 | 5 | 5 |
| 5 | 90 | 5 | 5 |
| 7 | 10 | 10 | 80 |
| 7.1 | 90 | 5 | 5 |
| 10 | 90 | 5 | 5 |

**Standard stock solution:** 25 µg/mL of USP 4-Aminophenol RS in *Diluent*. Prepare fresh in conjunction with the other solution preparations described below. Discard after 4 h or as supported by solution stability data. [NOTE—See *Chromatographic Adjustments*, solution stability, below.]

**System suitability solution:** 2.5 µg/mL of USP 4-Aminophenol RS in *Diluent*, from the *Standard stock solution*

**Sample stock solution:** Nominally 10 mg/mL of acetaminophen from a suitable quantity of drug product in *Diluent*. [NOTE—Either component of the *Diluent* may be introduced to the drug product first, followed by addition of the other component to maintain the proportions of acetonitrile and *Buffer* and to achieve the appropriate final volume defined for the *Diluent*.]

[NOTE—It is recommended that the *Sample solution* and *Standard solution* be prepared concurrently within a narrow window of time (e.g., 30 min) for each drug product sample.]

**Standard solution:** Add 25.0 mL of the *Sample stock solution* and 15.0 mL of the *Standard stock solution* to a 50-mL volumetric flask, and dilute with *Diluent* to volume. Pass through a suitable filter of 0.45-µm pore size, discarding the first 3 mL of filtrate.

**Sample solution:** Add 25.0 mL of the *Sample stock solution* to a 50-mL volumetric flask, and dilute with *Diluent* to volume. Pass through a suitable filter of 0.45-µm pore size, discarding the first 3 mL of filtrate.

### CHROMATOGRAPHIC METHOD

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 300 nm

**Column:** 4.6-mm × 15-cm; 5-µm packing L85

**Column temperature:** 30°

**Flow rate:** 1 mL/min

**Injection volume:** 10 µL

**System suitability**

**Samples:** *System suitability solution* and *Standard solution*

[NOTE—The typical retention time for 4-aminophenol is about 4.2–5.3 min.]

**Suitability requirements**

**Resolution:** NLT 1.0 between 4-aminophenol and the nearest peak, *Standard solution*

**Tailing factor:** NMT 1.5 for the 4-aminophenol peak, *Standard solution*

**Relative standard deviation:** NMT 5.0%, *Standard solution*

**Signal-to-noise ratio:** NLT 20 for the 4-aminophenol peak, *System suitability solution*

### ANALYSIS

**Samples:** *Standard solution* and *Sample solution*

Inject the *Sample solution* and *Standard solution* for each drug product sample sequentially, i.e., back-to-back.

Calculate the percentage of 4-aminophenol ($C_6H_7NO$) relative to acetaminophen in the portion of drug product taken:

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-May-2018
DOI Ref: f8251
DocId: GUID-6D26057D-423A-4474-A8A5-AF9F6FB68E2B_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M8006_02_01
@2024 USPC

$$\text{Result} = [r_U/(r_S - r_U)] \times (W_S/W_U) \times 100$$

$r_U$ = peak response of 4-aminophenol from the *Sample solution*
$r_S$ = peak response of 4-aminophenol from the *Standard solution*
$W_S$ = amount of USP 4-Aminophenol RS added to the *Standard solution* (mg)
$W_U$ = amount of acetaminophen in the *Sample solution* (mg)

**Acceptance criteria** (unless otherwise stated in the monograph): NMT 0.15% of 4-aminophenol relative to acetaminophen

**CHROMATOGRAPHIC ADJUSTMENTS**

The retention time of 4-aminophenol can be tuned to achieve specificity for a given product matrix. This allowance supersedes provisions in ⟨621⟩ for adjusting chromatographic conditions and is intended to provide a measure of flexibility when needed. Suggestions for changing 4-aminophenol retention are given in *Table 2*. The use of a ternary mobile phase system affords ready changes to the ionic strength (water from *Solution B*) and organic strength (acetonitrile from *Solution C*), but this can be simplified to a binary mobile phase system.

**Table 2**

| Condition Change | Change in 4-Aminophenol Retention |
|---|---|
| Increase in organic strength (*Solution C*) | Decreases 4-aminophenol retention |
| Decrease in pH (*Solution A*) | Increases 4-aminophenol retention |
| Increase in ionic strength (*Solution B*) | Decreases 4-aminophenol retention |
| Increase in column temperature | Increases 4-aminophenol retention |

Adjustments to the chromatographic procedure may require verification or validation. See *Validation of Compendial Procedures* ⟨1225⟩ and *Verification of Compendial Procedures* ⟨1226⟩ for guidance. Adjusted chromatographic conditions must meet all system suitability requirements.

Solution stability must be verified under actual conditions of use to ensure 4-aminophenol is stable in the *Sample solution* and the *Standard solution* as evidenced by NMT ±10% change of the 4-aminophenol peak areas.

# ⟨228⟩ ETHYLENE OXIDE AND DIOXANE

The following procedure is used to determine the contents of residual ethylene oxide and dioxane in the products prepared from ethylene oxide. Unless otherwise directed in the individual monograph, use *Method I*.

**Method I**

[**CAUTION**—Ethylene oxide is toxic and flammable. Prepare these solutions in a well-ventilated fume hood, using great care. Protect both hands and face by wearing polyethylene protective gloves and an appropriate face mask. Store all solutions in hermetic containers, and refrigerate between 4° and 8°.]

[NOTE—Before using the polyethylene glycol 200 in this test, remove any volatile components from it by placing 500 mL of polyethylene glycol 200 in a 1000-mL round-bottom flask and attaching the flask to a rotary evaporator maintained at 60° and under a vacuum of 10–20 mm Hg for 6 h.]

**Acetaldehyde solution:** 10 µg/mL of acetaldehyde. [NOTE—Prepare immediately before use.]

**Ethylene oxide stock solution:** 2.5 mg/g of ethylene oxide.

Prepare as follows: Tare a glass-stoppered conical flask, add 50 mL of polyethylene glycol 200, and reweigh the flask. Transfer 5 mL of the liquid ethylene oxide to a 100-mL beaker chilled in a mixture of sodium chloride and ice (1:3). Transfer 300 µL (corresponding to 250 mg) of liquid ethylene oxide to the polyethylene glycol 200, and swirl gently to mix. Replace the stopper, reweigh the flask, and determine the amount of ethylene oxide absorbed by weight difference. Adjust the weight of the mixture with polyethylene glycol 200 to 100.0 g, replace the stopper, and swirl gently to mix. [NOTE—Fill a chilled pressure bottle with liquid ethylene oxide, and store in a freezer when not in use. Use a small piece of polyethylene film to protect the liquid from contact with the rubber gasket. Use an adequately chilled apparatus where appropriate. Prepare this stock solution immediately prior to use, and store in a refrigerator after preparation.]

**Ethylene oxide solution:** Tare a glass-stoppered conical flask, and chill it in a refrigerator. Add 35 mL of polyethylene glycol 200, and reweigh the flask. Transfer 1 g of chilled *Ethylene oxide stock solution* to the tared conical flask. Adjust the weight of the solution with polyethylene glycol 200 to 50.0 g, replace the stopper, and swirl gently to mix. Transfer 10 g of this solution to a 50-mL volumetric flask. Add 30 mL of water, and mix. Dilute with water to volume, and mix to obtain a solution containing 10 µg/mL of ethylene oxide. [NOTE—Use an adequately chilled apparatus where appropriate. Prepare immediately before use.]

**Dioxane solution:** 500 µg/mL of dioxane

**Standard solution A:** Transfer 0.1 mL of *Ethylene oxide solution* to a 10-mL pressure headspace vial. [NOTE—Other sizes such as a 22-mL pressure headspace vial may be used, depending on operating conditions; however, the same size must be used for *Standard solution A*, *Standard solution B*, and the *Sample solution*.] Add 0.1 mL of *Acetaldehyde solution* and 0.1 mL of *Dioxane solution*, seal the vial, and mix.

**Standard solution B:** Transfer 1.0 g of the test substance to a 10-mL pressure headspace vial, and add 0.1 mL of *Ethylene oxide solution*, 0.1 mL of *Dioxane solution*, and 1.0 mL of *N*,*N*-dimethylacetamide. Seal the vial, and mix.

**Sample solution:** Transfer 1.0 g of the test substance to a 10-mL pressure headspace vial, and add 1.0 mL of *N*,*N*-dimethylacetamide and 0.2 mL of water. Seal the vial, and mix.

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** Headspace GC

**System suitability**
**Sample:** *Standard solution A*
[NOTE—The relative retention times for acetaldehyde and ethylene oxide are 0.94 and 1.0, respectively.]
**Suitability requirements**
**Resolution:** NLT 2.0 between acetaldehyde and ethylene oxide
**Signal-to-noise ratio:** NLT 5, determined from the dioxane peak
**Relative standard deviation:** NMT 15%
**Analysis**
**Samples:** *Standard solution B* and *Sample solution*
[NOTE—The relative retention times for ethylene oxide and dioxane are 1.0 and 2.5, respectively.]
Calculate the content of ethylene oxide, in ppm, in the portion of the test substance taken:

$$\text{Result} = A_E \times r_U/[(r_S \times W_U) - (r_U \times W_S)]$$

$A_E$ = quantity of ethylene oxide added to *Standard solution B* (µg)
$r_U$ = ethylene oxide peak responses from the *Sample solution*
$r_S$ = ethylene oxide peak responses from *Standard solution B*
$W_U$ = weight of the test substance taken to prepare the *Sample solution* (g)
$W_S$ = weight of the test substance taken to prepare *Standard solution B* (g)

Calculate the content of dioxane, in ppm, in the portion of the test substance taken:

$$\text{Result} = A_D \times r_U/[(r_S \times W_U) - (r_U \times W_S)]$$

$A_D$ = quantity of dioxane added to *Standard solution B* (µg)
$r_U$ = dioxane peak responses from the *Sample solution*
$r_S$ = dioxane peak responses from *Standard solution B*
$W_U$ = weight of the test substance taken to prepare the *Sample solution* (g)
$W_S$ = weight of the test substance taken to prepare *Standard solution B* (g)

## Method II

**Ethylene oxide standard solution:** Dilute 0.5 mL of ethylene oxide in methylene chloride (50 mg/mL)[1] with water to 50.0 mL. [NOTE—The solution is stable for 3 months if stored in vials with polytetrafluoroethylene (polytef)-coated silicon membrane crimped caps at –20°.] Allow to reach room temperature. Dilute 1.0 mL with water to 250.0 mL to obtain a solution having a concentration of 2 µg/mL of ethylene oxide. [NOTE—Use this solution immediately after preparation.]
**Dioxane standard solution:** 0.05 µL/mL of dioxane
**Acetaldehyde standard solution:** 10 µg/mL of acetaldehyde. [NOTE—Prepare immediately before use.]
**Resolution solution:** Add 2.0 mL of *Acetaldehyde standard solution* and 2.0 mL of *Ethylene oxide standard solution* to a 10-mL headspace vial. Seal the vial immediately with a polytef-coated silicon membrane and an aluminum cap, and mix carefully.
**Standard solution A:** 0.48 µg/mL of ethylene oxide, from *Ethylene oxide standard solution*, and 0.005 µL/mL of dioxane, from *Dioxane standard solution*, in water
**Standard solution B:** Transfer 1.0 g of the test substance into a 10-mL headspace vial. Add 2.0 mL of *Standard solution A*, seal the vial immediately with a polytef-coated silicon membrane and an aluminum cap, and mix carefully.
**Sample solution:** Transfer 1.0 g of the test substance into a 10-mL headspace vial. Add 2.0 mL of water, seal the vial immediately with a polytef-coated silicon membrane and an aluminum cap, and mix carefully.
**Chromatographic system**
(See *Chromatography* ⟨621⟩*, System Suitability*.)
**Mode:** Headspace GC
**Detector:** Flame ionization
**Column:** 0.53-mm × 50-m fused-silica capillary column; 5.0-µm layer of phase G27
**Temperature**
**Injector port:** 85°
**Detector:** 250°
**Column:** See the column temperature table below.

| Initial Temperature (°) | Temperature Ramp (°/min) | Final Temperature (°) | Hold Time at Final Temperature (min) |
|---|---|---|---|
| 70 | 10 | 250 | 5 |

**Carrier gas:** Helium
**Flow rate:** 4 mL/min
**Injection volume:** 1 mL (gaseous headspace)
**Injection type:** Split ratio 3.5 : 1
**Headspace sampler**
**Temperature equilibration time:** 30 min

**System suitability**

**Sample:** *Resolution solution*

[NOTE—The relative retention times for acetaldehyde and ethylene oxide are 0.9 and 1.0, respectively.]

**Suitability requirements**

**Resolution:** NLT 2.0 between acetaldehyde and ethylene oxide

**Analysis**

**Samples:** *Standard solution B* and *Sample solution*

[NOTE—The relative retention times for ethylene oxide and dioxane are 1.0 and 1.9, respectively.]

Calculate the content of ethylene oxide, in ppm, in the portion of the test substance taken:

$$\text{Result} = C_E \times V \times r_U/[(r_S \times W_U) - (r_U \times W_S)]$$

$C_E$ = concentration of ethylene oxide in the *Standard solution A* (µg/mL)
$V$ = volume of *Standard solution A* added to *Standard solution B* (2.0 mL)
$r_U$ = ethylene oxide peak responses from the *Sample solution*
$r_S$ = ethylene oxide peak responses from *Standard solution B*
$W_U$ = weight of the test substance taken to prepare the *Sample solution* (g)
$W_S$ = weight of the test substance taken to prepare *Standard solution B* (g)

Calculate the content of dioxane, in ppm, in the portion of the test substance taken:

$$\text{Result} = C_D \times V \times \rho \times F \times r_U/[(r_S \times W_U) - (r_U \times W_S)]$$

$C_D$ = concentration of dioxane in *Standard solution A* (µL/mL)
$V$ = volume of *Standard solution A* added to *Standard solution B* (2.0 mL)
$\rho$ = density of dioxane (1.03 g/mL = 1.03 mg/µL)
$F$ = conversion factor (1000 µg/mg)
$r_U$ = dioxane peak responses from the *Sample solution*
$r_S$ = dioxane peak responses from *Standard solution B*
$W_U$ = weight of the test substance taken to prepare the *Sample solution* (g)
$W_S$ = weight of the test substance taken to prepare *Standard solution B* (g)

# ⟨232⟩ ELEMENTAL IMPURITIES—LIMITS

## INTRODUCTION

This chapter specifies limits for the amounts of elemental impurities in drug products. Regardless of the approach used, compliance with the limits specified is required for all drug products unless otherwise specified in an individual monograph or specifically excluded in this *Introduction*.

Elemental impurities include catalysts and environmental contaminants that may be present in drug substances, excipients, or drug products. These impurities may occur naturally, be added intentionally, or be introduced inadvertently (e.g., by interactions with processing equipment and the container–closure system). When elemental impurities are known to be present, have been added, or have the potential for introduction, assurance of compliance to the specified levels is required. A risk-based control strategy may be appropriate when analysts determine how to assure compliance with this standard. Due to the ubiquitous nature of arsenic, cadmium, lead, and mercury, they (at the minimum) must be considered in the risk assessment.

This chapter does not apply to the following:

- Radiopharmaceuticals
- Articles intended only for veterinary use
- Vaccines
- Cell metabolites
- DNA products
- Allergenic extracts
- Cells, whole blood, cellular blood components, or blood derivatives, including plasma and plasma derivatives
- Products based on genes (gene therapy)
- Cells (cell therapy)
- Tissue (tissue engineering)
- Dialysate solutions not intended for systemic circulation
- Total parenteral nutrition (TPN)
- Elements that are intentionally included in the drug product for therapeutic benefit
- Dietary supplements and their ingredients, which are addressed in *Elemental Contaminants in Dietary Supplements* ⟨2232⟩

The limits presented in this chapter do not apply to excipients and drug substances, except where specified in an individual monograph. However, manufacturers of pharmaceutical products need certain information about the content of elemental impurities in drug substances or excipients in order to meet the criteria of this chapter. Drug product manufacturers can use elemental impurity test data on components from tests performed by drug substance or excipient manufacturers, who may provide test data, or if applicable, risk assessments. Elemental impurity data generated by a qualified supplier of drug product components are acceptable for use by a drug product manufacturer to demonstrate compliance with this chapter in the final drug product. Drug substance or excipient manufacturers who choose to perform a risk assessment must conduct that risk assessment using *Table 2* in this chapter. Elements that are inherent in the nature of the material, as in the case of some naturally sourced materials, must be considered in the risk assessment.

Official

## SPECIATION

The determination of the oxidation state, organic complex, or combination is termed “speciation”. Each of the elemental impurities has the potential to be present in differing oxidation or complexation states. However, arsenic and mercury are of particular concern because of the differing toxicities of their inorganic and complexed organic forms.

The arsenic limits are based on the inorganic (most toxic) form. Arsenic can be measured using a total-arsenic procedure under the assumption that all arsenic contained in the material under test is in the inorganic form. Where the limit is exceeded using a total-arsenic procedure, it may be possible to show, via a procedure that quantifies the different forms, that the inorganic form meets the specification.

The mercury limits are based upon the inorganic ($2^+$) oxidation state. The methyl mercury form (most toxic) is rarely an issue for pharmaceuticals. Thus, the limit was established assuming the most common (mercuric) inorganic form. Limits for articles that have the potential to contain methyl mercury (e.g., materials derived from fish) are to be provided in the monograph.

## ROUTES OF EXPOSURE

The elements included in the tables below have been placed into three classes, based on their toxicity and likelihood of occurrence in the drug product. The classification scheme is intended to focus the risk assessment on those elements that are the most toxic but also have a reasonable probability of inclusion in the drug product (see *Table 2*).

The toxicity of an elemental impurity is related to its extent of exposure (bioavailability). The extent of exposure has been determined for each of the elemental impurities of interest for three routes of administration: oral, parenteral, and inhalational. These limits are based on chronic exposure. Consider the oral permitted daily exposures (PDEs) in *Table 1* as a starting point in developing specific PDEs for other routes of administration, except where otherwise stated in the individual monograph.

[NOTE—The routes of administration of drug products are defined in *Pharmaceutical Dosage Forms* ⟨1151⟩.]

# DRUG PRODUCTS

The limits described in the third through fifth columns of *Table 1* are the base daily dose PDEs of the elemental impurities of interest for a drug product taken by a patient according to the indicated routes of administration.

## Parenteral Products

Parenteral drug products with maximum daily volumes up to 2 L may use the maximum daily volume to calculate permitted concentrations from PDEs. For products whose daily volumes, as specified by labeling and/or established by clinical practice, may exceed 2 L (e.g., saline, dextrose, and solutions for irrigation), a 2-L volume may be used to calculate permitted concentrations from PDEs.

**Table 1. Permitted Daily Exposures for Elemental Impurities**

| Element | Class | Oral PDE (µg/day) | Parenteral PDE (µg/day) | Inhalation PDE (µg/day) |
|---|---|---|---|---|
| Cadmium | 1 | 5 | 2 | ▲3▲ (USP 1-Dec-2020) |
| Lead | 1 | 5 | 5 | 5 |
| Arsenic | 1 | 15 | 15 | 2 |
| Mercury | 1 | 30 | 3 | 1 |
| Cobalt | 2A | 50 | 5 | 3 |
| Vanadium | 2A | 100 | 10 | 1 |
| Nickel | 2A | 200 | 20 | 5 |
| Thallium | 2B | 8 | 8 | 8 |
| Gold | 2B | 100 | 100 | 1 |
| Palladium | 2B | 100 | 10 | 1 |
| Iridium | 2B | 100 | 10 | 1 |
| Osmium | 2B | 100 | 10 | 1 |
| Rhodium | 2B | 100 | 10 | 1 |
| Ruthenium | 2B | 100 | 10 | 1 |
| Selenium | 2B | 150 | 80 | 130 |
| Silver | 2B | 150 | 10 | 7 |
| Platinum | 2B | 100 | 10 | 1 |
| Lithium | 3 | 550 | 250 | 25 |
| Antimony | 3 | 1200 | 90 | 20 |
| Barium | 3 | 1400 | 700 | 300 |
| Molybdenum | 3 | 3000 | 1500 | 10 |
| Copper | 3 | 3000 | 300 | 30 |
| Tin | 3 | 6000 | 600 | 60 |
| Chromium | 3 | 11000 | 1100 | 3 |

## Recommendations for Elements to Be Considered in the Risk Assessment

*Table 2* identifies elemental impurities for inclusion in the risk assessment. This table can be applied to all sources of elemental impurities in the drug product.

**Table 2. Elements to Be Considered in the Risk Assessment**

| Element | Class | If Intentionally Added (All Routes) | If Not Intentionally Added | | |
|---|---|---|---|---|---|
| | | | Oral | Parenteral | Inhalation |
| Cadmium | 1 | Yes | Yes | Yes | Yes |
| Lead | 1 | Yes | Yes | Yes | Yes |
| Arsenic | 1 | Yes | Yes | Yes | Yes |
| Mercury | 1 | Yes | Yes | Yes | Yes |

| Tin | 3 | Yes | No | No | Yes |
| Chromium | 3 | Yes | No | No | Yes |

## Options for Demonstrating Compliance

### DRUG PRODUCT ANALYSIS OPTION

The results obtained from the analysis of a typical dosage unit, scaled to a maximum daily dose, are compared with the daily dose PDE.

$$\text{Daily dose PDE} \geq \text{measured value } (\mu g/g) \times \text{maximum daily dose } (g/\text{day})$$

The measured amount of each impurity is NMT the daily dose PDE, unless otherwise stated in the individual monograph.

### SUMMATION OPTION

Separately, add the amounts of each elemental impurity (in µg/g) present in each of the components of the drug product:

$$\text{Daily dose PDE} \geq [\Sigma^{M}{}_{1}(C_M \times W_M)] \times D_D$$

$M$ = each ingredient used to manufacture a dosage unit
$C_M$ = element concentration in component (drug substance or excipient) (µg/g)
$W_M$ = weight of component in a dosage unit (g/dosage unit)
$D_D$ = number of units in the maximum daily dose (unit/day)

The result of the summation of each impurity is NMT the daily dose PDE, unless otherwise stated in the individual monograph. Before products can be evaluated using this option, the manufacturer must ensure that additional elemental impurities cannot be inadvertently added through the manufacturing process or via the container–closure system over the shelf life of the product.

### INDIVIDUAL COMPONENT OPTION

For drug products with a daily dose of NMT 10 g, if all drug substances and excipients in a formulation meet the concentration limits shown in *Table 3*, then these components may be used in any proportion. No further calculation is necessary. Although elemental impurities derived from the manufacturing process or the container–closure system are not specifically provided for in the *Individual Component Option*, it is expected that the drug product manufacturer will ensure that these sources do not contribute significantly to the total content of elemental impurities.

## DRUG SUBSTANCE AND EXCIPIENTS

The acceptable levels of elemental impurities depend on the material's ultimate use. Therefore, manufacturers of pharmaceutical products need certain information about the content of elemental impurities in drug substances or excipients in order to meet the criteria of this chapter. Drug product manufacturers can use elemental impurity test data on components from tests performed by drug substance manufacturers or excipient manufacturers, who may provide test data, or, if applicable, risk assessments. Elemental impurity data generated by a qualified supplier of drug product components are acceptable for use by a drug product manufacturer to demonstrate compliance with this chapter in the final drug product. Drug substance or excipient manufacturers who choose to perform a risk assessment must conduct that risk assessment using *Table 2* in this chapter. Elements that are inherent in the nature of the material, as in the case of some naturally sourced materials, must be considered in the risk assessment.

The values provided in *Table 3* are example concentration limits for components (drug substances and excipients) of drug products dosed at a maximum daily dose of 10 g/day. These values serve as default concentration limits to aid discussions between drug product manufacturers and the suppliers of the components of their drug products. [NOTE—Individual components may need to be limited at levels different from those in the table depending on monograph-specific mitigating factors.]

**Table 3. Permitted Concentrations of Elemental Impurities for Individual Component Option**

| Element | Class | Oral Concentration (µg/g) | Parenteral Concentration (µg/g) | Inhalation Concentration (µg/g) |
|---|---|---|---|---|
| Cadmium | 1 | 0.5 | 0.2 | ▲0.3▲ (USP 1-Dec-2020) |
| Lead | 1 | 0.5 | 0.5 | 0.5 |
| Arsenic | 1 | 1.5 | 1.5 | 0.2 |
| Mercury | 1 | 3 | 0.3 | 0.1 |
| Cobalt | 2A | 5 | 0.5 | 0.3 |
| Vanadium | 2A | 10 | 1 | 0.1 |
| Nickel | 2A | 20 | 2 | 0.5 |
| Thallium | 2B | 0.8 | 0.8 | 0.8 |
| Gold | 2B | 10 | 10 | 0.1 |
| Palladium | 2B | 10 | 1 | 0.1 |
| Iridium | 2B | 10 | 1 | 0.1 |
| Osmium | 2B | 10 | 1 | 0.1 |
| Rhodium | 2B | 10 | 1 | 0.1 |
| Ruthenium | 2B | 10 | 1 | 0.1 |
| Selenium | 2B | 15 | 8 | 13 |
| Silver | 2B | 15 | 1 | 0.7 |
| Platinum | 2B | 10 | 1 | 0.1 |
| Lithium | 3 | 55 | 25 | 2.5 |
| Antimony | 3 | 120 | 9 | 2 |
| Barium | 3 | 140 | 70 | 30 |
| Molybdenum | 3 | 300 | 150 | 1 |
| Copper | 3 | 300 | 30 | 3 |
| Tin | 3 | 600 | 60 | 6 |
| Chromium | 3 | 1100 | 110 | 0.3 |

## ANALYTICAL TESTING

If, by process monitoring and supply-chain control, manufacturers can demonstrate compliance, then further testing may not be needed. When testing is done to demonstrate compliance, proceed as directed in *Elemental Impurities—Procedures* ⟨233⟩.

Official

# ⟨233⟩ ELEMENTAL IMPURITIES—PROCEDURES

## INTRODUCTION

This chapter describes two analytical procedures (*Procedures 1* and *2*) for the evaluation of the levels of the elemental impurities. The chapter also describes criteria for acceptable alternative procedures. By means of validation studies, analysts will confirm that the analytical procedures described herein are suitable for use on specified material.

### Use of Alternative Procedures

The chapter also describes criteria for acceptable alternative procedures. Alternative procedures that meet the validation requirements herein may be used in accordance with *General Notices, 6.30 Alternative and Harmonized Methods and Procedures*. Information on the *Requirements for Alternate Procedure Validation* is provided later in this chapter.

### Speciation

The determination of the oxidation state, organic complex, or combination is termed *speciation*. Analytical procedures for speciation are not included in this chapter, but examples may be found elsewhere in *USP–NF* and in the literature.

## PROCEDURES

- **Compendial Procedures 1 and 2**

System standardization and suitability evaluation using applicable reference materials should be performed on the day of analysis.

**Procedure and detection technique:** *Procedure 1* can be used for elemental impurities generally amenable to detection by inductively coupled plasma–atomic (optical) emission spectroscopy (ICP–AES or ICP–OES). *Procedure 2* can be used for elemental impurities generally amenable to detection by ICP–MS. Before initial use, the analyst should verify that the procedure is appropriate for the instrument and sample used (procedural verification) by meeting the alternative procedure validation requirements below.

**Sample preparation:** Forms of sample preparation include *Neat*, *Direct aqueous solution*, *Direct organic solution*, and *Indirect solution*. The selection of the appropriate sample preparation depends on the material under test and is the responsibility of the analyst. When a sample preparation is not indicated in the monograph, an analyst may use any of the following appropriately validated preparation procedures. In cases where spiking of a material under test is necessary to provide an acceptable signal intensity, the blank should be spiked with the same *Target elements*, and where possible, using the same spiking solution. Standard solutions may contain multiple *Target elements*. [Note—All liquid samples should be weighed.]

**Neat:** Used for liquids or alternative procedures that allow the examination of unsolvated samples.

**Direct aqueous solution:** Used when the sample is soluble in an aqueous solvent.

**Direct organic solution:** Used where the sample is soluble in an organic solvent.

**Indirect solution:** Used when a material is not directly soluble in aqueous or organic solvents. Total metal extraction is the preferred sample preparation approach to obtain an *Indirect solution*. Digest the sample using the *Closed vessel digestion* procedure provided below or one similar to it. The sample preparation scheme should yield sufficient sample to allow quantification of each element at the limit specified in the corresponding monograph or chapter.

**Closed vessel digestion:** This sample preparation procedure is designed for samples that must be digested in a *Concentrated acid* using a closed vessel digestion apparatus. *Closed vessel digestion* minimizes the loss of volatile impurities. The choice of a *Concentrated acid* depends on the sample matrix. The use of any of the *Concentrated acids* may be appropriate, but each introduces inherent safety risks. Therefore, appropriate safety precautions should be used at all times. [Note—Weights and volumes provided may be adjusted to meet the requirements of the digestion apparatus used.]

An example procedure that has been shown to have broad applicability is the following. Dehydrate and predigest 0.5 g of primary sample in 5 mL of freshly prepared *Concentrated acid*. Allow to sit loosely covered for 30 min in a fume hood. Add an additional 10 mL of *Concentrated acid*, and digest, using a closed vessel technique, until digestion or extraction is complete. Repeat, if necessary, by adding an additional 5 mL of *Concentrated acid*. [Note—Where closed vessel digestion is necessary, follow the manufacturer's recommended procedures to ensure safe use.]

Alternatively, leachate extraction may be appropriate with justification following scientifically validated metal disposition studies, which may include animal studies, speciation, or other means of studying disposition of the specific metal in the drug product.

**Reagents:** All reagents used for the preparation of sample and standard solutions should be free of elemental impurities, in accordance with *Plasma Spectrochemistry* ⟨730⟩.

- **Procedure 1: ICP–OES**

**Standardization solution 1:** 1.5*J* of the *Target element(s)* in a *Matched matrix*

**Standardization solution 2:** 0.5*J* of the *Target element(s)* in a *Matched matrix*

**Sample stock solution:** Proceed as directed in *Sample preparation* above. Allow the sample to cool, if necessary. For mercury determination, add an appropriate stabilizer.

**Sample solution:** Dilute the *Sample stock solution* with an appropriate solvent to obtain a final concentration of the *Target elements* at NMT 1.5*J*.

**Blank:** *Matched matrix*

**Elemental spectrometric system**

(See *Plasma Spectrochemistry* ⟨730⟩.)

**Mode:** ICP

**Detector:** Optical detection system

**Rinse:** Diluent used

**Standardization:** *Standardization solution 1*, *Standardization solution 2*, and *Blank*

**System suitability**

**Sample:** *Standardization solution 1*

**Suitability requirements**

**Drift:** Compare results obtained from *Standardization solution 1* before and after the analysis of the *Sample solution*.

**Suitability criteria:** NMT 20% for each *Target element*. [NOTE—If samples are high in mineral content, rinse system well before introducing the *Sample* in order to minimize carryover.]

**Analysis:** Analyze according to the manufacturer's suggestions for program and wavelength. Calculate and report results on the basis of the original sample size. [NOTE—Appropriate measures must be taken to correct for matrix-induced interferences (e.g., wavelength overlaps).]

- **PROCEDURE 2: ICP–MS**

**Standardization solution 1:** 1.5*J* of the *Target element(s)* in a *Matched matrix*

**Standardization solution 2:** 0.5*J* of the *Target element(s)* in a *Matched matrix*

**Sample stock solution:** Proceed as directed for *Sample preparation* above. Allow the sample to cool, if necessary. For mercury determination, add an appropriate stabilizer.

**Sample solution:** Dilute the *Sample stock solution* with an appropriate solvent to obtain a final concentration of the *Target elements* at NMT 1.5*J*.

**Blank:** *Matched matrix*

**Elemental spectrometric system**

(See *Plasma Spectrochemistry* ⟨730⟩.)

**Mode:** ICP. [NOTE—An instrument with a cooled spray chamber is recommended. (A collision cell or reaction cell may also be beneficial.)]

**Detector:** Mass spectrometer

**Rinse:** Diluent used

**Standardization:** *Standardization solution 1*, *Standardization solution 2*, and *Blank*

**System suitability**

**Sample:** *Standardization solution 1*

**Suitability requirements**

**Drift:** Compare results obtained from *Standardization solution 1* before and after the analysis of the *Sample solution*.

**Suitability criteria:** *Drift* NMT 20% for each *Target element*. [NOTE—If samples are high in mineral content, rinse system well before introducing the *Sample* in order to minimize carryover.]

**Analysis:** Analyze according to the manufacturer's suggestions for program and $m/z$. Calculate and report results based on the original sample size. [NOTE—Appropriate measures must be taken to correct for matrix-induced interferences (e.g., argon chloride interference with arsenic determinations).]

## REQUIREMENTS FOR ALTERNATE PROCEDURE VALIDATION

If the specified compendial procedures do not meet the needs of a specific application, an alternative procedure may be developed (see *General Notices, 6.30 Alternative and Harmonized Methods and Procedures*). Alternative procedures must be validated and shown to be acceptable, in accordance with the validation requirements for alternative procedures as described below. The level of validation necessary to ensure that an alternative procedure is acceptable depends on whether a limit test or a quantitative determination is specified in the monograph. The requirements for the validation of an elemental impurities procedure for each type of determination are described below. Any alternative procedure that has been validated and meets the acceptance criteria that follow is considered to be suitable for use.

## LIMIT PROCEDURES

The following section defines the validation parameters for the acceptability of alternative limit procedures. Meeting these requirements must be demonstrated experimentally using an appropriate system suitability procedure and reference material.

The suitability of the method must be determined by conducting studies with the material or mixture under test supplemented with known concentrations of each *Target element* of interest at the appropriate acceptance limit concentration. The material or mixture under test must be spiked before any sample preparation steps are performed.

- **DETECTABILITY**

**Standard solution:** A preparation of reference materials for the *Target element(s)* at the *Target concentration*

**Spiked sample solution 1:** Prepare a solution of sample under test, spiked with appropriate reference materials for the *Target elements* at the *Target concentration*, solubilized or digested as described in *Sample preparation*.

**Spiked sample solution 2:** Prepare a solution of the sample under test, spiked with appropriate reference materials at 80% of the *Target concentration* for the *Target elements*, solubilized or digested as described in *Sample preparation*.

**Unspiked sample solution:** A sample of material under test, solubilized or digested in the same manner as the *Sample solutions*

**Acceptance criteria**

**Non-instrumental procedures:** *Spiked sample solution 1* provides a signal or intensity equivalent to or greater than that of the *Standard solution*. *Spiked sample solution 2* must provide a signal or intensity less than that of *Spiked sample solution 1*. [NOTE—The signal from each *Spiked sample solution* is NLT the *Unspiked sample solution* determination.]

**Instrumental procedures:** The average value of the three replicate measurements of *Spiked sample solution 1* is within ±15% of the average value obtained for the replicate measurements of the *Standard solution*. The average value of the replicate measurements of *Spiked sample solution 2* must provide a signal intensity or value less than that of the *Standard solution*. [NOTE—Correct the values obtained for each of the spiked solutions using the *Unspiked sample solution*.]

- **PRECISION FOR INSTRUMENTAL METHODS (REPEATABILITY)**

[NOTE—Non-instrumental precision is demonstrated by meeting the *Detectability* requirement above.]

**Sample solutions:** Six independent samples of the material under test, spiked with appropriate reference materials for the *Target elements* at the *Target concentration*

**Acceptance criteria**

**Relative standard deviation:** NMT 20% for each *Target element*

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M5193_02_01
@2024 USPC

- **SPECIFICITY**

The procedure must be able to unequivocally assess (see *Validation of Compendial Procedures* ⟨1225⟩) each *Target element* in the presence of components that may be expected to be present, including other *Target elements*, and matrix components.

**QUANTITATIVE PROCEDURES**

The following section defines the validation parameters for the acceptability of alternative quantitative procedures. Meeting these requirements must be demonstrated experimentally, using an appropriate system suitability procedure and reference materials. Meeting these requirements demonstrates that the procedure is equivalent to the compendial procedure for the purpose of quantifying the *Target elements*.

- **ACCURACY**

**Standard solutions:** Prepare solutions containing the *Target elements* at concentrations ranging from 50% to 150% of *J*, using appropriate reference materials.

**Test samples:** Prepare samples of the material under test spiked with appropriate reference materials before any sample preparation steps (digestion or solubilization) at concentrations ranging from 50% to 150% of *J* for each *Target element*.

**Acceptance criteria**

**Spike recovery:** 70%–150% for the mean of three replicate preparations at each concentration

- **PRECISION**

**Repeatability**

**Test samples:** Six independent samples of material under test (taken from the same lot) spiked with appropriate reference materials for the *Target element(s)* at the indicated level

**Acceptance criteria**

**Relative standard deviation:** NMT 20% ($N = 6$) for each *Target element*

**Intermediate precision (ruggedness)**

Perform the *Repeatability* analysis again either on a different day, with a different instrumentation, with a different analyst, or a combination thereof. Combine the results of this analysis with the *Repeatability* analysis so the total number of analyses is 12.

**Acceptance criteria**

**Relative standard deviation:** NMT 25% ($N = 12$) for each *Target element*

- **SPECIFICITY**

The procedure must be able to unequivocally assess (see ⟨1225⟩) each *Target element* in the presence of components that may be expected to be present, including other *Target elements*, and matrix components.

- **LIMIT OF QUANTITATION, RANGE, AND LINEARITY**

Demonstrated by meeting the *Accuracy* requirement.

## GLOSSARY

**Concentrated acid:** Concentrated ultra-pure nitric, sulfuric, hydrochloric, or hydrofluoric acids or *Aqua regia*

**Aqua regia:** *Aqua regia* is a mixture of concentrated hydrochloric and nitric acids, typically at ratios of 3:1 or 4:1, respectively.

**Matched matrix:** Solutions having the same solvent composition as the *Sample solution*. In the case of an aqueous solution, *Matched matrix* would indicate that the same acids, acid concentrations, and mercury stabilizer are used in both preparations.

**Target elements:** Elements with the potential of being present in the material under test. Include arsenic (As), cadmium (Cd), lead (Pb), and mercury (Hg) in the target element evaluation when testing is done to demonstrate compliance. *Target elements* should also include any elements that may be added through material processing or storage.

**Target limit or Target concentration:** The acceptance value for the elemental impurity being evaluated. Exceeding the *Target limit* indicates that a material under test exceeds the acceptable value. The determination of compliance is addressed in other chapters. [NOTE—When applying this chapter to *Elemental Impurities—Limits* ⟨232⟩ and *Elemental Contaminants in Dietary Supplements* ⟨2232⟩, *Target limits* can be approximated by dividing the *Daily Dose PDEs* by the maximum daily dose for the *Drug Product Analysis Option* in ⟨232⟩ or the *Daily Serving PDE* divided by the maximum daily serving size in ⟨2232⟩.]

**J:** The concentration (w/w) of the element(s) of interest at the *Target limit*, appropriately diluted to the working range of the instrument. For example, if the target elements are lead and arsenic for an analysis of an oral solid drug product with a daily dose of 10 g/day using inductively coupled plasma–mass spectrometry (ICP–MS), the target limit for these elements would be 0.5 µg/g and 1.5 µg/g (see *Table 2* in ⟨232⟩). However, in this case, the linear dynamic range of the ICP–MS is known to extend from 0.01 ng/mL to 0.1 µg/mL for these elements. Therefore, a dilution factor of at least 1:100 is required to ensure that the analysis occurs in the linear dynamic range of the instrument. *J* would thus equal 5 ng and 15 ng/mL for lead and arsenic, respectively, when the dilution factor is added.

**Appropriate reference materials:** Where *Appropriate reference materials* are specified in the chapter, certified reference materials (CRM) from a national metrology institute (NMI), or reference materials that are traceable to the CRM of an NMI should be used. An example of an NMI in the United States is the National Institute of Standards and Technology.

# ⟨241⟩ IRON

***Add the following:***

## ▲INTRODUCTION

This chapter describes three analytical procedures for the evaluation of the levels of iron (Fe). Use *Procedure 1*, *Procedure 2*, or *Procedure 3* as indicated in the individual monograph. *Procedure 2* or *Procedure 3* can be used in all circumstances, provided that suitability is demonstrated by meeting the *Requirements for Procedure Validation*.▲ (Official 1-Jun-2023)

***Change to read:***

## ▲PROCEDURES

**• PROCEDURE 1: CHEMICAL METHOD**▲ (Official 1-Jun-2023)

This limit test is provided to demonstrate that the content of iron, in either the ferric or the ferrous form, does not exceed the limit for iron specified in the individual monograph. The determination is made by concomitant visual comparison with a control prepared from a standard iron solution.

**Standard iron solution:** Dissolve 863.4 mg of ferric ammonium sulfate [$FeNH_4(SO_4)_2 \cdot 12H_2O$] in water, add 10 mL of 2 N sulfuric acid, and dilute with water to 100.0 mL. Pipet 10 mL of this solution into a 1000-mL volumetric flask, add 10 mL of 2 N sulfuric acid, dilute with water to volume, and mix. Each milliliter of *Standard iron solution* contains the equivalent of 0.01 mg (10 µg) of iron.

**Ammonium thiocyanate solution:** Dissolve 30 g of ammonium thiocyanate in water to make 100 mL.

**Standard preparation:** Into a 50-mL color-comparison tube pipet 1 mL of *Standard iron solution* (10 µg of iron), dilute with water to 45 mL, add 2 mL of hydrochloric acid, and mix.

**Test preparation:** Into a 50-mL color comparison tube place the solution prepared for the test as directed in the individual monograph, and, if necessary, dilute with water to 45 mL; or, dissolve in water and dilute with water to 45 mL the quantity, in grams, of the substance to be tested, calculated as follows:

$$\text{Result} = 1.0/(1000L)$$

$L$ = limit of iron (%)

Add 2 mL of hydrochloric acid, and mix.

**▲Analysis:**▲ (Official 1-Jun-2023) To each of the tubes containing the *Standard preparation* and the *Test preparation* add 50 mg of ammonium peroxydisulfate crystals and 3 mL of *Ammonium thiocyanate solution*, and mix. The color of the solution from the *Test preparation* is not darker than that of the solution from the *Standard preparation.*

**▲• PROCEDURE 2 AND PROCEDURE 3**

Both *Procedure 2* and *Procedure 3* are ICP-based procedures and can be used for the determination of iron. *Procedure 2* can be used for the determination of iron by inductively coupled plasma atomic (or optical) emission spectroscopy (ICP–AES or ICP–OES). *Procedure 3* can be used for the determination of iron by ICP–MS.

Before initial use, the analyst should verify that the procedure is appropriate for the instrument and sample used (procedural verification) by meeting the *Requirements for Procedure Validation*.

Where a monograph specifies a limit for iron concentration, the value listed in the monograph should be used as the *J* value for the purposes of this test.

System standardization and suitability evaluation using applicable reference materials should be performed on the day of analysis.

**Sample preparation:** Forms of sample preparation include neat, direct aqueous solution, direct organic solution, and indirect solution. The selection of the appropriate sample preparation depends on the material under test and is the responsibility of the analyst. When a sample preparation is not indicated in the monograph, an analyst may use any appropriately validated preparation procedure. In cases where spiking of a material under test is necessary to provide an acceptable signal intensity, the blank should be spiked with iron using, where possible, the same spiking solution. [NOTE—All liquid samples should be weighed.]

**Closed vessel digestion:** This sample preparation procedure is designed for samples that must be digested in a concentrated acid using a closed vessel digestion apparatus. Closed vessel digestion minimizes the loss of volatile impurities. The choice of a concentrated acid depends on the sample matrix. The use of any of the concentrated acids may be appropriate, but each introduces inherent safety risks. Therefore, appropriate safety precautions should be used at all times. [NOTE—Weights and volumes provided may be adjusted to meet the requirements of the digestion apparatus used.]

An example procedure that has been shown to have broad applicability is as follows. Dehydrate and predigest 0.5 g of the primary sample in 5 mL of freshly prepared concentrated acid. Allow to sit loosely covered for 30 min in a fume hood. Add an additional 10 mL of concentrated acid, and digest using a closed vessel technique until the digestion or extraction is complete. Repeat, if necessary, by adding an additional 5 mL of concentrated acid. [NOTE—Follow the manufacturer's recommended procedures to ensure safe use.]

**Reagents:** All reagents used for the preparation of sample and standard solutions should be free of elemental impurities, in accordance with *Plasma Spectrochemistry* ⟨730⟩.

**Procedure 2: ICP–OES**

**Standardization solution 1:** 1.5*J* of iron in a matched matrix

**Standardization solution 2:** 0.5*J* of iron in a matched matrix

**Sample stock solution:** Prepare as directed in *Sample preparation*. Allow the sample to cool, if necessary.

**Sample solution:** Dilute the *Sample stock solution* with an appropriate solvent to obtain a final concentration of iron of not more than 1.5*J*.
**Blank:** Matched matrix
**Elemental spectrometric system**
(See ⟨730⟩.)
**Mode:** ICP
**Detector:** Optical detection system
**Rinse:** Use diluent.
**Standardization:** *Standardization solution 1*, *Standardization solution 2*, and *Blank*
**System suitability**
**Sample:** *Standardization solution 1*
**Suitability requirements**
**Drift:** Compare results obtained from *Standardization solution 1* before and after the analysis of the *Sample solution*.
**Suitability criteria:** Not more than 20% for iron. [NOTE—If samples are high in mineral content, rinse the system well before introducing the *Sample* in order to minimize carryover.]
**Analysis:** Analyze according to the manufacturer's suggestions for program and wavelength. Calculate and report results on the basis of the original sample size. [NOTE—Appropriate measures must be taken to correct for matrix-induced interferences (e.g., wavelength overlaps).]
**Procedure 3: ICP–MS**
Follow *Procedure 2* except for *Detector* and *Analysis*.
[NOTE—An instrument with a cooled spray chamber is recommended. (A collision cell or reaction cell may also be beneficial.)]
**Mode:** ICP
**Detector:** Mass spectrometer
**Analysis:** Analyze according to the manufacturer's suggestions for program and mass-to-charge ratio. Calculate and report results based on the original sample size. [NOTE—Appropriate measures must be taken to correct for matrix-induced interferences.]▲ (Official 1-Jun-2023)

***Add the following:***

## ▲REQUIREMENTS FOR PROCEDURE VALIDATION

The following section defines the validation parameters and the acceptance criteria for performance-based procedures. Meeting these requirements must be demonstrated experimentally using an appropriate system suitability procedure and reference materials. Any alternative procedure (e.g., an atomic-absorption-based procedure) that has been validated and meets the acceptance criteria that follow is considered to be suitable for use.

Meeting these validation acceptance criteria is sufficient to demonstrate that the procedure will produce comparable results to those obtained using the procedure prescribed in the monograph.

- **ACCURACY**
  **Standard solutions:** Prepare solutions containing iron at concentrations ranging from 50% to 150% of *J* using appropriate reference materials.
  **Test samples:** Spike the material under test with the appropriate reference materials before any sample preparation steps (digestion or solubilization). Prepare three replicate samples at concentrations ranging from 50% to 150% of *J* for iron.
  **Acceptance criteria**
  **Spike recovery:** 70%–150% for the mean of three replicate preparations at each concentration
- **PRECISION**
  **Repeatability**
  **Test samples:** Six independent samples of material under test (taken from the same lot) spiked with appropriate reference materials for iron at the indicated concentration
  **Acceptance criteria**
  **Relative standard deviation:** Not more than 20% ($N = 6$) for iron
  **Intermediate precision (ruggedness)**
  **Analysis:** Perform the *Repeatability* analysis again on a different day, with different instrumentation, with a different analyst, or a combination thereof. Combine the results of this analysis with the *Repeatability* analysis so the total number of analyses is 12.
  **Acceptance criteria**
  **Relative standard deviation:** Not more than 25% ($N = 12$) for iron
- **SPECIFICITY:** The procedure must be able to unequivocally assess (see *Validation of Compendial Procedures* ⟨1225⟩) iron in the presence of components that may be expected to be present, including matrix components.
- **LIMIT OF QUANTITATION, RANGE, AND LINEARITY:** Demonstrated by meeting the *Accuracy* requirement.▲ (Official 1-Jun-2023)

***Add the following:***

## ▲GLOSSARY

**Concentrated acid:** Concentrated ultra-pure nitric, sulfuric, hydrochloric, or hydrofluoric acid or aqua regia.
**Aqua regia:** Aqua regia is a mixture of concentrated hydrochloric and nitric acids, typically at ratios of 3:1 or 4:1.
**Matched matrix:** Solutions having the same solvent composition as the *Sample solution*. In the case of an aqueous solution, a matched matrix would indicate that the same acids and acid concentrations are used in both preparations.

# ⟨251⟩ LEAD

***Change to read:***

**▲INTRODUCTION▲** (Official 1-Jun-2023)

The imposition of stringent limits on the amounts of lead (Pb) that may be present in pharmaceutical products has resulted in the use of ▲three▲ (Official 1-Jun-2023) methods, of which ▲*Procedure 1*,▲ (Official 1-Jun-2023) set forth in this chapter, depends upon extraction of lead by solutions of dithizone.

▲Use *Procedure 1*, *Procedure 2*, or *Procedure 3* as indicated in the individual monograph. *Procedure 2* or *Procedure 3* can be used in all circumstances, provided that suitability is demonstrated by meeting the requirements in *Requirements for Procedure Validation*.▲ (Official 1-Jun-2023)

***Change to read:***

**▲PROCEDURES**

• **PROCEDURE 1: CHEMICAL METHOD▲** (Official 1-Jun-2023)

Select all reagents for this test to have as low a content of lead as practicable, and store all reagent solutions in containers of borosilicate glass. Thoroughly rinse all glassware with warm dilute nitric acid (1 in 2), followed by water.

**Ammonium cyanide solution:** Dissolve 2 g of potassium cyanide in 15 mL of ammonium hydroxide, and dilute with water to 100 mL.

**Dithizone extraction solution:** Dissolve 30 mg of dithizone in 1000 mL of chloroform, and add 5 mL of alcohol. Store the solution in a refrigerator. Before use, shake a suitable volume of the *Dithizone extraction solution* with about half its volume of dilute nitric acid (1 in 100), discarding the nitric acid.

**Ammonium citrate solution:** Dissolve 40 g of citric acid in 90 mL of water. Add 2 or 3 drops of phenol red TS, then cautiously add ammonium hydroxide until the solution acquires a reddish color. Remove any lead that may be present by extracting the solution with 20-mL portions of *Dithizone extraction solution*, until the dithizone solution retains its orange–green color.

**Diluted standard lead solution:** Dilute an accurately measured volume of standard lead solution TS (containing 10 µg of lead per milliliter), with 9 volumes of dilute nitric acid (1 in 100) to obtain a solution that contains 1 µg of lead per milliliter.

**Hydroxylamine hydrochloride solution:** Dissolve 20 g of hydroxylamine hydrochloride in sufficient water to make approximately 65 mL. Transfer to a separator, add 5 drops of thymol blue TS, then add ammonium hydroxide until the solution assumes a yellow color. Add 10 mL of sodium diethyldithiocarbamate solution (1 in 25), mix, and allow to stand for 5 min. Extract this solution with successive 10- to 15-mL portions of chloroform until a 5-mL portion of the chloroform extract does not assume a yellow color when shaken with cupric sulfate TS. Add 3 N hydrochloric acid until the solution is pink (if necessary, add 1 or 2 drops more of thymol blue TS), then dilute with water to 100 mL.

**Potassium cyanide solution:** Dissolve 50 g of potassium cyanide in sufficient water to make 100 mL. Remove the lead from this solution by extraction with successive portions of *Dithizone extraction solution*, as described in *Ammonium citrate solution*, then extract any dithizone remaining in the cyanide solution by shaking with chloroform. Finally, dilute the cyanide solution with sufficient water so that each 100 mL contains 10 g of potassium cyanide.

**Standard dithizone solution:** Dissolve 10 mg of dithizone in 1000 mL of chloroform. Keep the solution in a glass-stoppered, lead-free bottle, suitably wrapped to protect it from light, and store in a refrigerator.

**Test preparation:** [NOTE—If, in the following preparation, the substance under test reacts too rapidly and begins charring with 5 mL of sulfuric acid before heating, instead use 10 mL of cooled dilute sulfuric acid (1 in 2), and add a few drops of hydrogen peroxide before heating.] Where the monograph does not specify preparation of a solution, prepare a *Test preparation* as follows.

[**CAUTION**—Exercise safety precautions in this procedure, because some substances may react with explosive violence when digested with hydrogen peroxide.]

Transfer 1.0 g of the substance under test to a suitable flask, add 5 mL of sulfuric acid and a few glass beads, and digest on a hot plate in a hood until charring begins. Other suitable means of heating may be substituted. (Add additional sulfuric acid, if necessary, to wet the substance completely, but do not add more than a total of 10 mL.) Add, dropwise and with caution, 30 percent hydrogen peroxide, allowing the reaction to subside and heat between drops. Add the first few drops very slowly, mix carefully to prevent a rapid reaction, and discontinue heating if foaming becomes excessive. Swirl the solution in the flask to prevent unreacted substance from caking on the walls of the flask. [NOTE—Add peroxide whenever the mixture turns brown or darkens.]

Continue the digestion until the substance is completely destroyed, copious fumes of sulfur trioxide are evolved, and the solution is colorless. Cool, and cautiously add 10 mL of water. Evaporate until sulfur trioxide again is evolved, and cool. Repeat this procedure with another 10 mL of water to remove any traces of hydrogen peroxide. Cautiously dilute with 10 mL of water, and cool.

**Analysis:** Transfer the *Test preparation*, rinsing with 10 mL of water, or the volume of the prepared sample specified in the monograph to a separator, and, unless otherwise directed in the monograph, add 6 mL of *Ammonium citrate solution* and 2 mL of *Hydroxylamine hydrochloride solution*. (For the determination of lead in iron salts, use 10 mL of *Ammonium citrate solution*.) Add 2 drops of phenol red TS, and make the solution just alkaline (red in color) by the addition of ammonium hydroxide. Cool the solution if necessary, and add 2 mL of *Potassium cyanide solution*. Immediately extract the solution with 5-mL portions of *Dithizone extraction solution*, draining off each extract into another separator, until the dithizone solution retains its green color. Shake the combined dithizone solutions for 30 s with 20 mL of dilute nitric acid (1 in 100), and discard the chloroform layer. Add to the acid solution 5.0 mL of *Standard dithizone solution* and 4 mL of ▲*Ammonium*▲ (ERR 1-Jun-2023) *cyanide solution*, and shake for 30 s.

Official

https://pharmacopeia.cn/

**Acceptance criteria:** The color of the chloroform layer is of no deeper shade of violet than that of a control made with a volume of *Diluted standard lead solution* equivalent to the amount of lead permitted in the sample under examination and made with the same quantities of the same reagents and in the same manner as in the test with the sample.

▲• **PROCEDURE 2 AND PROCEDURE 3**

Both *Procedure 2* and *Procedure 3* are ICP-based procedures and can be used for the determination of lead. *Procedure 2* can be used for the determination of lead by inductively coupled plasma atomic (or optical) emission spectroscopy (ICP–AES or ICP–OES). *Procedure 3* can be used for the determination of lead by ICP–MS.

Before initial use, the analyst should verify that the procedure is appropriate for the instrument and sample used (procedural verification) by meeting the *Requirements for Procedure Validation*.

Where a monograph specifies a limit for lead concentration, the value listed in the monograph should be used as the *J* value for the purposes of this test.

System standardization and suitability evaluation using applicable reference materials should be performed on the day of analysis.

**Sample preparation:** Forms of sample preparation include neat, direct aqueous solution, direct organic solution, and indirect solution. The selection of the appropriate sample preparation depends on the material under test and is the responsibility of the analyst. When a sample preparation is not indicated in the monograph, an analyst may use any appropriately validated preparation procedure. In cases where spiking of a material under test is necessary to provide an acceptable signal intensity, the blank should be spiked with lead using, where possible, the same spiking solution. [NOTE—All liquid samples should be weighed.]

**Closed vessel digestion:** This sample preparation procedure is designed for samples that must be digested in a concentrated acid using a closed vessel digestion apparatus. Closed vessel digestion minimizes the loss of volatile impurities. The choice of a concentrated acid depends on the sample matrix. The use of any of the concentrated acids may be appropriate, but each introduces inherent safety risks. Therefore, appropriate safety precautions should be used at all times. [NOTE—Weights and volumes provided may be adjusted to meet the requirements of the digestion apparatus used.]

An example procedure that has been shown to have broad applicability is as follows. Dehydrate and predigest 0.5 g of the primary sample in 5 mL of freshly prepared concentrated acid. Allow to sit loosely covered for 30 min in a fume hood. Add an additional 10 mL of concentrated acid, and digest using a closed vessel technique until the digestion or extraction is complete. Repeat, if necessary, by adding an additional 5 mL of concentrated acid. [NOTE—Follow the manufacturer's recommended procedures to ensure safe use.]

**Reagents:** All reagents used for the preparation of sample and standard solutions should be free of elemental impurities, in accordance with *Plasma Spectrochemistry* ⟨730⟩.

**Procedure 2: ICP–OES**

**Standardization solution 1:** 1.5*J* of lead in a matched matrix

**Standardization solution 2:** 0.5*J* of lead in a matched matrix

**Sample stock solution:** Prepare as directed in *Sample preparation*.

**Sample solution:** Dilute the *Sample stock solution* with an appropriate solvent to obtain a final lead concentration of not more than 1.5*J*.

**Blank:** Matched matrix

**Elemental spectrometric system**

(See ⟨730⟩.)

**Rinse:** Use diluent.

**Standardization:** *Standardization solution 1*, *Standardization solution 2*, and *Blank*

**System suitability**

**Sample:** *Standardization solution 1*

**Suitability requirements**

**Drift:** Compare results obtained from *Standardization solution 1* before and after the analysis of the *Sample solution*.

**Suitability criteria:** Not more than 20% for lead. [NOTE—If samples are high in mineral content, rinse the system well before introducing the *Sample* in order to minimize carryover.]

**Analysis:** Analyze according to the manufacturer's suggestions for program and wavelength. Calculate and report results on the basis of the original sample size. [NOTE—Appropriate measures must be taken to correct for matrix-induced interferences (e.g., wavelength overlaps).]

**Procedure 3: ICP–MS**

Follow *Procedure 2* except for *Detector* and *Analysis*.

[NOTE—An instrument with a cooled spray chamber is recommended. (A collision cell or reaction cell may also be beneficial.)]

**Detector:** Mass spectrometer

**Analysis:** Analyze according to the manufacturer's suggestions for program and mass-to-charge ratio. Calculate and report results based on the original sample size. [NOTE—Appropriate measures must be taken to correct for matrix-induced interferences.]▲ (Official 1-Jun-2023)

# ⟨261⟩ MERCURY

***Add the following:***

## ▲INTRODUCTION

This chapter describes five analytical procedures for the evaluation of the levels of mercury (Hg). Use *Procedure 1*, *Procedure 2*, *Procedure 3*, *Procedure 4*, or *Procedure 5* as indicated in the individual monograph. *Procedure 4* or *Procedure 5* can be used in all circumstances, provided that suitability is demonstrated by meeting the *Requirements for Procedure Validation*.▲ (Official 1-Jun-2023)

***Change to read:***

## ▲PROCEDURES

• **PROCEDURE 1: TITRATION**▲ (Official 1-Jun-2023)

[NOTE—Mercuric dithizonate is light sensitive. Perform this test in subdued light.]

**Dithizone stock solution:** Dissolve 40 mg of dithizone in 1000 mL of chloroform.

**Dithizone titrant:** Dilute 30.0 mL of *Dithizone stock solution* with chloroform to 100.0 mL. This solution contains approximately 12 mg of dithizone per liter.

**Mercury stock solution:** Transfer 135.4 mg of mercuric chloride to a 100-mL volumetric flask, and dilute with 1 N sulfuric acid to volume. This solution contains the equivalent of 100 mg of mercury in 100 mL.

**Mercury solution for standardizing dithizone titrant:** Transfer 2.0 mL of *Mercury stock solution* to a 100-mL volumetric flask, and dilute with 1 N sulfuric acid to volume. Each milliliter of this solution contains the equivalent of 20 µg of mercury.

The following solutions are called for in the limit test for mercury that is specified in the monographs for *Ferrous Fumarate*, *Ferrous Sulfate*, and *Dried Ferrous Sulfate*:

**Hydroxylamine hydrochloride solution:** ▲Dissolve 20 g of hydroxylamine hydrochloride in sufficient water to make approximately 65 mL. Transfer to a separator, add 5 drops of thymol blue TS, then add ammonium hydroxide until the solution assumes a yellow color. Add 10 mL of sodium diethyldithiocarbamate solution (1 in 25), mix, and allow to stand for 5 min. Extract this solution with successive 10- to 15-mL portions of chloroform until a 5-mL portion of the chloroform extract does not assume a yellow color when shaken with cupric sulfate TS. Add 3 N hydrochloric acid until the solution is pink (if necessary, add 1 or 2 drops more of thymol blue TS), then dilute with water to 100 mL.▲ (Official 1-Jun-2023)

**Standard mercury solution:** On the day of use, quantitatively dilute 1.0 mL of *Mercury stock solution* with 1 N sulfuric acid to 1000 mL. Each milliliter of the resulting solution contains the equivalent of 1 µg of mercury.

**Dithizone extraction solution:** ▲Dissolve 30 mg of dithizone in 1000 mL of chloroform, and add 5 mL of alcohol. Store the solution in a refrigerator. Before use, shake a suitable volume of the *Dithizone extraction solution* with about half its volume of dilute nitric acid (1 in 100), discarding the nitric acid.▲ (Official 1-Jun-2023)

**Diluted dithizone extraction solution:** Just prior to use, dilute 5 mL of *Dithizone extraction solution* with 25 mL of chloroform.

**Standardization of dithizone titrant:** Transfer 1.0 mL of *Mercury solution for standardizing dithizone titrant* to a 250-mL separator, and add 100 mL of 1 N sulfuric acid, 90 mL of water, 1 mL of glacial acetic acid, and 10 mL of hydroxylamine hydrochloride solution (1 in 5). Titrate the solution with *Dithizone titrant* from a 10-mL microburet, shaking the mixture 20 times after each addition and allowing the chloroform layer to separate, then discarding the chloroform layer. Continue until a final addition of *Dithizone titrant* is green in color after shaking. Calculate the quantity, in micrograms, of mercury equivalent to each milliliter of *Dithizone titrant*:

$$\text{Result} = 20/V$$

$V$ = volume of *Dithizone titrant* added (mL)

**Test preparation:** Transfer about 2 g of the substance under test, accurately weighed, to a glass-stoppered, 250-mL conical flask, add 20 mL of a mixture of equal volumes of nitric acid and sulfuric acid, attach a suitable condenser, reflux the mixture for 1 h, cool, cautiously dilute with water, and boil until fumes of nitrous acid are no longer noticeable. Cool the solution, cautiously dilute with water, transfer to a 200-mL volumetric flask, dilute with water to volume, mix, and filter.

**▲Analysis:**▲ (Official 1-Jun-2023) Transfer 50.0 mL of *Test preparation* to a 250-mL separator, and extract with successive small portions of chloroform until the last chloroform extract remains colorless. Discard the chloroform extract, and add to the extracted *Test preparation* 50 mL of 1 N sulfuric acid, 90 mL of water, 1 mL of glacial acetic acid, and 10 mL of hydroxylamine hydrochloride solution (1 in 5). Proceed as directed in *Standardization of dithizone titrant*, beginning with "Titrate the solution". Calculate the amount of mercury.

• **▲PROCEDURE 2 AND PROCEDURE 3**▲ (Official 1-Jun-2023)

[NOTE—Wash all glassware associated with the test with nitric acid, and rinse thoroughly with water before use.]

**Mercury detection instrument:** Use any suitable atomic absorption spectrophotometer equipped with a fast-response recorder and capable of measuring the radiation absorbed by mercury vapors at the mercury resonance line of 253.6 nm.

**Aeration apparatus:** The apparatus (see *Figure 1*) consists of a flow meter capable of measuring flow rates from 500–1000 mL/min, connected via a three-way stopcock fitted with a polytef plug to an aeration vessel (250-mL gas washing bottle), followed by a trap, a drying tube packed with magnesium perchlorate, a 10-cm × 25-mm flow-through cell with quartz windows, and terminating with a vent to a fume hood.

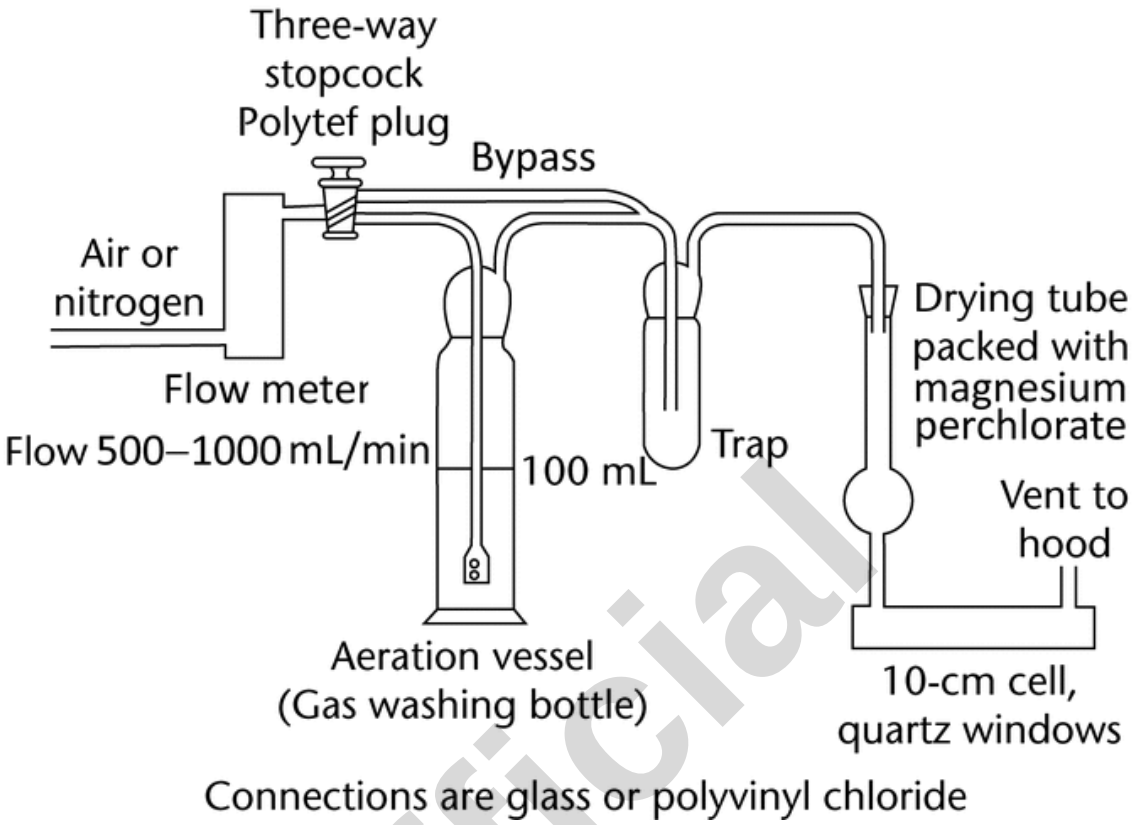

Figure 1. Mercury aeration apparatus.

**Potassium permanganate solution:** Dissolve 5 g of potassium permanganate in 100 mL of water.
**Hydroxylamine hydrochloride solution:** Dissolve 10 g of hydroxylamine hydrochloride in 100 mL of water.
**Stannous chloride solution:** Dissolve 10 g of stannous chloride dihydrate ($SnCl_2 \cdot 2H_2O$) in 20 mL of warm hydrochloric acid, and add 80 mL of water. Prepare fresh each week.
**Standard mercury solution:** Prepare from *Mercury stock solution* as directed under ▲Procedure 1.▲ (Official 1-Jun-2023) Each milliliter of the *Standard mercury solution* contains the equivalent of 1 µg of mercury.
**Test ▲sample▲** (Official 1-Jun-2023)**:** Unless otherwise directed in the individual monograph, use the quantity, in grams, of the test substance calculated as follows:

$$\text{Result} = 2.0/L$$

$L$ = limit of mercury (ppm)

**▲Procedure 2: Atomic Absorption Spectroscopy▲** (Official 1-Jun-2023)

**Standard preparation:** Pipet 2.0 mL of *Standard mercury solution* into a 100-mL beaker, and add 35 mL of water, 3 mL of sulfuric acid, and 1 mL of potassium permanganate solution. Cover the beaker with a watch glass, boil for a few seconds, and cool.

**Test preparation:** Transfer the calculated amount of the test substance to a 100-mL beaker, and add 35 mL of water. Stir, and warm to assist solution, if necessary. Add 2 drops of phenolphthalein TS, and, as necessary, slowly neutralize with constant stirring, using 1 N sodium hydroxide or 1 N sulfuric acid. Add 3 mL of sulfuric acid and 1 mL of *Potassium permanganate solution*. Cover the beaker with a watch glass, boil for a few seconds, and cool.

**▲Analysis:▲** (Official 1-Jun-2023) Assemble the aeration apparatus (see *Figure 1*), with the aeration vessel and the trap empty, and the stopcock in the bypass position. Connect the apparatus to the absorption cell, and adjust the air or nitrogen flow rate so that, in the following procedure, maximum absorption and reproducibility are obtained without excessive foaming in the test solution. Obtain a smooth baseline reading at 253.6 nm, following the manufacturer's instructions for operating the instrument.

Treat the *Standard preparation* and the *Test preparation* similarly, as follows. Destroy the excess permanganate by adding *Hydroxylamine hydrochloride solution*, dropwise, until the solution is colorless. Immediately wash the solution into the aeration vessel with water, and dilute with water to 100 mL. Add 2 mL of *Stannous chloride solution*, and immediately reconnect the aeration vessel to the aeration apparatus. Turn the stopcock from the bypass position to the aerating position, and continue the aeration until the absorption peak has been passed and the recorder pen returns to the baseline. Disconnect the aeration vessel from the apparatus, and wash with water after each use. After correcting for any reagent blank, any absorbance produced by the *Test preparation* does not exceed that produced by the *Standard preparation*.

Official

https://pharmacopeia.com/

▲**Procedure 3: Atomic Absorption Spectroscopy**▲ (Official 1-Jun-2023)

[**CAUTION**—Some substances may react with explosive violence when digested with hydrogen peroxide. Exercise safety precautions at all times.]

**Standard preparation:** Pipet 2.0 mL of *Standard mercury solution* into a 125-mL conical flask, add 3 mL each of nitric acid and sulfuric acid, mix, and add an amount of 30 percent hydrogen peroxide equal to the total amount used in preparing the *Test preparation*. Attach a suitable water-cooled condenser with a standard-taper joint to fit the flask, and reflux the mixture in a fume hood for 1 h. Turn off the water circulating through the condenser, and heat until white fumes appear in the flask. Cool, and cautiously add 10 mL of water through the condenser, while swirling the flask. Again heat until white fumes appear, cool, and add an additional 15 mL of water. Remove the condenser, and rinse the sides of the flask to obtain a volume of 35 mL. Add 1 mL of *Potassium permanganate solution*, boil for a few seconds, and cool.

**Test preparation:** Transfer the calculated amount of the test substance to a 125-mL conical flask. Add 5 mL each of nitric acid and sulfuric acid and a few glass beads. Attach a suitable water-cooled condenser with a standard-taper joint to fit the flask, and digest in a fume hood, preferably on a hot plate, and at a temperature not exceeding 120°, until charring begins. (If additional sulfuric acid is necessary to wet the specimen completely, add it carefully through the condenser, but do not allow the total volume added to exceed 10 mL.) After the test substance has been decomposed by the acid, cautiously add, dropwise through the condenser, 30 percent hydrogen peroxide, allowing the reaction to subside and again heating between drops (add the first few drops very slowly with sufficient mixing, in order to prevent a rapid reaction; discontinue heating if foaming becomes excessive). When the reaction has abated, heat cautiously, rotating the flask occasionally to prevent the specimen from caking on glass exposed to the heating unit. Maintain oxidizing conditions at all times during the digestion by adding small quantities of the hydrogen peroxide solution whenever the mixture turns brown or darkens. Continue the digestion until the organic matter is destroyed, and then reflux the mixture for 1 h. Turn off the water circulating through the condenser, and heat until fumes of sulfur trioxide are copiously evolved and the solution becomes colorless or retains only a light straw color. Cool, and cautiously add 10 mL of water through the condenser, while swirling the flask. Again heat until white fumes appear. Cool, and cautiously add 15 mL of water. Remove the condenser, and rinse the sides of the flask with a few milliliters of water to obtain a volume of 35 mL. Add 1 mL of *Potassium permanganate solution*, boil for a few seconds, and cool.

▲**Analysis:**▲ (Official 1-Jun-2023) Proceed as directed for *Analysis* under ▲*Procedure 2*.

- **PROCEDURE 4 AND PROCEDURE 5**

Both *Procedures 4* and *Procedure 5* are ICP-based procedures and can be used for the determination of mercury. *Procedure 4* can be used for the determination of mercury by inductively coupled plasma atomic (or optical) emission spectroscopy (ICP–AES or ICP–OES). *Procedure 5* can be used for the determination of mercury by ICP–MS.

Before initial use, the analyst should verify that the procedure is appropriate for the instrument and sample used (procedural verification) by meeting the *Requirements for Procedure Validation*.

Where a monograph specifies a limit for mercury concentration, the value listed in the monograph should be used as the *J* value for the purposes of this test.

System standardization and suitability evaluation using applicable reference materials should be performed on the day of analysis.

**Sample preparation:** Forms of sample preparation include neat, direct aqueous solution, direct organic solution, and indirect solution. The selection of the appropriate sample preparation depends on the material under test and is the responsibility of the analyst. When a sample preparation is not indicated in the monograph, an analyst may use any appropriately validated preparation procedure. In cases where spiking of a material under test is necessary to provide an acceptable signal intensity, the blank should be spiked with mercury using, where possible, the same spiking solution. [NOTE—All liquid samples should be weighed.]

**Closed vessel digestion:** This sample preparation procedure is designed for samples that must be digested in a concentrated acid using a closed vessel digestion apparatus. Closed vessel digestion minimizes the loss of volatile impurities. The choice of a concentrated acid depends on the sample matrix. The use of any of the concentrated acids may be appropriate, but each introduces inherent safety risks. Therefore, appropriate safety precautions should be used at all times. [NOTE—Weights and volumes provided may be adjusted to meet the requirements of the digestion apparatus used.]

An example procedure that has been shown to have broad applicability is as follows. Dehydrate and predigest 0.5 g of primary sample in 5 mL of freshly prepared concentrated acid. Allow to sit loosely covered for 30 min in a fume hood. Add an additional 10 mL of concentrated acid, and digest, using a closed vessel technique, until digestion or extraction is complete. Repeat, if necessary, by adding an additional 5 mL of concentrated acid. [NOTE—Follow the manufacturer's recommended procedures to ensure safe use.]

**Reagents:** All reagents used for the preparation of sample and standard solutions should be free of elemental impurities, in accordance with *Plasma Spectrochemistry* ⟨730⟩.

**Procedure 4: ICP–OES**

**Standardization solution 1:** 1.5*J* of mercury in a matched matrix

**Standardization solution 2:** 0.5*J* of mercury in a matched matrix

**Sample stock solution:** Prepare as directed in *Sample preparation*. Allow the sample to cool, if necessary. For mercury determination, add an appropriate stabilizer.

**Sample solution:** Dilute the *Sample stock solution* with an appropriate solvent to obtain a final concentration of mercury at not more than 1.5*J*.

**Blank:** Matched matrix

**Elemental spectrometric system**

(See ⟨730⟩.)

**Rinse:** Use diluent.

**Standardization:** *Standardization solution 1*, *Standardization solution 2*, and *Blank*

https://nhathuocngocanh.com/

**System suitability**
**Sample:** *Standardization solution 1*
**Suitability requirements**
**Drift:** Compare results obtained from *Standardization solution 1* before and after the analysis of the *Sample solution*.
**Suitability criteria:** Not more than 20% for mercury. [NOTE—If samples are high in mineral content, rinse the system well before introducing the *Sample* in order to minimize carryover.]
**Analysis:** Analyze according to the manufacturer's suggestions for program and wavelength. Calculate and report results on the basis of the original sample size. [NOTE—Appropriate measures must be taken to correct for matrix-induced interferences (e.g., wavelength overlaps).]

**Procedure 5: ICP–MS**
Follow *Procedure 4* except for *Detector* and *Analysis*.
[NOTE—An instrument with a cooled spray chamber is recommended. (A collision cell or reaction cell may also be beneficial.)]
**Detector:** Mass spectrometer
**Analysis:** Analyze according to the manufacturer's suggestions for program and mass-to-charge ratio. Calculate and report results based on the original sample size. [NOTE—Appropriate measures must be taken to correct for matrix-induced interferences.]▲ (Official 1-Jun-2023)

***Add the following:***

**▲REQUIREMENTS FOR PROCEDURE VALIDATION**

The following section defines the validation parameters and the acceptance criteria for performance-based procedures. Meeting these requirements must be demonstrated experimentally using an appropriate system suitability procedure and reference materials. Any alternative procedure (e.g., an atomic-absorption-based procedure) that has been validated and meets the acceptance criteria that follow is considered to be suitable for use.

Meeting these validation acceptance criteria is sufficient to demonstrate that the procedure will produce comparable results to those obtained using the procedure prescribed in the monograph.

- **ACCURACY**
  **Standard solutions:** Prepare solutions containing mercury at concentrations ranging from 50% to 150% of *J* using appropriate reference materials.
  **Test samples:** Spike the material under test with the appropriate reference materials before any sample preparation steps (digestion or solubilization). Prepare three replicate samples at concentrations ranging from 50% to 150% of *J* for mercury.
  **Acceptance criteria**
  **Spike recovery:** 70%–150% for the mean of three replicate preparations at each concentration
- **PRECISION**
  **Repeatability**
  **Test samples:** Six independent samples of material under test (taken from the same lot) spiked with appropriate reference materials for mercury at the indicated concentration
  **Acceptance criteria**
  **Relative standard deviation:** Not more than 20% ($N = 6$) for mercury
  **Intermediate precision (ruggedness)**
  **Analysis:** Perform the *Repeatability* analysis again on a different day, with different instrumentation, with a different analyst, or a combination thereof. Combine the results of this analysis with the *Repeatability* analysis so the total number of analyses is 12.
  **Acceptance criteria**
  **Relative standard deviation:** Not more than 25% ($N = 12$) for mercury
- **SPECIFICITY:** The procedure must be able to unequivocally assess (see *Validation of Compendial Procedures* ⟨1225⟩) mercury in the presence of components that may be expected to be present, including matrix components.
- **LIMIT OF QUANTITATION, RANGE, AND LINEARITY:** Demonstrated by meeting the *Accuracy* requirement.▲ (Official 1-Jun-2023)

***Add the following:***

## ▲GLOSSARY

**Concentrated acid:** Concentrated ultra-pure nitric, sulfuric, hydrochloric, or hydrofluoric acid or aqua regia.
**Aqua regia:** Aqua regia is a mixture of concentrated hydrochloric and nitric acids, typically at ratios of 3:1 or 4:1.
**Matched matrix:** Solutions having the same solvent composition as the *Sample solution*. In the case of an aqueous solution, matched matrix would indicate that the same acids, acid concentrations are used in both preparations.
**Target limit or target concentration:** The acceptance value for the elemental impurity being evaluated, in this case mercury. Where a monograph specifies a threshold limit, this shall become the target limit or target concentration for mercury for the material. Exceeding the target limit indicates that a material under test exceeds the acceptable value. The determination of compliance is addressed in other chapters.
***J*:** The concentration (w/w) of the element of interest, in this case mercury, at the target limit, appropriately diluted to the working range of the instrument.
**Appropriate reference materials:** Where "appropriate reference materials" are specified in the chapter, certified reference materials (CRMs) from a national metrology institute (NMI), or reference materials that are traceable to the CRM of an NMI should be used. An example of an NMI in the United States is the National Institute of Standards and Technology (NIST).▲ (Official 1-Jun-2023)

# ⟨267⟩ POROSIMETRY BY MERCURY INTRUSION

In general, different types of pores may be pictured as apertures, channels, or cavities within a solid body or as space (i.e., interstices or voids) between solid particles in a bed, compact, or aggregate. *Porosity* is a term that is often used to indicate the porous nature of solid material and is more precisely defined as the ratio of the volume of accessible pores and voids to the total volume occupied by a given amount of the solid. In addition to the accessible pores, a solid may contain closed pores, which are isolated from the external surface and into which fluids are not able to penetrate. The characterization of closed pores, i.e., cavities with no access to an external surface, is not covered in this general chapter.

Porous materials may take the form of fine or coarse powders, compacts, extrudates, sheets, or monoliths. Their characterization usually involves the determination of the total pore volume or porosity as well as the pore size distribution.

It is well established that the performance of a porous solid (e.g., its strength, reactivity, permeability, or adsorbent power) is dependent on its pore structure. Many different methods have been developed for the characterization of pore structure. In view of the complexity of most porous solids, it is not surprising to find that the results obtained are not always in agreement and that no single technique can be relied upon to provide a complete picture of the pore structure. The choice of the most appropriate method depends on the application of the porous solid, its chemical and physical nature, and the range of pore size.

This chapter provides guidance for measurement of porosity and pore size distribution by mercury porosimetry. It is a comparative test, usually destructive, in which the volume of mercury penetrating a pore or void is determined as a function of an applied hydrostatic pressure that can be related to a pore diameter. Other information such as pore shape and interconnectivity, the internal and external surface area, powder granulometry, and bulk and tapped density can also be inferred from volume–pressure curves; however, these aspects of the technique do not fall under the scope of this chapter.

Practical considerations presently limit the maximum applied absolute pressure reached by some equipment to about 400 MPa, corresponding to a minimum equivalent pore diameter of approximately 0.003 µm. The maximum diameter will be limited for samples having a significant depth because of the difference in the hydrostatic head of mercury from the top to the bottom of the sample. For most purposes this limit may be regarded as 400 µm.

Interparticle and intraparticle porosity can be determined, but the method does not distinguish between these porosities where they coexist.

The method is suitable for the study of most porous materials. Samples that amalgamate with mercury, such as certain metals, may be unsuitable for this technique or may require a preliminary passivation. Other materials may deform or compact under the applied pressure. In some cases, it may be possible to apply sample compressibility corrections, and useful comparative data may still be obtained.

The mercury porosimetry technique should be considered to be comparative, because for most porous media, a theory is not available to allow an absolute calculation of results of pore size distribution. Therefore, this technique is mainly recommended for development studies.

Mercury is toxic. Appropriate precautions must be observed to safeguard the health of the operator and others working in the area. Waste material must also be disposed of in a suitable manner, according to local regulations.

## PRINCIPLE

The technique is based on the measurement of the mercury volume intruded into a porous solid as a function of the applied pressure. The measurement includes only those pores into which mercury can penetrate at the pressure applied.

A nonwetting liquid penetrates into a porous system only under pressure. The pressure applied is in inverse proportion to the inner width of the pore aperture. In the case of cylindrical pores, the correlation between pore diameter and pressure is given by the Washburn equation:

$$d_p = -\frac{4 \cdot \sigma}{p}\cos(\theta) \quad [1]$$

$p$ = applied pressure, in pascals
$d_p$ = pore diameter, in meters
$\sigma$ = surface tension of mercury, in newtons per meter
$\theta$ = contact angle of mercury on the sample, in degrees

## APPARATUS

The sample holder, referred to as a penetrometer or dilatometer, has a calibrated capillary tube, through which the sample can be evacuated and through which mercury can enter. The capillary tube is attached to a wider tube in which the test sample is placed. The change in the volume of mercury intruded is usually measured by the change in capacitance between the mercury column in the capillary tube and a metal sleeve around the outside of the capillary tube. If precise measurements are required, the internal volume of the capillary tube should be between 20% and 90% of the expected pore and void volume of the sample. Because different materials exhibit a wide range of open porosities, a number of penetrometers with different diameter capillary tubes and sample volumes may be required. A typical setup for a mercury porosimeter instrument is given in *Figure 1*. The porosimeter may have separate ports for high- and low-pressure operation, or the low-pressure measurement may be carried out on a separate unit.

The pressure range is typically 4 kPa to 300 kPa for low-pressure operation and above 300 kPa for high-pressure operation, depending on the design of the particular apparatus and on the intended use.

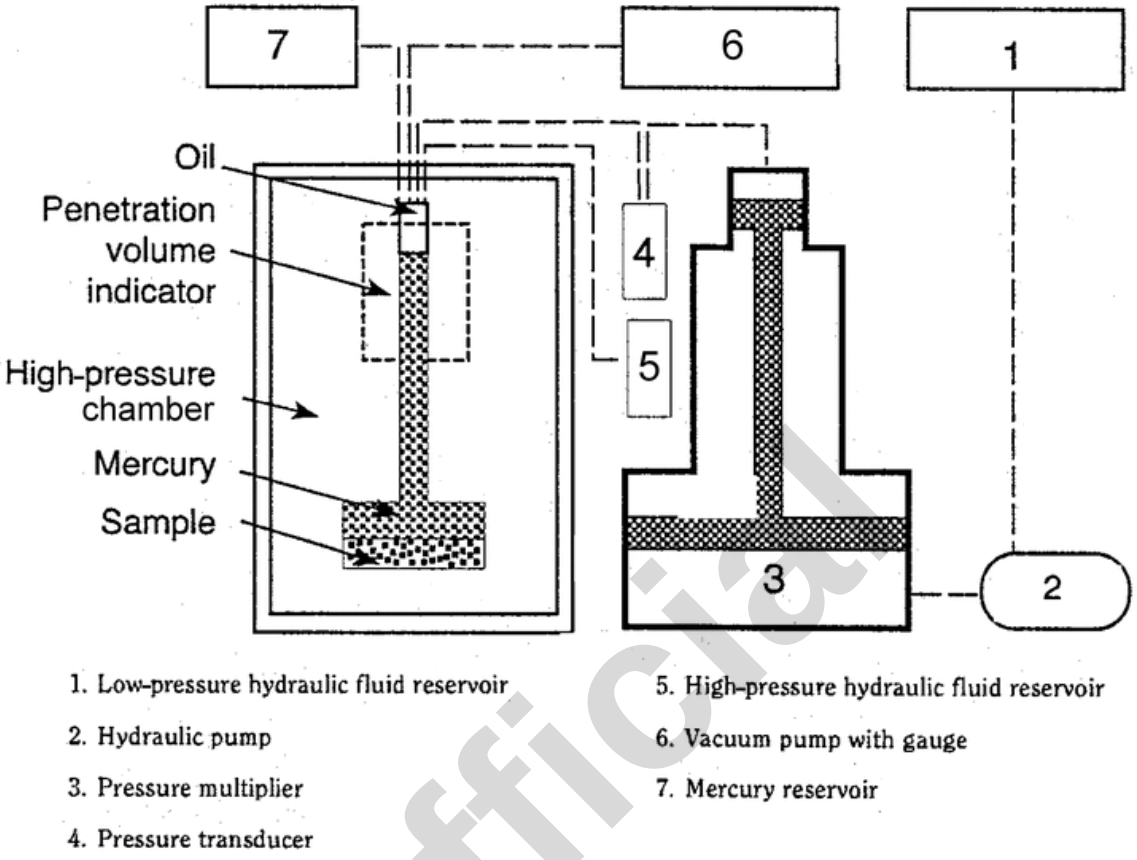

Figure 1. Example of the setup of a mercury porosimeter instrument.

## METHOD

### Sample Preparation

The sample is pretreated to remove adsorbed material that can obscure its accessible porosity by either heating and/or evacuation or by flowing inert gas. It may be possible to passivate the surface of wettable or amalgam-forming solids by producing a thin layer of oxide, or by coating with stearate. The sample of the pretreated solid is weighed and transferred to the penetrometer. The pore system of the sample is then degassed in a vacuum to a maximum residual pressure of 7 Pa.

### Filling the Penetrometer with Mercury

Use mercury of analytical quality. The sample is overlaid with mercury under vacuum. The vacuum is required to ensure the transfer of mercury from the reservoir to the penetrometer. In a filled penetrometer, the filling pressure is comprised of the applied pressure plus the pressure contribution created by the head of mercury contacting the sample. A typical filling pressure would be about 4 kPa. The hydrostatic pressure of the mercury over the sample can be minimized by filling the penetrometer in the horizontal positions.

### Low-Pressure Measurement

Admit air or nitrogen in a controlled manner to increase the pressure either in stages corresponding to the particular pore sizes of interest, or continuously at a slow rate. The concomitant change in the length of the mercury column in the capillary tube is recorded. When the maximum required pressure has been reached, reduce the pressure to ambient.

### High-Pressure Measurement

After measurement at low-pressure conditions, the penetrometer filled with mercury is transferred to the high-pressure port or unit of the instrument and overlaid with hydraulic fluid. Mercury is intruded into the pore system via the hydraulic fluid. Increase the pressure in the system to the maximum pressure reached in the low-pressure measurement, and record the intrusion volume at this pressure, because subsequent intrusion volumes are calculated from this initial volume. Increase the pressure

either in stages corresponding to the particular pore sizes of interest, or continuously at a slow rate. The fall in the mercury column is measured up to the maximum required pressure. If required, the pressure may be decreased either in stages or continuously at a slow rate to determine the mercury extrusion curve. Make corrections to take account of changes in the volume of the mercury, the penetrometer, and other components of the volume detector system under elevated pressure. The extent of the corrections may be determined by means of blank measurements under the same conditions. An experimentally determined volume–pressure curve is shown in *Figure 2*.

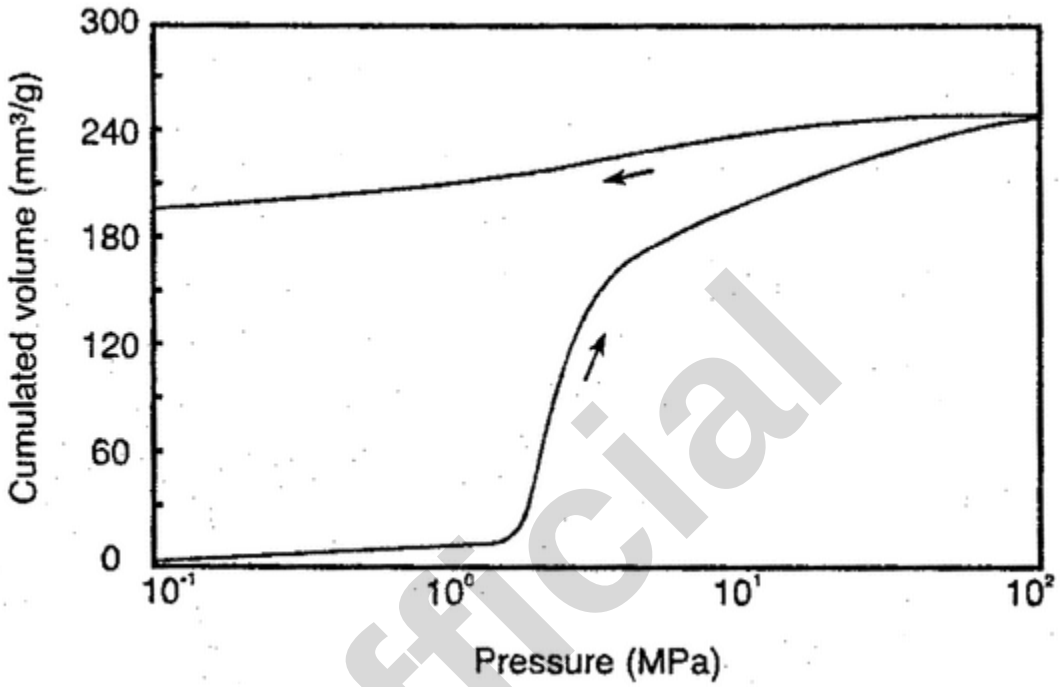

Figure 2. Volume–pressure curve as semilogarithmic plot.

## REPORTING OF RESULTS

The pressure readings are converted to pore diameter by means of the Washburn equation or by another model.

The surface tension of mercury, $\sigma$, depends not only on the temperature and the material, but also—in the case of markedly curved surface areas—on the radius of curvature. In general, values between 0.41 $N \cdot m^{-1}$ and 0.52 $N \cdot m^{-1}$ are measured at room temperature. If the value is not known, $\sigma = 0.48\ N \cdot m^{-1}$ can be used.

The contact angle of mercury $\theta$ in most cases is more than 90°. It may be determined using a contact angle instrument. If the $\theta$ value is not known, 130° can be used. Report the values of contact angle, surface tension, and the model used in the calculation. Visualization of the data can be done with several types of graphs. Frequently, in a graphical representation, the pore diameter is plotted on the abscissa and the dependent intruded specific volume on the ordinate to give the pore size distribution. It is appropriate here to choose a logarithmic scale for the abscissa (see *Figure 3*). The spaces between the particles of the solid sample are included as pores in the calculation. If the pores differ in size from the voids, the latter can be separated by choosing the relevant pore size range.

Extrusion curves may not be used for calculating the pore size distribution (for hysteresis, see *Figure 2*), because an intruded part of the mercury always remains in the pore system. The retention ratio may be useful for the qualitative characterization of pores that are only accessible via narrow openings (“ink-bottle pores”).

The most common characteristic values, such as the total intruded specific volume, the mean, and the median pore diameter are calculated from the pore size distribution. Moreover, sufficient information should be documented about the sample, the sample preparation, the evacuation conditions, and the instrument used.

## CONTROL OF THE INSTRUMENT'S PERFORMANCE

As the mercury porosimetry technique is considered as a comparative test, no details are given in this chapter. However, it is recommended that a stable comparison material should be tested on a regular basis to monitor instrument calibration and performance.

# ⟨268⟩ POROSITY BY NITROGEN ADSORPTION–DESORPTION

## INTRODUCTION

*Porosity* is a term typically used to indicate the porous nature of solid material and is more precisely defined as the ratio of the volume of accessible pores and voids to the total volume occupied by a given amount of the solid. Closed or inaccessible pores that are isolated from the external surface are excluded from this definition of pore volume. Pores (or voids) may consist of apertures, channels, or cavities within a solid body or spaces between solid particles in a compact or aggregate. Pores exist in a variety of solid materials beyond compacts and aggregates, such as powders and tablets, and their characterization usually involves the determination of the total pore volume or porosity, as well as the pore size distribution. Pores generally are classified by size into the following groups:

- Micropores—less than 2 nm
- Mesopores—2 to 50 nm
- Macropores—greater than 50 nm

The method in *Porosity by Nitrogen Adsorption–Desorption* ⟨268⟩ is complementary to that in general chapter *Porosimetry by Mercury Intrusion* ⟨267⟩. Mercury porosimetry may, in principle (in theory), be used with pore diameters from 3 nm to 400 µm but is most applicable in the range from 100 nm to 200 µm. Nitrogen adsorption–desorption may be used to characterize pores smaller than about 300 nm but is most appropriate for the analysis of mesopores and into the low macropore range from 2 to 100 nm.

## APPARATUS

Measurements are most commonly performed using the static volumetric procedure, although dynamic flow methods also may be employed. Users of commercially available equipment should refer to the manufacturer's literature and manual for a description of their particular apparatus. For example, a static volumetric apparatus must provide: evacuation of the system to a pressure of less than 10 Pa, delivery of known volumes of high-purity nitrogen and helium, accurate measurement of pressure and temperature, and a means of cooling the sample to liquid nitrogen temperature.

## MEASUREMENT PRINCIPLE

The adsorption of an inert gas onto solid surfaces at low temperatures is a well-known phenomenon and is the basis for measurement of the surface area of solids (see general chapter *Specific Surface Area* ⟨846⟩). As gas adsorbs to a surface, it can condense into accessible pores. The total pore volume and pore size distribution can be derived from the gas adsorption isotherm, which is the measure of amount adsorbed as a function of adsorbate partial pressure. Adsorption isotherms fall into six general categories, depending on the relative energetics of adsorption and the presence of pores. *Figure 1* shows six general categories of adsorption isotherms.

Reporting physisorption for gas/solid systems with special reference to the determination of surface area and porosity (recommendations 1984). *Pure Appl Chem.* 1985;57(4):603–619, *Figure 2*.]

Micropores (pore sizes less than 2 nm) frequently give rise to type I isotherms. Mesopores and macropores normally yield type IV isotherms, but for pores greater than about 100 nm hysteresis may be difficult to observe, thus yielding a type II isotherm. Although some information, such as the total porosity, can be derived for microporous materials, the determination of pore size distributions in that size range is outside the scope of this chapter.

The preferred adsorbate is nitrogen, and the isotherm is determined at liquid nitrogen temperature (77.4 K). Other adsorbates may be used for special purposes but are not discussed in this chapter.

# PROCEDURE

## Sample Preparation

Before analysis, analysts should outgas the sample to remove gases and vapors that may have become physically adsorbed onto the surface. The outgassing conditions must be demonstrated to yield reproducible adsorption–desorption, a constant sample weight, and no detectable physical or chemical changes in the sample. Outgassing of many substances often is achieved by applying a vacuum, by purging the sample in a flowing stream of a nonreactive, dry gas, or by applying an adsorption–desorption cycling procedure. If appropriate, analysts can apply elevated temperatures to increase the rate at which the contaminants leave the surface. Analysts should be cautious when outgassing samples using elevated temperatures to avoid affecting the nature of the surface and the integrity of the sample. If heating is employed, the recommended temperature and time of outgassing should be the minimum needed to achieve reproducible measurement of the adsorption–desorption isotherm.

Analysts should determine the sample mass after outgassing or, alternatively, should determine the mass after the adsorption–desorption measurement. The total surface area of the sample should be greater than 1 $m^2$ and preferably greater than 5 $m^2$.

## Isotherm Measurement

Specific details of the measurement process depend on the procedure used. Analysts should follow the manufacturer's instructions for the particular instrument used. The following description is applicable generally:

- Analysts should determine the saturated vapor pressure of the adsorbate, $p_0$. It is preferable to determine $p_0$ experimentally at the time of measurement, but analysts can use a calculated value.
- Analysts should determine the nitrogen sorption isotherm and should measure the volume adsorbed, $V_a$, at the lowest desired relative pressure ($p/p_0$, the ratio of the measured adsorbate pressure to its saturated vapor pressure).
- Analysts repeat the measurement of $V_a$ at successively higher relative pressure values to the maximum desired relative pressure (generally 0.99). Then they successively decrease the relative pressure to determine sorbed amounts on the desorption portion of the isotherm. Analysts should measure at least 20 points on both the adsorption and desorption segments, covering a relative pressure ($p/p_0$) range of approximately 0.05–0.99. The $p/p_0$ values can be distributed to achieve the best resolution of the pore size distribution. If only the desorption segment is being used to calculate the pore size distribution, fewer points can be used on the adsorption segment.

# DATA ANALYSIS

## Examination of the Isotherm

The isotherm is depicted as a plot of quantity of nitrogen adsorbed (as volume, $V_a$, or moles, $n_a$) vs. $p/p_0$. The isotherm data also can be presented in tabular form. From the graph, determine the isotherm and hysteresis types by comparison to the examples in *Figures 1* and *2*. A type I isotherm is common for microporous materials. A type IV isotherm usually is exhibited by materials that contain mesopores or small macropores.

al. Reporting physisorption for gas/solid systems with special reference to the determination of surface area and porosity (recommendations 1984). *Pure Appl Chem.* 1985;57(4):603–619, *Figure 3*.]

Constructing a *t*-plot or $\alpha_S$-plot to compare the isotherm of the test sample to that of a reference isotherm also helps to illustrate the presence of micro- and mesoporosity. The reference isotherm may be calculated using a mathematical expression, but it is recommended that an experimentally determined reference isotherm be used when the adsorbent has chemical properties that are similar to those of the test sample.

The *t*-plot method is based on the *t*-curve, which is a plot of the amount of nitrogen adsorbed on the nonporous solid as a function of *t*, the statistical thickness of the adsorbed layer. The *t* value is calculated:

$$t = \frac{n_a \times \delta_a}{n_m}$$

$n_m$ = monolayer amount

$\delta_a$ = thickness of a single molecular layer, usually taken as 0.354 nm for nitrogen

In the $\alpha_S$-plot method, the amount of nitrogen adsorbed by the reference nonporous solid is normalized by using the amount adsorbed at some fixed relative pressure ($n'_{a,x}$), often taken as 0.4. The normalized adsorption $\alpha_S$ (equal to $n_a/n'_{a,x}$) then is plotted against $p/p_0$ to obtain an $\alpha_S$-curve.

The *t*-plot or $\alpha_S$-plot is constructed by plotting the amount of nitrogen adsorbed by the test sample against *t* or $\alpha_S$ for the reference material, rather than $p/p_0$. The conversion of $p/p_0$ to *t* or $\alpha_S$ is carried out by reference to the *t*-curve or $\alpha_S$-curve. The shape of the plot depends on the nature of the porosity present in the test sample, as follows:

1. if the *t*- or $\alpha_S$-plot is linear and passes through the origin, the test sample is nonporous or macroporous
2. if the test sample contains mesopores, the plot shows an upward deviation at the relative pressure corresponding to the onset of capillary condensation in the smallest mesopores
3. if the test sample contains micropores, the plot exhibits a downward deviation because multilayers cannot fully develop within the constricted space inside the micropores.

Some materials contain combinations of pores, which may result in a complex plot that is difficult to interpret. In such cases analysts should be cautious when they analyze the isotherm.

## Calculation of Pore Size Distribution

This analysis is valid only for calculations of the size distributions of mesopores.

Calculation of the pore size distribution is based on the Kelvin equation:

$$r_k = \frac{2 \times \sigma_l \times v_l \times \cos(\theta) \times 10^3}{R \times T \times \ln(p/p_0)}$$

$r_k$ = core radius of the pore (or Kelvin radius) (nm)

$\sigma_l$ = adsorbate (nitrogen) liquid surface tension (N/m)

$v_l$ = molar volume of the condensed adsorbate (nitrogen) ($cm^3/mol$)

$R$ = universal gas constant, 8.3144 ($J \cdot K^{-1} \cdot mol^{-1}$)

$T$ = temperature (K)

$\theta$ = adsorbate contact angle (0 for a wetted surface)

For nitrogen, equation 2 reduces to:

$$r_k = \frac{-0.953}{\ln(p/p_0)}$$

The actual pore radius, $r_p$, is calculated from the Kelvin radius by correcting for the thickness, *t*, of the adsorbate on the pore walls. For cylindrical pores, $r_p = r_k + t$, and the pore diameter, $d_p$, is given by $d_p = 2(r_k + t)$. Because of the different geometry of parallel-sided slit-shaped pores, the slit width is given by $r_k + 2t$.

Analysts can calculate the volume pore size distribution using the method of Barrett, Joyner, and Halenda. This model assumes that the pores are rigid and of regular shape (e.g., cylindrical or slit-shaped), micropores are absent, and the pore size distribution does not extend continuously above the largest pores measurable by this procedure, which implies that all of the pores evaluated are filled at the highest relative pressure.

Porosity and pore size distribution calculations that employ the Kelvin equation must be performed using the desorption isotherm. The Kelvin equation was derived for macroscopic systems and is not strictly valid at the molecular scale. Thus, the Kelvin equation relies on an intact meniscus in order to accurately describe experimental phenomena. For the systems discussed in this chapter, this is achieved only for the desorption isotherm. However, for desorption the application of the Kelvin equation at lower pore sizes is limited by the surface tension of the adsorbate. The limit is illustrated by the point of closure of the hysteresis loop in the isotherm. For nitrogen, this point occurs at a relative pressure of about 0.45, corresponding to a limiting cylindrical pore radius of about 2 nm. Thus the Kelvin equation is not applicable for micropores.

https://pharmacopeia.cn/

### Calculation of Micropore Volume

If the $t$- or $\alpha_s$-plot indicates the presence of micropores, the micropore volume can be obtained from the intercept of the extrapolated linear portion of the curve.

### Reported Results

Typically reported results may include total pore volume or porosity, micropore volume, median or mean pore diameter, pore size distribution, and pore surface area.

## CALIBRATION AND VERIFICATION OF SYSTEM PERFORMANCE

Analysts should carry out calibration of individual components in accordance with the manufacturer's recommendations. Calibration of pressure transducers and temperature sensors is accomplished with reference to standard pressure- and temperature-measuring devices that have calibrations traceable to national standards. Manifold volume calibration is achieved by appropriate pressure and temperature measurements using constant-temperature volumetric spaces or solids of known, traceable volume.

A certified reference material or locally defined reference material that is traceable to a certified reference material should be tested on a regular basis in order to monitor instrument calibration and performance.

# ⟨271⟩ READILY CARBONIZABLE SUBSTANCES TEST

In tests for readily carbonizable substances, unless otherwise directed, add the specified quantity of the substance, finely powdered if in solid form, in small portions to the comparison container, which is made of colorless glass resistant to the action of sulfuric acid and contains the specified volume of sulfuric acid (see under *Reagent Specifications* in the section *Reagents, Indicators, and Solutions*).

Stir the mixture with a glass rod until solution is complete, allow the solution to stand for 15 minutes, unless otherwise directed, and compare the color of the solution with that of the specified Matching Fluid (see *Color and Achromicity* ⟨631⟩) in a comparison container, which also is of colorless glass and has the same internal and cross-section dimensions, viewing the fluids transversely against a background of white porcelain or white glass.

When heat is directed in order to effect solution of the substance in the sulfuric acid, mix the sample and the acid in a test tube, heat as directed, and transfer the solution to the comparison container for matching with the designated Matching Fluid (see *Color and Achromicity* ⟨631⟩).

# ⟨281⟩ RESIDUE ON IGNITION

Portions of this general chapter have been harmonized with the corresponding texts of the *European Pharmacopoeia* and the *Japanese Pharmacopoeia*. The portions that are not harmonized are marked with symbols (•,). The harmonized texts of these pharmacopeias are therefore interchangeable, and the methods of the *European Pharmacopoeia* and/or the *Japanese Pharmacopoeia* may be used for demonstration of compliance instead of the present *United States Pharmacopeia* general chapter. These pharmacopeias have undertaken not to make any unilateral change to this harmonized chapter.

The *Residue on Ignition/Sulfated Ash* test uses a procedure to measure the amount of residual substance not volatilized from a sample when the sample is ignited in the presence of sulfuric acid according to the procedure described below. This test is usually used for determining the content of inorganic impurities in an organic substance.

## PROCEDURE

Ignite a suitable crucible (for example, silica, platinum, quartz, or porcelain) at 600 ± 50° for 30 minutes, cool the crucible in a desiccator (silica gel or other suitable desiccant), and weigh it accurately. Weigh accurately •1 to 2 g of the substance, or,• the amount specified in the individual monograph, in the crucible.

Moisten the sample with a small amount (usually 1 mL) of sulfuric acid, then heat gently at a temperature as low as practicable until the sample is thoroughly charred. Cool; then,•unless otherwise directed in the individual monograph,• moisten the residue with a small amount (usually 1 mL) of sulfuric acid; heat gently until white fumes are no longer evolved; and ignite at 600 ± 50°, •unless another temperature is specified in the individual monograph,• until the residue is completely incinerated. Ensure that flames are not produced at any time during the procedure. Cool the crucible in a desiccator (silica gel or other suitable desiccant), weigh accurately, and calculate the percentage of residue.

Unless otherwise specified, if the amount of the residue so obtained exceeds the limit specified in the individual monograph, repeat the moistening with sulfuric acid, heating and igniting as before, using a 30-minute ignition period, until two consecutive weighings of the residue do not differ by more than 0.5 mg or until the percentage of residue complies with the limit in the individual monograph.

•Conduct the ignition in a well-ventilated hood, but protected from air currents, and at as low a temperature as is possible to effect the complete combustion of the carbon. A muffle furnace may be used, if desired, and its use is recommended for the final ignition at 600 ± 50°.

Calibration of the muffle furnace may be carried out using an appropriate digital temperature meter and a working thermocouple probe calibrated against a standard thermocouple traceable to the National Institute of Standards and Technology.

Verify the accuracy of the measuring and controlling circuitry of the muffle furnace by checking the positions in the furnace at the control set point temperature of intended use. Select positions that reflect the eventual method of use with respect to location of the specimen under test. The tolerance is ±25° at each position measured.•

# ⟨291⟩ SELENIUM

***Add the following:***

## ▲INTRODUCTION

This chapter describes three analytical procedures for the evaluation of the levels of selenium (Se). Use *Procedure 1*, *Procedure 2*, or *Procedure 3* as indicated in the individual monograph. *Procedure 2* or *Procedure 3* can be used in all circumstances, provided that suitability is demonstrated by meeting the *Requirements For Procedure Validation*.▲ (Official 1-Jun-2023)

***Change to read:***

## ▲PROCEDURES

- **PROCEDURE 1: SPECTROSCOPY**▲ (Official 1-Jun-2023)

**Stock solution:** Dissolve 40.0 mg of metallic selenium in 100 mL of dilute nitric acid (1 in 2) in a 1000-mL volumetric flask, warming gently on a steam bath if necessary to effect solution, add water to volume, and mix. Pipet 5 mL of this solution into a 200-mL volumetric flask, add water to volume, and mix. Each milliliter of the resulting solution contains the equivalent of 1 µg of selenium.

**Diaminonaphthalene solution:** Dissolve 100 mg of 2,3-diaminonaphthalene and 500 mg of hydroxylamine hydrochloride in 0.1 N hydrochloric acid to make 100 mL. Prepare this solution fresh on the day of use.

**Standard solution:** Pipet 6 mL of *Stock solution* into a 150-mL beaker, and add 25 mL of dilute nitric acid (1 in 30) and 25 mL of water.

**Test solution:** Clean combustion of the test material is an important factor in conducting the test. For compounds that burn poorly and produce soot, the addition of magnesium oxide usually results in more thorough combustion and reduces soot formation. Where the need to add magnesium oxide has been identified, it is specified in the individual monograph. Using a 1000-mL combustion flask and using 25 mL of dilute nitric acid (1 in 30) as the absorbing liquid, proceed as directed in *Oxygen Flask Combustion* ⟨471⟩, using a test specimen weighing 100–200 mg, unless directed otherwise in the individual monograph. Upon completion of the combustion, place a few milliliters of water in the cup, loosen the stopper, and rinse the stopper, the specimen holder, and the sides of the flask with about 10 mL of water. Transfer the solution with the aid of about 20 mL of water to a 150-mL beaker, and heat gently to the boiling temperature. Boil for 10 min, and allow the solution to cool to room temperature.

**▲Analysis:**▲ (Official 1-Jun-2023) Treat the *Standard solution*, the *Test solution*, and the reagent blank consisting of 25 mL of dilute nitric acid (1 in 30) and 25 mL of water, concomitantly and in parallel, as follows. Add ammonium hydroxide solution (1 in 2) to adjust to a pH of 2.0 ± 0.2. Dilute with water to 60 mL, and transfer to a low-actinic separator with the aid of 10 mL of water, adding the 10 mL of rinsings to the separator. Add 200 mg of hydroxylamine hydrochloride, swirl to dissolve, immediately add 5.0 mL of *Diaminonaphthalene solution*, insert the stopper, and swirl to mix. Allow the solution to stand at room temperature for 100 min. Add 5.0 mL of cyclohexane, shake vigorously for 2 min, and allow the layers to separate. Discard the aqueous layer, and centrifuge the cyclohexane extract to remove any dispersed water. Determine the absorbances of the cyclohexane extracts of the *Test solution* and the *Standard solution* in a 1-cm cell at the wavelength of maximum absorbance at about 380 nm, with a suitable spectrophotometer, using the cyclohexane extract of the reagent blank as the blank, and compare the absorbances: the absorbance of the *Test solution* is not greater than that of the *Standard solution* where a 200-mg test specimen has been taken, or is not greater than one-half that of the *Standard solution* where a 100-mg test specimen has been taken.

▲- **PROCEDURE 2 AND PROCEDURE 3**

Both *Procedure 2* and *Procedure 3* are ICP-based procedures and can be used for the determination of selenium. *Procedure 2* can be used for the determination of selenium by inductively coupled plasma atomic (or optical) emission spectroscopy (ICP–AES or ICP–OES). *Procedure 3* can be used for the determination of selenium by ICP–MS.

Before initial use, the analyst should verify that the procedure is appropriate for the instrument and sample used (procedural verification) by meeting the *Requirements for Procedure Validation*.

Where a monograph specifies a limit for selenium concentration, the value listed in the monograph should be used as the *J* value for the purposes of this test.

System standardization and suitability evaluation using applicable reference materials should be performed on the day of analysis.

**Sample preparation:** Forms of sample preparation include neat, direct aqueous solution, direct organic solution, and indirect solution. The selection of the appropriate sample preparation depends on the material under test and is the responsibility of the analyst. When a sample preparation is not indicated in the monograph, an analyst may use any appropriately validated preparation procedure. In cases where spiking of a material under test is necessary to provide an acceptable signal intensity, the blank should be spiked with selenium using, where possible, the same spiking solution. [NOTE—All liquid samples should be weighed.]

**Closed vessel digestion:** This sample preparation procedure is designed for samples that must be digested in a concentrated acid using a closed vessel digestion apparatus. Closed vessel digestion minimizes the loss of volatile impurities. The choice of a concentrated acid depends on the sample matrix. The use of any of the concentrated acids may be appropriate, but each introduces inherent safety risks. Therefore, appropriate safety precautions should be used at all times. [NOTE—Weights and volumes provided may be adjusted to meet the requirements of the digestion apparatus used.]

An example procedure that has been shown to have broad applicability is as follows. Dehydrate and predigest 0.5 g of primary sample in 5 mL of freshly prepared concentrated acid. Allow to sit loosely covered for 30 min in a fume hood. Add an additional 10 mL of concentrated acid, and digest using a closed vessel technique until digestion or

https://mathurca.gcoa.ir.ocm/

extraction is complete. Repeat, if necessary, by adding an additional 5 mL of concentrated acid. [NOTE—Follow the manufacturer's recommended procedures to ensure safe use.]

**Reagents:** All reagents used for the preparation of sample and standard solutions should be free of elemental impurities, in accordance with *Plasma Spectrochemistry* ⟨730⟩.

**Procedure 2: ICP–OES**

**Standardization solution 1:** 1.5*J* of selenium in a matched matrix

**Standardization solution 2:** 0.5*J* of selenium in a matched matrix

**Sample stock solution:** Prepare as directed in *Sample preparation*. Allow the sample to cool, if necessary.

**Sample solution:** Dilute the *Sample stock solution* with an appropriate solvent to obtain a final selenium concentration of not more than 1.5*J*.

**Blank:** Matched matrix

**Elemental spectrometric system**

(See ⟨730⟩.)

**Rinse:** Use diluent.

**Standardization:** *Standardization solution 1*, *Standardization solution 2*, and *Blank*

**System suitability**

**Sample:** *Standardization solution 1*

**Suitability requirements**

**Drift:** Compare results obtained from *Standardization solution 1* before and after the analysis of the *Sample solution.*

**Suitability criteria:** NMT 20% for selenium. [NOTE—If samples are high in mineral content, rinse the system well before introducing the *Sample* in order to minimize carryover.]

**Analysis:** Analyze according to the manufacturer's suggestions for program and wavelength. Calculate and report results on the basis of the original sample size. [NOTE—Appropriate measures must be taken to correct for matrix-induced interferences (e.g., wavelength overlaps).]

**Procedure 3: ICP–MS**

Follow *Procedure 2* except for *Detector* and *Analysis*.

[NOTE—An instrument with a cooled spray chamber is recommended. (A collision cell or reaction cell may also be beneficial.)]

**Detector:** Mass spectrometer

**Analysis:** Analyze according to the manufacturer's suggestions for program and mass-to-charge ratio. Calculate and report results based on the original sample size. [NOTE—Appropriate measures must be taken to correct for matrix-induced interferences.]▲ (Official 1-Jun-2023)

***Add the following:***

## ▲REQUIREMENTS FOR PROCEDURE VALIDATION

The following section defines the validation parameters and the acceptance criteria for performance-based procedures. Meeting these requirements must be demonstrated experimentally using an appropriate system suitability procedure and reference materials. Any alternative procedure (e.g., an atomic-absorption-based procedure) that has been validated and meets the acceptance criteria that follow is considered to be suitable for use.

Meeting these validation acceptance criteria is sufficient to demonstrate that the procedure will produce comparable results to those obtained using the procedure prescribed in the monograph.

- **ACCURACY**

**Standard solutions:** Prepare solutions containing selenium at concentrations ranging from 50% to 150% of *J* using appropriate reference materials.

**Test samples:** Spike the material under test with the appropriate reference materials before any sample preparation steps (digestion or solubilization). Prepare three replicate samples at concentrations ranging from 50% to 150% of *J* for selenium.

**Acceptance criteria**

**Spike recovery:** 70%–150% for the mean of three replicate preparations at each concentration

- **PRECISION**

**Repeatability**

**Test samples:** Six independent samples of material under test (taken from the same lot) spiked with appropriate reference materials for selenium at the indicated concentration

**Acceptance criteria**

**Relative standard deviation:** Not more than 20% ($N = 6$) for selenium

**Intermediate precision (ruggedness)**

**Analysis:** Perform the *Repeatability* analysis again on a different day, with different instrumentation, with a different analyst, or a combination thereof. Combine the results of this analysis with the first *Repeatability* analysis so the total number of analyses is 12.

**Acceptance criteria**

**Relative standard deviation:** Not more than 25% ($N = 12$) for selenium

- **SPECIFICITY:** The procedure must be able to unequivocally assess (see *Validation of Compendial Procedures* ⟨1225⟩) selenium in the presence of components that may be expected to be present, including matrix components.
- **LIMIT OF QUANTITATION, RANGE, AND LINEARITY:** Demonstrated by meeting the *Accuracy* requirement.▲ (Official 1-Jun-2023)

Official

https://pharmacopeia.cn/v-download/

***Add the following:***

## ▲GLOSSARY

**Concentrated acid:** Concentrated ultra-pure nitric, sulfuric, hydrochloric, or hydrofluoric acid or aqua regia.

**Aqua regia:** Aqua regia is a mixture of concentrated hydrochloric and nitric acids, typically at ratios of 3:1 or 4:1.

**Matched matrix:** Solutions having the same solvent composition as the *Sample solution*. In the case of an aqueous solution, a matched matrix would indicate that the same acids and acid concentrations are used in both preparations.

**Target limit or target concentration:** The acceptance value for the elemental impurity being evaluated, in this case selenium. Where a monograph specifies a threshold limit, this shall become the target limit or target concentration of selenium for the material. Exceeding the target limit indicates that a material under test exceeds the acceptable value. The determination of compliance is addressed in other chapters.

***J*:** The concentration (w/w) of the element of interest, in this case selenium, at the target limit, appropriately diluted to the working range of the instrument.

**Appropriate reference materials:** Where "appropriate reference materials" are specified in the chapter, certified reference materials (CRMs) from a national metrology institute (NMI), or reference materials that are traceable to the CRM of an NMI should be used. An example of an NMI in the United States is the National Institute of Standards and Technology (NIST).▲ (Official 1-Jun-2023)

# ⟨301⟩ ACID-NEUTRALIZING CAPACITY

[NOTE—All tests shall be conducted at a temperature of 37 ± 3°.]

**Standardization of pH meter:** Standardize a pH meter using the 0.05 m potassium biphthalate and 0.05 m potassium tetraoxalate standardizing buffers as described under *pH* ⟨791⟩.

**Magnetic stirrer:** Transfer 100 mL of water to a 250-mL beaker containing a 40- × 10-mm (or other suitable size) magnetic stirring bar that is coated with solid perfluorocarbon and has a spin ring at its center. Adjust the power setting of the magnetic stirrer to produce a stirring rate of 300 ± 30 rpm when the stirring bar is centered in the beaker, as determined by a suitable optical tachometer.

**Test preparation**

**Powders:** Transfer the accurately weighed portion of the substance specified in the individual monograph to a 250-mL beaker, add 70 mL of water, and mix on the *Magnetic stirrer* for 1 minute.

**Effervescent solids:** Transfer an accurately weighed quantity, equivalent to the minimum labeled dosage, to a 250-mL beaker, add 10 mL of water, and swirl the beaker gently while allowing the reaction to subside. Add another 10 mL of water, and swirl gently. Wash the walls of the beaker with 50 mL of water, and mix on the *Magnetic stirrer* for 1 minute.

**Suspensions and other liquids:** Shake the container until the contents are uniform, and determine the density. Transfer an accurately weighed quantity of the uniform mixture, equivalent to the minimum labeled dosage, to a 250-mL beaker, add water to make a total volume of about 70 mL, and mix on the *Magnetic stirrer* for 1 minute.

**Lozenges:** Accurately weigh not fewer than 20 lozenges, and determine the average weight. Select and weigh 2 lozenges, and transfer them to a 250-mL beaker containing 70 mL of water.

**Nonchewable tablets:** Weigh not fewer than 20 tablets, and determine the average tablet weight. Grind the tablets to a fine powder, mix to obtain a uniform mixture, and transfer an accurately weighed quantity of it, equivalent to the minimum labeled dosage, to a 250-mL beaker. If wetting is desired, add not more than 5 mL of alcohol (neutralized to an apparent pH of 3.5), and mix to wet the specimen thoroughly. Add 70 mL of water, and mix on the *Magnetic stirrer* for 1 minute.

**Chewable tablets:** Prepare as directed for *Nonchewable tablets*.

**Tablets that are required to be chewed:** Transfer 1 Tablet to a 250-mL beaker, add 50 mL of water, and mix on the *Magnetic stirrer* for 1 minute.

**Capsules:** Weigh accurately not fewer than 20 capsules. Remove the capsule contents completely, with the aid of a cotton swab if necessary. Accurately weigh the empty capsules, and determine the average weight of the contents per capsule. Mix the combined capsule contents to obtain a uniform mixture, and proceed as directed for *Nonchewable tablets*, beginning with "transfer an accurately weighed quantity of it."

**PROCEDURES**

**• PROCEDURE FOR POWDERS, EFFERVESCENT SOLIDS, SUSPENSIONS AND OTHER LIQUIDS, LOZENGES, NONCHEWABLE TABLETS, CHEWABLE TABLETS, AND CAPSULES**

Pipet 30.0 mL of 1.0 N hydrochloric acid VS into the *Test preparation* while continuing to stir with the *Magnetic stirrer*. [NOTE—Where the acid-neutralizing capacity of the specimen under test is greater than 25 mEq, use 60.0 mL of 1.0 N hydrochloric acid VS, and make the appropriate modifications in the calculation.] Stir for 15 minutes, accurately timed, after the addition of the acid, begin to titrate immediately, and in a period not to exceed an additional 5 minutes, titrate the excess hydrochloric acid with 0.5 N sodium hydroxide VS to attain a stable (for 10 to 15 seconds) pH of 3.5. Calculate the number of mEq of acid consumed by the formula:

$$\text{Total mEq} = (30 \times N_{HCl}) - (V_{NaOH} \times N_{NaOH})$$

$N_{HCl}$ = normality of hydrochloric acid VS
$V_{NaOH}$ = volume of sodium hydroxide VS used for titration
$N_{NaOH}$ = normality of sodium hydroxide VS

Express the result in terms of mEq of acid consumed per g of the substance tested.

**• PROCEDURE FOR TABLETS THAT ARE REQUIRED TO BE CHEWED**

Pipet 30.0 mL of 1.0 N hydrochloric acid VS into the *Test preparation* while continuing to stir with the *Magnetic stirrer* for 10 minutes, accurately timed, after the addition of the acid. Discontinue stirring briefly, and without delay remove any gum base from the beaker using a long needle. Promptly rinse the needle with 20 mL of water, collecting the washing in the beaker, and resume stirring for 5 minutes, accurately timed, then begin to titrate immediately, and in a period not to exceed an additional 5 minutes, titrate the excess hydrochloric acid with 0.5 N sodium hydroxide VS to attain a stable (for 10 to 15 seconds) pH of 3.5. Calculate the number of mEq of acid consumed by the Tablet tested by the formula:

$$\text{Total mEq} = (30 \times N_{HCl}) - (V_{NaOH} \times N_{NaOH})$$

# ⟨311⟩ ALGINATES ASSAY

## APPARATUS

The required apparatus (see *Figure 1*) contains a capillary metering valve, A, followed by a flowmeter, B, to control and monitor the flow of nitrogen through the system. Halogenated vinyl plastic tubing* and a rubber fitting, C, are used to connect the flowmeter to a sidearm of a reaction flask, D. Flask D is a 250-mL round-bottom, boiling flask, resting in a suitable heating mantle, E. Flask D is provided with a 225-mm Hopkins coil reflux condenser, F. The condenser terminates in a U-shaped trap, G, which contains two 25-g bands of 20-mesh zinc, the bands being bounded and separated by three 3-inch plugs of glass wool. The trap terminates in an adapter, H, that by means of a halogenated vinyl plastic tubing and a twistcock connector, I, connects with a 250-mL gas washing bottle, J. The inlet (bubbling) tube extends almost to the bottom of the gas washing bottle, and it terminates in a fritted disk having a coarse porosity. The size of all glass joints is $^{24}/_{40}$, except for the $^{45}/_{50}$ joint of the gas washing bottle.

Official

* This type of tubing is commonly referred to as Tygon tubing. This note is added for clarity and it does not constitute USP's endorsement of this product.

## SYSTEM SUITABILITY

Using D-glucuronolactone as the standard, proceed as directed for *Procedure,* but do not perform the preboiling steps. The system is suitable if the following criteria are met: (1) a blank determination results in a net titration value, C, between 0.02 and 0.06 mEq, calculated as follows:

$$A_b - B_b$$

in which $A_b$ is the number of mEq of 0.25 N sodium hydroxide in the 25 mL used, and $B_b$ is the number of mEq of 0.1 N hydrochloric acid used in the blank titration; and (2) the percentage of carbon dioxide, $CO_2$, obtained from the standard is between 24.2% and 25.7%.

## PROCEDURE

Unless otherwise directed in the individual monograph, transfer a specimen of about 250 mg, accurately weighed, into the reaction flask, D, add 50 mL of 0.1 N hydrochloric acid, insert several boiling chips, and connect the flask to the reflux condenser, F, using phosphoric acid as a lubricant. [NOTE—Stopcock grease may be used for the other connections.] Connect the nitrogen line to the sidearm of the flask, and adjust the flow of cooling water to about 2 L per minute.

[NOTE—The following preboiling steps, outlined in this paragraph, are optional and need only be performed when the presence of inorganic carbonates is suspected.] Maintain the flow of nitrogen through the apparatus at 90 to 100 mL per minute. Raise the heating mantle, E, to the flask, heat the specimen to boiling, and boil gently for 2 minutes. Turn the heat off, lower the mantle, E, and allow to cool for about 10 minutes.

Connect the empty gas washing bottle assembly, J, and sweep the system with nitrogen at a rate of 90 to 100 mL per minute for 5 minutes. Reduce the nitrogen flow to 60 to 65 mL per minute, add 10 drops of butyl alcohol, 25.0 mL of 0.25 N sodium hydroxide VS, and 50 mL of distilled water into the bottle, rinsing down the inside of the gas washing bottle, and replace the cap. Detach the rubber fitting, C, from sidearm, and add 46 mL of hydrochloric acid through the sidearm of the boiling flask. Reattach the nitrogen line, raise the heating mantle, and heat the reaction mixture to boiling. After 2 hours of boiling, increase the nitrogen flow to 90 to 100 mL per minute, discontinue the heating, and lower the mantle. Allow to cool for 10 minutes. Disconnect, and disassemble the gas washing bottle. Using a directed stream of distilled water, thoroughly rinse all parts of the bubbling tube and cap, collecting the washings in the gas washing bottle. Use nitrogen to gently force all water out of the bubbling tube. To the bottle immediately add 10 mL of 10% barium chloride solution and a stirring bar. Insert a tight stopper, and stir gently for 1 minute. Allow to stand for at least 5 minutes. Add three drops of phenolphthalein TS, and titrate with 0.1 N hydrochloric acid VS. Perform a blank determination (see *Residual Titrations* under *Titrimetry* ⟨541⟩). Calculate the percentage of carbon dioxide, $CO_2$, by the formula:

$$2200[(A - B) - C]/(1000W)(1 - D)$$

in which A is the number of mEq of 0.25 N sodium hydroxide in the 25 mL used; B is the number of mEq of 0.1 N hydrochloric acid used for the titration of the sample or the standard; C is the net titration value calculated in the blank determination; W is the weight, in g, of the sample or the standard taken; and D is the percentage expressed as a decimal (1 decimal place), obtained in the test for *Loss on drying* for the sample or for the standard.

# ▲⟨313⟩ MOLECULAR WEIGHT AND POLYMER CHAIN LENGTH DETERMINATION FOR POLYPROPYLENE GLYCOL FATTY ETHERS

Average molecular weight, polydispersity, and average polymer chain length are critical properties in understanding and control of excipient composition and variability during formulation development, manufacturing, and testing of polymeric excipients. The following gel permeation chromatography (GPC)/size exclusion chromatography (SEC) and nuclear magnetic resonance (NMR) spectroscopy procedures are used to determine average molecular weight, polydispersity, and average polymer chain length for polypropylene glycol fatty ethers. These procedures are suitable for the following substances:

- Polypropylene Glycol 11 Stearyl Ether
- Polypropylene Glycol 15 Stearyl Ether

## METHOD 1: APPARENT WEIGHT-AVERAGE MOLECULAR WEIGHT AND POLYDISPERSITY

**Mobile phase:** Tetrahydrofuran. [NOTE—Filter the solvent using a polytetrafluoroethylene (PTFE) filter of 0.45-µm pore size if necessary.]

**Standard solutions:** Prepare 1.0 mg/mL each of at least 5 polypropylene glycol (PPG) standards with peak molecular weights ranging from approximately 70–4500 Da (g/mol)[1] in *Mobile phase* separately.

**System suitability solution:** 1.0 mg/mL of PPG standard with a peak molecular weight of approximately 1000 Da (g/mol)[1] in *Mobile phase*

**Sample solution:** 1.0 mg/mL of the test substance in *Mobile phase*

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** Refractive index

**Columns:** Two 7.5-mm × 30-cm; 3-µm packing L21 columns in series

**Temperatures**

**Detector:** 30°

**Column:** 30°

**Flow rate:** 1.0 mL/min

**Injection volume:** 20 µL

**Run time:** 25 min

**System suitability**

**Samples:** *Standard solutions* and *System suitability solution*

**Calibration curve:** Plot the retention times on the *x* axis against the log $M_P$ ($M_P$: peak molecular weight) on the *y* axis for the PPG peaks from the *Standard solutions* to generate a calibration curve using suitable GPC/SEC software. The correlation coefficient for the calibration curve is NLT 0.99.

Determine weight-average molecular weights, $M_w$, in g/mol (Da), from the chromatograms of the *System suitability solution*.

**Suitability requirements**

**Relative standard deviation:** NMT 5% for determined weight-average molecular weights of the PPG standard from 6 replicates, *System suitability solution*

**Analysis**

**Samples:** *Standard solutions* and *Sample solution*

Compute the data using the same GPC/SEC software from the chromatograms of the *Standard solutions* and *Sample solution* and determine the number- and weight-average molecular weights, $M_n$ and $M_w$, in g/mol (Da), respectively, for the tested substance.

Calculate the polydispersity for the tested substance:

$$\text{Result} = M_w/M_n$$

$M_w$ = weight-average molecular weight from the *Sample solution* (g/mol)
$M_n$ = number-average molecular weight from the *Sample solution* (g/mol)

## METHOD 2: AVERAGE POLYMER LENGTH

**Diluent:** Deuterated chloroform containing 0.03% (v/v) tetramethylsilane[2]

**Sample solution:** Weigh about 100 mg of the tested substance. Dissolve it in 0.6 mL of *Diluent*.

**Instrumental conditions**

**Mode:** An NMR spectrometer that is capable of performing quantitative analysis (see *Nuclear Magnetic Resonance Spectroscopy* ⟨761⟩, *Qualitative and Quantitative NMR Analysis, Quantitative Applications*)

**Flip angle:** 90°

[1] A PPG standard kit from PSS (Polymer Standards Service; part number PSS-ppgkit) was used. The kit contained a total of 7 PPG standards with the peak molecular weight ($M_P$) range of approximately 70–4500 Da (g/mol). The PPG standard with an $M_P$ of approximately 1000 Da (g/mol) was used for the *System suitability solution* preparation. An equivalent standard kit can also be used.

[2] The reagent from Sigma Aldrich (product #225789) was used. An equivalent reagent can also be used.

Official

https://pharmacopeia.cn/v-cn/

**Analysis:** Place the tube in the NMR spectrometer, and record the NMR spectrum. Integrate the peak areas from 0.6–1.8 ppm ($A_1$) and from 2.8–4.2 ppm ($A_2$).

The following are the equations for the total number of protons in the two regions ($N_1$ and $N_2$):

$$N_1 = N_{N\,1} + N_{N\,2} \times n$$

$N_{\,1}$ = total number of protons in the region of 0.6–1.8 ppm
$N_{N1}$ = total number of protons in the fatty alcohol residual group (stearyl group for the two excipients currently listed in the chapter) not activated by oxygen, 35
$N_{N\,2}$ = number of protons not activated by oxygen in each oxypropylene unit, 3
$n$ = number of oxypropylene units per molecule

$$N_2 = N_{A1} + N_{A2} \times n$$

$N_2$ = total number of protons in the region of 2.8–4.2 ppm
$N_{A1}$ = total number of oxygen activated protons not included in the oxypropylene unit, 3
$N_{A2}$ = number of oxygen activated protons in each oxypropylene unit, 3
$n$ = number of oxypropylene units per molecule

The areas in the two regions ($A_1$ and $A_2$) are correlated to the total number of protons in the regions ($N_1$ and $N_2$) as in the following equation:

$$A_2/A_1 = N_2/N_1$$

Calculate the number of oxypropylene units per molecule ($n$):

$$n = (N_{N\,1} \times A_{\,2} - N_{A1} \times A_1)/(N_{A2} \times A_1 - N_{N2} \times A_2)$$

$N_{N1}$ = total number of protons in the fatty alcohol residual group (stearyl group for the two excipients currently listed in the chapter) not activated by oxygen, 35
$A_2$ = area from 2.8–4.2 ppm by integration
$N_{A1}$ = total number of oxygen activated protons not included in the oxypropylene unit, 3
$A_1$ = area from 0.6–1.8 ppm by integration
$N_{A2}$ = number of oxygen activated protons in each oxypropylene unit, 3
$N_{N2}$ = number of protons not activated by oxygen in each oxypropylene unit, 3▲ (USP 1-Aug-2023)

# ▲⟨314⟩ MOLECULAR WEIGHT DETERMINATION FOR COPOLYMERS CONTAINING ALKYL METHACRYLATE OR ALKYL ACRYLATE

Average molecular weight and polydispersity are critical properties in understanding and control of excipient composition and variability during formulation development, manufacturing, and testing of polymeric excipients. The following gel permeation chromatography (GPC)/size exclusion chromatography (SEC) procedures are used to determine the average molecular weight and polydispersity for copolymers containing alkyl methacrylate or alkyl acrylate. The procedure is suitable for the following substances:

- Methacrylic Acid and Methyl Methacrylate Copolymer including Methacrylic Acid and Methyl Methacrylate Copolymer (1:1) and Methacrylic Acid and Methyl Methacrylate Copolymer (1:2)
- Methacrylic Acid and Ethyl Acrylate Copolymer
- Methacrylic Acid and Ethyl Acrylate Copolymer Dispersion

## APPARENT WEIGHT-AVERAGE MOLECULAR WEIGHT AND POLYDISPERSITY

**Mobile phase:** Tetrahydrofuran. [NOTE—Filter the solvent using a polytetrafluoroethylene (PTFE) filter of 0.45-µm pore size if necessary.]

**Standard solutions:** Prepare 1.0 mg/mL each of at least 7 poly(methyl methacrylate) (PMMA) standards with peak molecular weights ranging from approximately 600–2,000,000 Da (g/mol)[1] in *Mobile phase* separately.
Pass each solution using a suitable syringe compatible with tetrahydrofuran through a suitable filter of 1-µm pore size into a high-performance liquid chromatography (HPLC) vial with the first 1–2 mL discarded before analysis.[2]

**System suitability solution:** 1.0 mg/mL of a PMMA standard with a peak molecular weight of approximately 190,000 Da (g/mol)[1] in *Mobile phase*. Pass the solution using a suitable syringe compatible with tetrahydrofuran through a suitable filter of 1-µm pore size into an HPLC vial with the first 1–2 mL discarded before analysis.[2]

**Sample solution:** 1.0 mg/mL of the test substance in *Mobile phase* for a sample in solid form; 1.0 mg/mL equivalent to the corresponding solid form substance in *Mobile phase* for a sample in dispersion form. [NOTE—A sample in dispersion form can be dissolved in *Mobile phase* directly (without any pretreatment).] Pass the solution using a suitable syringe compatible with tetrahydrofuran through a suitable filter of 1-µm pore size into an HPLC vial with the first 1–2 mL discarded before analysis.[2]

# ⟨341⟩ ANTIMICROBIAL AGENTS—CONTENT

An essential component of Injections preserved in multiple-dose containers is the antimicrobial agent or antimicrobial agents present to reduce the hazard of having introduced, in the course of removing some of the contents, accidental microbial contamination of the contents remaining. It is a Pharmacopeial requirement that the presence and amount added of such antimicrobial agent(s) be declared on the label of the container. This general chapter provides methods for the most commonly used antimicrobial agents. These methods or other suitably validated methods are to be used to demonstrate that the declared antimicrobial agent is present but does not exceed the labeled amount by more than 20%.

The concentration of an antimicrobial preservative added to a multiple-dose or single-dose parenteral, otic, nasal, and ophthalmic preparation may diminish during the shelf life of the product. Therefore, the manufacturer shall determine the lowest level at which the preservative is effective, and the product should be so formulated as to assure that this level is exceeded throughout the product's shelf life. At the time of its manufacture, the product should contain the declared amount of antimicrobial preservative (within ±20% to allow for manufacturing and analytical variations). The quantitative label statement of the preservative content is not intended to mean that the labeled quantity is retained during the shelf life of the product; rather, it is a statement of the amount added, within process limits, and which is not exceeded by more than 20%. An example of such a label statement is "____(unit) added as preservative". [NOTE—"____(unit)" would be a number followed by the unit of measurement, e.g., 0.015 mg/mL or 0.1%.]

The most commonly used antimicrobial agents include benzyl alcohol; chlorobutanol; phenol; the four homologous esters of *p*-hydroxybenzoic acid (methyl, ethyl, propyl, and butyl parabens); and the two mercurials, phenylmercuric nitrate and thimerosal. The method used for phenylmercuric nitrate is polarographic, whereas quantitative liquid chromatography was used for thimerosal and the four homologous esters of *p*-hydroxybenzoic acid. Gas chromatography is used in the determination of phenol, benzyl alcohol, and chlorobutanol.

## GENERAL GAS AND LIQUID CHROMATOGRAPHIC METHODS

The general gas chromatography procedures set forth in the following paragraphs are applicable to the quantitative determination of benzyl alcohol, chlorobutanol, and phenol. Prepare the *Internal standard solution* and the *Standard solution* for each antimicrobial agent as directed below. Unless otherwise directed by the individual monograph, prepare the *Sample solution* from accurately measured portions of the sample under test and the *Internal standard solution* such that the concentration of the antimicrobial agent and the composition of the solvent correspond closely to the concentration and composition of the *Standard solution*. Suggested operating parameters of the gas chromatograph are provided in this section.

The general high-pressure liquid chromatography (HPLC) procedures set forth in the following paragraphs are applicable to the quantitative determination of parabens and *Thimerosal*. Prepare the *Internal standard solution* and the *Standard solution* for each antimicrobial agent as directed below. Unless otherwise directed, prepare the *Sample solution* from accurately measured portions of the sample under test and the *Internal standard solution*, if applicable, such that the concentration of the antimicrobial agent and the composition of the solvent is about the same as the concentration and composition of the *Standard solution*. Suggested operating parameters of the liquid chromatograph are provided in this section.

• **BENZYL ALCOHOL**

**Diluent:** Methanol and water (20:80)

**Internal standard solution:** 3.8 mg/mL of phenol prepared as follows. Dissolve a suitable amount of phenol in 10% of the flask volume of methanol, and dilute with water to volume.

**Standard solution:** 1.8 mg/mL of USP Benzyl Alcohol RS and 1.5 mg/mL of phenol prepared as follows. Dissolve 180 mg of USP Benzyl Alcohol RS in 20 mL of methanol contained in a 100-mL volumetric flask. Add 40.0 mL of *Internal standard solution*, and dilute with water to volume.

**Chromatographic system**

(See *Chromatography* ⟨621⟩*, System Suitability*.)

**Mode:** GC

**Detector:** Flame ionization

**Column:** 30-m × 0.32-mm fused-silica; bonded with a 0.5-µm film of phase G16

**Temperatures**

**Injection port:** 200°

**Detector:** 310°

**Column:** See *Table 1*.

**Table 1**

| Initial Temperature (°) | Temperature Ramp (°/min) | Final Temperature (°) | Hold Time at Final Temperature (min) |
|---|---|---|---|
| 150 | 0 | 150 | 5 |
| 150 | 10 | 230 | 7 |

**Carrier gas:** Helium

**Flow rate (constant):** 2 mL/min

**Injection volume:** 1 µL

**Split ratio:** 10:1

**Run time:** 20 min

**System suitability**

**Sample:** *Standard solution*

[NOTE—The relative retention times for benzyl alcohol and phenol are about 1.0 and 1.25, respectively.]

**Suitability requirements**
**Resolution:** NLT 2.0 between the benzyl alcohol and phenol peaks
**Tailing factor:** NMT 2.0 for the benzyl alcohol peak
**Relative standard deviation:** NMT 2.0% for the peak response ratio of benzyl alcohol to phenol

**Analysis**
**Samples:** *Standard solution* and *Sample solution*
Calculate the percentage of the labeled amount of benzyl alcohol ($C_7H_8O$) in the portion of the sample taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

$R_U$ = peak response ratio of benzyl alcohol to phenol from the *Sample solution*
$R_S$ = peak response ratio of benzyl alcohol to phenol from the *Standard solution*
$C_S$ = concentration of USP Benzyl Alcohol RS in the *Standard solution*
$C_U$ = nominal concentration of benzyl alcohol in the *Sample solution*

- **CHLOROBUTANOL**

**Diluent:** Methanol and water (50:50)
**Internal standard solution:** 10 mg/mL of 2,2,2-trichloroethanol in *Diluent*
**Standard stock solution:** 5 mg/mL of USP Chlorobutanol RS in methanol
**Standard solution:** 1.25 mg/mL of USP Chlorobutanol RS and 2 mg/mL of 2,2,2-trichloroethanol prepared as follows. Transfer 2.5 mL of *Standard stock solution*, 2.0 mL of *Internal standard solution*, and 0.5 mL of methanol to a 10-mL volumetric flask. Dilute with water to volume.
**Sample stock solution:** Quantitatively dilute, if necessary, an accurately measured volume corresponding to 2.5 mg/mL of chlorobutanol in water.
**Sample solution:** Combine 5.0 mL of *Sample stock solution* with 2.0 mL of *Internal standard solution* in a 10-mL volumetric flask, and dilute with *Diluent* to volume.
**Chromatographic system**
(See *Chromatography* ⟨621⟩, *System Suitability*.)
**Mode:** GC
**Detector:** Flame ionization
**Column:** 30-m × 0.32-mm fused-silica; bonded with a 0.25-µm film of phase G16
**Temperatures**
**Injection port:** 260°
**Detector:** 280°
**Column:** 135°
**Carrier gas:** Helium

**Injection volume:** 0.5 µL
**Split ratio:** 10:1
**Run time:** 12 min
**System suitability**
**Sample:** *Standard solution*
[NOTE—The relative retention times for chlorobutanol and 2,2,2-trichloroethanol are about 1.0 and 1.4, respectively.]
**Suitability requirements**
**Resolution:** NLT 2.0 between chlorobutanol and 2,2,2-trichloroethanol
**Relative standard deviation:** NMT 1.0% for the peak response ratio of chlorobutanol to 2,2,2-trichloroethanol
**Analysis**
**Samples:** *Standard solution* and *Sample solution*
Calculate the percentage of the labeled amount of chlorobutanol ($C_4H_7Cl_3O$), on the anhydrous basis, in the portion of the sample taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

$R_U$ = peak response ratio of chlorobutanol to 2,2,2-trichloroethanol from the *Sample solution*
$R_S$ = peak response ratio of chlorobutanol to 2,2,2-trichloroethanol from the *Standard solution*
$C_S$ = concentration of USP Chlorobutanol RS in the *Standard solution*
$C_U$ = nominal concentration of chlorobutanol in the *Sample solution*

- **PHENOL**

**Internal standard solution:** 2 mg/mL of USP Benzyl Alcohol RS in methanol
**Standard stock solution:** 4 mg/mL of USP Phenol RS in water
**Standard solution:** 0.4 mg/mL each of USP Phenol RS and USP Benzyl Alcohol RS prepared as follows. Combine 5.0 mL of *Standard stock solution* with 10.0 mL of *Internal standard solution* in a 50-mL volumetric flask, and dilute with water to volume.
**Chromatographic system**
(See *Chromatography* ⟨621⟩, *System Suitability*.)
**Mode:** GC
**Detector:** Flame ionization

**Analysis**
**Samples:** *Standard solution* and *Sample solution*
Calculate the percentage of the labeled amount of methylparaben ($C_8H_8O_3$) in the portion of the sample taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

$R_U$ = peak response ratio of methylparaben to ethylparaben from the *Sample solution*
$R_S$ = peak response ratio of methylparaben to ethylparaben from the *Standard solution*
$C_S$ = concentration of USP Methylparaben RS in the *Standard solution*
$C_U$ = nominal concentration of methylparaben in the *Sample solution*

Calculate the percentage of the labeled amount of propylparaben ($C_{10}H_{12}O_3$) in the portion of the sample taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

$R_U$ = peak response ratio of propylparaben to ethylparaben from the *Sample solution*
$R_S$ = peak response ratio of propylparaben to ethylparaben from the *Standard solution*
$C_S$ = concentration of USP Propylparaben RS in the *Standard solution*
$C_U$ = nominal concentration of propylparaben in the *Sample solution*

Ethylparaben and butylparaben may be determined in a similar manner using appropriate internal standard solutions. However, because the extraction recovery is matrix dependent, the user should verify the suitability of the procedure for their drug product and for different product formulations.

- **THIMEROSAL**

**Solution A:** Trifluoroacetic acid and water (0.5: 1000)
**Mobile phase:** Methanol and *Solution A* (60:40)
**Standard solution:** 25 µg/mL of USP Thimerosal RS in water
**Chromatographic system**
(See *Chromatography* ⟨621⟩, *System Suitability*.)
**Mode:** LC
**Detector:** UV 222 nm
**Column:** 2.1-mm × 10-cm; 2-µm packing L1
**Autosampler temperature:** 4°
**Flow rate:** 0.35 mL/min
**Injection volume:** 2.5 µL
**System suitability**
**Sample:** *Standard solution*
**Tailing factor:** NMT 1.5
**Relative standard deviation:** NMT 1.0%
**Analysis**
**Samples:** *Standard solution* and *Sample solution*
Calculate the percentage of the labeled amount of thimerosal ($C_9H_9HgNaO_2S$) in the portion of the sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of thimerosal from the *Sample solution*
$r_S$ = peak response of thimerosal from the *Standard solution*
$C_S$ = concentration of USP Thimerosal RS in the *Standard solution*
$C_U$ = nominal concentration of thimerosal in the *Sample solution*

## POLAROGRAPHIC METHOD

- **PHENYLMERCURIC NITRATE**

**Standard stock solution:** 0.1 mg/mL of phenylmercuric nitrate in sodium hydroxide solution (1 in 250). Warm, if necessary, to dissolve.
**Standard solution:** Pipet 10 mL of *Standard stock solution* into a 25-mL volumetric flask, and proceed as directed under *Sample solution* beginning with "add 2 mL of potassium nitrate solution (1 in 100)".
**Sample solution:** Pipet 10 mL of the specimen under test into a 25-mL volumetric flask, add 2 mL of potassium nitrate solution (1 in 100) and 10 mL of pH 9.2 alkaline borate buffer (see in *Buffer Solutions* in the section *Reagents, Indicators, and Solutions*), and adjust to a pH of 9.2, if necessary, by the addition of 2 N nitric acid. Add 1.5 mL of freshly prepared gelatin solution (1 in 1000), then add the pH 9.2 alkaline borate buffer to volume.
**Analysis:** Pipet a portion of the *Sample solution* into the polarographic cell, and deaerate by bubbling nitrogen through the solution for 15 min. Insert the dropping mercury electrode of a suitable polarograph (see *Polarography* ⟨801⟩), and record the polarogram from –0.6 to –1.5 volts versus the saturated calomel electrode.
Calculate the quantity, in µg/mL, of phenylmercuric nitrate ($C_6H_5HgNO_3$) in the portion of the sample taken:

$$\text{Result} = 2.5C[(i_d)_U/(i_d)_S]$$

$C$ = concentration of phenylmercuric nitrate in the *Standard solution* (µg/mL)

# ⟨345⟩ ASSAY FOR CITRIC ACID/CITRATE AND PHOSPHATE

## INTRODUCTION

The following ion chromatographic general procedure is provided for the determination of citric acid/citrate and phosphate in compendial articles, when specified in the individual monographs. See *Ion Chromatography* ⟨1065⟩ for discussion of the theory and principles of measurements using ion chromatography.

***Change to read:***

**ASSAY** ▲[NOTE—Use procedure A if the monograph does not specify a procedure.]▲ (USP 1-May-2023)

***Change to read:***

• **PROCEDURE** ▲**A**▲ (USP 1-May-2023)

**Mobile phase:** 20 mM sodium hydroxide or potassium hydroxide from an appropriate volume of carbonate-free sodium hydroxide or potassium hydroxide solution of known concentration and water (resistivity NLT 18 megohm-cm). Alternatively, *Mobile phase* can be generated electrolytically using an automatic eluent generator. Protect the *Mobile phase* from atmospheric carbon dioxide.

**Standard solution 1 (for the assay of citric acid/citrate only):** 20 µg/mL of citrate ($C_6H_5O_7$) in freshly prepared 1 mM sodium hydroxide from USP Citric Acid RS

**Standard solution 2 (for the concomitant assay of citrate and phosphate):** 20 µg/mL of citrate ($C_6H_5O_7$) and 12 µg/mL of phosphate ($PO_4$) in freshly prepared 1 mM sodium hydroxide from USP Citric Acid RS and monobasic sodium phosphate

**Sample solution (for the assay of citric acid/citrate):** Nominally 20 µg/mL of citrate in freshly prepared 1 mM sodium hydroxide, unless otherwise stated in the monograph

**Sample solution (for the assay of phosphate):** Nominally 12 µg/mL of phosphate in freshly prepared 1 mM sodium hydroxide, unless otherwise stated in the monograph

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** Conductivity with suppression

**Columns**

**Analytical:** 4-mm × 25-cm; 13-µm packing L61

**Guard:** 4-mm × 5-cm; 13-µm packing L61

**Temperatures**

**Column:** 30°

**Detector:** 35°

**Suppressor:** 4-mm membrane anionic autosuppressor or a suitable chemical suppression system

**Flow rate:** 2 mL/min

**Injection volume:** 10 µL

**System suitability**

**Samples:** *Standard solution 1* and/or *Standard solution 2*, as appropriate

[NOTE—The relative retention times for phosphate and citrate are 0.57 and 1.0, respectively.]

**Suitability requirements**

**Tailing factor:** NMT 2.0 for the citrate and/or phosphate peaks, as appropriate

**Relative standard deviation:** NMT 1.5% for six replicate injections for the citrate and/or phosphate peaks, as appropriate

**Analysis**

**Samples:** *Standard solution 1* and/or *Standard solution 2*, and *Sample solution*

Unless otherwise stated in the monograph, calculate the concentration of citrate or phosphate in the portion of the *Sample solution* taken:

$$\text{Result} = (r_U/r_S) \times C_S$$

$r_U$ = peak response of citrate or phosphate from the *Sample solution*

$r_S$ = peak response of citrate or phosphate from *Standard solution 1* or *Standard solution 2*

$C_S$ = concentration of citrate or phosphate from *Standard solution 1* or *Standard solution 2* (µg/mL)

***Add the following:***

▲• **PROCEDURE B**

**Mobile phase, Standard solution 1, Standard solution 2,** and **Sample solution(s):** Prepare as directed in *Procedure A*.

**System suitability**

**Samples:** *Standard solution 1* and/or *Standard solution 2*, as appropriate

[NOTE—The relative retention times for phosphate and citrate are 0.65 and 1.0, respectively.]

**Suitability requirements**

**Resolution:** NLT 6.5 between phosphate and citrate, *Standard solution 2*

**Tailing factor:** NMT 1.5 for citrate and/or phosphate, as appropriate

**Relative standard deviation:** NMT 1.5% for 6 replicate injections for citrate and/or phosphate, as appropriate

**Analysis:** Proceed as directed in *Procedure A.*▲ (USP 1-May-2023)

## ADDITIONAL REQUIREMENTS

• **USP REFERENCE STANDARDS** ⟨11⟩

USP Citric Acid RS

Official

https://pharmacopeia.com/

# ⟨351⟩ ASSAY FOR STEROIDS

The following procedure is applicable for determination of those Pharmacopeial steroids that possess reducing functional groups such as α-ketols.

## STANDARD PREPARATION

Dissolve in alcohol a suitable quantity of the USP Reference Standard specified in the individual monograph, previously dried under the conditions specified in the individual monograph and accurately weighed, and dilute quantitatively and stepwise with alcohol to obtain a solution having a concentration of about 10 µg per mL. Pipet 20 mL of this solution into a glass-stoppered, 50-mL conical flask.

## ASSAY PREPARATION

Prepare as directed in the individual monograph.

## PROCEDURE

To each of the two flasks containing the *Assay Preparation* and the *Standard Preparation,* respectively, and to a similar flask containing 20.0 mL of alcohol to serve as the blank, add 2.0 mL of a solution prepared by dissolving 50 mg of blue tetrazolium in 10 mL of methanol, and mix. Then to each flask add 2.0 mL of a mixture of alcohol and tetramethylammonium hydroxide TS (9:1), mix, and allow to stand in the dark for 90 minutes. Without delay, concomitantly determine the absorbances of the solutions from the *Assay Preparation* and the *Standard Preparation* at about 525 nm, with a suitable spectrophotometer, against the blank. Calculate the result by the formula given in the individual monograph, in which C is the concentration, in µg per mL, of the Reference Standard in the *Standard Preparation;* and $A_U$ and $A_S$ are the absorbances of the solutions from the *Assay Preparation* and the *Standard Preparation,* respectively.

# ⟨381⟩ ELASTOMERIC ▲COMPONENTS IN INJECTABLE PHARMACEUTICAL PRODUCT PACKAGING/DELIVERY SYSTEMS

1. INTRODUCTION
2. SCOPE
3. TEST SAMPLES
4. PROCEDURES
    4.1 Biological Reactivity
    4.2 Physicochemical Tests
    4.3 Functionality Tests

## 1. INTRODUCTION

Packaging systems, also referred to as container–closure systems, are defined in *Packaging and Storage Requirements* ⟨659⟩; these systems are the sum of components that together contain and protect the drug product. Elastomeric components are formulated with elastomeric substances and can be either thermoset or thermoplastic in nature.

Every elastomeric component used in a pharmaceutical packaging/delivery system should be proven suitable for its intended use. The purpose of this chapter is to provide baseline chemical and biological reactivity requirements for the selection of elastomeric injectable packaging/delivery system components.

The establishment of the potential suitability of an elastomeric component does not rely on a single testing strategy. No single strategy can cover all elastomeric component attributes that have the potential to impact suitability. The chemical testing prescribed includes physicochemical tests. Extractable elements may also be relevant to the selection of a packaging system's materials of construction and therefore a relevant aspect of material characterization. Materials of construction can vary widely in terms of their intentionally and unintentionally added elements and their potential use. Because of this, it is challenging to provide universally effective and efficient test methodologies, lists of target elements, and reporting requirements. It is the material user's responsibility to evaluate the need for extractable elements testing and, if such testing is necessary, to establish and justify the means by which testing is accomplished, taking into account extraction conditions, target elements, and reporting requirement. Elastomeric components can vary widely in terms of their intentionally and unintentionally added elements as well as the components' potential use. Because of this, it is challenging to provide universally effective and efficient test methodologies, lists of target elements, and reporting requirements. It is the elastomeric component user's responsibility to evaluate the need for extractable elements testing and, if such testing is necessary, to establish and justify the means by which testing is accomplished, taking into account extraction conditions, target elements, and reporting requirements. The physicochemical tests are also augmented with biological reactivity tests.

If elastomeric components comply with the requirements outlined in this chapter, studies should follow to determine their suitability as recommended in *Assessment of Extractables Associated with Pharmaceutical Packaging/Delivery Systems* ⟨1663⟩ and *Assessment of Drug Product Leachables Associated with Pharmaceutical Packaging/Delivery Systems* ⟨1664⟩.

In summary, establishing chemical suitability of elastomeric components for injectable product packaging/delivery systems involves multiple tests and testing procedures including:

- Elastomeric component screening—baseline requirements for biological reactivity and physicochemical tests described in this chapter.
- Controlled extraction studies—studies as described in ⟨1663⟩ to create extractables profile(s) of particular pharmaceutical packaging/delivery systems and/or packaging components.
- Pharmaceutical product assessment—Actual-case measurement of confirmed leachables in the pharmaceutical product in the packaging/delivery system intended for the commercial market. (For additional information, see ⟨1664⟩.)

Additional information about elastomeric components, such as their composition, manufacturing processes, considerations for use, and testing procedures is found in ⟨1381⟩.

## 2. SCOPE

Elastomeric components within scope are those used in the packaging systems of products described in *Injections and Implanted Drug Products* ⟨1⟩.

Elastomeric components utilized for injectable products within chapter scope include, but are not limited to, those used for vials and bottles (stoppers and cap liners), prefilled syringes (plungers, needle shields, and tip caps), cartridges (plungers and seal liners), flexible bags (injection ports), and blow-fill-seal containers (cap liners). The specified procedures and requirements outlined in this chapter are not applicable to elastomeric components used in products regulated by the Center for Devices and Radiological Health. All elastomeric components in direct or indirect contact with the pharmaceutical product are within scope. An example of indirect contact is an elastomeric layer of a multilayer cap liner that does not directly contact the product but may leach into the product via migration through the product contact layer. Another example is an elastomeric cap liner that may contact the product after being punctured to attain product access.

Also within scope are elastomeric components of systems or packages that are intended for transient product storage and/or product delivery intended for specific pharmaceutical products.

Elastomeric components outside of scope include those components of containers and closures that do not have direct or indirect contact with the pharmaceutical product or hold intermediate compounds, active pharmaceutical ingredients (APIs), and excipients. Also outside chapter scope are elastomeric components of containment and/or transport systems used in product, intermediate compound, API, or excipient manufacturing. Although outside of the chapter scope, chapter tests and requirements may be applied.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99140_06_01
@2024 USPC

Chapter procedures and requirements are specified for physicochemical and biological reactivity tests. Elastomeric component identification tests fall beyond the chapter scope. Elastomeric components are made of a wide variety of elastomeric materials and optional polymeric coatings. For this reason, it is not possible to have identification tests that encompass all possible elastomeric component presentations.

Elastomeric component functional suitability tests described in this chapter are within scope until *Elastomeric Component Functional Suitability in Parenteral Product Packaging/Delivery Systems* ⟨382⟩ is fully implemented. As part of a finished product packaging system, elastomeric components must appropriately function to seal the container and, in some cases, aid in safe and effective product delivery. The essential principles and demonstrated best practices for such assessments for injectable product packaging/delivery systems can be found in ⟨382⟩ and *Assessment of Elastomeric Component Functional Suitability in Parenteral Product Packaging/Delivery Systems* ⟨1382⟩.

## 3. TEST SAMPLES

Test samples should mimic finished elastomeric components after the completion of all manufacturing and processing steps (e.g., molding conditions, sterilization, etc.), and surface modifications (such as siliconization, chlorinated surface treatments, fluoropolymer coatings and films).

## 4. PROCEDURES

**4.1 BIOLOGICAL REACTIVITY:** Elastomeric components (Type I and Type II) meet the requirements of *Biological Reactivity Tests, In Vitro* ⟨87⟩.[1] If components do not meet the requirements of ⟨87⟩, they can be subjected to in vivo testing set forth in *Biological Reactivity Tests, In Vivo* ⟨88⟩, *Systemic Injection Test* and ⟨88⟩, *Intracutaneous Test*. Components that meet the requirements of ⟨87⟩ are not required to undergo ⟨88⟩ testing.

Type I and Type II closures must both conform to the requirements of either the in vitro or the in vivo biological reactivity tests.

**Acceptance criteria:** Test selection and results are consistent with ⟨87⟩ and/or ⟨88⟩.

**4.2 PHYSICOCHEMICAL TESTS**

**Sample solution:** Place whole, uncut elastomeric components corresponding to a surface area of 100 ± 10 $cm^2$ into a borosilicate glass, wide-necked flask (see *Containers—Glass* ⟨660⟩). If it is not possible to achieve the prescribed closure surface area (100 ± 10 $cm^2$) using uncut elastomeric components, select the number of components that will most closely approximate 100 $cm^2$ and adjust the volume of water used to the equivalent of 2 mL/1 $cm^2$ of the actual elastomeric component's surface area. Add 200 mL of *Purified Water* or *Water for Injection* to the elastomeric components, and weigh. Cover the mouth of the flask with a borosilicate glass beaker, or similar non interacting container. Immerse the temperature probe for the autoclave program control in water in a container comparable to that used for the sample. Heat in an autoclave so that a temperature of 121 ± 2° is reached within 20–30 min, and maintain this temperature for 30 min. Cool to room temperature over a period of about 30 min. Add *Purified Water* or *Water for Injection* to bring it up to the original mass. Shake, and immediately decant and collect the solution. [NOTE—This solution must be shaken before being used in each of the tests.]

**Blank:** Prepare a blank solution similarly, using 200 mL of *Purified Water* or *Water for Injection*, omitting the elastomeric components.

**Elastomeric component categories, Type I and II:** Elastomeric components may be classified in two types: Type I elastomeric closures meet the strictest requirements and are preferred; Type II elastomeric closures have mechanical properties suitable for special uses (e.g., multiple piercing) but cannot meet the Type I acceptance criteria for *4.2.1 Appearance, 4.2.4 Absorbance*, and *4.2.5 Reducing Substances*. For these tests, Type II elastomeric closures have alternative acceptance criteria that must be met. The intended final product application will determine whether a Type I or Type II elastomeric component is more appropriate.

**4.2.1 Appearance (Turbidity/Opalescence):** The determination of turbidity may be performed using either a visual or instrumental comparison. For a discussion of turbidimetry, see *Nephelometry and Turbidimetry* ⟨855⟩. Instrumental assessment of clarity provides a more discriminatory test that does not depend on the visual acuity of the analyst.

**Hydrazine sulfate solution:** Dissolve 1.000 g of analytical grade hydrazine sulfate in particle-free water and dilute with particle-free water to 100.0 mL. Allow this solution to stand for 4–6 h.

**Hexamethylenetetramine solution:** Dissolve 2.5 g of analytical grade hexamethylenetetramine in 25.0 mL of particle-free water in a 100-mL glass-stoppered flask.

**Formazin stock suspension:** Add 25.0 mL of *Hydrazine sulfate solution* to the *Hexamethylenetetramine solution* in the 100-mL flask. Mix, and allow to stand for 48 h at 25 ± 1° before using. This suspension is stable for 2 months, provided it is stored in a glass container free from surface defects. The suspension must not adhere to the glass and must be well mixed before use.

**Formazin standard suspension:** Prepare a suspension by diluting 15.0 mL of the *Formazin stock suspension* with particle-free water to 1000.0 mL. It is stable for about 24 h after preparation.

**Reference suspensions:** Prepare according to *Table 1*. Mix and shake before use. [NOTE—Stabilized formazin suspensions that can be used to prepare stable, diluted turbidity standards are available commercially and may be used after comparison with the standards prepared as described.]

**Table 1. Reference Suspensions**

| | Reference Suspension A | Reference Suspension B | Reference Suspension C | Reference Suspension D |
|---|---|---|---|---|
| Standard of opalescence | 5.0 mL | 10.0 mL | 30.0 mL | 50.0 mL |
| Particle-free water | 95.0 mL | 90.0 mL | 70.0 mL | 50.0 mL |

[1] Biological reactivity testing in support of elastomeric components used for final pharmaceutical product packaging/delivery systems (drugs and drug/device combination products) provides baseline information and will often not be sufficient to assess the final suitability for use expectations of regulatory authorities. Thus, it is important to work with the appropriate regulatory authority for guidance regarding a product-specific application.

| Nephelometric turbidity units (NTU) | 3 NTU | 6 NTU | 18 NTU | 30 NTU |

**Procedure A (Visual Comparison ⟨630⟩):** Use identical test tubes made of colorless, transparent, neutral glass with a flat base and an internal diameter of 15–25 mm. Fill one tube to a depth of 40 mm with *Sample solution*, one tube to the same depth with water, and 4 other tubes to the same depth with *Reference suspension A*, *Reference suspension B*, *Reference suspension C*, and *Reference suspension D*. Compare the solutions in diffuse daylight 5 min after preparation of the *Reference suspensions*, viewing vertically against a black background. The light conditions must be such that *Reference suspension A* can be readily distinguished from water, and *Reference suspension B* can be readily distinguished from *Reference suspension A*.

**Acceptance criteria:** *Type I—Sample solution* is not more opalescent than *Reference suspension B*. *Type II—Sample solution* is not more opalescent than *Reference suspension C*.

**Procedure B (instrumental comparison):** Measure the turbidity of the *Reference suspensions* in a suitable calibrated turbidimeter (see *Nephelometry and Turbidimetry* ⟨855⟩). The *Blank* should be run and the results corrected for the *Blank*. *Reference suspension A, Reference suspension B, Reference suspension C*, and *Reference suspension D* represent 3, 6, 18, and 30 NTUs, respectively. Measure the turbidity of *Sample solution* using the calibrated turbidimeter.

**Acceptance criteria:** *Type I*—The turbidity of *Sample solution* [in nephelometric turbidity units (NTUs) or formazin turbidity units (FTUs) corrected for the blank] is NMT that for *Reference suspension B* (6 NTU/FTU). *Type II*—The turbidity of *Sample solution* (in nephelometric turbidity units or formazin turbidity units, corrected for the blank) is NMT that for *Reference suspension C* (18 NTU/FTU).

**4.2.2 Color**

**Color standard:** Prepare a solution by diluting 3.0 mL of *Matching Fluid O* (see *Color and Achromicity* ⟨631⟩) with 97.0 mL of diluted hydrochloric acid (10 ± 0.5%).

**Procedure:** Use identical tubes made of colorless, transparent, neutral glass with a flat base and an internal diameter of 15–25 mm. Fill one tube to a depth of 40 mm with *Sample solution*, and fill the second tube with the *Color standard*. Compare the liquids in diffuse daylight, viewing vertically against a white background.

**Acceptance criteria:** *Sample solution* is not more intensely colored than the *Color standard*.

**4.2.3 Acidity or Alkalinity**

**Bromothymol blue solution:** Dissolve 50 mg of bromothymol blue in a mixture of 4 mL of 0.02 M sodium hydroxide and 20 mL of alcohol. Dilute with water to 100 mL.

**Test solution:** To 20 mL of *Sample solution* add 0.1 mL of *Bromothymol blue solution*.

**Procedure:** If the solution is yellow, titrate with 0.01 N sodium hydroxide until a blue endpoint is reached. If the solution is blue, titrate with 0.01 N hydrochloric acid until a yellow endpoint is reached. If the solution is green, it is neutral and no titration is required.

**Blank correction:** Test 20 mL of *Blank* similarly. Correct the results obtained for *Sample solution* by subtracting or adding the volume of titrant required for the *Blank*, as appropriate. (See *Titrimetry* ⟨541⟩.)

**Acceptance criteria:** NMT 0.3 mL of 0.01 N sodium hydroxide produces a blue color or NMT 0.8 mL of 0.01 N hydrochloric acid produces a yellow color, or no titration is required.

**4.2.4 Absorbance**

[NOTE—Perform this test within 5 h of preparing *Sample solution*.]

**Procedure:** Pass *Sample solution* through an inert filter of 0.45-µm pore size, discarding the first few milliliters of filtrate. Measure the absorbance of the filtrate at wavelengths between 220 and 360 nm in a 1-cm cell using the *Blank* in a matched cell in the reference beam. If dilution of the filtrate is required before measurement of the absorbance, correct the test results for the dilution.

**Acceptance criteria:** *Type I*—NMT 0.2 *Type II*—NMT 4.0.

**4.2.5 Reducing Substances**

[NOTE—Perform this test within 4 h of preparing *Sample solution*.]

**Procedure:** To 20.0 mL of *Sample solution* add 1 mL of diluted sulfuric acid and 20.0 mL of 0.002 M potassium permanganate. Boil for 3 min. Cool, add 1 g of potassium iodide, and titrate immediately with 0.01 M sodium thiosulfate using 0.25 mL of starch solution TS as the indicator. Perform a titration using 20.0 mL of *Blank* and note the difference in volume of 0.01 M sodium thiosulfate required.

**Acceptance criteria:** *Type I*—The difference between titration volumes is NMT 3.0 mL of 0.01 M sodium thiosulfate. *Type II*—The difference between titration volumes is NMT 7.0 mL of 0.01 M sodium thiosulfate.

**4.2.6 Volatile Sulfides**

**Procedure:** Place elastomeric components, cut if necessary, with a total surface area of 20 ± 2 $cm^2$ in a 100-mL flask, and add 50 mL of a 20-g/L citric acid solution. In the same manner and at the same time, prepare a control solution in a separate flask by dissolving 0.154 mg of sodium sulfide in 50 mL of a 20-g/L citric acid solution. Place a piece of lead acetate paper over the mouth of each flask, and hold the paper in position by placing an inverted weighing bottle over it. Immerse the temperature probe for the autoclave program control in water in a container comparable to that used for the sample. Heat the flasks in an autoclave so that a temperature of 121 ± 2° is reached within 20–30 min, and then maintain this temperature for 30 min. Cool to room temperature over a period of about 30 min.

**Acceptance criteria:** Any black stain on the paper produced by the test solution is not more intense than that produced by the control solution.

#### 4.2.7 Ammonium

**Alkaline potassium tetraiodomercurate solution:** Prepare a 100-mL solution containing 11 g of potassium iodide and 15 g of mercuric iodide in water. Immediately before use, mix one volume of this solution with an equal volume of a 250-g/L solution of sodium hydroxide.

**Test solution:** Dilute 5 mL of *Sample solution* with water to 14 mL. Make alkaline, if necessary, by adding 1 N sodium hydroxide, and dilute with water to 15 mL. Add 0.3 mL of *Alkaline potassium tetraiodomercurate solution* and close the container.

**Ammonium standard solution:** Prepare a solution of ammonium chloride in water [1 ppm of ammonium ($NH_4^+$)]. Mix 10 mL of the 1 ppm ammonium chloride solution with 5 mL of water and 0.3 mL of *Alkaline potassium tetraiodomercurate solution*. Close the container.

**Acceptance criteria:** After 5 min, any yellow color in the *Test solution* is no darker than the *Ammonium standard solution* [NMT 2 ppm of ammonium ($NH_4^+$) in *Sample solution*].

### 4.3 FUNCTIONALITY TESTS

[NOTE—Samples treated as described for preparation of *Sample solution* and air-dried should be used for the functionality tests of *4.3.1 Penetrability, 4.3.2 Fragmentation,* and *4.3.3 Self-Sealing Capacity.* Functionality tests are performed on closures intended to be pierced by a hypodermic needle. The *4.3.3 Self-Sealing Capacity* test is required only for closures intended for multiple-dose containers. The needle specified for each test is a lubricated, long-bevel (bevel angle 12 ± 2°) hypodermic needle with an external diameter of 0.8 mm (21 gauge).[2] ]

#### 4.3.1 Penetrability

**Procedure:** Fill 10 suitable vials to the nominal volume with water, fit the closures to be examined, and secure with a cap. Using a new hypodermic needle as described above for each closure, pierce the closure with the needle perpendicular to the surface.

**Acceptance criteria:** The force for piercing is no greater than 10 N (1 kilogram-force) for each closure, determined with an accuracy of ±0.25 N (25 gram-force).

#### 4.3.2 Fragmentation

**Closures for liquid preparations:** Fill 12 clean vials with water to 4 mL less than the nominal capacity. Fit the closures to be examined, secure with a cap, and allow to stand for 16 h.

**Closures for dry preparations:** Fit closures to be examined into 12 clean vials, and secure each with a cap.

**Procedure:** Using a hypodermic needle as described above fitted to a clean syringe, inject into each vial 1 mL of water while removing 1 mL of air. Repeat this procedure 4 times for each closure, piercing each time at a different site. Use a new needle for each closure, checking that it is not blunted during the test. Filter the total volume of liquid in all the vials through a single filter with a nominal pore size NMT 0.5 µm. Count the rubber fragments on the surface of the filter visible to the naked eye.

**Acceptance criteria:** There are no more than 5 fragments visible. This limit is based on the assumption that fragments with a diameter >50 µm are visible to the naked eye. In case of doubt or dispute, the particles are examined microscopically to verify their nature and size.

#### 4.3.3 Self-Sealing Capacity

**Procedure:** Fill 10 suitable vials with water to the nominal volume. Fit the closures that are to be examined, and cap. Using a new hypodermic needle as described above for each closure, pierce each closure 10 times, piercing each time at a different site. Immerse the 10 vials in a solution of 0.1% (1 g/L) methylene blue, and reduce the external pressure by 27 kPa for 10 min. Restore to atmospheric pressure, and leave the vials immersed for 30 min. Rinse the outside of the vials.

**Acceptance criteria:** None of the vials contain any trace of blue solution.▲ (USP 1-Dec-2020)

# ⟨391⟩ EPINEPHRINE ASSAY

## ASSAY

**Ferro-citrate solution:** On the day needed, dissolve 1.5 g of ferrous sulfate in 200 mL of water to which have been added 1.0 mL of dilute hydrochloric acid (1 in 12) and 1.0 g of sodium bisulfite. Dissolve 500 mg of sodium citrate in 10 mL of this solution, and mix.

**Buffer solution:** In a 50-mL volumetric flask mix 4.2 g of sodium bicarbonate, 5.0 g of potassium bicarbonate, and 18 mL of water (not all of the solids will dissolve at this stage). To another 18 mL of water add 3.75 g of aminoacetic acid and 1.7 mL of 6 N ammonium hydroxide, mix to dissolve, and transfer this solution to the 50-mL volumetric flask containing the other mixture. Dilute with water to volume, and mix until solution is complete.

**Standard preparation:** Transfer about 18 mg of USP Epinephrine Bitartrate RS, accurately weighed, to a 100-mL volumetric flask with the aid of 20 mL of sodium bisulfite solution (1 in 50), dilute with water to volume, and mix. Transfer 5.0 mL of this solution to a 50-mL volumetric flask, dilute with sodium bisulfite solution (1 in 500) to volume, and mix. [NOTE—Make the final dilution when the assay is carried out.] The concentration of USP Epinephrine Bitartrate RS in the *Standard preparation* is about 18 µg per mL.

**Assay preparation:** Transfer to a 50-mL volumetric flask an accurately measured volume of the Injection under assay, equivalent to about 500 µg of epinephrine, dilute with sodium bisulfite solution (1 in 500) to volume, if necessary, and mix. [NOTE—The final concentration of sodium bisulfite is in the range of 1 to 3 mg per mL, any bisulfite present in the Injection under assay being taken into consideration.]

**Procedure:** Into three 50-mL glass-stoppered conical flasks transfer, separately, 20.0-mL aliquots of the *Standard preparation*, the *Assay preparation*, and sodium bisulfite solution (1 in 500) to provide the blank. To each flask add 200 µL of *Ferro-citrate solution* and 2.0 mL of *Buffer solution*, mix, and allow the solutions to stand for 30 minutes. Determine the absorbances of the solutions in 5-cm cells at the wavelength of maximum absorbance at about 530 nm, with a suitable spectrophotometer, using the blank to set the instrument.

Calculate the quantity, in mg, of epinephrine ($C_9H_{13}NO_3$) in each mL of the Injection taken by the formula, in which 183.21 and 333.30 are the molecular weights of epinephrine and epinephrine bitartrate, respectively:

$$\text{Result} = (183.21/333.30)(0.05C/V)(A_U/A_S)$$

$C$ = concentration of USP Epinephrine Bitartrate RS in the *Standard preparation* (µg/mL)
$V$ = volume of Injection taken (mL)
$A_U$ = absorbance of the *Assay preparation*
$A_S$ = absorbance of the *Standard preparation*

# ⟨401⟩ FATS AND FIXED OILS

The following definitions and general procedures apply to fats, fixed oils, waxes, resins, balsalms, and similar substances.

• **Preparation of Specimen**

If a specimen of oil shows turbidity owing to separated stearin, warm the container in a water bath at 50° until the oil is clear, or if the oil does not become clear on warming, pass it through dry filter paper in a funnel contained in a hot-water jacket. Mix thoroughly, and weigh at one time as many portions as are needed for the various determinations, preferably using a bottle that has a pipet dropper or a weighing buret. If the specimen is solid at room temperature, keep it melted until the desired portions of specimen are withdrawn.

## PROCEDURES

• **Specific Gravity:** Determine the specific gravity of a fat or oil as directed in *Specific Gravity* ⟨841⟩.

• **Melting Temperature:** Determine the melting temperature as directed for *Class II* substances (see *Melting Range or Temperature* ⟨741⟩).

• **Acid Value (Free Fatty Acids)**

The acidity of fats and fixed oils in this pharmacopeia may be expressed as the number of mL of 0.1 N alkali required to neutralize the free acids in 10.0 g of substance. Acidity frequently is expressed as the Acid Value, which is the number of mg of potassium hydroxide required to neutralize the free acids in 1.0 g of the substance. Unless directed otherwise in the individual monograph, use *Method I*.

### Method I

**Procedure:** Unless directed otherwise, dissolve about 10.0 g of the substance, accurately weighed, in 50 mL of a mixture of equal volumes of alcohol and ether (which has been neutralized to phenolphthalein with 0.1 N potassium hydroxide or 0.1 N sodium hydroxide, unless otherwise specified) contained in a flask. If the test specimen does not dissolve in the cold solvent, connect the flask with a suitable condenser and warm slowly, with frequent shaking, until the specimen dissolves. Add 1 mL of phenolphthalein TS, and titrate with 0.1 N potassium hydroxide VS or 0.1 N sodium hydroxide VS until the solution remains faintly pink after shaking for 30 s. Calculate either the Acid Value or the volume of 0.1 N alkali required to neutralize 10.0 g of specimen (free fatty acids), whichever is appropriate. Calculate the Acid Value:

$$\text{Result} = (M_r \times V) \times (N/W)$$

$M_r$ = molecular weight of potassium hydroxide, 56.11
$V$ = volume (mL)
$N$ = normality of the potassium hydroxide solution or the sodium hydroxide solution
$W$ = weight of the sample taken (g)

If the volume of 0.1 N potassium hydroxide VS or 0.1 N sodium hydroxide VS required for the titration is less than 2 mL, a more dilute titrant may be used, or the sample size may be adjusted accordingly. The results may be expressed in terms of the volume of titrant used or in terms of the equivalent volume of 0.1 N potassium hydroxide or 0.1 N sodium hydroxide.

If the oil has been saturated with carbon dioxide for the purpose of preservation, gently reflux the alcohol–ether solution for 10 min before titration. The oil may be freed from carbon dioxide also by exposing it in a shallow dish in a vacuum desiccator for 24 h before weighing the test specimens.

### Method II

**Procedure:** Prepare 125 mL of a solvent mixture consisting of equal volumes of isopropyl alcohol and toluene. Before use, add 2 mL of a 1% solution of phenolphthalein in isopropyl alcohol to the 125-mL mixture, and neutralize with alkali to a faint but permanent pink color. Accurately weigh the appropriate amount of well-mixed liquid sample indicated in *Table 1*, and dissolve it in the neutralized solvent mixture. If the test specimen does not dissolve in the cold solvent, connect the flask with a suitable condenser and warm slowly, with frequent shaking, until the specimen dissolves. Shake vigorously while titrating with 0.1 N potassium hydroxide VS or 0.1 N sodium hydroxide VS to the first permanent pink of the same intensity as that of the neutralized solvent before mixing with the sample. Calculate the Acid Value as indicated in *Method I*.

**Table 1**

| Acid Value | Sample Weight (g) |
|---|---|
| 0–1 | 20 |
| 1–4 | 10 |
| 4–15 | 2.5 |
| 15–74.9 | 0.5 |
| ≥75.0 | 0.1 |

• **Ester Value**

The Ester Value is the number of mg of potassium hydroxide required to saponify the esters in 1.0 g of the substance. If the Saponification Value and the Acid Value have been determined, the difference between these two represents the Ester Value (i.e., Ester Value = Saponification Value – Acid Value).

Official

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-May-2022
DOI Ref: h5qn4
DocId: GUID-DA3A8434-91C3-4E62-9AF4-33ED2BEE8369_4_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99160_04_01
@2024 USPC

**Procedure:** Place 1.5–2 g of the substance, accurately weighed, in a tared, 250-mL flask, add 20–30 mL of neutralized alcohol, and shake. Add 1 mL of phenolphthalein TS, and titrate with 0.5 N alcoholic potassium hydroxide VS until the free acid is neutralized. Add 25.0 mL of 0.5 N alcoholic potassium hydroxide VS, and proceed as directed in *Saponification Value*, beginning with "Heat the flask" and omitting the further addition of phenolphthalein TS. Calculate the Ester Value:

$$\text{Result} = [M_r \times (V_B - V_T) \times N]/W$$

$M_r$ = molecular weight of potassium hydroxide, 56.11
$V_B$ = volume of 0.5 N hydrochloric acid consumed in the blank test (mL)
$V_T$ = volume of 0.5 N hydrochloric acid consumed in the actual test (mL)
$N$ = exact normality of the hydrochloric acid
$W$ = weight of the substance taken for the test (g)

• **Hydroxyl Value**

The Hydroxyl Value is the number of mg of potassium hydroxide equivalent to the hydroxyl content of 1.0 g of the substance.

**Pyridine–acetic anhydride reagent:** Just before use, mix 3 volumes of freshly opened or freshly distilled pyridine with 1 volume of freshly opened or freshly distilled acetic anhydride.

**Procedure:** Transfer a quantity of the substance, determined by reference to *Table 2* and accurately weighed, to a glass-stoppered, 250-mL conical flask, and add 5.0 mL of *Pyridine–acetic anhydride reagent*. Transfer 5.0 mL of *Pyridine–acetic anhydride reagent* to a second glass-stoppered, 250-mL conical flask to provide the reagent blank. Fit both flasks with suitable glass-jointed reflux condensers, heat on a steam bath for 1 h, add 10 mL of water through each condenser, and heat on the steam bath for 10 min more. Cool, and to each add 25 mL of butyl alcohol, previously neutralized to phenolphthalein TS with 0.5 N alcoholic potassium hydroxide, by pouring 15 mL through each condenser and, after removing the condensers, washing the sides of both flasks with the remaining 10-mL portions. To each flask add 1 mL of phenolphthalein TS, and titrate with 0.5 N alcoholic potassium hydroxide VS, recording the volume, in mL, consumed by the residual acid in the test solution as *T* and that consumed by the blank as *B*. In a 125-mL conical flask, mix about 10 g of the substance, accurately weighed, with 10 mL of freshly distilled pyridine, previously neutralized to phenolphthalein TS, add 1 mL of phenolphthalein TS, and titrate with 0.5 N alcoholic potassium hydroxide VS, recording the volume, in mL, consumed by the free acid in the test specimen as *A*.
Calculate the Hydroxyl Value:

$$\text{Result} = [(M_r \times N)/W] \times \{B + [(W \times A)/C] - T\}$$

$M_r$ = molecular weight of potassium hydroxide, 56.11
$N$ = exact normality of the alcoholic potassium hydroxide
$W$ = weight of the substances taken for the acetylation (g)
$C$ = weight of the substances taken for the free acid determination (g)

If the Acid Value for the test substance is known, calculate the Hydroxyl Value:

$$\text{Result} = [(M_r \times N)/W] \times (B - T) + \text{Acid Value}$$

$M_r$ = molecular weight of potassium hydroxide, 56.11
$N$ = exact normality of the alcoholic potassium hydroxide
$W$ = weight of the substance taken for the acetylation (g)

**Table 2**

| Hydroxyl Value Range | Weight of Test Specimen (g) |
|---|---|
| 0–20 | 10 |
| 20–50 | 5 |
| 50–100 | 3 |
| 100–150 | 2 |
| 150–200 | 1.5 |
| 200–250 | 1.25 |
| 250–300 | 1.0 |
| 300–350 | 0.75 |

• **Iodine Value**

The Iodine Value represents the number of g of iodine absorbed, under the prescribed conditions, by 100 g of the substance. Unless otherwise specified in the individual monograph, determine the Iodine Value by *Method I*.

Official

https://nhathuoc.gdoat.info/

**Method I (Hanus method)**

**Procedure:** Transfer an accurately weighed quantity of sample, as determined from *Table 3*, into a 250-mL iodine flask, dissolve it in 10 mL of chloroform, add 25.0 mL of iodobromide TS, insert the stopper in the vessel securely, and allow it to stand for 30 min protected from light, with occasional shaking. Then add, in the order named, 30 mL of potassium iodide TS and 100 mL of water, and titrate the liberated iodine with 0.1 N sodium thiosulfate VS, shaking thoroughly after each addition of thiosulfate. When the iodine color becomes quite pale, add 3 mL of starch TS, and continue the titration with 0.1 N sodium thiosulfate VS until the blue color is discharged. Perform a blank test at the same time with the same quantities of the same reagents and in the same manner (see *Titrimetry* ⟨541⟩, *Residual Titrations*).

Calculate the Iodine Value:

$$\text{Result} = [A_r \times (V_B - V_S) \times N]/(10 \times W)$$

$A_r$ = atomic weight of iodine, 126.90
$V_B$ = volume of 0.1 N sodium thiosulfate VS consumed by the blank test (mL)
$V_S$ = volume of 0.1 N sodium thiosulfate VS consumed by the actual test (mL)
$N$ = exact normality of the sodium thiosulfate VS
$W$ = weight of the substance taken for the test (g)

[NOTE—If more than half of the iodobromide TS is absorbed by the portion of the substance taken, repeat the determination, using a smaller portion of the substance under examination.]

**Table 3. Sample Weights**

| Iodine Value Expected | Weight (g) ±0.1 |
|---|---|
| <5 | 3.0 |
| 5–20 | 1.0 |
| 21–50 | 0.4 |
| 51–100 | 0.2 |
| 101–150 | 0.13 |
| 151–200 | 0.1 |

**Method II**

**Potassium iodide solution:** Dissolve 10.0 g of potassium iodide in water to make 100 mL. Store in light-resistant containers.

**Starch indicator solution:** Mix 1 g of soluble starch with sufficient cold water to make a thin paste. Add, while stirring, to 100 mL of boiling water. Mix, and cool. Use only the clear solution.

**Procedure:** Melt the sample, if it is not already liquid. [NOTE—The temperature during melting should exceed the melting point of the sample by not more than 10°.] Pass through two pieces of filter paper to remove any solid impurities and the last traces of moisture. The filtration may be performed in an air oven at 100° but should be completed within 5 min ± 30 s. The sample must be absolutely dry. All glassware must be absolutely clean and completely dry. After filtration, allow the filtered sample to achieve a temperature of 68°–71 ± 1° before weighing the sample. Once the sample has achieved a temperature of 68°–71 ± 1°, immediately weigh the sample into a 500-mL iodine flask, using the weights and weighing accuracy noted in the accompanying table. [NOTE—The weight of the substance must be such that there will be an excess of iodochloride TS of 50%–60% of the amount added, that is, 100%–150% of the amount absorbed.] Add 15 mL of a fresh mixture of cyclohexane and glacial acetic acid (1:1), and swirl to dissolve the sample. Add 25.0 mL of iodochloride TS, insert the stopper securely in the flask, and swirl to mix. Allow it to stand at 25 ± 5°, protected from light, with occasional shaking, for 1.0 or 2.0 h, depending on the Iodine Value (IV) of the sample: IV < 150, 1.0 h; IV ≥ 150, 2.0 h. Then, within 3 min after the indicated reaction time, add, in the order named, 20 mL of *Potassium iodide solution* and 150 mL of recently boiled and cooled water, and mix. Within 30 min, titrate the liberated iodine with 0.1 N sodium thiosulfate VS, while stirring by mechanical means after each addition of thiosulfate. When the yellow iodine color has almost disappeared, add 1–2 mL of *Starch indicator solution*, and continue the titration with 0.1 N sodium thiosulfate VS until the blue color is discharged. Perform a blank test at the same time with the same quantities of the same reagents and in the same manner (see ⟨541⟩, *Residual Titrations*). Calculate the Iodine Value as indicated in *Method I*.

• **PEROXIDE VALUE**

The Peroxide Value is the number that expresses, in milliequivalents of active oxygen, the quantity of peroxide contained in 1000 g of the substance. [NOTE—This test must be performed promptly after sampling to avoid oxidation of the test specimen.]

**Procedure:** Unless otherwise directed, place about 5 g of the substance, accurately weighed, in a 250-mL conical flask fitted with a ground-glass stopper. Add 30 mL of a mixture of glacial acetic acid and chloroform (3:2), shake to dissolve, and add 0.5 mL of saturated potassium iodide solution. Shake for exactly 1 min, and add 30 mL of water. Titrate with 0.01 N sodium thiosulfate VS, adding the titrant slowly with continuous shaking, until the yellow color is almost discharged. Add 5 mL of starch TS, and continue the titration, shaking vigorously, until the blue color is discharged. Perform a blank determination under the same conditions. [NOTE—The volume of titrant used in the blank determination must not exceed 0.1 mL.]

Calculate the Peroxide Value:

Official

https://pharmacopeia.cn/v29240/

$$\text{Result} = [1000\ (V_T - V_B) \times N]/W$$

$V_T$ = volume of 0.01 N sodium thiosulfate consumed in the actual test (mL)
$V_B$ = volume of 0.01 N sodium thiosulfate consumed in the blank test (mL)
$N$ = exact normality of the sodium thiosulfate solution
$W$ = weight of the substance taken for the test (g)

- **Saponification Value**

The Saponification Value is the number of mg of potassium hydroxide required to neutralize the free acids and saponify the esters contained in 1.0 g of the substance.

**Procedure:** Place 1.5–2 g of the substance in a tared, 250-mL flask, weigh accurately, and add to it 25.0 mL of 0.5 N alcoholic potassium hydroxide. Heat the flask on a steam bath, under a suitable condenser to maintain reflux for 30 min, frequently rotating the contents. [Note—Reflux time can be up to 90 min to ensure complete saponification, depending on the type of ester to be tested.] Then add 1 mL of phenolphthalein TS, and titrate the excess potassium hydroxide with 0.5 N hydrochloric acid VS. Perform a blank determination under the same conditions (see ⟨541⟩, *Residual Titrations*). The titration also can be carried out potentiometrically.

Calculate the Saponification Value:

$$\text{Result} = [M_r \times (V_B - V_T) \times N]/W$$

$M_r$ = molecular weight of potassium hydroxide, 56.11
$V_B$ = volume of 0.5 N hydrochloric acid consumed in the blank test (mL)
$V_T$ = volume of 0.5 N hydrochloric acid consumed in the actual test (mL)
$N$ = exact normality of the hydrochloric acid
$W$ = weight of the substance taken for the test (g)

If the oil has been saturated with carbon dioxide for the purpose of preservation, expose it in a shallow dish in a vacuum desiccator for 24 h before weighing the test specimens.

- **Unsaponifiable Matter**

The term "unsaponifiable matter" in oils or fats refers to those substances that are not saponifiable by alkali hydroxides but are soluble in the ordinary fat solvents, and to products of saponification that are soluble in such solvents.

**Procedure:** Transfer about 5.0 g of the oil or fat, accurately weighed, to a 250-mL conical flask, add 50 mL of an alcoholic potassium hydroxide solution prepared by dissolving 12 g of potassium hydroxide in 10 mL of water and diluting this solution with alcohol to 100 mL, and heat the flask on a steam bath under a suitable condenser to maintain reflux for 1 h, swirling frequently. Cool to a temperature below 25°, and transfer the contents of the flask to a separator with a polytetrafluoroethylene stopcock, rinsing the flask with two 50-mL portions of water that are added to the separator (do not use grease on stopcock). Extract with three 100-mL portions of ether, combining the ether extracts in another separator containing 40 mL of water. Gently rotate or shake the separator for a few minutes. [Note—Violent agitation may result in the formation of a difficult-to-separate emulsion.] Allow the mixture to separate, and discard the lower aqueous phase. Wash the ether extract with two additional 40-mL portions of water, and discard the lower aqueous phase. Wash the ether extract successively with a 40-mL portion of potassium hydroxide solution (3 in 100) and a 40-mL portion of water. Repeat this potassium hydroxide solution–water wash sequence three times. Wash the ether extract with 40-mL portions of water until the last washing is not reddened by the addition of 2 drops of phenolphthalein TS. Transfer the ether extract to a tared flask, and rinse the separator with 10 mL of ether, adding the rinsings to the flask. Evaporate the ether on a steam bath, and add 6 mL of acetone to the residue. Remove the acetone in a current of air, and dry the residue at 105° until successive weighings differ by not more than 1 mg.

Calculate the percentage of unsaponifiable matter in the portion of oil or fat taken:

$$\text{Result} = 100 \times (W_R/W_S)$$

$W_R$ = weight of the residue (g)
$W_S$ = weight of the oil or fat taken for the test (g)

Dissolve the residue in 20 mL of alcohol, previously neutralized to the phenolphthalein endpoint, add phenolphthalein TS, and titrate with 0.1 N alcoholic sodium hydroxide VS to the first appearance of a faint pink color that persists for not less than 30 s. If the volume of 0.1 N alcoholic sodium hydroxide required is greater than 0.2 mL, the separation of the layers was incomplete; the residue weighed cannot be considered "unsaponifiable matter," and the test must be repeated.

- **Solidification Temperature of Fatty Acids**

**Preparation of the fatty acids:** Heat 75 mL of glycerin–potassium hydroxide solution (made by dissolving 25 g of potassium hydroxide in 100 mL of glycerin) in an 800-mL beaker to 150°, and add 50 mL of the clarified fat, melted if necessary. Heat the mixture for 15 min with frequent stirring, but do not allow the temperature to rise above 150°. Saponification is complete when the mixture is homogeneous and no particles cling to the beaker at the meniscus. Pour the contents of the beaker into 500 mL of nearly boiling water in an 800-mL beaker or casserole, add slowly 50 mL of dilute sulfuric acid [made by adding water and sulfuric acid (3:1)], and heat the solution, with frequent stirring, until the fatty acids separate cleanly as a transparent layer. Wash the acids with boiling water until free from sulfuric acid, collect them in a small beaker, place on a steam bath until the water has settled and the fatty acids are clear, filter into a dry beaker while hot, and dry at 105° for 20 min. Place the warm fatty acids in a suitable container, and cool in an ice bath until they congeal.

**Test for complete saponification:** Place 3 mL of the dry acids in a test tube, and add 15 mL of alcohol. Heat the solution to boiling, and add an equal volume of 6 N ammonium hydroxide. A clear solution results.

**Procedure:** Using an apparatus similar to the *Congealing Temperature Apparatus* specified therein, proceed as directed in *Congealing Temperature* ⟨651⟩*, Procedure*, reading "solidification temperature" for "congealing point" (the terms are synonymous). The average of not less than four consecutive readings of the highest point to which the temperature rises is the solidification temperature of the fatty acids.

• **FATTY ACID COMPOSITION**

**Standard solution:** Prepare an ester mixture of known composition containing the esters required in the individual monograph. This *Standard solution* may contain other components. [NOTE—Ester mixtures are available commercially from Nu-Chek-Prep, Inc., PO Box 295, Elysian, MN 56028. Typical Nu-Chek-Prep ester mixtures useful in this test include Nu-Chek 17A and Nu-Chek 19A.] Nu-Chek mixture 17A has the following composition:

**Table 4**

| Percentage | Fatty Acid Ester | Carbon-Chain Length | Number of Double Bonds |
|---|---|---|---|
| 1.0 | Methyl myristate | 14 | 0 |
| 4.0 | Methyl palmitate | 16 | 0 |
| 3.0 | Methyl stearate | 18 | 0 |
| 3.0 | Methyl arachidate | 20 | 0 |
| 3.0 | Methyl behenate | 22 | 0 |
| 3.0 | Methyl lignocerate | 24 | 0 |
| 45.0 | Methyl oleate | 18 | 1 |
| 15.0 | Methyl linoleate | 18 | 2 |
| 3.0 | Methyl linolenate | 18 | 3 |
| 20.0 | Methyl erucate | 22 | 1 |

Nu-Chek mixture 19A has the following composition:

**Table 5**

| Percentage | Fatty Acid Ester | Carbon-Chain Length | Number of Double Bonds |
|---|---|---|---|
| 7.0 | Methyl caprylate | 8 | 0 |
| 5.0 | Methyl caprate | 10 | 0 |
| 48.0 | Methyl laurate | 12 | 0 |
| 15.0 | Methyl myristate | 14 | 0 |
| 7.0 | Methyl palmitate | 16 | 0 |
| 3.0 | Methyl stearate | 18 | 0 |
| 12.0 | Methyl oleate | 18 | 1 |
| 3.0 | Methyl linoleate | 18 | 2 |

**0.5 N Methanolic sodium hydroxide solution:** Dissolve 2 g of sodium hydroxide in 100 mL of methanol.

**Test solution:** [NOTE—If fatty acids containing more than 2 double bonds are present in the test specimen, remove air from the flask by purging it with nitrogen for a few minutes.] Transfer about 100 mg of the test specimen to a 50-mL conical flask fitted with a suitable water-cooled reflux condenser and a magnetic stir bar. Add 4 mL of *0.5 N Methanolic sodium hydroxide solution,* and reflux until fat globules disappear (usually 5–10 min). Add 5 mL of a solution prepared by dissolving 14 g of boron trifluoride in methanol to make 100 mL, swirl to mix, and reflux for 2 min. Add 4 mL of chromatographic *n*-heptane through the condenser, and reflux for 1 min. Cool, remove the condenser, add about 15 mL of saturated sodium chloride solution, shake, and allow the layers to separate. Pass the *n*-heptane layer through 0.1 g of anhydrous sodium sulfate (previously washed with chromatographic *n*-heptane) into a suitable flask. Transfer 1.0 mL of this solution to a 10-mL volumetric flask, dilute with chromatographic *n*-heptane to volume, and mix.

**System suitability solution:** Transfer about 20 mg each of stearic acid, palmitic acid, and oleic acid to a 25-mL conical flask fitted with a suitable water-cooled reflux condenser and a magnetic stir bar, and prepare as directed for *Test solution* beginning with "Add 5.0 mL of a solution prepared by dissolving".

**Chromatographic system**

(See *Chromatography* ⟨621⟩.)

The gas chromatograph is equipped with a flame-ionization detector, maintained at a temperature of about 260°, a splitless injection system, and a 0.53-mm × 30-m fused-silica capillary column bonded with a 1.0-µm layer of phase G16. The chromatograph is programmed to maintain the column temperature at 70° for about 2 min after injection, then to increase the temperature at the rate of 5°/min to 240°, and finally to maintain this temperature for 5 min. The

@2024 USPC

injection port temperature is maintained at about 220°. The carrier gas is helium with a linear velocity of about 50 cm/s.

Chromatograph the *System suitability solution*, and record the peak responses as directed for *Procedure:* the relative retention times are about 0.87 for methyl palmitate, 0.99 for methyl stearate, and 1.0 for methyl oleate; the resolution, *R,* between methyl stearate and methyl oleate is not less than 1.5; and the relative standard deviation of the peak area responses for the palmitate and stearate peaks for replicate injections is not more than 6.0%. The relative standard deviation of the peak area response ratio of the palmitate to stearate peaks from these replicate injections is not more than 1.0%.

**Procedure:** Separately inject equal volumes (about 1 µL) of the *Standard solution* and the *Test solution* into the chromatograph, record the chromatograms, identify the fatty acid ester peaks in the chromatogram of the *Test solution* by comparing the retention times of these peaks with those in the chromatogram of the *Standard solution*, and measure the peak areas for all of the fatty acid ester peaks in the chromatogram from the *Test solution*.

Calculate the percentage of each fatty acid component in the test specimen:

$$\text{Result} = 100 \times (A/B)$$

*A* = area of the peak response obtained for each individual fatty acid ester component
*B* = sum of the peak areas of all of the peaks, excluding the solvent peak, in the chromatogram from the *Test solution*

***Change to read:***

• **Omega-3 Fatty Acids Determination and Profile**

The following procedure may be used for the determination of eicosapentaenoic acid (EPA) (C20:5 n–3), docosahexaenoic acid (DHA) (C22:6 n–3), and total omega-3 acids obtained from fish, plant, or microbial sources in bulk oils and encapsulated oil, either as triglycerides or as ethyl esters. The term "triglyceride" is applicable to algal oils, fish oils, fish liver oils, and products containing omega-3-acids in triglycerides form. The results are expressed as free fatty acids or ethyl esters. Perform the tests as rapidly as possible. Protect the solutions from actinic light, oxidizing agents, oxidation catalysts, and air.

**Content of EPA and DHA**

**Antioxidant solution:** Dissolve an accurately weighed quantity of butylated hydroxytoluene in 2,2,4-trimethylpentane to obtain a solution with a concentration of 0.05 mg per mL.

**Internal standard solution:** Transfer an accurately weighed quantity of USP Methyl Tricosanoate RS to a volumetric flask. Dissolve in *Antioxidant solution*, and dilute with the same solvent to obtain a solution with a concentration of about 7.0 mg/mL. [Note—Guard the solution against evaporation during use.]

**Test solution 1** (for triglycerides): ▲ (USP 1-May-2022)Dissolve the mass of sample to be examined, according to *Table 6*, in ▲10.0 mL of▲ (USP 1-May-2022) *Antioxidant solution.*▲ (USP 1-May-2022)Transfer 2.0 mL of this solution to a glass tube, and evaporate the solvent with a gentle stream of nitrogen. Add 1.5 mL of a 2% (w/v) solution of sodium hydroxide in methanol, cap tightly with a polytetrafluoroethylene-lined cap, mix, and heat in a boiling water bath for 7 min. Cool, add 2 mL of boron trichloride–methanol solution (120 g in 1000 mL of methanol), cover with nitrogen, cap tightly, mix, and heat in a boiling water bath for 30 min. Cool to 40°–50°, add 1.0 mL of 2,2,4-trimethylpentane, cap, and mix on a vortex mixer or shake vigorously for at least 30 s. Immediately add 5 mL of saturated sodium chloride solution containing 1 volume of sodium chloride and 2 volumes of water. [Note—Shake from time to time. Before use, decant the solution from any undissolved substance, and filter if necessary.] Cover with nitrogen, cap, and mix on a vortex mixer or shake thoroughly for at least 15 s. Allow the upper layer to become clear, and transfer to a separate tube. Shake the methanol layer once more with 1.0 mL of 2,2,4-trimethylpentane, and combine the 2,2,4-trimethylpentane extracts. Wash the combined extracts with two quantities, 1 mL each, of water, and dry over anhydrous sodium sulfate.

**Table 6**

| Approx. Sum EPA + DHA | Amount of Sample to Be Weighed (g) |
|---|---|
| 30%–50% | 0.4–0.5 |
| 50%–70% | 0.3 |
| >70% | 0.25 |

**Test solution 2** (for triglycerides): ▲Dissolve▲ (USP 1-May-2022) the equivalent amount of sample used to prepare *Test solution 1* ▲in 10.0 mL of *Internal standard solution.*▲ (USP 1-May-2022)Gentle heating (up to 60°) may be applied to obtain a clear solution. Then prepare as directed in *Test solution 1* starting with "Transfer 2.0 mL".

**Test solution 3** (for ethyl esters): ▲ (USP 1-May-2022)Dissolve the mass of sample to be examined, according to *Table 6*, ▲in 10.0 mL of▲ (USP 1-May-2022) the *Internal standard solution.*▲ (USP 1-May-2022) Gentle heating (up to 60°) may be applied to obtain a clear solution.

• **Water and Sediment in Fixed Oils**
**Apparatus:** The preferred centrifuge has a diameter of swing (*d* = distance from tip to tip of whirling tubes) of 38–43 cm and is operated at a speed of about 1500 rpm. If a centrifuge of different dimensions is used, calculate the desired rate of revolution:

$$\text{rpm} = 1500\sqrt{40.6ld}$$

The centrifuge tubes are pear-shaped and are shaped to accept closures. The total capacity of each tube is about 125 mL. The graduations are clear and distinct, reading upward from the bottom of the tube according to the scale shown in *Table 9*.

**Table 9**

| Volume (mL) | Scale Division (mL) |
|---|---|
| 0–3 | 0.1 |
| 3–5 | 0.5 |
| 5–10 | 1.0 |
| 10–25 | 5.0 |
| 25–50 | 25.0 |
| 50–100 | 50.0 |

**Procedure:** Place 50.0 mL of benzene in each of two centrifuge tubes, and to each tube add 50.0 mL of the oil, warmed if necessary to re-incorporate separated stearin, and mixed thoroughly at 25°. Insert the stopper tightly into the tubes, shake them vigorously until the contents are mixed thoroughly, and then immerse the tubes in a water bath at 50° for 10 min. Centrifuge for 10 min. Read the combined volume of water and sediment at the bottom of each tube. Centrifuge repeatedly for 10-min periods until the combined volume of water and sediment remains constant for three consecutive readings. The sum of the volumes of combined water and sediment in the two tubes represents the percentage, by volume, of water and sediment in the oil.

• **Anisidine Value**
The Anisidine Value is defined as 100 times the optical density measured in a 1-cm cell of a solution containing 1 g of the substance to be examined in 100 mL of a mixture of solvents and reagents according to the following method described. [Note—Carry out the operations as rapidly as possible, avoiding exposure to actinic light.]
**Test solution A:** Dissolve 0.500 g of the substance to be examined in isooctane, and dilute with the same solvent to 25.0 mL.
**Test solution B:** To 5.0 mL of *Test solution A* add 1.0 mL of a 2.5-g/L solution of *p*-anisidine in glacial acetic acid, shake, and store protected from light.
**Standard solution:** To 5.0 mL of isooctane add 1.0 mL of a 2.5-g/L solution of *p*-anisidine in glacial acetic acid, shake, and store protected from light.
**Procedure:** Measure the absorbance of *Test solution A* at 350 nm using isooctane as the blank. Measure the absorbance of *Test solution B* at 350 nm exactly 10 min after its preparation, using the *Standard solution* as the compensation liquid. Calculate the Anisidine Value:

$$\text{Result} = [25 \times (1.2A_S - A_B)]/m$$

$A_S$ = absorbance of *Test solution B* at 350 nm
$A_B$ = absorbance of *Test solution A* at 350 nm
$m$ = weight of the substance to be examined in *Test solution A* (g)

• **TOTAL OXIDATION VALUE (TOTOX)**
Total Oxidation Value is defined:

$$\text{Result} = 2PV + AV$$

*PV* = Peroxide Value
*AV* = Anisidine Value

• **TRACE METALS**
**Apparatus**
The apparatus typically consists of the following:
**Digestion flasks:** Use a polytetrafluoroethylene flask with a volume of about 120 mL, fitted with an airtight closure, a valve to adjust the pressure inside the container, and a polytetrafluoroethylene tube to allow the release of gas.
**System:** Make the flask airtight, using the same torsional force for each of them.
**Microwave oven:** It has a magnetron frequency of 2450 MHz with a selectable output from 0 to 630 ± 70 W in 1% increments, a programmable digital computer, a polytetrafluoroethylene-coated microwave cavity with a variable speed exhaust fan, a rotating turntable drive system, and exhaust tubing to vent fumes.
**Atomic absorption spectrometer:** It is equipped with a hollow-cathode lamp as the source of radiation and a deuterium lamp as a background corrector. The system is fitted with the following:
1. A graphite furnace as the atomization device for cadmium, copper, iron, lead, nickel, and zinc.
2. An automated continuous-flow hydride vapor generation system for arsenic and mercury.

**General procedure**
[**CAUTION**—When using closed high-pressure digestion vessels and microwave laboratory equipment, the safety precautions and operating instructions given by the manufacturer must be followed.]
[NOTE—If an alternative apparatus is used, adjustment of the instrument parameters may be necessary.]
**Cleaning:** Clean all the glassware and laboratory equipment with a 10-mg/mL solution of nitric acid before use.
**Trace metal–free nitric acid:** Nitric acid meets the requirements with the maximum values for arsenic (As), cadmium (Cd), copper (Cu), iron (Fe), mercury (Hg), lead (Pb), nickel (Ni), and zinc (Zn) equal to 0.005, 0.005, 0.001, 0.02, 0.002, 0.001, 0.005, and 0.01 ppm, respectively.
**Trace metal–free hydrochloric acid:** Hydrochloric acid meets the requirements with the maximum values for arsenic (As), cadmium (Cd), copper (Cu), iron (Fe), mercury (Hg), lead (Pb), nickel (Ni), and zinc (Zn) equal to 0.005, 0.003, 0.003, 0.05, 0.005, 0.001, 0.004, and 0.005 ppm, respectively.
**Trace metal–free sulfuric acid:** Sulfuric acid meets the requirements with the maximum values for arsenic (As), cadmium (Cd), copper (Cu), iron (Fe), mercury (Hg), lead (Pb), nickel (Ni), and zinc (Zn) equal to 0.005, 0.002, 0.001, 0.05, 0.005, 0.001, 0.002, and 0.005 ppm, respectively.
**Test stock solution:** In a digestion flask place about 0.5 g of fatty oil, accurately weighed, as indicated in each individual monograph. Add 6 mL of *Trace metal–free nitric acid* and 4 mL of *Trace metal–free hydrochloric acid*. Close the flask.
**Blank stock solution:** Mix 6 mL of *Trace metal–free nitric acid* and 4 mL of *Trace metal–free hydrochloric acid* in a digestion flask.
**Test solution 1:** Place the digestion flask containing the *Test stock solution* in the microwave oven. Carry out the digestion in three steps according to the following program: 80% power for 15 min, 100% power for 5 min, and 80% power for 20 min.
At the end of the cycle allow the flask to cool. Add 4 mL of *Trace metal–free sulfuric acid* to the flask. Repeat the digestion program. After completing the digestion, allow the flask to cool to room temperature. Open the digestion flask, and transfer the clear, colorless solution obtained into a 50-mL volumetric flask. Rinse the digestion flask with 2 quantities, 15 mL each, of water, and collect the rinsings in the volumetric flask. Add 1.0 mL of a 10-mg/mL solution of magnesium nitrate and 1.0 mL of a 100-mg/mL solution of ammonium dihydrogen phosphate to the volumetric flask. Dilute with water to volume, and mix. This solution is *Test solution 1*.
**Blank solution 1:** Place the digestion flask containing *Blank stock solution* in the microwave oven. Prepare as directed in *Test solution 1* beginning with "Carry out the digestion in three steps according to the following program".
**Direct calibration:** [NOTE—Concentrations of the standard solutions will depend on the metal contents of the test substance.] For routine measurements, 3 standard solutions, *Blank solution 1*, and *Test solution 1* are prepared and examined. Use *Test solution 1* and *Blank solution 1* as prepared previously or as indicated in the monograph. Prepare not less than 3 standard solutions containing all the metal elements to be tested. The expected absorbance value in *Test solution 1* for each metal element should be within its corresponding calibrated absorbance range, preferably in the middle of the calibrated absorbance range. Any reagents used in the preparation of *Test solution 1* are added at the same concentration to the standard solutions.
Introduce each of the solutions into the instrument using the same number of replicates for each of the solutions to obtain a steady reading.
Prepare a calibration curve from the mean of the readings obtained with the standard solutions by plotting the means as a function of concentration. Determine the concentration of the element in *Test solution 1* from the curve obtained.
**Standard additions:** Add to at least four identical volumetric flasks equal volumes of *Test solution 1* as prepared previously or as indicated in the monograph. Add to all but one of the flasks progressively larger volumes of a standard solution containing a known concentration of the test element to produce a series of solutions containing steadily increasing concentrations of that element known to give responses in the linear part of the curve. Dilute the contents of each flask with the solvent specified in the monograph to volume, and mix. The flask without an addition of standard solution is labeled as the test solution.
Introduce each of the solutions into the instrument, using the same number of replicates for each of the solutions, to obtain a steady reading.

Plot the absorbances of the standard solutions and the test solution versus the added quantity of test element. [NOTE—The test solution should be plotted as if it had a content of added test element equivalent to 0 mg or µg.] Extrapolate the line joining the points on the graph until it meets the concentration axis. The distance between this point and the intersection of the axes represents the concentration of test element in the test solution.

**Specific Tests**

**Cadmium (Cd), copper (Cu), iron (Fe), lead (Pb), nickel (Ni), and zinc (Zn)**

**Standard stock solution:** Prepare a solution containing known concentrations of 5 µg/mL for each test element.

**Standard solutions:** In three identical 10-mL volumetric flasks introduce 10, 20, and 40 µL of *Standard stock solution*, respectively. To each flask add 5.0 mL of *Test solution 1*, dilute with water to volume, and mix.

**Test solution 2:** In a 10-mL volumetric flask add 5.0 mL of *Test solution 1*, dilute with water to volume, and mix.

**Blank solution 2:** In a 10-mL volumetric flask add 5.0 mL of *Blank solution 1*, dilute with water to volume, and mix.

**Procedure:** Measure the content of Cd, Cu, Fe, Pb, Ni, and Zn using a suitable graphite furnace atomic absorption spectrophotometer. Concomitantly determine the absorbances of *Blank solution 2,* the *Standard solutions,* and *Test solution 2* at least three times each. The absorbance value of *Blank solution 2* is subtracted from the value obtained using the *Standard solutions* and *Test solution 2*. Proceed as directed in the *Standard additions* method in *General Procedure*. See *Table 10* for instrumental parameters that may be used.

**Table 10**

**Arsenic and mercury**

Measure the content of arsenic and mercury against their standard solutions at a known concentration using the *Direct calibration* method in *General Procedure*, with an automated continuous-flow hydride vapor generation system.

For the 1 ppm arsenic specification limit and 1 ppm mercury specification limit, prepare three working calibration solutions with known concentrations of 5, 10, and 20 ng/mL for each test element, respectively.

The absorbance value of the blank solution is automatically subtracted from the value obtained using the test solution.

**Arsenic**

**Blank solution 3:** Add 1.0 mL of a 200-mg/mL solution of potassium iodide to 19.0 mL of *Blank solution 1* prepared previously. Allow this solution to stand at room temperature for about 50 min or at 70° for about 4 min.

**Test solution 3:** Add 1.0 mL of a 200-mg/mL solution of potassium iodide to 19.0 mL of *Test solution 1* prepared previously. Allow this solution to stand at room temperature for about 50 min or at 70° for about 4 min.

**Acid reagent 1:** *Trace metal-free hydrochloric acid*

**Reducing reagent 1:** A 6-mg/mL solution of sodium tetrahydroborate in a 5-mg/mL solution of sodium hydroxide

The instrumental parameters in *Table 11* may be used.

**Mercury**

**Blank solution 4:** Prepare as directed in *Blank solution 3*.

**Test solution 4:** Prepare as directed in *Test solution 3*.

**Acid reagent 2:** A 515-mg/mL solution of *Trace metal–free hydrochloric acid*

**Reducing reagent 2:** A 10-mg/mL solution of stannous chloride in a 200-mg/mL solution of *Trace metal–free hydrochloric acid*

The instrumental parameters in *Table 11* may be used.

- **STEROL COMPOSITION**

**Separation of the sterol fraction**

**Reference solution A:** Dissolve an accurately weighed quantity of cholesterol in chloroform to obtain a solution of 5% (w/v).

**Developing solvent system:** A mixture of toluene and acetone (95:5) or a mixture of hexane and ether (65:35)

**Test solution A:** Accurately weigh 5 g of the test substance into a 250-mL flask. Add 50 mL of alcoholic potassium hydroxide TS 2 (2 N alcoholic potassium hydroxide), and heat to gentle boiling with continuous vigorous stirring until saponification takes place (the solution becomes clear). Continue heating for a further 20 min, and add 50 mL of water from the top of the condenser. Cool the flask to approximately 30°. Transfer the contents of the flask to a 500-mL separating funnel with several rinses of water, amounting in all to about 50 mL. Add approximately 80 mL of ether, shake vigorously for approximately 30 s, and allow to settle. [NOTE—Any emulsion can be destroyed by adding small quantities of ethyl or methyl alcohol by means of a spray.] Separate the lower aqueous phase, and collect it into a second separating funnel. Perform two further extractions on the water–alcohol phase in the same way, using 60–70 mL of ether on each occasion. Pool the ether extracts into a single separating funnel, and wash with water, 50 mL at a time, until the wash water is no longer alkaline to phenolphthalein. Dry the ether phase with anhydrous sodium sulfate, and filter on anhydrous sodium sulfate into a previously weighed 250-mL flask, washing the funnel and filter with small quantities of ether. Distill the ether down to a few mL, and bring to dryness under a slight vacuum or in a stream of nitrogen. Complete the drying at 100° for approximately 15 min, and then weigh after cooling in a desiccator. Dissolve the unsaponifiables so obtained in chloroform to obtain a solution with a concentration of approximately 5%.

**Test solution B:** Treat 5 g of canola oil in the same way as prescribed for the test substance in *Test solution A*, beginning with "Add 50 mL of alcoholic potassium hydroxide TS 2 (2 N alcoholic potassium hydroxide)".

**Test solution C:** Treat 5 g of sunflower oil in the same way as prescribed for the test substance in *Test solution A*, beginning with "Add 50 mL of alcoholic potassium hydroxide TS 2 (2 N alcoholic potassium hydroxide)".

**Procedure:** Immerse the thin-layer chromatographic plate (see ⟨621⟩), 20-cm × 20-cm silica gel on polyester with a layer thickness of 200 µm and particle size of 5–17 µm,[1] completely in the 0.2 N alcoholic potassium hydroxide for 10 s, allow to dry in a fume cupboard for 2 h, and finally place at 100° for 1 h. [NOTE—Remove from the validated heating device, and keep the plate in a desiccator until required for use. The plates must be used within 15 days. Thin-layer chromatographic plates that do not require the preconditioning also are commercially available.] Use a separate plate for each test solution.

Place a mixture of toluene and acetone (95:5) or a mixture of hexane and ether (65:35) in the chamber to a depth of approximately 1 cm. Close the chamber with the appropriate cover, and leave for at least 30 min. Strips of filter paper dipping into the eluant may be placed on the internal surfaces of the chamber. [NOTE—The developing mixture should be replaced for every test to ensure reproducible elution conditions.] Apply 0.3 mL of *Test solution A* approximately 2 cm from the lower edge in a streak that is as thin and as uniform as possible. In line with the streak, place 2–3 µL of *Reference solution A* at one end of the plate. Develop the chromatograms in an equilibrated chamber with the *Developing solvent system* until the solvent front reaches approximately 1 cm from the upper edge of the plate. Remove the plate from the developing chamber, and evaporate the solvent under a current of hot air [NOTE—avoid excessive heat] or by leaving the plate for a short while under a hood. Spray the plate with a 0.2% alcoholic solution of 2,7-dichlorofluorescein, and examine in UV light at 254 nm. [NOTE—The plates pretreated with UV indicator also are commercially available and are used equivalently.] In each of the plates, mark the limits of the sterol band identified by being aligned with the stain obtained from *Reference solution A* along the edges of the fluorescence, and additionally include the area of the zones 2–3 mm above and below the visible zones corresponding to *Reference solution A*. Remove the silica gel in the marked area into a filter funnel with a G3 porous septum.[2] Add 10 mL of hot chloroform, mix carefully with the metal spatula, filter under vacuum, and collect the filtrate in the conical flask attached to the filter funnel. Wash the residue in the funnel three times with ether, about 10 mL each time, and collect the filtrate in the same flask attached to the funnel. Evaporate the filtrate to a volume of 4–5 mL, transfer the residual solution to a previously weighed 10-mL test tube with a tapering bottom and a sealing stopper, and evaporate to dryness by mild heating in a gentle stream of nitrogen. Dissolve the residue in a few drops of acetone, and evaporate again to dryness. Place at 105° for approximately 10 min, allow to cool in a desiccator, and weigh.

Treat *Test solution B* and *Test solution C* the same way as directed for *Test solution A*.

**Determination of the sterols**

**Test solution D:** To the test tube containing the sterol fraction separated from the test substance by thin-layer chromatography add a freshly prepared mixture of anhydrous pyridine, hexamethyldisilazane, and chlorotrimethylsilane (9:3:1) [NOTE—This reagent also is commercially available and is used equivalently.] in the ratio of 50 µL for every mg of sterols, avoiding any uptake of moisture. Insert the stopper into the test tube, and shake carefully until the sterols are completely dissolved. Allow it to stand for at least 15 min at ambient temperature, and centrifuge for a few minutes if necessary. Use the supernatant. [NOTE—The slight opalescence that may form is normal and does not cause an anomaly. However, the formation of a white floc or the appearance of a pink color is indicative of the presence of moisture or deterioration of the reagent. If these occur, the test must be repeated.]

[1] A commercial TLC plate may be obtained from Sigma-Aldrich, catalog #z122785.
[2] A commercial product may be obtained from Kimble/Kontes as a filter, Buchner with fritted disc, Kimax 28400-152.

**Reference solution E:** To 9 parts of the sterols separated from canola oil by thin-layer chromatography, add 1 part of cholesterol. Treat the mixture in the same way as directed in *Test solution D*.

**Reference solution F:** Treat the sterols separated from sunflower oil by thin-layer chromatography in the same way as directed in *Test solution D*.

**Chromatographic system**

(See *Chromatography* ⟨621⟩.)

The gas chromatograph is equipped with a flame-ionization detector and a glass or fused-silica capillary column 20–30 m in length, internal diameter 0.25–0.32 mm, entirely coated with a 0.10- to 0.30-µm layer of stationary phase G27 or G36. The injection port temperature is maintained at 280°, the detector temperature is maintained at 290°, and the column temperature is maintained at 260 ± 5°. The carrier gas is either helium with a linear velocity of 20–35 cm/s or hydrogen with a linear velocity of 30–50 cm/s. A split ratio of 1:50 to 1:100 is used. Chromatograph *Reference solution E* and *Reference solution F,* and record the peak responses as directed in *Procedure:* the retention time should be 20 ± 5 min for β-sitosterol, and all the sterols present must be separated. The chromatogram obtained with *Reference solution E* shows four principal peaks corresponding to cholesterol, brassicasterol, campesterol, and β-sitosterol; and the chromatogram obtained with *Reference solution F* shows four principal peaks corresponding to campesterol, stigmasterol, β-sitosterol, and Δ7-stigmastenol. The retention times of the sterols with reference to β-sitosterol are given in *Table 12*.

**Table 12. Relative Retention Times of Sterols for Two Different Columns**

| Identification | G36 Column | G27 Column |
|---|---|---|
| Cholesterol | 0.67 | 0.63 |
| Brassicasterol | 0.73 | 0.71 |
| 24-Methylene-cholesterol | 0.82 | 0.80 |
| Campesterol | 0.83 | 0.81 |
| Campestanol | 0.85 | 0.82 |
| Stigmasterol | 0.88 | 0.87 |
| Δ7-Campesterol | 0.93 | 0.92 |
| Δ5,23-Stigmastadienol | 0.95 | 0.95 |
| Clerosterol | 0.96 | 0.96 |
| β-Sitosterol | 1.00 | 1.00 |
| Sitostanol | 1.02 | 1.02 |
| Δ5-Avenasterol | 1.03 | 1.03 |
| Δ5,24-Stigmastadienol | 1.08 | 1.08 |
| Δ7-Stigmastenol | 1.12 | 1.12 |
| Δ7-Avenasterol | 1.16 | 1.16 |

**Procedure:** Separately inject equal volumes (about 1 µL) of *Test solution D, Reference solution E,* and *Reference solution F* into the chromatograph, record the chromatograms, and measure the peak areas for the sterols.

Calculate the percentage of each individual sterol in the sterol fraction of the test substance taken:

$$\text{Result} = 100 \times (A/S)$$

$A$ = area of the peak due to the sterol component to be determined
$S$ = sum of the areas of the peaks due to the components indicated in *Table 12*

# ⟨411⟩ FOLIC ACID ASSAY

## INTRODUCTION

The following liquid chromatographic procedures are provided for the determination of folic acid as an active pharmaceutical ingredient, a dietary supplement ingredient, or a component of dietary supplements or pharmaceutical dosage forms.

Throughout these procedures, protect solutions containing and derived from the test specimen and the Reference Standards from the atmosphere and light, preferably by using low-actinic glassware.

## ASSAY

• **PROCEDURE 1**

This procedure can be used to determine folic acid in the following:

- Oil- and Water-Soluble Vitamins with Minerals Tablets
- Oil- and Water-Soluble Vitamins with Minerals Capsules
- Oil- and Water-Soluble Vitamins Tablets
- Oil- and Water-Soluble Vitamins Capsules
- Water-Soluble Vitamins with Minerals Tablets
- Water-Soluble Vitamins with Minerals Capsules
- Water-Soluble Vitamins Tablets
- Water-Soluble Vitamins Capsules

This procedure involves the extraction of analytes from the formulation by using an *Internal standard solution* that contains methylparaben, tetrabutylammonium hydroxide, and pentetic acid in alcoholic phosphate buffer and by mechanically shaking to release the analytes from the matrices.

Unless specified in the individual monographs, the reagent solutions, *Internal standard solution*, *Standard solution*, and *Sample solutions* are prepared as follows.

**Reagent A:** 25% solution of tetrabutylammonium hydroxide in methanol

**Reagent B:** Transfer 5.0 g of pentetic acid to a 50-mL volumetric flask. Using sonication if necessary, dissolve in and dilute with 1 N sodium hydroxide to volume.

**Mobile phase:** 2 g of monobasic potassium phosphate in 650 mL of water. Add 12.0 mL of *Reagent A*, 7.0 mL of 3 N phosphoric acid, and 240 mL of methanol. Cool to room temperature, adjust with phosphoric acid or ammonia TS to a pH of 7.0, dilute with water to 1000 mL, and filter. Recheck the pH before use by adding water or methanol to the prepared *Mobile phase* to obtain baseline separation of folic acid and the internal standard. The pH may be increased up to 7.15 to obtain better separation. [NOTE—The methanol and water content may be varied (1%–3%).]

**Internal standard solution:** Transfer 40 mg of methylparaben to a 1000-mL volumetric flask, and add 220 mL of methanol to dissolve. Dissolve 2.0 g of monobasic potassium phosphate in 300 mL of water in a separate beaker, quantitatively transfer this solution to the flask containing the methylparaben solution, and add an additional 300 mL of water. Add 19 mL of *Reagent A*, 7 mL of 3 N phosphoric acid, and 30 mL of *Reagent B*. Adjust with ammonia TS to a pH of 9.8, bubble nitrogen through the solution for 30 min, dilute with water to volume, and mix.

**Standard solution:** 0.016 mg/mL of USP Folic Acid RS in the *Internal standard solution*

**Sample solution for Tablets:** Crush not less than 30 Tablets until finely powdered. Transfer a portion of powder, equivalent to 0.4 mg of folic acid, to a 50-mL amber-colored centrifuge tube. Add 25.0 mL of the *Internal standard solution*, shake by mechanical means for 10 min, and centrifuge. Filter a portion of the clear supernatant, and use the filtrate.

**Sample solution for Capsules:** Weigh not less than 20 Capsules in a tared weighing bottle. Open the Capsules, without the loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing, if necessary, with several portions of ether. Discard the washings, and dry the Capsule shells with the aid of a current of dry air until the odor of ether is no longer perceptible. Weigh the empty Capsule shells in the tared weighing bottle, and calculate the average net weight per Capsule. Transfer an amount of the Capsule contents to a suitable centrifuge tube, and add a volume of the *Internal standard solution* to obtain a concentration of 0.016 mg/mL of folic acid. Shake by mechanical means for 10 min, and centrifuge. Filter a portion of the clear supernatant, and use the filtrate.

**Chromatographic system**

(See *Chromatography* ⟨621⟩*, System Suitability*.)

**Mode:** LC

**Detector:** UV 280 nm

**Column:** 4.6-mm × 25-cm; packing L1

**Flow rate:** 1 mL/min

**Injection volume:** 15 µL

**System suitability**

**Sample:** *Standard solution*

[NOTE—The relative retention times for folic acid and methylparaben are about 0.8 and 1.0, respectively.]

**Suitability requirements**

**Relative standard deviation:** NMT 3.0%

**Analysis**

**Samples:** *Standard solution* and appropriate *Sample solution*

Calculate the percentage of the labeled amount of folic acid ($C_{19}H_{19}N_7O_6$) in the portion of the *Sample* taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

$R_U$ = internal standard ratio (peak response of folic acid/peak response of the internal standard) from the appropriate *Sample solution*
$R_S$ = internal standard ratio (peak response of folic acid/peak response of the internal standard) from the *Standard solution*
$C_S$ = concentration of USP Folic Acid RS in the *Standard solution* (µg/mL)
$C_U$ = nominal concentration of folic acid in the appropriate *Sample solution* (µg/mL)

- **PROCEDURE 2**

This procedure can be used to determine folic acid in the following:

- Oil- and Water-Soluble Vitamins with Minerals Tablets
- Oil- and Water-Soluble Vitamins with Minerals Capsules
- Oil- and Water-Soluble Vitamins Tablets
- Oil- and Water-Soluble Vitamins Capsules
- Water-Soluble Vitamins with Minerals Tablets
- Water-Soluble Vitamins with Minerals Capsules
- Water-Soluble Vitamins Tablets
- Water-Soluble Vitamins Capsules

This procedure involves the extraction of analytes from the formulation by using an extracting solution that contains either a mixture of edetate disodium and ammonium hydroxide or a mixture of methanol, glacial acetic acid, and ethylene glycol, and by mechanically shaking to release the analytes from the matrices.

Unless specified in the individual monographs, the reagent solutions, *Diluent*, *Standard stock solution*, *Standard solutions*, and *Sample solutions* are prepared as follows.

**Reagent:** Dissolve 7.5 g of edetate disodium, with stirring, in 500 mL of water containing 10 mL of ammonium hydroxide.

**Diluent:** 60 µg/mL of ammonium hydroxide

**Mobile phase:** Transfer 0.4 mL of triethylamine, 15 mL of glacial acetic acid, and 350 mL of methanol to a 2000-mL volumetric flask, and dilute with 0.008 M sodium 1-hexanesulfonate to volume.

**Standard stock solution:** 60 µg/mL of USP Folic Acid RS in *Diluent*. Prepare this solution fresh daily.

**Standard solution for Tablets:** Mix 5.0 mL of the *Standard stock solution* with 10.0 mL of methanol and 35.0 mL of *Reagent*. Shake for 15 min in a water bath maintained at 60°, and cool. Filter, discarding the first few milliliters of the filtrate.

**Standard solution for Capsules:** Mix 5.0 mL of the *Standard stock solution* with 10.0 mL of a mixture of methanol and glacial acetic acid (9:1) and 30.0 mL of a mixture of methanol and ethylene glycol (1:1). Shake for 15 min in a water bath maintained at 60°, and cool. Filter, discarding the first few milliliters of the filtrate.

**Sample solution for Tablets:** Transfer a portion of finely powdered Tablets, equivalent to 0.3 mg of folic acid, to a 125-mL stoppered flask. Add 10.0 mL of methanol and 35.0 mL of *Reagent*. Shake for 15 min in a water bath maintained at 60°, and cool. Filter, discarding the first few milliliters of the filtrate.

**Sample solution for Capsules:** Weigh not less than 20 Capsules in a tared weighing bottle. Open the Capsules, without the loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing, if necessary, with several portions of ether. Discard the washings, and dry the Capsule shells with the aid of a current of dry air until the odor of ether is no longer perceptible. Weigh the empty Capsule shells in the tared weighing bottle, and calculate the average net weight per Capsule. Transfer an amount of the Capsule contents, equivalent to 0.3 mg of folic acid, to a 125-mL stoppered flask. Add 10.0 mL of a mixture of methanol and glacial acetic acid (9:1) and 30.0 mL of a mixture of methanol and ethylene glycol (1:1). Shake for 15 min in a water bath maintained at 60°, and cool. Filter, discarding the first few milliliters of the filtrate.

- **PROCEDURE 3**

This procedure can be used to determine folic acid in the following:

- Active pharmaceutical ingredient
- Dietary ingredient

This procedure involves the dissolution of analytes and internal standard in *Mobile phase*.

Unless specified in the individual monographs, the reagent solutions, *Internal standard solution*, *Standard stock solution*, *Standard solution*, *Sample stock solution*, and *Sample solution* are prepared as follows.

**3 N phosphoric acid:** 98 g/L of phosphoric acid in water

**6 N ammonium hydroxide:** Dilute 40 mL of ammonium hydroxide with water to 100 mL.

**Mobile phase:** Transfer 2.0 g of monobasic potassium phosphate to a 1000-mL volumetric flask, and dissolve in 650 mL of water. Add 15.0 mL of a solution of 0.5 M tetrabutylammonium hydroxide in methanol, 7.0 mL of *3 N phosphoric acid*, and 270 mL of methanol. Cool to room temperature, adjust with *3 N phosphoric acid* or *6 N ammonium hydroxide* to a pH of 5.0, and dilute with water to volume. Recheck the pH before use.

**Internal standard solution:** 2 mg/mL of methylparaben in *Mobile phase*. Dissolve the methylparaben first with methanol (about 4% of the final volume), and dilute with *Mobile phase* to volume.

**Standard stock solution:** 1 mg/mL of USP Folic Acid RS in *Mobile phase*. Dissolve the folic acid with the aid of 10% ammonium hydroxide (about 1% of the final volume), and dilute with *Mobile phase* to volume.

**Standard solution:** Transfer 4.0 mL of the *Standard stock solution* and 4.0 mL of the *Internal standard solution* to a 50-mL volumetric flask, and dilute with *Mobile phase* to volume.

**Sample stock solution:** Transfer 100 mg of folic acid to a 100-mL volumetric flask, and dissolve in 40 mL of *Mobile phase* and 1 mL of 10% ammonium hydroxide. Dilute with *Mobile phase* to volume.

**Sample solution:** Transfer 4.0 mL of the *Sample stock solution* and 4.0 mL of the *Internal standard solution* to a 50-mL volumetric flask, and dilute with *Mobile phase* to volume.

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 280 nm

**Column:** 4.6-mm × 25-cm; packing L1

**Flow rate:** 1.2 mL/min

**Injection volume:** 10 µL

**System suitability**

**Sample:** *Standard solution*

**Suitability requirements**

**Resolution:** NLT 3.6 between methylparaben and folic acid

**Relative standard deviation:** NMT 2.0% for the ratios of the folic acid peak response to the internal standard peak response

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Calculate the percentage of folic acid ($C_{19}H_{19}N_7O_6$) in the portion of the *Sample* taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

$R_U$ = internal standard ratio (peak response of folic acid/peak response of the internal standard) from the *Sample solution*
$R_S$ = internal standard ratio (peak response of folic acid/peak response of the internal standard) from the *Standard solution*
$C_S$ = concentration of USP Folic Acid RS in the *Standard stock solution* (mg/mL)
$C_U$ = concentration of folic acid in the *Sample stock solution* (mg/mL)

***Change to read:***

- **PROCEDURE 4**

This procedure can be used to determine folic acid in the following:

- Folic Acid Tablets
- Folic Acid Injection

This procedure involves the dissolution of analytes in a *Diluent* that contains 2 mL of ammonium hydroxide and 1 g of sodium perchlorate per 100 mL of water.

Unless specified in the individual monographs, *Diluent*, *System suitability solution*, *Standard solution*, and *Sample solutions* are prepared as follows.

**Mobile phase:** Transfer 35.1 g of sodium perchlorate and 1.40 g of monobasic potassium phosphate to a 1-L volumetric flask. Add 7.0 mL of 1 N potassium hydroxide and 40 mL of methanol, dilute with water to volume, and mix. Adjust with 1 N potassium hydroxide or phosphoric acid to a pH of 7.2.

**Diluent:** Aqueous solution containing 2 mL of ammonium hydroxide and 1 g of sodium perchlorate per 100 mL

**System suitability solution:** 0.2 mg/mL each of USP Folic Acid RS and ▲USP Leucovorin Calcium RS▲ (IRA 1-Nov-2022) in *Diluent*. [NOTE—Before use, pass through a filter of 1-µm or finer pore size.]

**Standard solution:** 0.20 mg/mL of USP Folic Acid RS in *Diluent*

**Sample solution for Tablets:** Equivalent to 0.2 mg/mL of folic acid from not less than 20 powdered Tablets in *Diluent*. Shake gently to aid dissolution, and filter, discarding the first few milliliters of the filtrate.

**Sample solution for Injection:** Dilute with *Diluent* an accurately measured volume of Injection, quantitatively and stepwise, to obtain a solution having a concentration close to that of the *Standard solution* and between 0.20 and 0.80 mg/mL.

**Chromatographic system**
(See *Chromatography* ⟨621⟩, *System Suitability*.)
**Mode:** LC
**Detector:** UV 254 nm
**Column:** 4.6-mm × 25-cm; packing L1
**Flow rate:** 1 mL/min
**Injection volume:** 25 µL
**System suitability**
**Samples:** *System suitability solution* and *Standard solution*
**Suitability requirements**
**Resolution:** NLT 3.6 between ▲leucovorin▲ (IRA 1-Nov-2022) and folic acid, *System suitability solution*
**Relative standard deviation:** NMT 2.0%, *Standard solution*
**Analysis**
**Samples:** *Standard solution* and appropriate *Sample solution*
Calculate the percentage of folic acid ($C_{19}H_{19}N_7O_6$) in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of folic acid from the *Sample solution for Tablets*
$r_S$ = peak response of folic acid from the *Standard solution*
$C_S$ = concentration of USP Folic Acid RS in the *Standard solution* (mg/mL)
$C_U$ = nominal concentration of folic acid in the *Sample solution for Tablets* (mg/mL)

Calculate the quantity, in milligrams, of folic acid ($C_{19}H_{19}N_7O_6$) in each milliliter of Injection taken:

$$\text{Result} = (r_U/r_S) \times (C_S/V_U) \times V$$

$r_U$ = peak response of folic acid from the *Sample solution for Injection*
$r_S$ = peak response of folic acid from the *Standard solution*
$C_S$ = concentration of USP Folic Acid RS in the *Standard solution* (mg/mL)
$V_U$ = volume of Injection taken for preparation of the *Sample solution for Injection* (mL)
$V$ = total volume used to dilute the Injection (mL)

# ⟨413⟩ IMPURITIES TESTING IN MEDICAL GASES

## INTRODUCTION

This general test chapter defines the safe and proper means to sample high-pressure gas containers of different medical gas compositions using the detector tube manufacturer's suggested total gas volume for the purpose of conducting detector tube analysis to satisfy the *USP* monographs. See *Reagents* in the section *Reagents, Indicators, and Solutions* for information on each referenced detector tube.

There are two types of detector tubes currently manufactured: those to be used with a manual hand pump of fixed volume (e.g., 100 mL/pump stroke) and those used in a continuous flow system that can be set to pass a volume of gas through the detector tube at approximately 1 atmosphere. It is important to match the appropriate detector tube type to the mode of gas volume exchange.

To ensure that the required gas volume has passed through the detector tube, measure the gas volume at the time of the analysis either by using a hand pump or using a flowmeter that is calibrated to the subject gas or corrected via a calibration chart. Flowmeter manufacturers generally provide a chart of the gas volume flow of common gases for each of the flow tubes identified in this general chapter.

[NOTE—See general chapter *Medical Gases Assay* ⟨415⟩ for sampling.]

## CONTINUOUS FLOW SYSTEM

Identify the gas contained in the container, and select the appropriate gas regulator. Secure the regulator to the gas container. Do not apply lubricant or Teflon tape to the container-to-regulator connections. Purge the regulator with the gas under test. Select float setting to obtain the proper flow rate to achieve total gas volume as recommended by the manufacturer. Attach the detector tube, then adjust the flow rate to the required level as indicated by the charts that accompany the flowmeter and the detector tube. Time the gas flow to achieve the desired total gas volume ±10 s. At the allotted time close the regulator valve, then the main container valve. Observe the tube while it is still attached to determine the degree of color change, and record the result. Remove the tube, and disconnect the apparatus, vent the regulator gas pressure to atmosphere, and remove the regulator from the container. Dispose of the tube after use.

## HAND PUMP—FIXED VOLUME

The alternative approach is to apply the gas detector hand pump. The system draws a consistent volume with each pump stroke. To ensure the accuracy of the total gas volume, the user must follow the pump manufacturer's suggested recommendation about how to pump.

# ⟨415⟩ MEDICAL GASES ASSAY

## INTRODUCTION

The evaluation of the purity of a gas used for medical treatment or as a component of a pharmaceutical process is the purpose of a *USP* medical gas monograph. The purity generally is evaluated by an assay for the content of the article and by analyses for trace impurities. The application of gas chromatography, paramagnetic analysis, and detector tubes to medical gases is somewhat different from traditional procedures used for analytes in the liquid phase and therefore warrants a separate description. This general test chapter focuses on the assay for content tests. Sampling for impurities is addressed in general chapter *Impurities Testing in Medical Gases* ⟨413⟩.

This chapter includes sampling and qualification aspects of gas chromatographic and paramagnetic analyses of medical gases. In addition, it includes a description of the initial set-up, validation, and calibration of these instruments. The specific assay procedures are defined in the specific monograph for that gas.

The basic definitions of instrumental qualification and validation are included in general information chapters *Analytical Instrument Qualification* ⟨1058⟩ and *Validation of Compendial Procedures* ⟨1225⟩, respectively, and will not be repeated. However, when variations of the materials presented in these chapters are necessary due to the character of the analyte, this chapter will define those variations.

## METHODS

### Gas Chromatography (GC)

See *Chromatography* ⟨621⟩.

### Detectors for Medical Gases Assay

The two most common detectors used in the analyses of medical gases are the thermal conductivity detector (TCD) and flame ionization detector (FID).

The TCD will detect any gas or vapor that has a thermal conductivity (TC) that differs significantly from the high TC of the reference gas, usually helium, therefore it is virtually universal. However, the generally accepted lower detection limit for the TCD is 50 ppm v/v. This represents a limitation for the evaluation of trace impurities in medical gases.

The FID is also used for the evaluation of trace impurities in medical gases, because it is more sensitive to organic compounds but does not produce a signal for most common medical gases.

## QUALIFICATION

### Installation Qualification (IQ)

The IQ requirements ensure the gas chromatograph hardware and software (or readout device) is installed safely and in accordance with the GC manufacturer's instructions.

Consideration should be given to the following as applicable:

- Suitability of the sample system (including connections);
- Leakage (should be leak free);
- Representative sampling;
- Sample flow rates;
- Response time;
- Correct output signals;
- Power supply (including voltage regulation); and
- Appropriate environmental conditions of the instrument and of the sample itself (e.g., temperature and pressure).

### Operational Qualification (OQ)

OQ verifies that the GC performs as intended within its anticipated operating range. For medical gas final product testing, the GC is tested to ensure repeatability (verification that relative standard deviation is consistent with claims) for each analyte of interest. Due to the specific nature of medical gas testing and the limited number of analytes, routine calibration and periodic calibration verification of a GC instrument and the testing procedure may be used in place of initial or periodic OQ. When an instrument is used for a broader range of analytes, the replacement of OQ with calibration and periodic calibration verification is inappropriate.

Official

https://pharmacopeia.cn/v-download/

## Performance Qualification (PQ)

For medical gas final product testing, the GC is periodically checked at appropriate intervals during analytical runs with a calibration gas (i.e., verifying that the results are consistent with a named concentration within acceptable accuracy and precision ranges after a specific number of sample injections).

## Paramagnetic Oxygen Measurement

### THEORY

The paramagnetic analyzer measures the displacement of a diamagnetic gas (nitrogen) by a paramagnetic gas (oxygen), in a strong magnetic field. A measuring cell typically employs a glass dumbbell with nitrogen-filled spheres that is suspended on a torsion strip between magnets that concentrate the flux around the dumbbell. When oxygen molecules enter the measuring cell, the dumbbell is deflected by the force exerted by the oxygen molecules that are attracted to the strongest part of the magnetic field. By using optical sensors, a feedback coil, and suitable electronics, analysts measure an output that is directly proportional to the partial pressure of oxygen.

Oxygen is the only paramagnetic gas present above trace levels in the atmosphere. However, paramagnetic analyzers can be affected by the magnetic susceptibility of the background gas. Therefore changes to background gases in *USP* monographs should be avoided.

## Design Considerations

The design considerations for the purchase of new instruments may include the following parameters.

### DRIFT

A change of the output of the instrument for a given concentration over a stated period of time under constant conditions and without any adjustments being made to the instrument by external means. Drift is the summation of two components, zero drift and span drift. Drift determines the frequency of instrument calibration.

### ZERO DRIFT

A change in the output when zero gas is being measured.

### SPAN DRIFT

A change in the output at the level of oxygen concentration that is being measured.

### OPERATING TEMPERATURE

The ambient temperature range for which the stated performance specification of the instrument will remain valid. A larger temperature coefficient will indicate that a smaller change in ambient temperature is permitted before re-calibration is required.

### OPERATING PRESSURE

The instrument should operate at the inlet pressures of the samples to be tested.

## Qualification Aspects

### INSTALLATION QUALIFICATION (IQ)

The IQ requirements ensure the oxygen analyzer hardware and software (or readout device) is installed safely and in accordance with the oxygen analyzer manufacturer's instructions.

Consideration should be given to the following as applicable:

- Suitability of the sample system (including connections);
- Leakage (should be leak free);
- Representative sampling;
- Sample flow rates;
- Response time;
- Correct output signals;
- Power supply (including voltage regulation); and
- Appropriate environmental conditions of the instrument and of the sample itself (e.g., temperature and pressure).

### OPERATIONAL QUALIFICATION (OQ)

The OQ requirements verify that the paramagnetic analyzer performs as intended within its anticipated operating range and is suitable for the actual conditions of use. Instruments and apparatus should be calibrated and used in accordance with the

Official

https://pharmacopeia.com/

oxygen analyzer manufacturer's instructions. Because of the specific nature of the instrument, routine calibration may be used in place of initial or periodic OQ testing.

### PERFORMANCE QUALIFICATION (PQ)

The PQ requirements verify that the paramagnetic analyzer performs as intended in its normal operating environment. For medical gas final product testing, the paramagnetic analyzer is initially calibrated (zeroed and spanned using a certified standard) in accordance with the oxygen analyzer manufacturer's instructions and is periodically recalibrated to ensure continued acceptable performance.

### ZEROING THE INSTRUMENT (ESTABLISHING THE LOWER LIMIT)

Using the certified standard defined in the monograph, establish a zero setting on the analyzer by passing the zero gas into the analyzer at the oxygen analyzer manufacturer's suggested flow rate. Maintain the flow until a stable reading is observed on the instrument. As necessary, adjust the zero setting to a value of 0.0% according to the oxygen analyzer manufacturer's instructions. Confirm the reading is stable.

[NOTE—Depending on the intended use of the instrument, zeroing to a setting other than 0.0% is an acceptable alternative to this procedure if it provides greater measurement precision.]

### SPANNING THE RANGE OF USE

Establish the upper limit (span) with a span gas defined in the monograph and appropriate for the range of use. Pass the span gas through the instrument at the manufacturer's suggested flow rate. Confirm the reading is stable. Adjust the span setting to the certified value of the reference standard according to the oxygen analyzer manufacturer's instructions. Confirm the reading is stable.

## VALIDATION

Validation of this instrument is generally completed during the (IQ/OQ) process. Routine verification is performed as described in the OQ/PQ sections of this chapter; and, therefore, specific information on instrument validation is unnecessary.

## PROCEDURE

### For Off-line Instrument

Before analysis, the instrument is calibrated by zeroing and spanning as described in the PQ section.

[NOTE—The calibration need not be run concomitantly with the test samples.]

Connect the sample gas to the instrument, and establish a constant flow into the analyzer at the analyzer manufacturer's suggested flow rate. Maintain the flow until a constant reading is observed on the instrument. The definition of a constant reading is included in the analyzer manufacturer's instructions or in the user's instrument qualification documentation.

### For On-line Instrument

The calibration intervals are defined by the analyzer manufacturer, by past history, or by statistical means. Establish a constant flow into the analyzer at the manufacturer's suggested flow rate.

## SAMPLING

### Sampling from Liquid Phase

Cylinders containing a dip tube allow a liquid sample to be obtained from the valve outlet with the cylinder in the upright position. If a dip tube is not present, the cylinder should be placed in an inverted position with the cylinder and main valve safely supported (so the liquid phase is in contact with the valve).

Sampling of medical gases should always be conducted using the required regulator. Regulators should be purged with the gas that will be sampled. When necessary, the flow to the analyzer should be measured using a calibrated flow-measuring device.

### Sampling from Gaseous Phase

Cylinders that do not contain a dip tube allow a gaseous sample to be obtained from the valve outlet with the cylinder in the upright position. If a dip tube is present, the cylinder should be in an inverted position with the cylinder and main valve safely supported (so the gaseous phase is in contact with the end of the dip tube). Sampling of medical gases should always be conducted using the required regulator.

# CERTIFIED STANDARDS FOR MEDICAL GAS ANALYSIS

*USP* monographs for medical gases require tests that use certified standards for instrument calibration and analytical determinations. Such compendial testing may be conducted using reference materials that are traceable to the U.S. National Institute of Standards and Technology or other National standards-setting organizations, e.g., Institute for National Measurement Standards (Canada). The individual monographs and the reagents, indicators, and solutions section refer to the nominal percent of various certified standards required to perform medical gas analysis. The requirements for the actual certified concentrations in terms of variance from the nominal value are indicated in the *Reagents, Indicators, and Solutions* section for each respective certified standard.

# ⟨425⟩ IODOMETRIC ASSAY—ANTIBIOTICS

The following method is provided for the assay of most of the Pharmacopeial penicillin antibiotic drugs and their dosage forms, for which iodometric titration is particularly suitable.

## ASSAY

**Standard preparation:** Dissolve in the solvent specified in the table of *Solvents and Final Concentrations* a suitable quantity of the USP Reference Standard specified in the individual monograph, previously dried under the conditions specified in the individual monograph and accurately weighed, and dilute quantitatively and stepwise with the same solvent to obtain a solution having a known concentration of about that specified in the table. Pipet 2.0 mL of this solution into each of two 125-mL glass-stoppered conical flasks.

**Solvents and Final Concentrations**

| Antibiotic | Solvent* | Final Concentration |
|---|---|---|
| Amoxicillin | Water | 1.0 mg/mL |
| Ampicillin | Water | 1.25 mg/mL |
| Ampicillin Sodium | *Buffer B.1* | 1.25 mg/mL |
| Cloxacillin Sodium | Water | 1.25 mg/mL |
| Cyclacillin | Water | 1.0 mg/mL |
| Dicloxacillin Sodium | *Buffer B.1* | 1.25 mg/mL |
| Methicillin Sodium | *Buffer B.1* | 1.25 mg/mL |
| Nafcillin Sodium | *Buffer B.1* | 1.25 mg/mL |
| Oxacillin Sodium | *Buffer B.1* | 1.25 mg/mL |
| Penicillin G Potassium | *Buffer B.1* | 2,000 units/mL |
| Penicillin G Sodium | *Buffer B.1* | 2,000 units/mL |
| Penicillin V Potassium | *Buffer B.1* | 2,000 units/mL |
| Phenethicillin Potassium | *Buffer B.1* | 2,000 units/mL |

* Unless otherwise noted, the *Buffers* are the potassium phosphate buffers defined in the section *Media and Diluents* under *Antibiotics—Microbial Assays* ⟨81⟩, except that sterilization is not required before use.

Official

**Assay preparation:** Unless otherwise specified in the individual monograph, dissolve in the solvent specified in the table of *Solvents and Final Concentrations* a suitable quantity, accurately weighed, of the specimen under test, and dilute quantitatively with the same solvent to obtain a solution having a known final concentration of about that specified in the table. Pipet 2 mL of this solution into each of two 125-mL glass-stoppered conical flasks.

### Procedure

**Inactivation and titration:** To 2.0 mL of the *Standard preparation* and of the *Assay preparation*, in respective flasks, add 2.0 mL of 1.0 N sodium hydroxide, mix by swirling, and allow to stand for 15 minutes. To each flask add 2.0 mL of 1.2 N hydrochloric acid, add 10.0 mL of 0.01 N iodine VS, immediately insert the stopper, and allow to stand for 15 minutes. Titrate with 0.01 N sodium thiosulfate VS. As the endpoint is approached, add 1 drop of starch iodide paste TS, and continue the titration to the discharge of the blue color.

**Blank determination:** To a flask containing 2.0 mL of the *Standard preparation* add 10.0 mL of 0.01 N iodine VS. If the *Standard Preparation* contains amoxicillin or ampicillin, immediately add 0.1 mL of 1.2 N hydrochloric acid. Immediately titrate with 0.01 N sodium thiosulfate VS. As the endpoint is approached, add 1 drop of starch iodide paste TS, and continue the titration to the discharge of the blue color. Similarly treat a flask containing 2.0 mL of the *Assay preparation.*

### Calculations

Calculate the microgram (or unit) equivalent (F) of each mL of 0.01 N sodium thiosulfate consumed by the *Standard preparation* by the formula:

$$\text{Result} = (2CP)/(B - I)$$

$C$ = concentration of Reference Standard in the *Standard preparation* (mg/mL)
$P$ = potency of the Reference Standard (µg/mg or units/mg)
$B$ = volume of 0.01 N sodium thiosulfate consumed in the *Blank determination* (mL)
$I$ = volume of 0.01 N sodium thiosulfate consumed in the *Inactivation and titration* (mL)

Calculate the potency of the specimen under test by the formula given in the individual monograph.

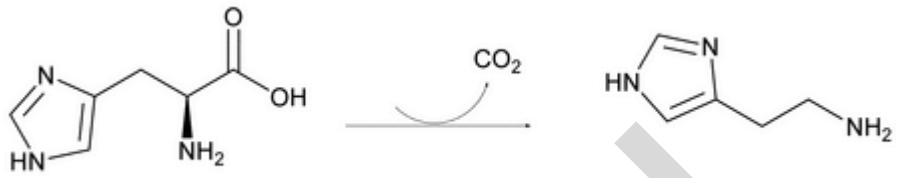
# ▲⟨426⟩ HISTAMINE TEST METHOD

## INTRODUCTION

High levels of histamine in drug products can lead to severe adverse drug reactions, including flushing, itching, hives, shortness of breath, decreased blood pressure, increased heart rate, and even fatality.

A potential source of histamine impurity is peptone of animal origin, particularly fish peptone, which is a critical raw material used as a protein source in the fermentation process. Free histidine is a naturally-occurring amino acid present in animals that can be converted to histamine by histidine decarboxylase.



**Histidine** **Histamine**

Fish peptone has a higher histamine contamination risk than other animal-derived peptones because some species of fish have larger quantities of histidine. Special attention must be paid to histamine levels when peptones of animal origin are used in the manufacturing process. This general chapter is intended to provide users with validated analytical methods to quantify the histamine levels in antibiotics.

Applicable requirements for histamine content are determined by the appropriate regulatory agency.

This chapter contains an LC-MS method to determine the histamine content. This method is validated for use with gentamicin sulfate, and must be validated for use with other drug substances.

## HISTAMINE CONTENT IN GENTAMICIN SULFATE

• **PROCEDURE**

**Solution A:** Acetonitrile

**Solution B:** 10 mM ammonium formate in 0.1% formic acid

**Sensitivity solution:** 2 ng/mL solution of USP Histamine Dihydrochloride RS

**Standard solutions:** Accurately weigh an appropriate amount of USP Histamine Dihydrochloride RS, and dissolve and dilute with *Solution B*. Dilute further with *Solution B* to obtain a series of standard solutions (NLT 3) appropriately spaced and at concentrations appropriate for the assay within the range from 2 to 20 ng/mL.

**Sample solution:** Accurately weigh a suitable quantity of gentamicin sulfate, and dissolve and dilute with *Solution B* to prepare a 1 mg/mL solution.

**Check standard:** Accurately weigh an appropriate amount of USP Histamine Dihydrochloride RS, and dissolve and dilute with *Solution B*. Dilute further with *Solution B* to obtain a check standard within the range of the concentrations prepared for the *Standard curve*.

**Mobile phase gradient:** See *Table 1*.

**Table 1**

| Time (min) | Solution A (% v/v) | Solution B (% v/v) |
|---|---|---|
| 0 | 90 | 10 |
| 4 | 40 | 60 |
| 5 | 40 | 60 |
| 5.01 | 90 | 10 |
| 7 | 90 | 10 |

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** MS

**MS conditions**

**Ionization mode:** Electrospray (+) ionization

**Single-ion monitoring (SIM) mode:** m/z 112.1

**Probe temperature:** 600°

**Column:** 2.1-mm × 10-cm; 1.7-µm packing L68

**Column temperature:** 35°

**Flow rate:** 0.5 mL/min

**Injection volume:** 1 µL

[NOTE—The approximate retention time of the histamine peak is 2.8 min.]

**Standard curve**

**Samples:** *Standard solutions*

Inject 1 µl of a series of *Standard solutions* and record the chromatograms and peak area of MS signals. Using the linear regression method, plot the histamine peak areas of the *Standard solutions* versus the histamine concentrations, and determine the standard curve best fitting the plotted points.

**System suitability**

**Samples:** *Sensitivity solution*, *Standard solutions*, and *Check standard*

**Suitability requirements**

**Linearity:** The correlation coefficient (*R*) of the *Standard curve* should be NLT 0.99.

**Percent recovery of the *Check standard*:** 80%–120%

**Relative standard deviation:** Inject 3 replicates of the *Standard solution* prepared at 10 ng/mL, and record the histamine peak areas. The percent relative standard deviation (%RSD) of the histamine peak areas is NMT 10%. If the sample MS signals are lower than the *Standard curve*, the %RSD is not required.

**Signal-to-noise ratio:** NLT 10 of the histamine peak, *Sensitivity solution*

**Analysis**

**Sample:** *Sample solution*

Inject 1 µl of the *Sample solution*, and record chromatograms and peak area of MS signals.

**Calculation:** From the *Standard curve* obtained and the histamine peak area of the *Sample solution*, determine the histamine concentration, *C*, in the *Sample solution*. Calculate the content of histamine, in ng/mg (ppm), in the gentamicin sulfate sample:

$$\text{Result} = C/S$$

$C$ = concentration of histamine in the *Sample solution* (ng/mL)
$S$ = concentration of gentamicin sulfate in the *Sample solution* (mg/mL)

# ⟨429⟩ LIGHT DIFFRACTION MEASUREMENT OF PARTICLE SIZE

## INTRODUCTION

*The method is based on the ISO standards 13320-1(1999) and 9276-1(1998).*

This general chapter has been harmonized with the corresponding texts of the *European Pharmacopoeia* and/or the *Japanese Pharmacopoeia.*

The laser light diffraction technique used for the determination of particle-size distribution is based on the analysis of the diffraction pattern produced when particles are exposed to a beam of monochromatic light. Historically, the early laser diffraction instruments only used scattering at small angles. However, the technique has since been broadened to include laser light scattering in a wider angular range and application of the Mie theory, in addition to the Fraunhofer approximation and anomalous diffraction.

The technique cannot distinguish between scattering by single particles and scattering by clusters of primary particles, i.e., by agglomerates or aggregates. As most particulate samples contain agglomerates or aggregates and as the focus of interest is generally on the size distribution of primary particles, the clusters are usually dispersed into primary particles before measurement.

For nonspherical particles, an equivalent sphere-size distribution is obtained because the technique assumes spherical particles in its optical model. The resulting particle-size distribution may differ from those obtained by methods based on other physical principles (e.g., sedimentation, sieving).

This chapter provides guidance for the measurement of size distributions of particles in different dispersed systems (e.g., powders, sprays, aerosols, suspensions, emulsions, and gas bubbles in liquids), through analysis of their angular light-scattering patterns. It does not address specific requirements of particle-size measurement of specific products.

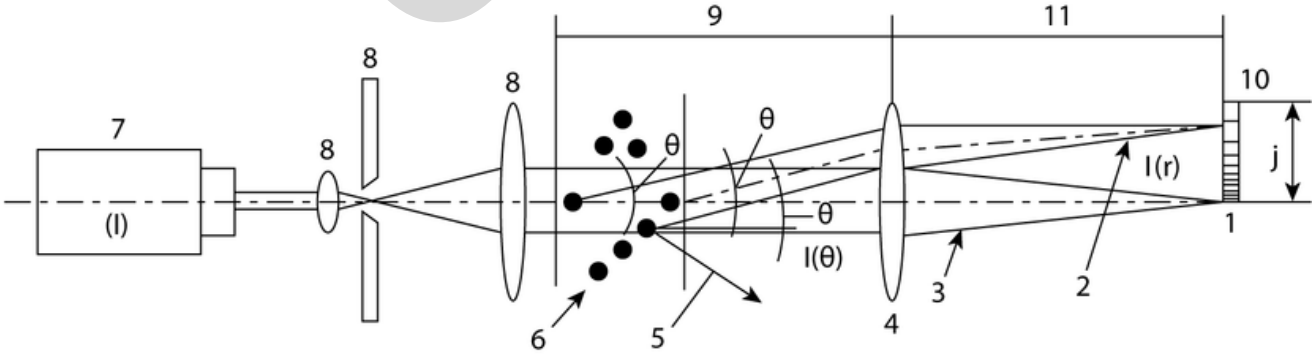
## PRINCIPLE

A representative sample, dispersed at an adequate concentration in a suitable liquid or gas, is passed through a beam of monochromatic light, usually a laser. The light scattered by the particles at various angles is measured by a multi-element detector. Numerical values representing the scattering pattern are then recorded for subsequent analysis. These scattering pattern values are then transformed, using an appropriate optical model and mathematical procedure, to yield the proportion of total volume to a discrete number of size classes, forming a volumetric particle-size distribution.

## INSTRUMENT

The instrument is located in an environment where it is not affected by electrical noise, mechanical vibrations, temperature fluctuations, humidity, or direct bright light.

An example of a setup of a laser light diffraction instrument is given in *Figure 1.* Other equipment may be used.



1. Obscuration detector
2. Scattered beam
3. Direct beam
4. Fourier lens
5. Scattered light not collected by lens (4)
6. Particle ensemble
7. Light source laser
8. Beam processing unit
9. Working distance lens (4)
10. Multi-element detector
11. Focal distance of lens (4)

Figure 1. Example of a set-up of a laser light diffraction instrument.

The instrument comprises a laser light source, beam processing optics, a sample measurement region (or cell), a Fourier lens, and a multi-element detector for measuring the scattered light pattern. A data system is also required for deconvolution of the scattering data into a volumetric size distribution and associated data analysis and reporting.

The particles can enter the laser beam in two positions. In the conventional case the particles enter the parallel beam before the collecting lens and within its working distance. In so-called reversed Fourier optics the particles enter behind the collecting

@2024 USPC

lens and thus in a converging beam. The advantage of the conventional setup is that a reasonable path length for the sample is allowed within the working distance of the lens. The second setup allows only small path lengths but enables measurement of scattered light at larger angles, which is useful when submicron particles are present.

The interaction of the incident light beam and the ensemble of dispersed particles results in a scattering pattern with different light intensities at various angles. The total angular intensity distribution, consisting of both direct and scattered light, is then focused onto a multi-element detector by a lens or a series of lenses. These lenses create a scattering pattern that, within limits, does not depend on the location of the particles in the light beam. Hence, the continuous angular intensity distribution is converted into a discrete spatial intensity distribution on a set of detector elements.

It is assumed that the measured scattering pattern of the particle ensemble is identical to the sum of the patterns from all individual single scattering particles presented in random relative positions. Note that only a limited angular range of scattered light is collected by the lens(es) and, therefore, by the detector.

## DEVELOPMENT OF THE METHOD

The measurement of particle size by laser diffraction can give reproducible data, even in the submicron region, provided the instrument used and the sample tested are carefully controlled to limit variability of the test conditions (e.g., dispersion medium, method of preparation of the sample dispersion).

Traditionally, the measurement of particle size using laser diffraction has been limited to particles in the range of approximately 0.1 µm to 3 mm. Because of recent advances in lens and equipment design, newer instruments are routinely capable of exceeding this range. With the validation report, the user demonstrates the applicability of the method for its intended use.

### Sampling

The sampling technique must be adequate to obtain a representative sample of a suitable volume for the particle-size measurement. Sample splitting techniques such as rotating riffler or the cone and quartering method may be applied.

### Evaluation of the Dispersion Procedure

The sample to be analyzed is inspected, visually or with the aid of a microscope, to estimate its size range and particle shape. The dispersion procedure must be adjusted to the purpose of the measurement. The purpose may be such that it is preferable to deagglomerate clusters into primary particles as far as possible, or it may be desirable to retain clusters as intact as possible. In this sense, the particles of interest may be either primary particles or clusters.

For the development of a method, it is highly advisable to check that comminution of the particles does not occur and, conversely, that dispersion of particles or clusters is satisfactory. This can usually be done by changing the dispersing energy and monitoring the change of the particle-size distribution. The measured size distribution must not change significantly when the sample is well dispersed and the particles are neither fragile nor soluble. Moreover, if the manufacturing process (e.g., crystallization, milling) of the material has changed, the applicability of the method must be verified (e.g., by microscopic comparison).

Sprays, aerosols, and gas bubbles in a liquid should be measured directly, provided that their concentration is adequate, because sampling or dilution generally alters the particle-size distribution.

In other cases (such as emulsions, pastes, and powders), representative samples may be dispersed in suitable liquids. Dispersing aids (wetting agents, stabilizers) and/or mechanical forces (e.g., agitation, sonication) are often applied for deagglomeration or deaggregation of clusters and stabilization of the dispersion. For these liquid dispersions, a recirculating system consisting of an optical measuring cell, a dispersion bath usually equipped with stirrer and ultrasonic elements, a pump, and tubing is most commonly used. Nonrecirculating, stirred cells are useful when only small amounts of a sample are available or when special dispersion liquids are used.

Dry powders can also be converted into aerosols through the use of suitable dry powder dispersers that apply mechanical force for deagglomeration or deaggregation. Generally, the dispersers use the energy of compressed gas or the differential pressure of a vacuum to disperse the particles to an aerosol that is blown through the measuring zone, usually into the inlet of a vacuum unit that collects the particles. However, for free-flowing, coarser particles or granules, the effect of gravity may be sufficient to disperse the particles adequately.

If the maximum particle size of the sample exceeds the measuring range of the instrument, the material that is too coarse can be removed by sieving, and the mass and percentage of removed material are reported. However, after presieving, note that the sample is no longer representative, unless proven otherwise.

### Optimization of the Liquid Dispersion

Liquids, surfactants, and dispersing aids used to disperse powders must

- be transparent at the laser wavelength and practically free from air bubbles or particles;
- have a refractive index that differs from that of the test material;
- be a nonsolvent of the test material (pure liquid or prefiltered, saturated solution);
- not alter the size of the test materials (e.g., by solubility, solubility enhancement, or recrystallization effects);
- favor easy formation and stability of the dispersion;
- be compatible with the materials used in the instrument (such as O-rings, gaskets, tubing, etc.); and
- possess a suitable viscosity to facilitate recirculation, stirring, and filtration.

DOI: https://doi.org/10.31003/USPNF_M99188_01_01

Surfactants and/or dispersing aids are often used to wet the particles and to stabilize the dispersion. For weak acids and weak bases, buffering of the dispersing medium at low or high pH, respectively, can assist in identifying a suitable dispersant.

A preliminary check of the dispersion quality can be performed by visual or microscopic inspection. It is also possible to take fractional samples out of a well-mixed stock dispersion. Such stock dispersions are formed by adding a liquid to the sample while mixing it with, for example, a glass rod, a spatula or a vortex mixer. Care must be taken to ensure the transfer of a representative sample and that settling of larger particles does not occur. Therefore, a sample paste is prepared or sampling is carried out quickly from a suspension maintained under agitation.

## Optimization of the Gas Dispersion

For sprays and dry powder dispersions, a compressed gas free from oil, water, and particles may be used. To remove such materials from the compressed gas, a dryer with a filter can be used. Any vacuum unit should be located away from the measurement zone, so that its output does not disturb the measurement.

## Determination of the Concentration Range

In order to produce an acceptable signal-to-noise ratio in the detector, the particle concentration in the dispersion must exceed a minimum level. Likewise, it must be below a maximum level in order to avoid multiple scattering. The concentration range is influenced by the width of the laser beam, the path length of the measurement zone, the optical properties of the particles, and the sensitivity of the detector elements.

In view of the above, measurements must be performed at different particle concentrations to determine the appropriate concentration range for any typical sample of material. [NOTE—In different instruments, particle concentrations are usually represented by differently scaled and differently named numbers, e.g., obscuration, optical concentration, proportional number of total mass.]

## Determination of the Measuring Time

The time of measurement, the reading time of the detector, and the acquisition frequency is determined experimentally in accordance with the required precision. Generally, the time for measurement permits a large number of detector scans or sweeps at short time intervals.

## Selection of an Appropriate Optical Model

Most instruments use either the Fraunhofer or the Mie theory, though other approximation theories are sometimes applied for calculation of the scattering matrix. The choice of the theoretical model depends on the intended application and the different assumptions (size, absorbance, refractive index, roughness, crystal orientation, mixture, etc.) made for the test material. If the refractive index values (real and imaginary parts for the used wavelength) are not exactly known, then the Fraunhofer approximation or the Mie theory with a realistic estimate of the refractive index can be used. The former has the advantages that it is simple and it does not need refractive index values; the latter usually provides less-biased particle-size distributions for small particles. For instance, if the Fraunhofer model is used for samples containing an appreciable amount of small, transparent particles, a significantly larger amount of small particles may be calculated. In order to obtain traceable results, it is essential to document the refractive index values used, because small differences in the values assumed for the real and imaginary part of the complex refractive index may cause significant differences in the resulting particle-size distributions. Small values of the imaginary part of the refractive index (about 0.01–0.1 i) are often applied to allow the correction of the absorbance for the surface roughness of the particles. It should be noted, in general, that the optical properties of the substance to be tested, as well as the structure (e.g., shape, surface roughness, and porosity) bear upon the final result.

## Validation

Typically, the validity of a procedure may be assessed by the evaluation of its specificity, linearity, range, accuracy, precision, and robustness. In particle-size analysis by laser light diffraction, specificity as defined by ICH is not applicable as it is not possible to discriminate different components into a sample, nor is it possible to discriminate between agglomerates from dispersed particles unless properly complemented by microscopic techniques. Exploring a linear relationship between concentration and response, or a mathematical model for interpolation, is not applicable to this procedure. Rather than evaluating linearity, this method requires the definition of a concentration range within which the result of the measurements does not vary significantly. Concentrations below that range produce an error due to a poor signal-to-noise ratio, while concentrations above that range produce an error due to multiple scattering. The range depends mostly on the instrument hardware. Accuracy should be confirmed through an appropriate instrument qualification and comparison with microscopy, while precision may be assessed by means of a repeatability determination.

The attainable repeatability of the method mainly depends on the characteristics of the material (milled/not milled, robust/fragile, width of its size distribution, etc.), whereas the required repeatability depends on the purpose of the measurement. Mandatory limits cannot be specified in this chapter, as repeatabilities (different sample preparations) may vary appreciably from one substance to another. However, it is good practice to aim at acceptance criteria for repeatability such as % RSD $\leq$ 10% [n = 6] for any central value of the distribution (e.g., for $x_{50}$). Values at the sides of the distribution (e.g., $x_{10}$ and $x_{90}$) are oriented towards less stringent acceptance criteria such as % RSD $\leq$ 15% [n = 6]. Below 10 µm, these values must be doubled. Robustness may be tested during the selection and optimization of the dispersion media and forces. The change of the dispersing energy may be monitored by the change in the particle-size distribution.

# MEASUREMENT

## Precautions

The instructions given in the instrument manual are followed:

- never look into the direct path of the laser beam or its reflections;
- earth all instrument components to prevent ignition of solvents or dust explosions;
- check the instrument set-up (e.g., warm-up, required measuring range and lens, appropriate working distance, position of the detector, no direct bright daylight); and
- in the case of wet dispersions, avoid air bubbles, evaporation of liquid, schlieren or other inhomogeneities in the dispersion; similarly, avoid improper mass-flow from the disperser or turbulent airflow in the case of dry dispersions; such effects can cause erroneous particle-size distributions.

## Measurement of the Light Scattering of Dispersed Sample(s)

After proper alignment of the optical part of the instrument, a blank measurement of the particle-free dispersion medium must be performed using the same method as that used for the measurement of the sample. The background signal must be below an appropriate threshold. The detector data are saved in order to subtract them later from the data obtained with the sample. The sample dispersion is measured according to the developed method.

For each detector element, an average signal is calculated, sometimes together with its standard deviation. The magnitude of the signal from each detector element depends upon the detection area, the light intensity, and the quantum efficiency. The coordinates (size and position) of the detector elements together with the focal distance of the lens determine the range of scattering angles for each element. Most instruments also measure the intensity of the central (unscattered) laser beam. The ratio of the intensity of a dispersed sample to that in its absence (the blank measurement) indicates the proportion of scattered light and hence the particle concentration.

## Conversion of Scattering Pattern Into Particle-Size Distribution

This deconvolution step is the inverse of the calculation of a scattering pattern for a given particle-size distribution. The assumption of spherical particle shape is particularly important as most algorithms use the mathematical solution for scattering from spherical particles. Furthermore, the measured data always contain some random and systematic errors, which may vitiate the size distributions. Several mathematical procedures have been developed for use in the available instruments. They contain some weighting of deviations between measured and calculated scattering patterns (e.g., least squares), some constraints (e.g., non-negativity for amounts of particles), and/or some smoothing of the size distribution curve.

The algorithms used are specific to each make and model of equipment, and are proprietary. The differences in the algorithms between different instruments may give rise to differences in the calculated particle-size distributions.

## Replicates

The number of replicate measurements (with individual sample preparations) to be performed, depends on the required measurement precision. It is recommended to set this number in a substance-specific method.

# REPORTING RESULTS

The particle-size distribution data are usually reported as cumulative undersize distribution and/or as density distribution by volume. The symbol x is used to denote the particle size, which in turn is defined as the diameter of a volume-equivalent sphere. Q3(x) denotes the volume fraction undersize at the particle size x. In a graphical representation, x is plotted on the abscissa and the dependent variable Q3 on the ordinate. Most common characteristic values are calculated from the particle-size distribution by interpolation. The particle sizes at the undersize values of 10%, 50%, and 90% (denoted as $x_{10}$, $x_{50}$, and $x_{90}$, respectively) are frequently used. $x_{50}$ is also known as the median particle size. It is recognized that the symbol d is also widely used to designate the particle size, thus the symbol x may be replaced by d.

Moreover, sufficient information must be documented about the sample, the sample preparation, the dispersion conditions, and the cell type. Because the results depend on the particular instrument, data analysis program, and optical model used, these details must also be documented.

# CONTROL OF THE INSTRUMENT PERFORMANCE

Use the instrument according to the manufacturer's instructions and carry out the prescribed qualifications at an appropriate frequency, according to the use of the instrument and substances to be tested.

## Calibration

Laser diffraction systems, although assuming idealized properties of the particles, are based on first principles of laser light scattering. Thus, calibration in the strict sense is not required. However, it is still necessary to confirm that the instrument is

Status: Currently Official on 05-Jan-2024
Official Date: Official Prior to 2013
DOI Ref: vcu8u
DocId: GUID-B3D11DFA-2021-4961-9F88-F942F7C96D5D_1_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99188_01_01

operating correctly. This can be undertaken using any certified reference material that is acceptable in industrial practice. The entire measurement procedure is examined, including sample collection, sample dispersion, sample transport through the measuring zone, measurement, and the deconvolution procedure. It is essential that the total operational procedure is fully described.

The preferred certified reference materials consist of spherical particles of a known distribution. They must be certified as to the mass-percentage size distribution by an absolute technique, if available, and used in conjunction with an agreed, detailed operation procedure. It is essential that the real and imaginary parts of the complex refractive index of the material are indicated if the Mie theory is applied in data analysis. The representation of the particle-size distribution by volume will equal that of the distribution by mass, provided that the density of the particles is the same for all size fractions.

The response of a laser diffraction instrument meets the requirements if the mean value of $x_{50}$ from at least three independent measurements does not deviate by more than 3% from the certified range of values of the certified reference material. The mean values for $x_{10}$ and $x_{90}$ must not deviate by more than 5% from the certified range of values. Below 10 µm, these values must be doubled.

Although the use of materials consisting of spherical particles is preferable, nonspherical particles may also be employed. Preferably, these particles have certified or typical values from laser diffraction analysis performed according to an agreed, detailed operating procedure. The use of reference values from methods other than laser diffraction may cause a significant bias. The reason for this bias is that the different principles inherent in the various methods may lead to different sphere-equivalent diameters for the same nonspherical particle.

Although the use of certified reference materials is preferred, other well-defined reference materials may also be employed. They consist of substances of typical composition and particle-size distribution for a specified class of substances. Their particle-size distribution has proven to be stable over time. The results must comply with previously determined data, with the same precision and bias as for the certified reference material.

## Qualification of the System

In addition to the calibration, the performance of the instrument must be qualified at regular time intervals or as frequently as appropriate. This can be undertaken using any suitable reference material as mentioned in the previous paragraph.

The qualification of the system is based on the concept that the equipment, electronics, software, and analytical operations constitute an integral system, which can be evaluated as an entity. Thus the entire measurement procedure is examined, including sample collection, sample dispersion, sample transport through the measuring zone, and the measurement and deconvolution procedure. It is essential that the total operational procedure is fully described.

In general, unless otherwise specified in the individual monograph, the response of a laser diffraction instrument is considered to meet the requirements if the $x_{50}$ value does not deviate by more than 10% from the range of values of the reference material. If optionally the values at the sides of the distribution are evaluated (e.g., $x_{10}$ and $x_{90}$), then these values must not deviate by more than 15% from the certified range of values. Below 10 µm, these values must be doubled.

[NOTE—For calibration of the instrument, stricter requirements are laid down in the paragraph on *Calibration*.]

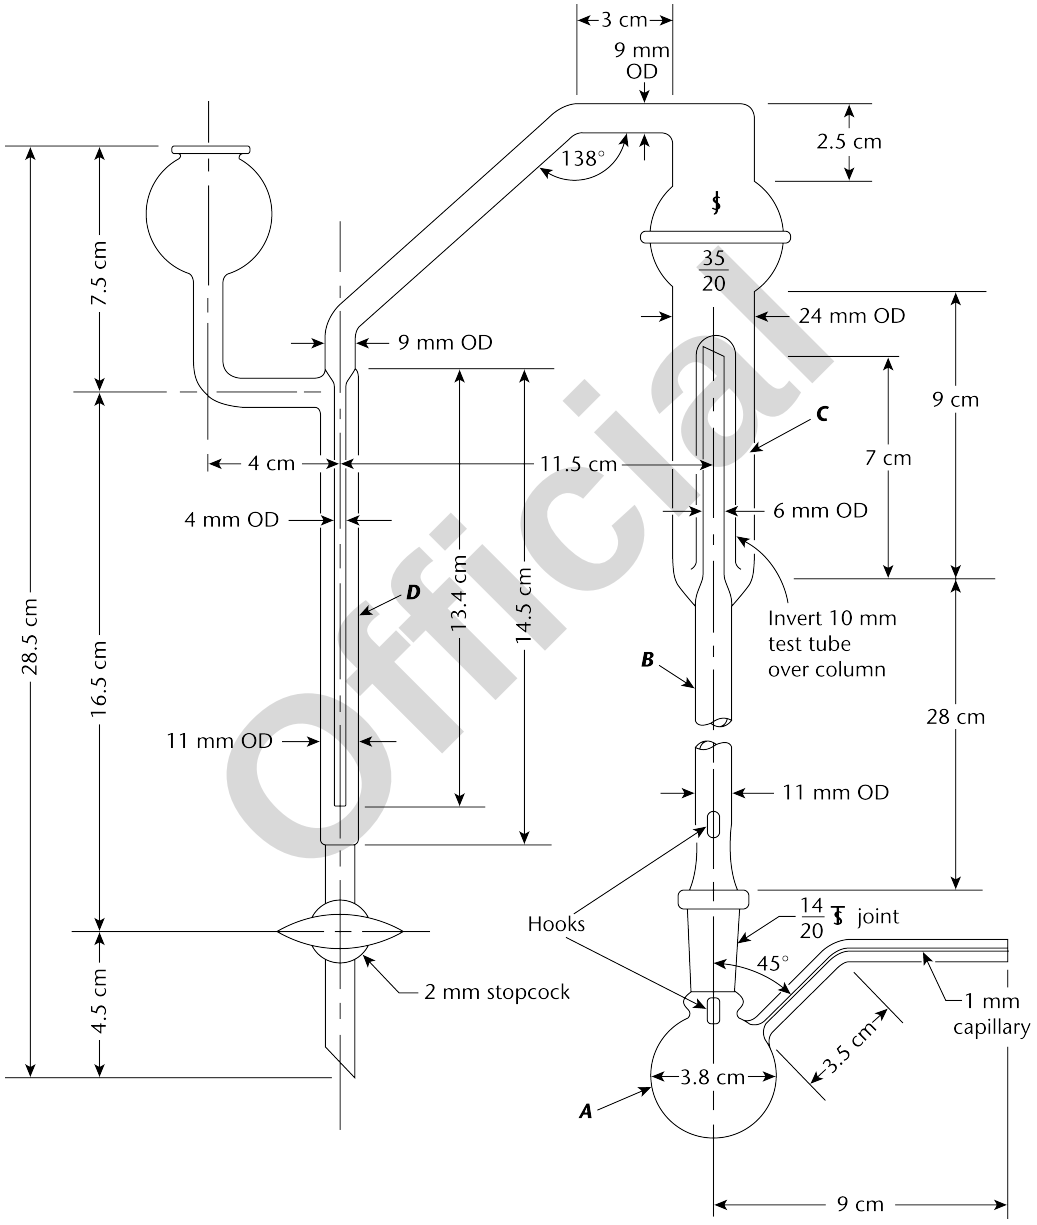
# ⟨431⟩ METHOXY DETERMINATION

## APPARATUS

The apparatus for methoxy determination is shown diagrammatically in the *accompanying figure.*



Apparatus for Methoxy Determination

The boiling flask, A, is fitted with a capillary side-arm for the introduction of carbon dioxide or nitrogen and is connected to a column, B, which serves to separate aqueous hydriodic acid from the more volatile methyl iodide. The methyl iodide passes through water in a scrubber trap, C, and is finally absorbed in the bromine–acetic acid solution in absorption tube D. The carbon dioxide or nitrogen is introduced through a pressure-regulating device and connected to the apparatus by a small capillary containing a small cotton pledget.

[NOTE—Avoid the use of organic solvents in cleaning this apparatus, since traces remaining may interfere with the determination. This test is used also for ethoxy determination with an 80-minute reaction time and a titrant equivalent of 0.751 mg of ($OC_2H_5$).]

For greater convenience in use and cleaning, a ground-glass ball joint connects the two upright columns of the apparatus. The top of the scrubber C consists of a 35/20 ball joint, the upper half of which is connected to the side-arm leading into tube

https://pharmacopeia.cn/v-about/

D. This permits taking the apparatus apart and facilitates adding the water to the trap. Also, it allows access to the loose inverted (10-mm) test tube that serves as the trap over the inner tube of the scrubber C.

## REAGENTS

### Bromine-Acetic Acid Solution

Dissolve 100 g of potassium acetate in 1000 mL of a solution consisting of 900 mL of glacial acetic acid and 100 mL of acetic anhydride. On the day of use, to 145 mL of this solution add 5 mL of bromine.

### Hydriodic Acid

A colorless, or nearly colorless, constant-boiling reagent solution, prepared for this purpose, is available commercially. If not obtained commercially, it may be prepared by distilling hydriodic acid over red phosphorus, passing carbon dioxide or nitrogen through the apparatus during the distillation. Use the constant-boiling mixture (between 55% and 58% of HI) distilling between 126° and 127°, which is colorless or nearly colorless. [**Caution**—Exercise safety precautions when distilling Hydriodic Acid.] Place the acid in small, amber, glass-stoppered bottles previously flushed with carbon dioxide, or nitrogen, seal with paraffin, and store in a cool, dark place.

## PROCEDURE

Prepare the apparatus by disconnecting the ball joint and pouring water into trap C until it is half-full. Connect the two parts, using a minimal amount of a suitable silicone grease to seal the ball joint. Add 7 mL of *Bromine-Acetic Acid Solution* to absorption tube D. Weigh the sample in a tared gelatin capsule, and add it to the boiling flask along with a few boiling chips or pieces of porous plate. Finally add 6 mL of *Hydriodic Acid* and attach the flask to the column, using a minimal amount of a suitable silicone grease to seal the junction. Bubble the carbon dioxide or nitrogen through the apparatus at the rate of 2 bubbles per second, place the boiling flask in an oil bath or heating mantle heated to 150°, and continue the reaction for 40 minutes for methoxy determination, or 80 minutes for ethoxy determination. Drain the contents of the absorption tube into a 500-mL conical flask containing 10 mL of sodium acetate solution (1 in 4). Rinse the tube with water, adding the rinsings to the flask, and finally dilute with water to about 125 mL. Add formic acid, dropwise, with swirling, until the reddish brown color of the bromine is discharged, then add 3 additional drops. A total of 12 to 15 drops usually is required. Allow to stand for 3 minutes, and add 15 mL of diluted sulfuric acid and 3 g of potassium iodide, and titrate immediately with 0.1 N sodium thiosulfate VS, using 3 mL of starch TS as the indicator. Perform a blank determination, including also a gelatin capsule, and make any necessary correction. Each mL of 0.1 N sodium thiosulfate is equivalent to 0.517 mg of ($OCH_3$).

# ⟨432⟩ DETERMINATION OF ZETA POTENTIAL BY ELECTROPHORETIC LIGHT SCATTERING

## INTRODUCTION

The zeta potential determination test method is based on the International Organization for Standardization (ISO) 13099-2:2012, *Colloidal systems—Methods for zeta-potential determination—Part 2: Optical methods*, as well as the scientific and technological developments that followed.

Zeta potential, denoted by the Greek letter ζ (hence the name), is a physicochemical characteristic of colloidal systems (suspensions and emulsions) that describes the electric potential difference between the mobile dispersion medium and the stationary layer of the dispersion medium attached to the dispersed particle. It is expressed in units of millivolts (mV). Zeta potential is often used to infer surface properties and to assess colloidal stability. Zeta potential cannot be directly measured but may be derived from experimentally measurable properties, including electroacoustic, electrokinetic, and electrophoretic phenomena.

This chapter provides procedures for the measurement of electrophoretic mobility based on light scattering phenomena, method development, and control of instrument performance. It does not address specific requirements of zeta potential measurement, or the acceptance value for particular products.

## PRINCIPLE

A representative sample dispersed at an adequate concentration in a suitable dispersion medium is placed in a cell equipped with a pair of electrodes to apply an electric potential. Although cell configuration can vary considerably, typically cells consist either of a cylindrical or rectangular capillary with electrodes at both ends, a cuvette, or another type of vessel into which a pair of electrodes are inserted at a known fixed distance. The cell is illuminated by a monochromatic coherent light beam, usually generated by a laser. Because of the applied electric potential, the particles that bear a net electric charge are attracted toward the oppositely charged electrode, a process known as electrophoresis. In the case of charged capillary walls, the dispersion medium stream flows along the capillary wall, a process known as electroosmosis. The overall movement of particles in the cell is the result of both processes. The electrophoretic light scattering technique uses a photoelectric detector to measure the Doppler shift (observed change in the frequency of a wave when the measuring apparatus and the wave source are in relative motion) of the scattered light. The Doppler shift is used to determine the velocity and direction of particle movement from which the electrophoretic mobility (μ) is calculated. Zeta potential is derived from the electrophoretic mobility using the Henry function, which can be approximated by the Smoluchowski equation or Hückel equation according to the relative thickness of the electrical double layer compared to the hydrodynamic radius of the particle.

For discussion of the theory and principles of measurements, see *Analytical Methodologies Based on Scattering Phenomena—Electrophoretic Light Scattering (Determination of Zeta Potential)* ⟨1430.4⟩, which is a helpful, but not mandatory resource.

***Change to read:***

## INSTRUMENT

The instrument should be located in a controlled environment with reduced dust, ▲▲ (USP 1-May-2023) electrical noise, vibrations, temperature fluctuations, humidity, and direct light. The instrument should contain a rigid internal optical system fixed on a bench with a vibration damp setup, and should be installed on a rigid table or bench.

An example of a setup of a zeta potential instrument is given in ⟨1430.4⟩, *Figure 1*. Other possibilities for optical arrangements are shown in ⟨1430.4⟩, *Figure 2*.

As shown in those figures, a typical zeta potential measurement instrument is comprised of the following components:

1. A sample cell to contain the test suspension between two electrodes so that an electric field can be applied
2. A suitable laser to illuminate the particles within the sample
3. A suitable detector to capture the scattered light and Doppler shifts in the scattered light when the electric field is applied
4. A software and computer system to process the collected scattering data and compute the mobility and zeta potential using appropriate models and algorithms

Typically, the Doppler shifts that occur during electrophoresis are quite small (ranging from a few to several hundred Hertz) and cannot be measured directly. To overcome this issue, interferometers are used to combine light that is frequency shifted by the sample with a reference beam. When the scattered light and the reference beam interfere, the result is a beat. The frequency of the beat is the frequency difference between the two underlying beams, which is the Doppler shift induced by the particles.

In practice, however, a simple interferometer cannot determine the sign of the Doppler shift and thus cannot determine the sign of the zeta potential. The measured beat frequency is always positive, whether the Doppler shift is positive or negative.

To overcome this problem, modern zeta potential instruments use a frequency modulator in the reference beam. This modulator causes a controlled Doppler shift at the frequency of the reference light. This means that the measured Doppler shift is the sum of the Doppler shift induced by the modulator plus the Doppler shift induced by the motion of the particles. Thus, the use of a frequency modulator enables the determination of the sign (positive or negative voltage) of the zeta potential.

# DEVELOPMENT OF THE METHOD

## Sample Considerations—Effect of Physicochemical Parameters of the Colloidal System on the Zeta Potential

### pH

Depending on particle surface chemistry, a change of the dispersion's pH affects the zeta potential. When the pH changes, the ion concentration changes, and it affects the composition of the double layer on the surface of the particles. This, in turn, changes the electrophoretic mobility and the resulting zeta potential.

### CONDUCTIVITY

The conductivity of the dispersion should be ▲appropriate to avoid▲ (USP 1-May-2023) heating and electrolysis.▲▲ (USP 1-May-2023) It is recommended to use a 10 mM saline or similar media. High conductivity media may result in increased Joule–Thomson heating, and thus a reduced voltage should be used. Typically, the conductivity should be within 1–5 millisiemens per cm (mS/cm).

### CONCENTRATION RANGE OF THE COLLOIDAL SYSTEM

The effect of the dispersed material concentration on the zeta potential must be evaluated, and the concentration range of a constant zeta potential established (see *Determination of the Concentration Range*).

### CONCENTRATION OF OTHER ADDED COMPONENTS IN THE SYSTEM

The effects of other system components that need to be part of the colloidal system in a particular application must be evaluated.

### VISCOSITY

The electrophoretic mobility of the moving particles is related to the dispersion medium viscosity as shown in ⟨1430.4⟩, *Equation 3*. The dispersion medium's viscosity should preferably be lower than 10 mPa · s, so that the system does not deviate from Newtonian fluid. For high concentration dispersions, the viscosity of the dispersion medium is used, and consideration is given to other factors.

## Sample Preparation

### SAMPLE STABILITY CONSIDERATIONS

The following two aspects of sample stability are considered when performing zeta potential measurements:

1. Based on the nature of the dispersion being tested, the electrodes in the sample cell and the dispersion itself may change after a zeta potential measurement is performed. Therefore, when reusing the same sample volume or cell for replicate zeta potential testing, the data should be reviewed carefully to ensure the measurements are acceptable. With certain dispersions, a fresh dispersant aliquot may need to be tested for each replicate measurement.
2. The zeta potential determination of a concentrated dispersion may require further dilution of the dispersion using filtered dispersion medium prior to the measurement, in order to lower the particle concentration, and to avoid measurement artifacts due to multiple scattering or inter-particle interactions. It is important to ensure that the diluting dispersion medium has the same electrolyte composition and pH as the dispersion being tested, especially when the goal of the study is to understand the formulation properties of that particular medium. However, the resulting conductivity of the media needs to be within the workable range as shown under *Conductivity*. If the diluted dispersion is prepared well before measurement, the stability of this diluted dispersion should be evaluated by measuring the zeta potential over the expected measurement time, to ensure that there is no time-dependent behavior on the measured zeta potential. Testing of serial dilutions bracketing the expected target dilution factor may also be useful.

## Determination of the Concentration Range

A reliable measurement requires reaching an acceptable signal-to-noise ratio in the detector. To achieve this feat, the dispersed material concentration in the colloidal system being measured must exceed a certain level. Likewise, it must be below a maximum level in order to avoid multiple scattering and ▲colloidal particles▲ (USP 1-May-2023) interaction. The concentration range is influenced by the width of the laser beam, the path length between the electrodes, the optical properties of the materials, and the sensitivity of the detector. Therefore, measurements must be performed at different dispersion concentrations to determine the appropriate concentration range for any specific sample being tested.

Official

https://pharmacopeia.cn/

## Method Validation

Typically, the validity of an analytical procedure is assessed by the evaluation of its specificity, linearity, range, accuracy, precision, robustness, and quantitation limit (QL) or detection limit (DL) as needed (see *Validation of Compendial Procedures* ⟨1225⟩). In zeta potential analysis by electrophoretic light scattering, specificity as defined by the International Council for Harmonisation (ICH) is not applicable because it is not possible to discriminate different components of a sample. The range, linearity, DL, and QL as defined in ICH Q2 guidelines and ⟨1225⟩ are also not applicable. Exploring a linear relationship between concentration and response, or a mathematical model for interpolation is not applicable to this procedure since Zeta potential should be a constant value, and should be constant for the optimized concentration range. The DL and QL are also not applicable because the concentration range of the method for the zeta potential measurement represents a different concept from the minimum concentration above which the property could be detected or quantified.

Rather than evaluating linearity, DL, and QL, this method requires the definition of a concentration range and measurement conditions within which the result of the measurements does not vary significantly. Concentrations below that range produce an error due to poor signal-to-noise ratio, while concentrations above that range produce an error due to multiple scattering and ▲colloidal particles▲ (USP 1-May-2023) interaction (e.g., flocculation, aggregation). Evaluation of accuracy is not applicable to the actual sample, but it should be confirmed through an appropriate verification of instrument calibration using appropriate reference materials (see *Verification of Calibration*). Precision may be assessed by means of a repeatability determination and intermediate precision determination (on different days or with different analysts) using the same instrument.

The feasible repeatability of the method depends mainly on the characteristics of the material and dispersion medium, whereas the required repeatability depends on the purpose of the measurement. Mandatory limits cannot be specified in this chapter, as repeatability (different sample preparations) may vary appreciably from one substance to another. However, it is good practice to aim for a variance lower than 10% as acceptance criteria for repeatability, and lower than 15% for intermediate precision.

The robustness assessment should address the sensitivity of the method to other likely sources of variation, and should establish a set of acceptable measurement conditions (see *Measurement Procedure*) and sample considerations (see *Sample Considerations—Effect of Physicochemical Parameters of the Colloidal System on the Zeta Potential*).

# MEASUREMENT PROCEDURE

## Precautions

The instructions provided in the instrument manual should be followed:

- Never look into the direct path of the laser beam or its reflections
- Check the instrument set-up (e.g., warm-up time, required measuring range and lens position, angle of analysis, temperature equilibration)
- Avoid air bubbles, evaporation of liquid, or other inhomogeneities in the suspension (emulsion) being tested

## Dispersion Media

It is critical to ensure that the sample and the sample cell/cuvette are compatible with the dispersion medium. The electrophoretic mobility of the sample is dependent on the chemical characteristics of the dispersion medium. Specifically, the pH and the ion type and concentration need to be controlled if the sample is diluted prior to measurement.

## Measurement Cell

To avoid contamination, the measurement cell must be thoroughly rinsed prior to and after measurement. It is important to control and monitor the temperature of the measurement cell because the dispersion medium viscosity is a function of temperature, and has a significant impact on the measured results.

## Sample Inspection

It is important to visually inspect the sample prior to analysis to check for large particles or sedimentation, which can negatively impact the results and/or reproducibility.

## Preparation

It is important to avoid changing the electrophoretic mobility of the sample during the sample preparation process. Many materials such as pipettes, spatulas, or syringes may have ions on their surface that can contaminate the sample. Disposable plastic materials are recommended if they are chemically compatible with the sample.

### Measurement of the Light Scattering of Dispersed Sample(s)

REPLICATES

The number of replicate measurements (with individual sample preparations) to be performed depends on the required measurement precision. It is recommended to set this number in a substance-specific method. Typically, three consecutive measurements are performed.

## DATA PROCESSING AND INTERPRETATION

Data processing is done by spectrum analysis, or autocorrelation function, or modulated Brownian motion power spectrum method.

For a more detailed information on data processing, see ⟨1430.4⟩, *5. Data Analysis*.

### Conversion of Doppler Shifts into Electrophoretic Mobility

The relationship between observed Doppler frequency shifts ($\Delta\omega$) of scattered light and corresponding electrophoretic mobility, μ, is shown in *Equation 1* and *Equation 2* for a reference beam optic alignment and a cross beam optic alignment, respectively:

$$\mu = \frac{\Delta\omega\lambda}{4\pi n E \sin(\theta/2)\sin[(\theta/2)+\xi]} \quad \text{Equation 1}$$

$$\mu = \frac{\Delta\omega\lambda}{4\pi n E \sin(\theta'/2)} \quad \text{Equation 2}$$

### Calculation of Zeta Potential

For large solute particles (the hydrodynamic radius is large compared to the thickness of the electrical double layer), the Smoluchowski equation is used to calculate ζ from μ:

$$\zeta = \frac{\eta_0 \mu}{\varepsilon_r \varepsilon_0} \quad \text{Equation 3}$$

For small solute particles (the hydrodynamic radius is small compared to the thickness of the electrical double layer), the Hückel equation is used to calculate ζ from μ:

$$\zeta = \frac{3\eta_0 \mu}{2\varepsilon_r \varepsilon_0} \quad \text{Equation 4}$$

For more detailed information on these equations, see ⟨1430.4⟩, *5.2 Calculation of Zeta Potential*.

***Change to read:***

## CONTROL OF THE INSTRUMENT PERFORMANCE

Use the instrument according to the manufacturer's instructions and carry out the prescribed qualifications at an appropriate frequency for the use of the instrument and substances to be tested.

### Verification of Calibration

The method is based on first principles and no calibration is needed. Verification is usually done with a standard sample.▲▲ (USP 1-May-2023) In general, it is not necessary to do a standard measurement each time a sample is being measured. Rather, it is recommended to run the standard sample "regularly" at predefined intervals.

### Qualification of the System

The performance of the instrument must be qualified at regular time intervals or as frequently as appropriate. This can be achieved using any suitable standard sample as mentioned in the previous paragraph.

The qualification of the system is based on the concept that the equipment, electronics, software, and analytical operations constitute an integral system, which can be evaluated as an entity. Thus, the entire measurement procedure is examined, including sample collection, sample dispersion, sample transport through the measuring zone, and the measurement and deconvolution procedure. It is essential that the total operational procedure is fully described.

Official

https://pharmacopeia.cn/v-download/

An instrument meets the requirement if the coefficient of variation for the mean electrophoretic mobility values from each measurement for a standard sample is less than 10%, provided that the absolute value of the standard sample mobility is higher than $2 \times 10^{-8}$ $m^2/V \cdot s$.

# ⟨441⟩ NIACIN OR NIACINAMIDE ASSAY

## ASSAY

### Chemical Method

- **PROCEDURE**

The following photometric procedure involves the colorimetric reaction of niacin or niacinamide with cyanogen bromide in the presence of sulfanilic acid. It can be used for the determination of niacin or niacinamide in the monographs such as *Niacin Injection*, *Niacinamide Injection*, and *Niacinamide Tablets*.

[NOTE—Determine from the labeling if the vitamin in the assay specimen is niacin or niacinamide, and use the corresponding standard preparation (either *Standard niacin preparation* or *Standard niacinamide preparation*) as directed in the *Procedure*.]

**Cyanogen bromide solution:** Dissolve 5 g of cyanogen bromide in water to make 50 mL. [**CAUTION**—Prepare this solution under a hood, as cyanogen bromide volatilizes at room temperature, and the vapor is highly irritating and poisonous.]

**Sulfanilic acid solution:** To 2.5 g of sulfanilic acid add 15 mL of water and 3 mL of 6 N ammonium hydroxide. Mix, and add while stirring, more 6 N ammonium hydroxide, if necessary, until the acid dissolves. Adjust the solution with 3 N hydrochloric acid to a pH of about 4.5 using bromocresol green TS as an external indicator, and dilute with water to 25 mL.

**Standard niacin stock solution:** Transfer 25.0 mg of USP Niacin RS to a 500-mL volumetric flask, dissolve in alcohol solution (1 in 4), dilute with alcohol solution (1 in 4) to volume, and mix. Store in a refrigerator. Each mL of this solution contains 50 µg of USP Niacin RS.

**Standard niacin preparation:** Transfer 10.0 mL of *Standard niacin stock solution* to a 100-mL volumetric flask, dilute with water to volume, and mix. Each mL of this solution contains 5 µg of USP Niacin RS.

**Standard niacinamide stock solution:** Transfer 50.0 mg of USP Niacinamide RS to a 500-mL volumetric flask, dissolve in alcohol solution (1 in 4), dilute with alcohol solution (1 in 4) to volume, and mix. Store in a refrigerator. Each mL of this solution contains 100 µg of USP Niacinamide RS.

**Standard niacinamide preparation:** Transfer 10.0 mL of *Standard niacinamide stock solution* to a 100-mL volumetric flask, dilute with water to volume, and mix. Each mL of this solution contains 10 µg of USP Niacinamide RS.

**Assay preparation:** Prepare as directed in the individual monograph.

**Procedure:** Pipet into four marked tubes the quantities of the appropriate *Standard preparation*, *Assay preparation*, *Ammonia dilution*, and *Water* indicated in *Table 1*. Then add the other constituents, respectively, as listed in the table, according to the directions given herein.

**Table 1. Reaction Mixtures for Niacin or Niacinamide Assay—Chemical Method**

| Constituent | Tube 1 (mL) | Tube 2 (mL) | Tube 3 (mL) | Tube 4 (mL) |
|---|---|---|---|---|
| Standard preparation | 1.0 | 1.0 | — | — |
| Assay preparation | — | — | 1.0 | 1.0 |
| Ammonia dilution (ammonium hydroxide, diluted to 1 in 50) | 0.5 | 0.5 | 0.5 | 0.5 |
| Water | 6.5 | 1.5 | 6.5 | 1.5 |
| Cyanogen bromide solution | — | 5.0 | — | 5.0 |
| Sulfanilic acid solution | 2.0 | 2.0 | 2.0 | 2.0 |
| Hydrochloric acid | 1 drop | — | 1 drop | — |

To *Tube 1* add the *Sulfanilic acid solution*, shake well, and add the *Hydrochloric acid*. Mix, place in a suitable spectrophotometer, and adjust to zero absorbance at 450 nm. To *Tube 2* add the *Cyanogen bromide solution*, mix, and 30 s accurately timed after completion of the addition of the cyanogen bromide, add the *Sulfanilic acid solution*, with swirling. Close the tube, place it in the spectrophotometer, and after 2 min measure its absorbance at 450 nm against *Tube 1* as a blank, designating the absorbance as $A_S$. Repeat the procedure with *Tube 3* (as blank) and *Tube 4*, designating the absorbance of *Tube 4* as $A_U$. Calculate the quantity of niacin or niacinamide in the sample as directed in the individual monograph.

### Chromatographic Methods

The following liquid chromatographic procedures are provided for the determination of niacin or niacinamide as an active pharmaceutical ingredient, a dietary supplement ingredient, or a component in the dietary supplements or pharmaceutical dosage forms.

Use the appropriate USP Reference Standard for the niacin or niacinamide present in the formulation.

Throughout these procedures, protect solutions containing and derived from the test specimen and the Reference Standards from the atmosphere and light, preferably by the use of low-actinic glassware.

- **PROCEDURE 1**

  - This procedure can be used to determine niacin or niacinamide in:
    - Oil- and water-soluble vitamins with minerals tablets
  - This procedure involves the extraction of analytes from the formulation by hot water or mechanical shaking
  - Unless specified in the individual monographs, the *Standard solution*, *Sample solution*, and reagent solutions are prepared as follows.

@2024 USPC

**Diluent:** Acetonitrile, glacial acetic acid, and water (5:1:94)
**Mobile phase:** A mixture of methanol, glacial acetic acid, and water (27:1:73) containing 140 mg of sodium 1-hexanesulfonate per 100 mL
**Standard solution:** Transfer 80 mg of either USP Niacin RS or USP Niacinamide RS to a 200-mL volumetric flask, and add 180 mL of *Diluent*. Immerse the flask in a hot water bath maintained at 65°–70° for 10 min with regular shaking or using a vortex mixer, until all the solid materials are dissolved. Chill rapidly in a cold water bath for 10 min to room temperature, and dilute with *Diluent* to volume.
**Sample solution:** For tablets, finely powder NLT 30 tablets. Transfer a portion of the powder, equivalent to 10 mg of niacinamide and 2.5 mg each of pyridoxine hydrochloride, riboflavin, and thiamine hydrochloride, to a 50-mL centrifuge tube. Add 25.0 mL of *Diluent*, and mix using a vortex mixer for 30 s to completely suspend the powder. Immerse the centrifuge tube in a hot water bath maintained at 65°–70°, heat for 5 min, and mix on a vortex mixer for 30 s. Return the tube to the hot water bath, heat for another 5 min, and mix on a vortex mixer for 30 s. Filter a portion of the solution, cool to room temperature, and use the clear filtrate. [NOTE—Use the filtrate within 3 h of filtration.]
**Chromatographic system**
(See *Chromatography* ⟨621⟩, *System Suitability*.)
**Mode:** LC
**Detector:** UV 280 nm
**Column:** 3.9-mm × 30-cm; packing L1
**Flow rate:** 1 mL/min
**Injection volume:** 10 µL
**System suitability**
**Sample:** *Standard solution*
**Suitability requirements**
**Relative standard deviation:** NMT 3.0%
**Analysis**
**Samples:** *Standard solution* and *Sample solution*
Measure the peak areas for niacin or niacinamide.
Calculate the percentage of the labeled amount of niacin ($C_6H_5NO_2$) or niacinamide ($C_6H_6N_2O$) in the portion of the *Sample* taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of niacin or niacinamide from the *Sample solution*
$r_S$ = peak response of niacin or niacinamide from the *Standard solution*
$C_S$ = concentration of USP Niacin RS or USP Niacinamide RS in the *Standard solution* (mg/mL)
$C_U$ = nominal concentration of niacin or niacinamide in the *Sample solution* (mg/mL)

- **PROCEDURE 2**
  - This procedure can be used to determine niacin or niacinamide in:
    - Oil- and water-soluble vitamins with minerals tablets
  - This procedure involves the extraction of analytes from the formulation by the *Extraction solvent*, heat, and mechanical shaking
  - Unless specified in the individual monographs, the *Standard solution*, *Sample solution*, and reagent solutions are prepared as follows.

**Solution A:** Transfer 1 mL of glacial acetic acid and 2.5 g of edetate disodium to a 100-mL volumetric flask. Dissolve in and dilute with water to volume.
**Extraction solvent:** *Solution A* and methanol (3:1)
**Mobile phase:** 0.1 M sodium acetate solution (13.6 mg/mL of sodium acetate in water). Adjust with acetic acid to a pH of 5.4. [NOTE—A small amount of methanol (up to 1%) may be added to the *Mobile phase* to improve resolution.]
**Standard stock solution:** 1 mg/mL of USP Niacin RS or USP Niacinamide RS in *Extraction solvent*
**Standard solution:** Transfer 5.0 mL of *Standard stock solution* to a 25-mL volumetric flask, and dilute with *Extraction solvent* to volume.
**Sample solution:** [NOTE—This preparation is suitable for the determination of niacin or niacinamide, pyridoxine, and riboflavin, when present in the formulation.] For tablets, finely powder NLT 20 tablets. Transfer a portion of the powder, equivalent to 2 mg of riboflavin, to a 200-mL volumetric flask. If riboflavin is not present in the formulation, transfer a portion of the powder, equivalent to 2 mg of pyridoxine. If pyridoxine is not present in the formulation, transfer a portion of the powder, equivalent to 20 mg of niacin or niacinamide. Add 100.0 mL of *Extraction solvent*, and mix for 20 min, using a wrist-action shaker. Immerse the flask in a water bath maintained at 70°–75°, and heat for 20 min. Mix on a vortex mixer for 30 s, cool to room temperature, and filter. Use the clear filtrate.

  - This procedure can be used to determine niacin or niacinamide in:
    - Oil- and water-soluble vitamins with minerals tablets
  - This procedure involves the extraction of analytes from the formulation by mixtures of organic solvents, heat, and mechanical shaking
  - Unless specified in the individual monographs, the *Standard solution*, *Sample solution*, and reagent solutions are prepared as follows.

**Reagent:** 25 mg/mL of edetate disodium in water

**Mobile phase:** Transfer 0.4 mL of triethylamine, 15.0 mL of glacial acetic acid, and 350 mL of methanol to a 2000-mL volumetric flask. Dilute with 0.008 M sodium 1-hexanesulfonate to volume.

**Standard stock solution:** 1.5 mg/mL of USP Niacin RS or USP Niacinamide RS in the *Reagent*, with heating if necessary

**Standard solution:** Transfer 5.0 mL of *Standard stock solution* to a stoppered 125-mL flask. Add 10.0 mL of a mixture of methanol and glacial acetic acid (9:1) and 30.0 mL of a mixture of methanol and ethylene glycol (1:1). Insert the stopper, shake for 15 min in a water bath maintained at 60°, and cool. Filter, discarding the first few mL of the filtrate.

**Sample solution:** For tablets, weigh and finely powder NLT 20 tablets. Transfer a portion of the powder, equivalent to 7.5 mg of niacin or niacinamide, to a stoppered 125-mL flask. Add 10.0 mL of a mixture of methanol and glacial acetic acid (9:1) and 30.0 mL of a mixture of methanol and ethylene glycol (1:1). Insert the stopper, shake for 15 min in a water bath maintained at 60°, and cool. Filter, discarding the first few mL of the filtrate.

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 270 nm

**Column:** 4.6-mm × 25-cm; packing L7

**Column temperature:** 50°

**Flow rate:** 2 mL/min

**Injection volume:** 5 µL

**System suitability**

**Sample:** *Standard solution*

**Suitability requirements**

**Relative standard deviation:** NMT 2.0%

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of niacin ($C_6H_5NO_2$) or niacinamide ($C_6H_6N_2O$) in the portion of the *Sample* taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of niacin or niacinamide from the *Sample solution*
$r_S$ = peak response of niacin or niacinamide from the *Standard solution*
$C_S$ = concentration of USP Niacin RS or USP Niacinamide RS in the *Standard solution* (mg/mL)
$C_U$ = nominal concentration of niacin or niacinamide in the *Sample solution* (mg/mL)

- **PROCEDURE 4**
  - This procedure can be used to describe niacin as:
    - An active pharmaceutical ingredient
    - A dietary supplement ingredient
    - An ingredient in the niacin extended-release tablets
  - This procedure involves either dissolving the analyte in the *Diluent*, a mixture of methanol and water (82:18), or extracting the analyte from the formulation with *Diluent* and mechanical shaking
  - Unless specified in the individual monographs, the *System suitability solution*, *Standard solution A*, *Standard solution B*, *Sample solution A*, *Sample solution B*, and reagent solutions are prepared as follows.

**Diluent:** Methanol and water (82:18)

**Mobile phase:** Methanol and water (82:18), adjusted with glacial acetic acid to a pH of 3.15 ± 0.05

**System suitability solution:** 0.25 mg/mL of USP Niacin RS, 0.050 mg/mL of USP 6-Hydroxynicotinic Acid RS, and 0.10 mg/mL of pyridine in *Diluent*

**Standard solution A:** For active pharmaceutical ingredient or dietary supplement ingredient, use 0.25 mg/mL of USP Niacin RS in *Diluent*.

**Standard solution B:** For extended-release tablets, use 0.25 mg/mL of USP Niacin RS, 0.050 mg/mL of USP 6-Hydroxynicotinic Acid RS, and 0.0978 mg/mL of pyridine in *Diluent*.

**Sample solution A:** For active pharmaceutical ingredient or dietary supplement ingredient, use 0.25 mg/mL of Niacin in *Diluent*.

**Sample solution B:** For extended-release tablets, transfer a quantity of powder, equivalent to 50 mg of niacin from NLT 20 finely powdered tablets, to a suitable flask. Add *Diluent*, and stir for 2 h. Dilute with *Diluent* to a final concentration of 0.25 mg/mL of niacin.

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 260 nm

**Column:** 4.6-mm × 15-cm; 5-µm packing L8

**Flow rate:** 1 mL/min

**Injection volume:** 25 µL

**System suitability**

**Samples:** *System suitability solution* and *Standard solution A* or *Standard solution B*

[NOTE—The relative retention times for pyridine, 6-hydroxynicotinic acid, and niacin are 0.14, 0.64, and 1.0, respectively, *System suitability solution*.]

**Suitability requirements**

**Resolution:** NLT 1.5 between pyridine and 6-hydroxynicotinic acid, and NLT 1.5 between 6-hydroxynicotinic acid and niacin, *System suitability solution*

**Relative standard deviation:** NMT 2.0% for the niacin peak from replicate injections, *Standard solution A* or *Standard solution B*

**Analysis**

**Samples:** *Standard solution A* and *Sample solution A* or *Standard solution B* and *Sample solution B*

Calculate the percentage of niacin ($C_6H_5NO_2$) in the portion of the *Sample* taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of niacin from *Sample solution A* or *Sample solution B*
$r_S$ = peak response of niacin from *Standard solution A* or *Standard solution B*
$C_S$ = concentration of USP Niacin RS in *Standard solution A* or *Standard solution B* (mg/mL)
$C_U$ = concentration of Niacin in *Sample solution A* or nominal concentration of niacin in *Sample solution B* (mg/mL)

- **PROCEDURE 5**
  - This procedure can be used to determine niacinamide as:
    - An active pharmaceutical ingredient
    - A dietary supplement ingredient
  - This procedure involves dissolving the niacinamide as the active pharmaceutical ingredient or a dietary supplement ingredient in the *Mobile phase*
  - Unless specified in the individual monographs, the *System suitability solution*, *Standard solution*, *Niacin solution*, *Sample solution*, and reagent solutions are prepared as follows.

**Mobile phase:** Methanol and 0.005 M sodium 1-heptanesulfonate (30:70)

**Standard solution:** Transfer 50 mg of USP Niacinamide RS to a 100-mL volumetric flask. Add 3 mL of water to dissolve, and dilute with *Mobile phase* to volume. Dilute with *Mobile phase* to 0.04 mg/mL.

**Niacin solution:** Prepare as directed in the *Standard solution*, using USP Niacin RS instead of USP Niacinamide RS.

**System suitability solution:** Mix equal volumes of the *Standard solution* and *Niacin solution*.

**Sample solution:** Prepare as directed in the *Standard solution*, using Niacinamide instead of USP Niacinamide RS.

**Chromatographic system**

# ⟨451⟩ NITRITE TITRATION

The following general method is provided for the determination of most of the Pharmacopeial sulfonamide drugs and their dosage forms, as well as of other Pharmacopeial drugs for which nitrite titration is particularly suitable.

**PROCEDURE**

Accurately weigh about 500 mg in the case of a sulfonamide, or otherwise the quantity specified in the individual monograph, and transfer to a suitable open vessel. Add 20 mL of hydrochloric acid and 50 mL of water, stir until dissolved, cool to about 15°, and slowly titrate with 0.1 M sodium nitrite VS that previously has been standardized against USP Sulfanilamide RS.

Determine the endpoint electrometrically, using suitable electrodes (platinum-calomel or platinum-platinum). Place the buret tip below the surface of the solution to eliminate air oxidation of the sodium nitrite, and stir the solution gently, using a magnetic stirrer, without pulling a vortex of air under the surface, maintaining the temperature at about 15°. The titration may be carried out manually, or by means of an automatic titrator. In performing it manually, add the titrant until the titration is within 1 mL of the endpoint, and then add it in 0.1-mL portions, allowing not less than 1 minute between additions. (The instrument needle deflects and then returns to approximately its original position until the endpoint is reached.)

The weight, in mg, of the substance to which each mL of 0.1 M sodium nitrite VS is equivalent is as stated in the individual monograph.

For the assay of Tablets of the sulfonamides or other drugs, reduce not less than 20 tablets to a fine powder, weigh accurately a portion of the powder, equivalent to about 500 mg if a sulfonamide, or the quantity of drug specified in the individual monograph, and proceed as directed in the foregoing, beginning with “transfer to a suitable open vessel.”

For the assay of Injections and other liquid forms where the nitrite titration is specified, pipet a portion, equivalent to about 500 mg if a sulfonamide, or the quantity of drug specified in the individual monograph, into a suitable open vessel, and proceed as directed in the foregoing, beginning with “Add 20 mL of hydrochloric acid.”

**ADDITIONAL REQUIREMENTS**

- **USP Reference Standards** ⟨11⟩
  USP Sulfanilamide RS

Official

# ⟨461⟩ NITROGEN DETERMINATION

Some alkaloids and other nitrogen-containing organic compounds fail to yield all of their nitrogen upon digestion with sulfuric acid; therefore these methods cannot be used for the determination of nitrogen in all organic compounds.

## METHOD I

### Nitrates and Nitrites Absent

Place about 1 g of the substance, accurately weighed, in a 500-mL Kjeldahl flask of hard borosilicate glass. The material to be tested, if solid or semisolid, may be wrapped in a sheet of nitrogen-free filter paper for convenience in transferring it to the flask. Add 10 g of powdered potassium sulfate or anhydrous sodium sulfate, 500 mg of powdered cupric sulfate, and 20 mL of sulfuric acid. Incline the flask at an angle of about 45°, and gently heat the mixture, keeping the temperature below the boiling point until frothing has ceased. Increase the heat until the acid boils briskly, and continue the heating until the solution has been clear green in color or almost colorless for 30 minutes. Allow to cool, add 150 mL of water, mix the contents of the flask, and again cool. Add cautiously 100 mL of sodium hydroxide solution (2 in 5), in such manner as to cause the solution to flow down the inner side of the flask to form a layer under the acid solution. Immediately add a few pieces of granulated zinc, and without delay connect the flask to a Kjeldahl connecting bulb (trap), previously attached to a condenser, the delivery tube from which dips beneath the surface of 100 mL of boric acid solution (1 in 25) contained in a conical flask or a wide-mouth bottle of about 500-mL capacity. Mix the contents of the Kjeldahl flask by gentle rotation, and distill until about four-fifths of the contents of the flask has distilled over. Titrate with 0.5 N sulfuric acid VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary correction. Each mL of 0.5 N sulfuric acid VS is equivalent to 7.003 mg of nitrogen.

When the nitrogen content of the substance is known to be low, the 0.5 N sulfuric acid VS may be replaced by 0.1 N sulfuric acid VS. Each mL of 0.1 N sulfuric acid VS is equivalent to 1.401 mg of nitrogen.

### Nitrates and Nitrites Present

Place a quantity of the substance, accurately weighed, corresponding to about 150 mg of nitrogen, in a 500-mL Kjeldahl flask of hard borosilicate glass, and add 25 mL of sulfuric acid in which 1 g of salicylic acid previously has been dissolved. Mix the contents of the flask, and allow the mixture to stand for 30 minutes with frequent shaking. To the mixture add 5 g of powdered sodium thiosulfate, again mix, then add 500 mg of powdered cupric sulfate, and proceed as directed under *Nitrates and Nitrites Absent*, beginning with "Incline the flask at an angle of about 45°."

When the nitrogen content of the substance is known to exceed 10%, 500 mg to 1 g of benzoic acid may be added, prior to digestion, to facilitate the decomposition of the substance.

## METHOD II

### Apparatus

Select an appropriate 300-mL Kjeldahl flask, from which the nitrogen is first liberated by acid digestion and then transferred quantitatively to the titration vessel by steam distillation.

### Procedure

Place an accurately weighed or measured quantity of the material, equivalent to 2 to 3 mg of nitrogen, in the digestion flask of the apparatus. Add 1 g of a powdered mixture of potassium sulfate and cupric sulfate (10:1), and wash down any adhering material from the neck of the flask with a fine jet of water. Add 7 mL of sulfuric acid, allowing it to rinse down the wall of the flask, then, while swirling the flask, add 1 mL of 30 percent hydrogen peroxide cautiously down the side of the flask. (Do not add hydrogen peroxide during the digestion.)

Heat the flask over a free flame or an electric heater until the solution has a clear blue color and the sides of the flask are free from carbonaceous material. Cautiously add to the digestion mixture 70 mL of water, cool the solution, and arrange for steam distillation. Add through a funnel 30 mL of sodium hydroxide solution (2 in 5) in such manner as to cause the solution to flow down the inner side of the flask to form a layer under the acid solution, rinse the funnel with 10 mL of water, tightly close the apparatus, and begin the distillation with steam immediately. Receive the distillate in 15 mL of boric acid solution (1 in 25), to which has been added 3 drops of methyl red-methylene blue TS and sufficient water to cover the end of the condensing tube. Continue the distillation until the distillate measures 80 to 100 mL. Remove the absorption flask, rinse the end of the condensing tube with a small quantity of water, and titrate the distillate with 0.01 N sulfuric acid VS. Perform a blank determination, and make any necessary correction. Each mL of 0.01 N sulfuric acid VS is equivalent to 140.1 µg of nitrogen.

When a quantity of material containing more than 2 to 3 mg of nitrogen is taken, 0.02 N or 0.1 N sulfuric acid may be employed, provided that at least 15 mL is required for the titration. If the total dry weight of material taken is greater than 100 mg, increase proportionately the quantities of sulfuric acid and sodium hydroxide.

# ⟨466⟩ ORDINARY IMPURITIES

This test, where called for in the individual monograph, is provided to evaluate the presence of ordinary impurities in official articles. Ordinary impurities are defined as those species in drug substances and/or drug products that have no significant, undesirable biological activity in the amounts present. These impurities may arise out of the synthesis, preparation, or degradation of compendial articles. In certain instances, impurities that pose a potential health risk may be detected. Because these impurities would not be individually identified by the strict use of this General Chapter, a separate evaluation may be necessary to ensure that the detected impurities fit the requirements set forth in the definition of Ordinary Impurities. Selections of tests and assays allow for anticipated amounts of impurities that are unobjectionable for the customary use of the article.

## REPORTING AND SPECIFICATIONS

The value of 2.0%, unless otherwise specified in the individual monograph, was selected as the general limit for the total amount of ordinary impurities in monographs where documentation did not support adoption of other values.

Where a monograph sets limits on concomitant components and/or specified impurities/degradation products, these species are not to be included in the estimation of ordinary impurities unless so stated in the individual monograph. Concomitant components are defined as species characteristic of many drug substances that are not considered to be impurities in the Pharmacopeial sense. Examples of concomitant components are geometric and optical isomers (or racemates) and antibiotics that are mixtures. Any component that can be considered a toxic impurity because of significant undesirable biological effect is not considered to be a concomitant component.

## METHODOLOGY

Unless otherwise specified in an individual monograph, estimation of the amount and number of ordinary impurities is made by relative methods rather than by strict comparison to individual Reference Standards. Nonspecific detection of ordinary impurities is also consistent with this classification.

Typical evaluation methods used for ordinary impurities are thin-layer chromatographic (TLC) techniques. See *Chromatography* ⟨621⟩ for a general discussion of the thin-layer chromatographic technique. Tests for related substances or chromatographic purity may also be used to evaluate the presence of ordinary impurities. Other methods (e.g., HPLC, HPTLC, etc.) may also be used with adequate justification as an alternate method. Unless otherwise specified in the individual monograph, use the following method.

### Test Solution

Prepare, in the solvent specified in the monograph, a solution of the substance under test having an accurately known final concentration of about 10 mg per mL. [NOTE—Heat or sonication may be used to dissolve the drug substance where use of such does not adversely affect the compound.]

### Standard Solutions

Prepare, in the solvent specified in the monograph, solutions of the USP Reference Standard or designated substance having accurately known concentrations of 0.01 mg per mL, 0.05 mg per mL, 0.1 mg per mL, and 0.2 mg per mL.

[NOTE—Heat or sonication may be used to dissolve the drug substance where use of such does not adversely affect the compound.]

### Procedure

Use a thin-layer chromatographic plate coated with a 0.25-mm layer of chromatographic silica gel mixture, and the *Eluant* specified in the monograph. Apply equal volumes (20 µL) of the *Test Solution* and *Standard Solutions* to the plate, using a stream of nitrogen to dry the spots.

Allow the chromatogram to develop in a pre-equilibrated chamber until the solvent front has moved about three-fourths of the length of the plate. Remove the plate from the chamber, and air-dry. View the plate using the visualization technique(s) specified. Locate any spots other than the principal spot in the chromatogram of the *Test Solution,* and determine their relative intensities by comparison with the chromatograms of the appropriate *Standard Solutions.* See discussion above with regard to reporting and specifying total ordinary impurities.

***Change to read:***

## KEY FOR VISUALIZATION TECHNIQUES

1. Use UV light at 254 nm and at about 366 nm.
2. Use Iodoplatinate TS.
▲3. *Solution A*—Mix 850 mg of bismuth subnitrate with 40 mL of water and 10 mL of glacial acetic acid.

Official

https://pharmacopeia.cn/v29240/

*Solution B*—Dissolve 8 g of potassium iodide in 20 mL of water. Mix A and B together to obtain a Stock Solution which can be stored for several months in a dark bottle. Mix 10 mL of the Stock Solution with 20 mL of glacial acetic acid, and dilute with water to make 100 mL, to prepare the spray reagent.

4.▲ (ERR 1-Oct-2018) *Ninhydrin Spray*—Dissolve 200 mg of ninhydrin in 100 mL of alcohol. Heat the plate after spraying.

▲5.▲ (ERR 1-Oct-2018) *Acid Spray*—In an ice bath, add slowly and cautiously, with stirring, 10 mL of sulfuric acid to 90 mL of alcohol. Spray the plate, and heat until charred.

▲6.▲ (ERR 1-Oct-2018) *Acid–Dichromate Spray*—Add sufficient potassium dichromate to 100 mL of sulfuric acid to make a saturated solution. Spray the plate, and heat until charred.

▲7.▲ (ERR 1-Oct-2018) *Vanillin*—Dissolve 1 g of vanillin in 100 mL of sulfuric acid.

▲8.▲ (ERR 1-Oct-2018) *Chloramine T–Trichloroacetic Acid*—Mix 10 mL of a 3% aqueous solution of chloramine T with 40 mL of a 25% alcoholic solution of trichloroacetic acid. Prepare immediately before use.

▲9.▲ (ERR 1-Oct-2018) *Folin-C*—Add 10 g of sodium tungstate and 2.5 g of sodium molybdate to 70 mL of water, add 5 mL of 85% phosphoric acid and 10 mL of 36% hydrochloric acid, and reflux this solution for 10 hours.

▲10.▲ (ERR 1-Oct-2018) $KMnO_4$—Dissolve 100 mg of Potassium Permanganate in 100 mL of water.

▲11.▲ (ERR 1-Oct-2018) *DAB*—Mix 1 g of *p*-dimethylaminobenzaldehyde in 100 mL of 0.6 N hydrochloric acid.

▲12.▲ (ERR 1-Oct-2018) *DAC*—Mix 100 mg of *p*-dimethylaminocinnamaldehyde in 100 mL of 1 N hydrochloric acid.

▲13.▲ (ERR 1-Oct-2018) *Ferricyanide*—Mix equal volumes of a 1% ferric chloride solution and a 1% potassium ferricyanide solution. Use immediately.

▲14.▲ (ERR 1-Oct-2018) *Fast Blue B*—Reagent A—Dissolve 500 mg of Fast Blue B Salt in 100 mL of water. Reagent B—0.1 N sodium hydroxide.
Spray first with A, then with B.

▲15.▲ (ERR 1-Oct-2018) *Alkaline Ferric Cyanide*—Dilute 1.5 mL of a 1% potassium ferricyanide solution with water to 20 mL, and add 10 mL of 15% sodium hydroxide solution.

▲16.▲ (ERR 1-Oct-2018) *Iodine Spray*—Prepare a 0.5% solution of iodine in chloroform.

▲17.▲ (ERR 1-Oct-2018) Expose the plate for 10 minutes to iodine vapors in a pre-equilibrated closed chamber, on the bottom of which there are iodine crystals.

▲18.▲ (ERR 1-Oct-2018) *Solution A*—Dissolve 0.5 g of potassium iodide in 50 mL of water. *Solution B*—Prepare a solution of 0.5 g of soluble starch in 50 mL of hot water.
Just prior to use, mix equal volumes of *Solution A* and *Solution B*.

▲19.▲ (ERR 1-Oct-2018) *PTSS*—Dissolve 20 g of *p*-toluenesulfonic acid in 100 mL of alcohol, spray the plate, dry for 15 minutes at 110°, and view under UV light at 366 nm.

▲20.▲ (ERR 1-Oct-2018) *o-Tolidine Spray*—Dissolve 160 mg of *o*-tolidine in 30 mL of glacial acetic acid, dilute with water to make 500 mL, add 1 g of potassium iodide, and mix until the potassium iodide has dissolved.

▲21.▲ (ERR 1-Oct-2018) Mix 3 mL of chloroplatinic acid solution (1 in 10) with 97 mL of water, followed by the addition of 100 mL of potassium iodide solution (6 in 100) to prepare the spray reagent.

▲22.▲ (ERR 1-Oct-2018) *Iodine–Methanol Spray*—Prepare a mixture of iodine TS and methanol (1:1).

## 1. INTRODUCTION

For pharmacopeial purposes, residual solvents in pharmaceuticals are defined as organic volatile chemicals that are used or produced in the manufacturing of drug substances, excipients, or dietary ingredients, or in the preparation of drug products or dietary supplement products. Appropriate selection of the solvent for the synthesis of a drug substance or an excipient may enhance the yield or determine characteristics such as crystal form, purity, and solubility. Therefore, the solvent may sometimes be a critical element in the synthetic process and may not be completely removed by the manufacturing process. Because residual solvents do not provide therapeutic benefit, they should be removed, to the extent possible, to meet safety-based limits, ingredient and product specifications, good manufacturing practices, or other quality-based requirements.

The objective of this general chapter is to define acceptable amounts of residual solvents in pharmaceutical drug products and dietary supplement products for the safety of the patient. Tests for residual solvents are not generally mentioned in specific monographs because the solvents used may vary from one manufacturer to another; however, the limits to be applied must comply with those specified in this general chapter.

This chapter provides procedures for the analysis of residual solvents, although alternative validated methodologies may also be used to demonstrate compliance with the defined limits. For guidance on verification of *USP* procedures or validation of alternative methods for residual solvents, see *Residual Solvents—Verification of Compendial Procedures and Validation of Alternative Procedures* ⟨1467⟩. This chapter does not address solvents deliberately used as excipients, nor does it address solvates. The limits specified in this chapter do not apply directly to excipients, drug substances, or dietary ingredients except where specified in the individual monographs. However, residual solvent levels present in drug substances, excipients, and dietary ingredients may be used to demonstrate compliance as an integral part of the control strategy, thereby reducing or eliminating the need for analysis in the product (see *3. Control Strategy*).

Information on residual solvents in coating materials, colorants, flavors, capsules, and imprinting inks is generally not needed unless Class 1 solvents are used in the manufacture of these components.

Throughout this chapter, the term “likely to be present” (LTBP) refers to 1) solvents used or produced in the final manufacturing step; 2) solvents used or produced in earlier manufacturing steps that are not consistently removed by a validated process; and 3) solvents properly declared by a validated supplier of a drug substance, excipient, or dietary ingredient.

## 2. CLASSIFICATION OF RESIDUAL SOLVENTS BY RISK ASSESSMENT

Residual solvents assessed in this general chapter are listed in *Appendix 1* by common names and structures. USP is aligned with the International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use (ICH) Harmonised Tripartite Guideline for Residual Solvents Q3C (R5) approach for the classification of residual solvents

(see *Appendix 2* for additional details). These solvents were evaluated for their possible risk to human health and were placed into one of three classes based on their toxicity data and their environmental impact as shown in *Table 1*.

**Table 1. Classification of Residual Solvents and Their Assessments**

| Residual Solvent Classes | Assessment |
|---|---|
| Class 1 (solvents to be avoided) | Known human carcinogens<br>Strongly suspected human carcinogens<br>Solvents particularly known to have ozone-depleting properties |
| Class 2 (solvents to be limited) | Nongenotoxic animal carcinogens or possible causative agents of other irreversible toxicity, such as neurotoxicity or teratogenicity<br>Solvents suspected of other significant but reversible toxicities |
| Class 3 (solvents with low toxic potential) | Solvents with low toxic potential to humans; no health-based exposure limit is needed |

The limits for Class 2 solvents are based on the toxicological permitted daily exposure (PDE), calculated as defined in *Appendix 3*, whereas Class 3 solvents are considered less toxic, and control to 50 mg/day or less for each of these solvents is acceptable without justification. The lists in this chapter are not exhaustive and are subject to revision. For solvents not listed, *Appendix 3* may be used to define PDE limits if sufficient toxicological data are available. A flow diagram for potential sources of residual solvents in pharmaceutical drug products and dietary supplements is shown in *Figure 1*.

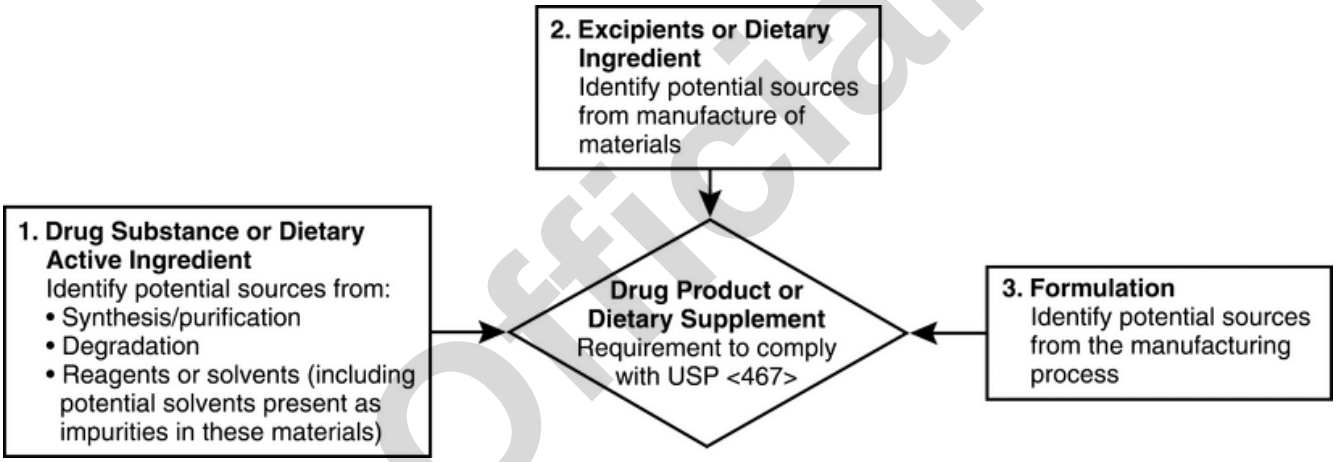

Figure 1. Potential sources of residual solvents in pharmaceutical drug products and dietary supplements.

There are three potential sources of residual solvents in the pharmaceutical drug products and dietary supplement products that should be considered (see *Figure 1*):

1. Drug substance or dietary active ingredient
   - Potential solvent sources include their use or formation during the synthesis or purification of the drug substance; their presence in raw materials or reagents used in their synthesis; or degradation of the drug substance.
2. Excipients and/or dietary ingredient
   - Potential solvent sources include their use or formation during the manufacture or purification of excipients.
3. Formulation
   - Potential solvent sources are associated with their use or formation during the official product manufacturing process.

The potential presence of other solvents as impurities in the solvents used must be taken into consideration in the assessment of solvents LTBP. Because of the high toxicity of benzene and other Class 1 solvents, all likely sources of these solvents must be considered. For example, potential sources of benzene may include its presence as an impurity in a solvent used in the manufacturing process; its use in the manufacture of starting material; or its production as a reaction by-product. In the event that the user has insufficient information to complete a thorough assessment of the potential sources of residual solvents (or as an alternative to performing this assessment), solvent screening may be used (see *8. Analytical Procedures for Class 1 and Class 2 Residual Solvents*).

Pharmaceutical drug products and dietary supplement products should contain no higher levels of residual solvents than can be supported by safety data. All solvents included in this general chapter are listed in *Appendix 1*. Those solvents that show toxicity of special concern or carcinogenicity, and/or atmospheric ozone-depletion effects (Class 1, see *Table 2*), should be avoided in the production of drug substances, dietary supplement ingredients, excipients, pharmaceutical drug products, and dietary supplement products unless their use can be strongly justified in a risk-benefit assessment. Those solvents associated with less severe but still significant toxicity (Class 2, see *Table 3*) should be limited to protect patients from potential adverse effects. Whenever it is practicable, less toxic solvents (Class 3, see *Table 4*) should be used. For the purposes of this pharmacopeia, when a manufacturer has received approval from a regulatory authority for the use of a solvent not currently listed in this

chapter, or for a level of a listed solvent higher than the limit currently given in this chapter, it is the responsibility of that manufacturer to notify USP of the identity and level of the solvent, and the appropriate test procedure. USP will then address the information in the individual monograph. A new solvent or revised limit that has been approved through the ICH process will be added to the appropriate list in this general chapter. See *Appendix 2* for additional background information related to residual solvents.

## 3. CONTROL STRATEGY

The user may choose to demonstrate compliance with this chapter by analysis for residual solvents in the official product or by analysis of the official substances. These control strategy options are presented in *Figure 2*.

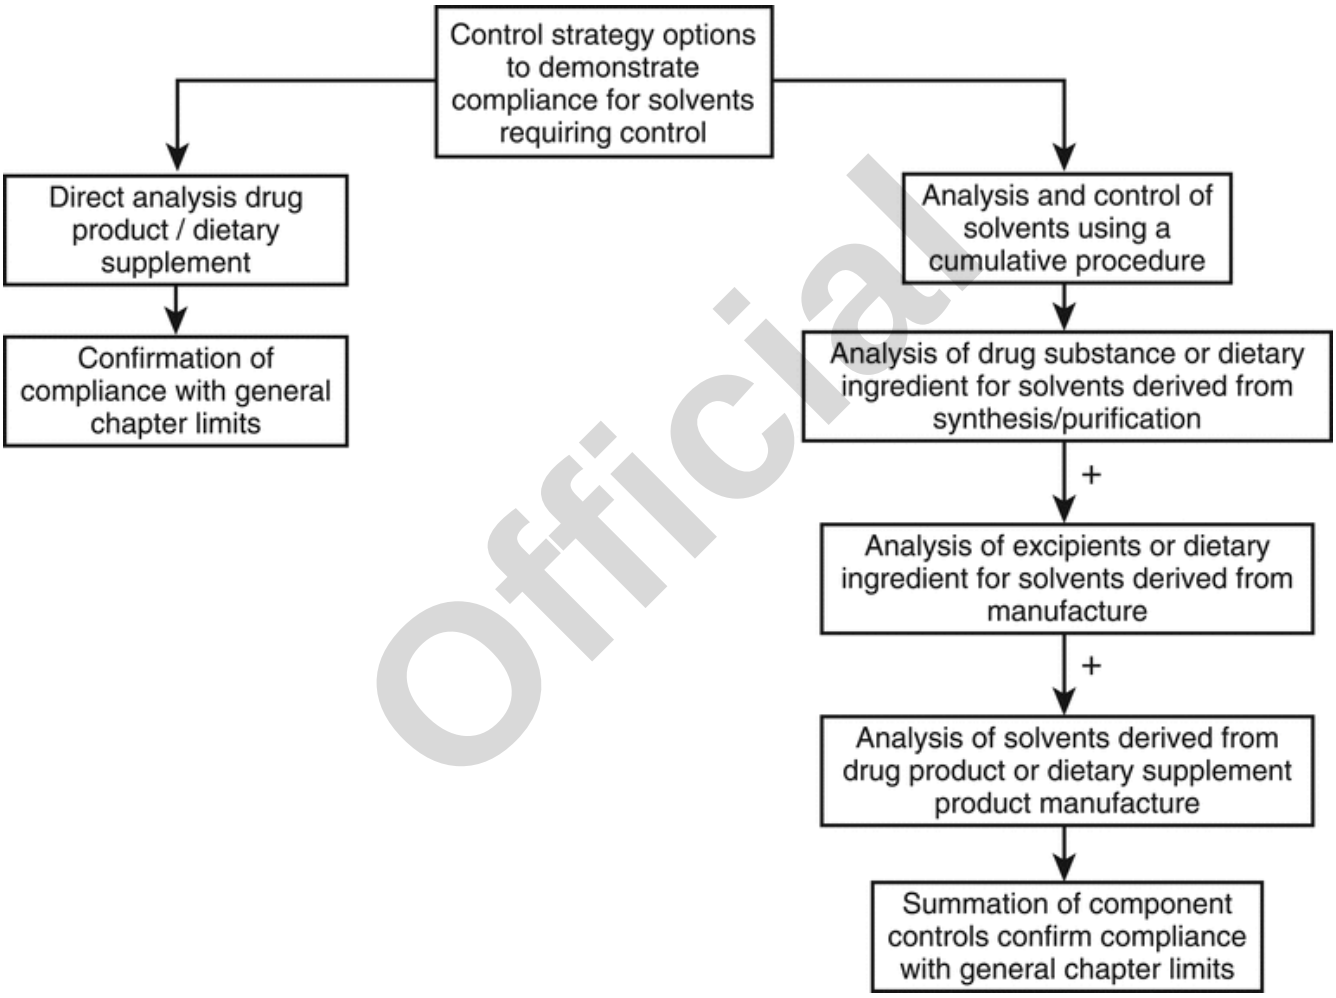

Figure 2. Control strategy options.

Compliance with the chapter requires that all solvents LTBP comply with the control limits.
The following options are to be considered when designing the control strategy.

1. **Testing the official product:** This approach is acceptable in all cases.
2. **Analysis of the official substances and using a cumulative approach to determine the solvent content in the official product:**
    A. **If no solvent(s) are used during the manufacture of the official product,** use the cumulative approach to determine the solvent content in the active pharmaceutical ingredient (API) and excipients or dietary ingredients to calculate solvent levels in the official product.
    B. **If solvent(s) are used during the manufacture of the official product,** use the cumulative approach as described in (a) above. Then, for each solvent used in the manufacture, determine the content in the finished product or after the manufacturing step where the solvent(s) were used.

In all cases, the solvent levels in the final official product must not exceed the limits defined in the chapter.

# 4. LIMITS OF RESIDUAL SOLVENTS

## 4.1 Class 1: Solvents to Be Avoided

Class 1 residual solvents (*Table 2*) should not be used in the manufacture of drug substances, excipients, dietary ingredients, or official products because of their unacceptable toxicities or deleterious environmental effects. However, if their use in order to produce an official product with a significant therapeutic advance is unavoidable, their levels should be restricted as shown in *Table 2*, unless otherwise stated in the individual monograph. The solvent 1,1,1-trichloroethane is included in *Table 2* because it is a severe environmental hazard. The stated limit of 1500 ppm is based on a review of safety data.

The procedures described in *7. Identification, Control, and Quantification of Residual Solvents* in this general chapter are to be applied wherever possible. Otherwise an appropriate validated procedure is to be used.

**Table 2. Control Limits for Class 1 Residual Solvents in Official Products: Solvents to Be Avoided**

| Solvent | Concentration Limit (ppm) | Concern |
|---|---|---|
| Benzene | 2 | Carcinogen |
| Carbon tetrachloride | 4 | Toxic and environmental hazard |
| 1,2-Dichloroethane | 5 | Toxic |
| 1,1-Dichloroethene | 8 | Toxic |
| 1,1,1-Trichloroethane | 1500 | Environmental hazard |

## 4.2 Class 2: Solvents to Be Limited

Class 2 residual solvents (*Table 3*) should be limited in drug substances, excipients, dietary ingredients, and official products because of the inherent toxicities of these residual solvents. PDEs are given to the nearest 0.1 mg/day, and concentrations are given to the nearest 10 ppm. The method used to establish PDEs for residual solvents is presented in *Appendix 3*.

**Table 3. Class 2 Residual Solvents in Official Products**

| Solvent | PDE (mg/day) | Concentration Limit (ppm) |
|---|---|---|
| Acetonitrile | 4.1 | 410 |
| Chlorobenzene | 3.6 | 360 |
| Chloroform | 0.6 | 60 |
| Cumene | 0.7 | 70 |
| Cyclohexane | 38.8 | 3880 |
| 1,2-Dichloroethene | 18.7 | 1870 |
| 1,2-Dimethoxyethane | 1.0 | 100 |
| *N,N*-Dimethylacetamide | 10.9 | 1090 |
| *N,N*-Dimethylformamide | 8.8 | 880 |
| 1,4-Dioxane | 3.8 | 380 |
| 2-Ethoxyethanol | 1.6 | 160 |
| Ethylene glycol | 6.2 | 620 |
| Formamide | 2.2 | 220 |
| Hexane | 2.9 | 290 |
| Methanol | 30.0 | 3000 |
| 2-Methoxyethanol | 0.5 | 50 |
| Methylbutylketone | 0.5 | 50 |
| Methylcyclohexane | 11.8 | 1180 |
| Methylene chloride | 6.0 | 600 |
| Methylisobutylketone | 45 | 4500 |
| *N*-Methylpyrrolidone | 5.3 | 530 |
| Nitromethane | 0.5 | 50 |
| Pyridine | 2.0 | 200 |
| Sulfolane | 1.6 | 160 |

| Solvent | PDE (mg/day) | Concentration Limit (ppm) |
|---|---|---|
| Tetrahydrofuran | 7.2 | 720 |
| Tetralin | 1.0 | 100 |
| Toluene | 8.9 | 890 |
| Trichloroethylene | 0.8 | 80 |
| Xylene[a] | 21.7 | 2170 |

[a] Usually 60% *m*-xylene, 14% *p*-xylene, and 9% *o*-xylene with 17% ethyl benzene.

## 4.3 Class 3: Solvents with Low Toxic Potential

Class 3 solvents (*Table 4*) are regarded as less toxic and of lower risk to human health than Class 1 and Class 2 residual solvents. Class 3 includes no solvent known to be a human health hazard at levels normally accepted in pharmaceuticals. However, there are no long-term toxicity or carcinogenicity studies for many of the residual solvents in Class 3. Available data indicate that they are less toxic in acute or short-term studies and negative in genotoxicity studies.

It is considered that amounts of these residual solvents of 50 mg/day or less of each solvent (corresponding to 5000 ppm or 0.5% w/w in *Option 1*, which is described below) would be acceptable for each solvent without justification. Higher amounts may also be acceptable, provided that they are realistic in relation to manufacturing capability and good manufacturing practice. If a Class 3 solvent limit in an individual monograph is greater than 0.5%, that residual solvent should be identified and quantified. The procedures described in *7. Identification, Control, and Quantification of Residual Solvents*, with appropriate modifications to the standard solutions, are to be applied wherever possible. Otherwise, an appropriate validated procedure is to be used.

**Table 4. Class 3 Residual Solvents in Official Products**

| | |
|---|---|
| Acetic acid | Isobutyl acetate |
| Acetone | Isopropyl acetate |
| Anisole | Methyl acetate |

| Dimethyl sulfoxide | Pentane |
| Ethanol | 1-Pentanol |
| Ethyl acetate | 1-Propanol |
| Ethyl ether | 2-Propanol |
| Ethyl formate | Propyl acetate |
| Formic acid | Triethylamine |
| Heptane | |

# 5. OPTIONS FOR DESCRIBING LIMITS OF CLASS 2 AND CLASS 3 RESIDUAL SOLVENTS

This chapter provides two options for establishing compliance. Both *Option 1* and *Option 2* are based on the PDE.

## 5.1 Option 1—Concentration Limit

The concentration limits in ppm stated in *Table 3* for Class 2 solvents and the general requirement for Class 3 (5000 ppm, equivalent to 0.5% w/w) are used. The values for Class 2 solvents were calculated using the equation below by assuming a product weight of 10 g administered daily.

$$\text{Concentration (ppm)} = (1000\ \mu g/mg \times \text{PDE})/\text{dose}$$

Here, PDE is given in terms of milligrams per day (mg/day), and dose is given in grams per day (g/day). These limits are considered acceptable for all drug substances, excipients, dietary ingredients, and official products. Therefore, *Option 1* may be applied if the daily amount is not known or does not exceed 10 g. If all official substances (drug substances, excipients, and/or dietary ingredients) in a formulation or dietary supplement meet the limits given in *Option 1*, these components may be used in any proportions. No further calculation is necessary, provided that the daily amount does not exceed 10 g. Products

@2024 USPC

that are administered in doses (daily intake for dietary supplements) greater than 10 g/day are to be considered under *Option 2*.

## 5.2 Option 2—Summation of Components Content

*Option 2* uses the PDE and the actual maximum daily amount of the product to calculate solvent exposure and assess compliance.

*Option 2* must be used to demonstrate compliance with this chapter where the maximum daily dose of the official product exceeds 10 g/day or where at least one component in the formulation exceeds the *Option 1* limits.

These limits are applied by summing the amounts of a residual solvent present in each of the components of the official product. The contribution of each solvent per day should result in a total amount that does not exceed the PDE.

Consider the example of the application of *Option 1* and *Option 2* limits to acetonitrile concentration in an official product. The PDE for acetonitrile is 4.1 mg/day, thus the *Option 1* limit is 410 ppm. The maximum administered daily mass of an official product is 5.0 g, and the official product contains two excipients. Assuming that there is no other source of acetonitrile in the manufacturing process, the calculated official product content of acetonitrile and the daily exposure are given in *Table 5*.

**Table 5. Example of Meeting the Requirement for Acetonitrile as per Option 2**

| Component | Amount in Formulation (g) | Acetonitrile Content (ppm) | Daily Exposure (mg) |
|---|---|---|---|
| Drug substance | 0.3 | 800 | 0.24 |
| Excipient 1 | 0.9 | 400 | 0.36 |
| Excipient 2 | 3.8 | 800 | 3.04 |
| Official product | 5.0 | 728 | 3.64 |

*Excipient 1* meets the *Option 1* limit, but the official substance, *Excipient 2*, and *Official product* do not meet the *Option 1* limit. Nevertheless, the product meets the *Option 2* limit of 4.1 mg/day and thus conforms to the recommendations in this chapter.

Consider another example using acetonitrile as a residual solvent. The maximum administered daily mass of an official product is 5.0 g, and the official product contains two excipients. Assuming no other source of acetonitrile in the manufacturing process, the *Official product's* content of acetonitrile and the maximum content of residual acetonitrile are given in *Table 6*.

**Table 6. Example of Failing the Requirement for Acetonitrile as per Option 2**

| Component | Amount in Formulation (g) | Acetonitrile Content (ppm) | Daily Exposure (mg) |
|---|---|---|---|
| Drug substance | 0.3 | 800 | 0.24 |
| Excipient 1 | 0.9 | 2000 | 1.8 |
| Excipient 2 | 3.8 | 800 | 3.04 |
| Official product | 5.0 | 1016 | 5.08 |

In this example, the product meets neither the *Option 1* nor the *Option 2* limit according to the summation. Compliance with the chapter may still be demonstrated via analysis of the *Official product* as it is possible that the formulation process may have reduced the level of acetonitrile below the calculated content. If the level of acetonitrile was not reduced during formulation to the allowed limit, then the manufacturer of the *Official product* should take other steps to reduce the amount of acetonitrile in the official product. If the manufacturer receives approval from the regulatory authority for such a higher level of residual solvent, it is the responsibility of that manufacturer to notify USP regarding the identity of this solvent and the approved residual solvent limit in the article. USP will then address this topic in the individual monograph.

# 6. REPORTING LEVELS OF RESIDUAL SOLVENTS

Manufacturers of pharmaceutical products need certain information about the content of residual solvents in drug substances and excipients to meet the criteria of this chapter. The following statements are given as acceptable examples of the information that could be provided from a supplier of drug substances or excipients to a pharmaceutical manufacturer. The supplier might choose one of the following as appropriate:

- If Class 1 solvents are present, they should be identified and quantified.
- Only Class 2 solvents X, Y,… are LTBP. All are below the *Option 1* limit. (Here the supplier would name the Class 2 solvents represented by X, Y,…)
- Only Class 2 solvents X, Y,…, and Class 3 solvents are LTBP. Residual Class 2 solvents are below the *Option 1* limit and residual Class 3 solvents are below 0.5% each.
- Only Class 3 solvents are LTBP. Loss on drying (LOD) is not greater than 0.5%.
- If only Class 3 solvents are LTBP and LOD is more than 0.5%, they should be identified and quantified.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99226_08_01
@2024 USPC

- If solvents of Class 2 or Class 3 are present at greater than their *Option 1* limits or 0.5%, respectively, they should be identified and quantified to allow compliance with *Option 2*.

The term LTBP as used in the above examples refers to the solvent used or produced in the final manufacturing step and to solvents used or produced in earlier manufacturing steps and not removed consistently by a validated process.

## 7. IDENTIFICATION, CONTROL, AND QUANTIFICATION OF RESIDUAL SOLVENTS

Whenever possible, the substance under test needs to be dissolved to release the residual solvent. The control strategy may involve analysis of official products, active ingredients, excipients, and dietary ingredients. In some cases the sample does not dissolve completely. In such cases it may be acceptable to pulverize the sample into a fine powder carefully, avoiding the generation of frictional heat and in a manner that minimizes the loss of volatile solvents. This technique ensures that any residual solvent that may be present can be released. It should be performed as fast as possible immediately prior to dispersion in the sample solvent, to minimize the loss of volatile solvents during the procedure.

[NOTE—The organic-free water specified in the following procedures produces no significantly interfering peaks when chromatographed.]

### 7.1 Class 1 and Class 2 Residual Solvents

This chapter describes analytical procedures (*Procedures A*, *B*, and *C*) for evaluating the levels of all Class 1 and the majority of Class 2 residual solvents. For each test matrix, verification is needed to demonstrate reliability of the compendial procedure, as described in ⟨1467⟩.

When the solvents that are present or potentially present in the sample are known, they can be determined using a limit test such as *Procedure A* or *Procedure B*, or by a quantitative test, such as *Procedure C*.

When the solvents LTBP are not known, use the screening tests of *Procedure A* and *Procedure B* as required. *Procedure A* and *Procedure B* can separate most of the solvents listed in this chapter. Additionally, *Figure 3* can be used as a decision tree to demonstrate compliance.

In a screening test, if the article does not meet the acceptance criteria of *Procedure A*, then *Procedure B* is to be used to demonstrate compliance. If the article does not meet the criteria using *Procedure A* and *Procedure B*, then *Procedure C* must be used to quantify the residual solvent(s) present in the article.

When the information about solvents LTBP in the material is known, the system suitability requirements only need to be demonstrated for the solvents expected to be present. Several residual solvents listed in this chapter are not detected at the limit concentration using the analytical procedure described below. Those solvents include formamide, 2-ethoxyethanol, 2-methoxyethanol, ethylene glycol, *N*-methylpyrrolidone, sulfolane, *N,N*-dimethylacetamide, and *N,N*-dimethylformamide. Those solvents should be determined using an alternative method that has been appropriately validated to demonstrate that the method is suitable for its intended purpose, i.e., quantitative determination of residual solvent or limit tests for them (see *Category II* in *Validation of Compendial Procedures* ⟨1225⟩, *Table 2*, which provides definitions and general guidance on analytical procedures validation without indicating specific validation criteria for each characteristic). Chapter ⟨1467⟩ provides additional guidance on the specific validation criteria for alternative methods used for identification and quantification of residual solvents.

### 7.2 Class 3 Residual Solvents

*Procedures A* and *B* can separate most solvents in Classes 1, 2, and 3. However, the procedures have not been validated for Class 3 solvents, and appropriate validation will be required (see the entry for alternative methods under *7.1 Class 1 and Class 2 Residual Solvents*).

## 8. ANALYTICAL PROCEDURES FOR CLASS 1 AND CLASS 2 RESIDUAL SOLVENTS

### 8.1 Chromatographic Systems

(See *Chromatography* ⟨621⟩, *System Suitability* and *Figure 4*.)

#### PROCEDURE A

**Mode:** GC
**Injector:** Headspace (see *Table 9* for headspace settings)
**Injection type:** Split ratio, 1:5. [NOTE—Split ratio can be modified to optimize sensitivity.]
**Detector:** Flame ionization
**Column:** 0.32-mm × 30-m capillary fused silica coated with 1.8-µm layer of phase G43 or 0.53-mm × 30-m wide-bore coated with a 3.0-µm layer of phase G43
**Column temperature:** See *Table 7*.

**Table 7. Procedure A Column Temperature**

| Initial Temperature (°) | Temperature Ramp (°/min) | Final Temperature (°) | Hold Time at Final Temperature (min) |
|---|---|---|---|
| 40 | 0 | 40 | 20 |
| 40 | 10 | 240 | — |
| 240 | 0 | 240 | 20 |

**Temperatures**
*Injection port:* 140°
*Detector:* 250°
**Carrier gas:** Helium, nitrogen, or hydrogen
**Linear velocity:** About 35 cm/s for helium (adjustment and verification are necessary for other carrier gases)

#### PROCEDURE B

**Mode:** GC
**Injector:** Headspace (see *Table 9* for headspace settings)
**Injection type:** Split ratio, 1:5. [NOTE—Split ratio can be modified to optimize sensitivity.]
**Detector:** Flame ionization
**Column:** 0.32-mm × 30-m fused-silica coated with a 0.25-µm layer of phase G16 or a 0.53-mm × 30-m wide-bore coated with a 0.25-µm layer of phase G16
**Column temperature:** See *Table 8*.

**Table 8. Procedure B Column Temperature**

| Initial Temperature (°) | Temperature Ramp (°/min) | Final Temperature (°) | Hold Time at Final Temperature (min) |
|---|---|---|---|
| 50 | 0 | 50 | 20 |
| 50 | 6 | 165 | — |
| 165 | 0 | 165 | 20 |

**Temperatures**
*Injection port:* 140°
*Detector:* 250°
**Carrier gas:** Helium, nitrogen, or hydrogen
**Linear velocity:** About 35 cm/s for helium (adjustment and verification are necessary for other carrier gases)

## PROCEDURE C

Use the chromatographic conditions, from either *Procedure A* or *Procedure B*, that provide the best performance for the solvent(s) being tested.

## HEADSPACE PARAMETER SETTINGS

There are three general sets of headspace operating parameters that are used for *Procedures A* and *B* (*Table 9*).

**Table 9. Headspace Operating Parameters**

| Procedure Parameters | Headspace Instrumental Setting | | |
|---|---|---|---|
| | Set 1 | Set 2 | Set 3 |
| Equilibration temperature (°) | 80 | 105 | 80 |
| Equilibration time (min) | 60 | 45 | 45 |
| Transfer-line temperature (°) [if appropriate][a] | 85 | 110 | 105 |
| Syringe temperature (°) [if appropriate] | 80–90 | 105–115 | 80–90 |
| Carrier gas: helium, nitrogen,[b] or hydrogen[b] at an appropriate pressure[b] | — | — | — |
| Pressurization time(s) (sec) [if appropriate] | ≥60 | ≥60 | ≥60 |
| Injection volume (mL)[c] | 1 | 1 | 1 |

[a] It is recommended to increase the temperature of the transfer line between runs to eliminate any potential condensation of solvents.
[b] The use of nitrogen or hydrogen as the carrier gas requires adjustment and verification.
[c] Injection volume may be expressed in terms of the injection time.

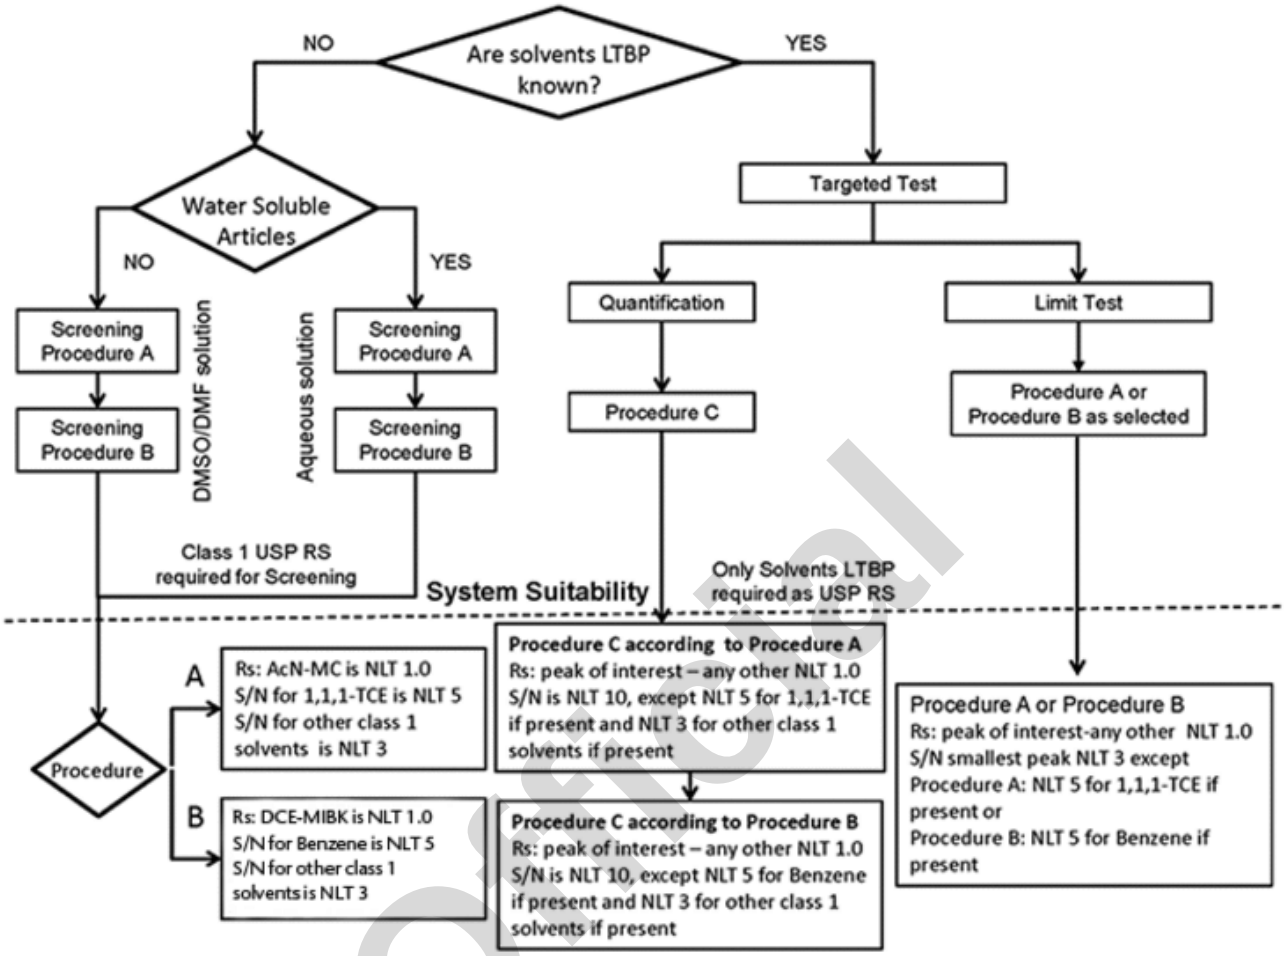

Figure 4. System suitability requirements based on the method of choice and previous knowledge about solvents LTBP. The acceptance criteria are based on the solvents LTBP (AcN: acetonitrile; 1,1,1-TCE: 1,1,1-trichloroethane; DCE: *cis*-dichloroethene; MC: methylene chloride; MIBK: Methylisobutylketone).

## 8.2 Screening of Water-Soluble Articles

STOCK SOLUTIONS

**Class 1 standard stock solution:** [NOTE—When transferring solutions, place the tip of the pipet just below the surface of the liquid and mix.] Transfer 1.0 mL of USP Residual Solvents Mixture—Class 1 RS to a 100-mL volumetric flask containing about 9 mL of dimethylsulfoxide, dilute with water to volume, and mix. Transfer 1.0 mL of this solution to a 100-mL volumetric flask containing about 50 mL of water, dilute with water to volume, and mix. Transfer 10 mL of this solution to a 100-mL volumetric flask containing about 50 mL of water, dilute with water to volume, and mix.
**Class 2 mixture A standard stock solution:** Transfer 1.0 mL of USP Residual Solvents Class 2—Mixture A RS to a 100-mL volumetric flask, dilute with water to volume, and mix.
**Class 2 mixture B standard stock solution:** Transfer 1.0 mL of USP Residual Solvents Class 2—Mixture B RS to a 100-mL volumetric flask, dilute with water to volume, and mix.
**Sample stock solution:** Transfer about 250 mg of the article under test, accurately weighed, to a 25-mL volumetric flask, dissolve in and dilute with water to volume, and mix.

SYSTEM SUITABILITY SOLUTION

**Class 1 system suitability solution:** Transfer 1.0 mL of *Class 1 standard stock solution* to an appropriate headspace vial, add 5.0 mL of *Sample stock solution*, apply the stopper, cap, and mix.

STANDARD SOLUTIONS

**Class 1 standard solution:** [NOTE—When transferring solutions, place the tip of the pipet just below the surface of the liquid and mix.] Transfer 1.0 mL of *Class 1 standard stock solution* to an appropriate headspace vial containing 5.0 mL of water. Apply the stopper, cap, and mix.
**Class 2 mixture A standard solution:** Transfer 1.0 mL of *Class 2 mixture A standard stock solution* to an appropriate headspace vial containing 5.0 mL of water, apply the stopper, cap, and mix.
**Class 2 mixture B standard solution:** Transfer 5.0 mL of *Class 2 mixture B standard stock solution* to an appropriate headspace vial, add 1.0 mL of water, apply the stopper, cap, and mix.

SAMPLE SOLUTION

**Sample solution:** Transfer 5.0 mL of *Sample stock solution* to an appropriate headspace vial, add 1.0 mL of water, apply the stopper, cap, and mix.

PROCEDURE A

**Analysis:** Using *Procedure A Chromatographic System*, separately inject (using one of the headspace operating parameter sets described in *Table 9*) equal volumes of headspace of the *Class 1 standard solution*, *Class 1 system suitability solution*, *Class 2 mixture A standard solution*, *Class 2 mixture B standard solution*, and *Sample solution* into the chromatograph, record the chromatograms, and measure the responses for the peaks of interest.
**System suitability requirements (**see *Figure 4***):** The signal-to-noise (S/N) ratio for 1,1,1-trichloroethane in the *Class 1 standard solution* is NLT 5. The S/N ratio of each peak in the *Class 1 system suitability solution* is NLT 3, and the resolution between acetonitrile and methylene chloride in the *Class 2 mixture A standard solution* is NLT 1.0.
**Acceptance criteria:** If a response of any peak, other than the peak for 1,1,1-TCE, in the *Sample solution* is greater than or equal to a corresponding peak in either the *Class 1 standard solution*, or either *Class 2 mixture A standard solution* or *Class 2 mixture B standard solution*, or a peak response of 1,1,1-trichloroethane is greater than or equal to 150 times the peak response corresponding to 1,1,1-trichloroethane in the *Class 1 standard solution*, proceed to *Procedure B* to verify the identity of the peak; otherwise the article meets the requirements of this test.

PROCEDURE B

**Analysis:** Using *Procedure B Chromatographic System*, separately inject (using one of the headspace operating parameter sets described in *Table 9*) equal volumes of headspace of the *Class 1 standard solution*, *Class 1 system suitability solution*, *Class 2 mixture A standard solution*, *Class 2 mixture B standard solution*, and *Sample solution* into the chromatograph, record the chromatograms, and measure the responses for the peaks of interest.
**System suitability requirements (**see *Figure 4***):** The S/N ratio for benzene in the *Class 1 standard solution* is NLT 5. The S/N ratio of each peak in the *Class 1 system suitability solution* is NLT 3, and the resolution between methylisobutylketone and *cis*-dichloroethene in the *Class 2 mixture A standard solution* is NLT 1.0.
**Acceptance criteria:** If the response(s) in the *Sample solution* of the peak(s) identified in *Procedure A* is/are greater than or equal to corresponding peak(s) in either the *Class 1 standard solution*, or either *Class 2 mixture A standard solution* or *Class 2 mixture B standard solution*, proceed to *Procedure C* to quantify the peak(s); otherwise the article meets the requirements of this test.

## 8.3 Screening of Water-Insoluble Articles

STOCK SOLUTIONS

[NOTE—Dimethyl sulfoxide may be substituted as an alternative solvent to dimethylformamide. When transferring solutions, place the tip of the pipet just below the surface of the liquid and mix.]
**Class 1 standard stock solution:** Transfer 1.0 mL of USP Residual Solvents Mixture—Class 1 RS to a 100-mL volumetric flask previously filled with about 80 mL of dimethylformamide, dilute with dimethylformamide to volume, and mix. Transfer 1.0 mL of this solution to a 100-mL volumetric flask, previously filled with about 80 mL of dimethylformamide, dilute with dimethylformamide to volume, and mix (reserve a portion of this solution for the *Class 1 system suitability solution*). Transfer 1.0 mL of this solution to a 10-mL volumetric flask, dilute with dimethylformamide to volume, and mix.
**Class 2 mixture A standard stock solution:** Transfer 1.0 mL of USP Residual Solvents Class 2—Mixture A RS to a 100-mL volumetric flask containing about 80 mL of dimethylformamide, dilute with dimethylformamide to volume, and mix.
**Class 2 mixture B standard stock solution:** Transfer 0.5 mL of USP Residual Solvents Class 2—Mixture B RS to a 10-mL volumetric flask, dilute with dimethylformamide to volume, and mix.
**Sample stock solution:** Transfer about 500 mg of the article under test, accurately weighed, to a 10-mL volumetric flask, dissolve in and dilute with dimethylformamide to volume, and mix.

SYSTEM SUITABILITY SOLUTION

**Class 1 system suitability solution:** Mix 5 mL of *Sample stock solution* with 0.5 mL of the intermediate dilution reserved from *Class 1 standard stock solution*. Transfer 1 mL of this solution to an appropriate headspace vial containing 5 mL of water. Apply the stopper, cap, and mix.

Official

https://pharmacopeia.com/

STANDARD SOLUTIONS

**Class 1 standard solution:** Transfer 1.0 mL of *Class 1 standard stock solution* to an appropriate headspace vial containing 5.0 mL of water, apply the stopper, cap, and mix.
**Class 2 mixture A standard solution:** Transfer 1.0 mL of *Class 2 mixture A standard stock solution* to an appropriate headspace vial containing 5.0 mL of water, apply the stopper, cap, and mix.
**Class 2 mixture B standard solution:** Transfer 1.0 mL of *Class 2 mixture B standard stock solution* to an appropriate headspace vial containing 5.0 mL of water, apply the stopper, cap, and mix.

SAMPLE SOLUTION

**Sample solution:** Transfer 1.0 mL of *Sample stock solution* to an appropriate headspace vial containing 5.0 mL of water, apply the stopper, cap, and mix.

PROCEDURE A

**Analysis:** Proceed as directed for *Procedure A* in *8.2 Screening of Water-Soluble Articles* with a split ratio of 1:3. [NOTE—The split ratio can be modified in order to optimize sensitivity.] Separately inject (using one of the headspace operating parameter sets described in *Table 9* with a recommended vial pressure of 10 psi) equal volumes of headspace of the *Class 1 standard solution*, *Class 2 mixture A standard solution*, *Class 2 mixture B standard solution*, and *Sample solution* into the chromatograph, record the chromatograms, and measure the responses for the major peaks.
**System suitability requirements (**see *Figure 4***):** The S/N ratio for 1,1,1-trichloroethane in the *Class 1 standard solution* is NLT 5. The S/N ratio of each peak in the *Class 1 system suitability solution* is NLT 3; and the resolution between acetonitrile and methylene chloride in the *Class 2 mixture A standard solution* is NLT 1.0.
**Acceptance criteria:** If a response of any peak, other than the peak for 1,1,1-TCE in the *Sample solution* is greater than or equal to a corresponding peak in either the *Class 1 standard solution*, or either *Class 2 mixture A standard solution* or *Class 2 mixture B standard solution*, or a peak response of 1,1,1-trichloroethane is greater than or equal to 150 times the peak response corresponding to 1,1,1-trichloroethane in the *Class 1 standard solution*, proceed to *Procedure B* to verify the identity of the peak; otherwise the article meets the requirements of this test.

PROCEDURE B

**Analysis:** Proceed as directed for *Procedure B* in *8.2 Screening of Water-Soluble Articles* with a split ratio of 1:3. Separately inject (using one of the headspace operating parameter sets described in *Table 9* with a recommended vial pressure of 10 psi) equal volumes of headspace of the *Class 1 standard solution*, *Class 2 mixture A standard solution*, *Class 2 mixture B standard solution*, *Sample solution*, and *Class 1 system suitability solution* into the chromatograph, record the chromatograms, and measure the responses for the peaks of interest.
**System suitability requirements (**see *Figure 4***):** The S/N ratio for benzene in the *Class 1 standard solution* is NLT 5. The S/N ratio of each peak in the *Class 1 system suitability solution* is NLT 3; and the resolution between methylisobutylketone and *cis*-dichloroethene in the *Class 2 mixture A standard solution* is NLT 1.0.
**Acceptance criteria:** If the peak response(s) in the *Sample solution* of the peak(s) identified in *Procedure A* is/are greater than or equal to corresponding peak(s) in either the *Class 1 standard solution*, or either *Class 2 mixture A standard solution* or *Class 2 mixture B standard solution*, proceed to *Procedure C* to quantify the peak(s); otherwise the article meets the requirements of this test.

## 8.4 Limit Tests When Solvents LTBP Are Known

SOLUTIONS

Prepare the standard solution and the *Sample solution* as directed in *8.2 Screening of Water-Soluble Articles* or *8.3 Screening of Water-Insoluble Articles* according to the procedure chosen based on the sample solubility. Use USP Reference Standards for those solvents LTBP to prepare the standard solution.

When solvents LTBP are known, only the standards of those solvents LTBP are needed, and determination may be done using a limit test or a quantitative test. Only quantitative tests can be used for *Option 2*.
**System suitability solution:** Prepare the *System suitability solution* according to the solubility of the sample for screening for water-soluble or water-insoluble articles at the concentration of the standard solutions there. Use only those solvents LTBP.

PROCEDURE A

**Analysis (limit test):** Separately inject (using one of the headspace operating parameter sets described in *Table 9*) equal volumes of headspace of the *System suitability solution*, *Standard solution*, and *Sample solution* into the chromatograph, record the chromatograms, and measure the responses for the peaks of interest.
**System suitability requirements (**see *Figure 4***):** The S/N ratio for 1,1,1-trichloroethane, if present, is NLT 5. The S/N ratio is NLT 3 for any other solvent. If there is more than one solvent LTBP, the resolution between a peak of interest and any adjacent peak is NLT 1.0.
**Acceptance criteria:** If the peak response of every peak of interest in the *Sample solution* is smaller than the corresponding peak in the *Standard solution*, the article meets the requirements of this test.

@2024 USPC

PROCEDURE B

**Analysis (limit test):** Separately inject (following one of the headspace operating parameter sets described in *Table 9*) equal volumes of headspace of the *Standard solution* and *Sample solution* into the chromatograph, record the chromatograms, and measure the responses for the peaks of interest.
**System suitability requirements (**see *Figure 4*): The S/N ratio for benzene, if present, is NLT 5. The S/N ratio is NLT 3 for any other solvent. If there is more than one solvent LTBP, the resolution between a peak of interest and any other peak is NLT 1.0.
**Acceptance criteria:** If the peak response of every peak of interest in the *Sample solution* is smaller than the corresponding peak in the *Standard solution*, the article meets the requirements of this test.

## 8.5 Quantitative Tests—Procedure C

QUANTIFICATION FOR WATER-SOLUBLE ARTICLES

(Use the requirement for *General* or *Targeted test*, as applicable.)
**Sample stock solution:** Prepare a *Sample stock solution* as directed in *8.2 Screening of Water-Soluble Articles, Stock Solutions*.
**Standard stock solution:** [NOTE—Prepare a separate *Standard stock solution* for each solvent LTBP or potentially LTBP, or identified and verified by *Procedure A* and *Procedure B*. For the Class 1 solvents other than 1,1,1-trichloroethane, prepare the first dilution as directed for the first dilution under *Class 1 standard stock solution*.] Transfer an accurately measured volume of each individual USP Reference Standard corresponding to each residual solvent peak LTBP or identified and verified by *Procedure A* and *Procedure B* to a suitable container, and dilute quantitatively and stepwise, if necessary, with water to obtain a solution with a final concentration of 1/20 of the value stated in *Table 2* or *Table 3* under *Concentration Limit*.
**Standard solution:** Transfer 1.0 mL of *Standard stock solution* to an appropriate headspace vial, add 5.0 mL of water, apply the stopper, cap, and mix.
**Sample solution:** Prepare as directed in *8.2 Screening of Water-Soluble Articles, Sample Solution*.
**Spiked sample solution:** [NOTE—Prepare a separate *Spiked sample solution* for each peak LTBP or potentially LTBP or identified and verified by *Procedure A* and *Procedure B*.] Transfer 5.0 mL of each *Sample stock solution* to an appropriate headspace vial, add 1.0 mL of the *Standard stock solution*, apply the stopper, cap, and mix. The use of a vial containing the sample spiked with multiple standards is permitted, provided that the procedure is validated accordingly.
**Analysis:** Proceed as directed for *Procedure A*. [NOTE—If the performance of *Procedure B* is better than that shown by *Procedure A*, then *Procedure B* may be used for quantification.] Separately inject (using one of the headspace operating parameter sets described in *Table 9* with a recommended vial pressure of 10 psi) equal volumes of headspace of the *Standard solution*, *Sample solution*, and *Spiked sample solution* into the chromatograph, record the chromatograms, and measure the responses for the peaks of interest.
**System suitability requirements for Procedure A** (see *Figure 4*)**:**
**General:** Same as in *8.2 Screening of Water-Soluble Articles*, *Procedure A*.
**Targeted test:** The S/N ratio is NLT 10 for any solvent except NLT 5 for 1,1,1-trichloroethane and NLT 3 for any other Class 1 solvent, if present. If there is more than one solvent LTBP, the resolution between a peak of interest and any adjacent peak is NLT 1.0.
**System suitability requirements for Procedure B** (see *Figure 4*)**:**
**General:** Same as in *8.2 Screening of Water-Soluble Articles*, *Procedure B*.
**Targeted test:** The S/N ratio is NLT 10 for any solvent except NLT 5 for benzene and NLT 3 for any other Class 1 solvent, if present. If there is more than one solvent LTBP, the resolution between a peak of interest and any adjacent peak is NLT 1.0.
Calculate the amount, in ppm, of each residual solvent found in the article under test:

$$\text{Result} = 5(C/W)[r_U/(r_{ST} - r_U)]$$

$C$ = concentration of the appropriate USP Reference Standard in the *Standard stock solution* (µg/mL)
$W$ = weight of the article under test taken to prepare the *Sample stock solution* (g)
$r_U$ = peak responses of each residual solvent obtained from the *Sample solution*
$r_{ST}$ = peak responses of each residual solvent obtained from the *Spiked sample solution*

QUANTIFICATION FOR WATER-INSOLUBLE ARTICLES

(Use the requirement for *General* or *Targeted test* as applicable.)
**Sample stock solution:** Prepare a *Sample stock solution* as directed in *8.3 Screening of Water-Insoluble Articles, Stock Solutions*. Only the Reference Standard for those solvents identified by *Procedure A* or *Procedure B* or LTBP need to be used.
**Standard stock solution:** [NOTE—Prepare a separate *Standard stock solution* for each solvent LTBP or potentially LTBP, or identified and verified by *Procedure A* and *Procedure B*. For the Class 1 solvents other than 1,1,1-trichloroethane, prepare the first dilution as directed for the first dilution under *Class 1 standard stock solution*.] Transfer an accurately measured volume of each individual USP Reference Standard corresponding to each residual solvent peak LTBP or identified and verified by *Procedure A* and *Procedure B* to a suitable container, and dilute quantitatively and stepwise, if necessary, with water to obtain a solution with a final concentration of 1/20 of the value stated in *Table 2* or *Table 3* under *Concentration Limit*.
**Standard solution:** Transfer 1.0 mL of *Standard stock solution* to an appropriate headspace vial, containing 5.0 mL of water, apply the stopper, cap, and mix.
**Sample solution:** Transfer 1.0 mL of *Sample stock solution* to an appropriate headspace vial, containing 5.0 mL of water, apply the stopper, cap, and mix.
**Spiked sample solution:** [NOTE—Prepare a separate *Spiked sample solution* for each peak LTBP or potentially LTBP, or identified and verified by *Procedure A* and *Procedure B*.] Transfer 1.0 mL of each *Sample stock solution* to an appropriate headspace vial,

https://pharmacopeia.cn/

add 1.0 mL of *Standard stock solution* and 4.0 mL of water, and apply the stopper, cap, and mix. The use of a vial containing the sample spiked with multiple standards is permitted, provided that the procedure is validated accordingly.
**Analysis:** Proceed as directed for *Procedure A*. [NOTE—If the performance of *Procedure B* is better than that shown by *Procedure A*, then *Procedure B* may be used for quantification.] Separately inject (using one of the headspace operating parameter sets described in *Table 9* with a recommended vial pressure of 10 psi) equal volumes of headspace of the *Standard solution*, *Sample solution*, and *Spiked sample solution* into the chromatograph, record the chromatograms, and measure the responses for the peaks of interest. If Class 1 solvents are LTBP, also inject the *Class 1 system suitability solution*.
**System suitability requirements for Procedure A** (see *Figure 4*)**:**
**General:** Same as in *8.3 Screening of Water-Insoluble Articles*, *Procedure A*.
**Targeted test:** The S/N ratio is NLT 10 for any solvent except NLT 5 for 1,1,1-trichloroethane and NLT 3 for any other Class 1 solvent, if present. If there is more than one solvent LTBP, the resolution between a peak of interest and any adjacent peak is NLT 1.0.
**System suitability requirements for Procedure B** (see *Figure 4*)**:**
**General:** Same as in *8.3 Screening of Water-Insoluble Articles, Procedure B*.
**Targeted test:** The S/N ratio is NLT 10 for any solvent except NLT 5 for benzene and NLT 3 for any other Class 1 solvent, if present. If there is more than one solvent LTBP, the resolution between a peak of interest and any adjacent peak is NLT 1.0.

Calculate the amount, in ppm, of each residual solvent found in the article under test:

$$\text{Result} = 10(C/W)[r_U/(r_{ST} - r_U)]$$

$C$ = concentration of the appropriate USP Reference Standard in the *Standard stock solution* (µg/mL)
$W$ = weight of the article under test taken to prepare the *Sample stock solution* (g)
$r_U$ = peak responses of each residual solvent obtained from the *Sample solution*
$r_{ST}$ = peak responses of each residual solvent obtained from the *Spiked sample solution*

## 9. ANALYTICAL PROCEDURES FOR CLASS 3 RESIDUAL SOLVENTS

If only Class 3 solvents are present, and the monograph for the article under test contains an LOD procedure specifying an upper limit of NMT 0.5% (per *Option 1* in this chapter), then the level of residual solvent can be determined as directed in *Loss on Drying* ⟨731⟩. If Class 3 solvents are present with other solvents, e.g., Class 1 or Class 2 solvents, or if there is no LOD procedure in the monograph for the article under test, or if the limit for Class 3 solvent(s) in an individual monograph is greater than 50 mg/day (corresponding to 5000 ppm or 0.5% under *Option 1*), then the Class 3 residual solvent or solvents present in the article under test should be identified and quantified. In that case, the procedures described in this chapter, with appropriate adjustments, are to be applied wherever possible and USP Reference Standards, where available, should be used in these procedures. Such procedures should be properly validated as described in ⟨1467⟩. If Class 1 or Class 2 solvents are present and LOD is less than 0.5%, then identification of Class 3 solvents is not required and only Class 1 and Class 2 solvents should be identified and quantified. See *Figure 5*.

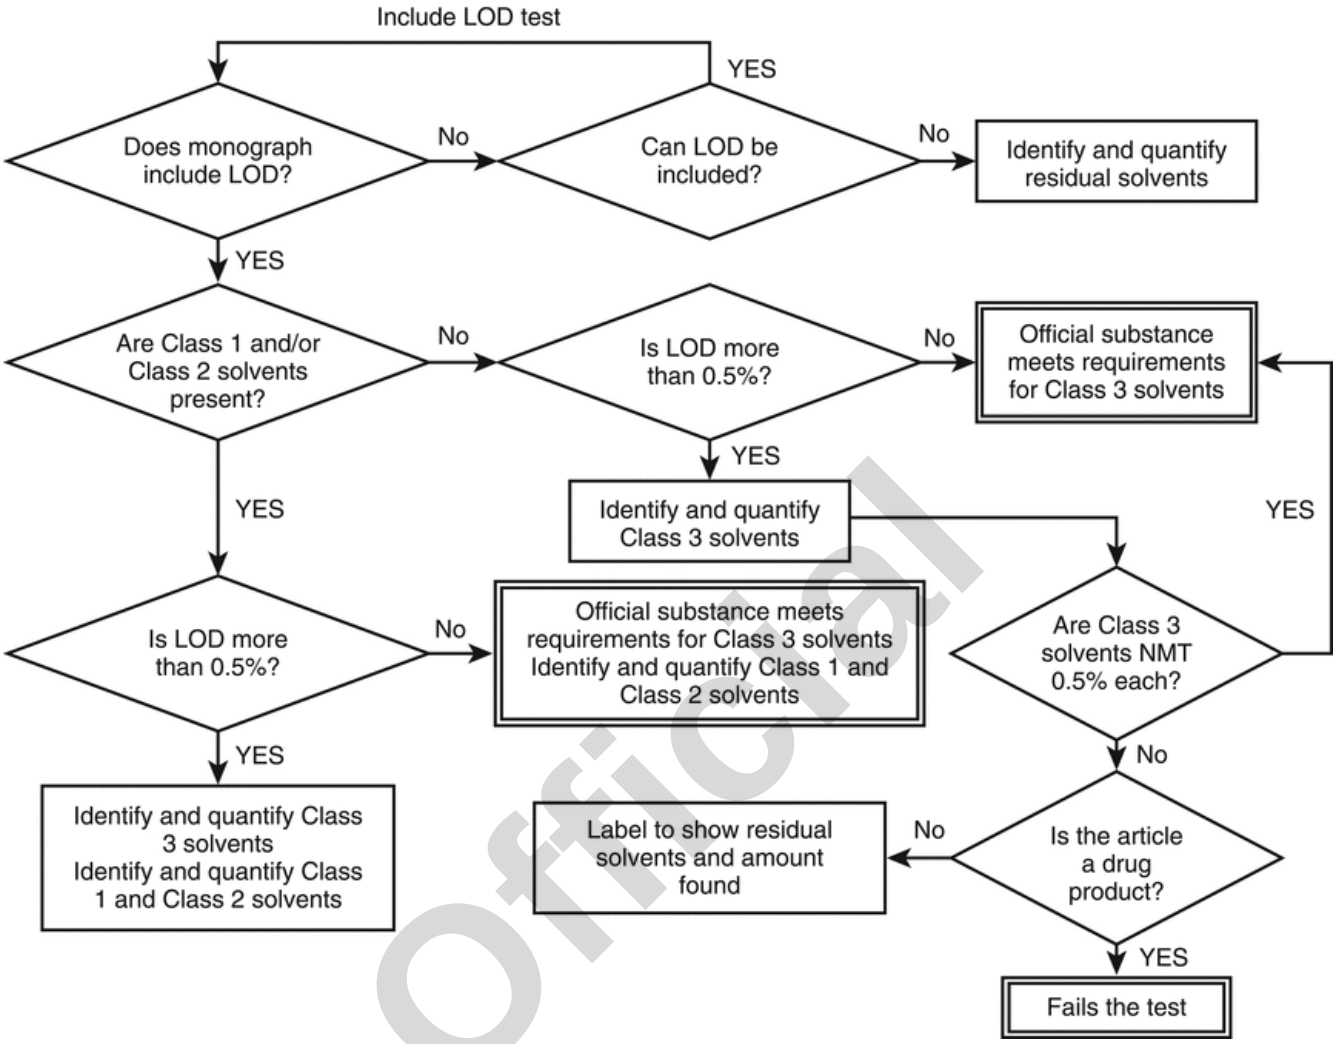

Figure 5. Decision tree for the control of Class 3 residual solvents. LOD: Loss on drying.

## GLOSSARY

**Genotoxic carcinogens:** Carcinogens that produce cancer by affecting genes or chromosomes.

**Likely to be present (LTBP):** Those solvents that are 1) used or produced in the final manufacturing step; 2) used or produced in earlier manufacturing steps but they are not consistently removed by a validated process; 3) the solvents properly declared by a validated supplier of a drug substance, excipient, or dietary ingredient.

**Lowest-observed-effect level (LOEL):** The lowest dose of a substance in a study or group of studies that produces biologically significant increases in frequency or severity of any effects in exposed humans or animals.

**Modifying factor:** A factor determined by professional judgment of a toxicologist and applied to bioassay data so that the data can be safely related to humans.

**Neurotoxicity:** The ability of a substance to cause adverse effects on the nervous system.

**No-observed-effect level (NOEL):** The highest dose of a substance at which there are no biologically significant increases in frequency or severity of any effects in exposed humans or animals.

**Permitted daily exposure (PDE):** The maximum acceptable intake per day of a residual solvent in pharmaceutical products or dietary supplements

**Reversible toxicity:** The occurrence of harmful effects that are caused by a substance and then disappear after the exposure to the substance ends.

**Strongly suspected human carcinogen:** A substance for which there is no epidemiological evidence of carcinogenesis but for which there are positive genotoxicity data and clear evidence of carcinogenesis in rodents.

**Teratogenicity:** The occurrence of structural malformations in a developing fetus when a substance is administered during pregnancy.

# APPENDICES

## Appendix 1: Residual Solvents Included in this General Chapter

See *Table A-1* for a list of residual solvents included in this chapter.

**Table A-1. List of Residual Solvents Included in this General Chapter**

| Solvent | Other Names | Structure | Class |
|---|---|---|---|
| Acetic acid | Ethanoic acid | $CH_3COOH$ | Class 3 |
| Acetone | 2-Propanone; Propan-2-one | $CH_3COCH_3$ | Class 3 |
| Acetonitrile | AcN | $CH_3CN$ | Class 2 |
| Anisole | Methoxybenzene |  | Class 3 |
| Benzene | Benzol | | Class 1 |
| 1-Butanol | *n*-Butyl alcohol; Butan-1-ol | $CH_3(CH_2)_3OH$ | Class 3 |
| 2-Butanol | *sec*-Butyl alcohol; Butan-2-ol | $CH_3CH_2CH(OH)CH_3$ | Class 3 |
| Butyl acetate | Acetic acid butyl ester | $CH_3COO(CH_2)_3CH_3$ | Class 3 |
| *tert*-Butylmethyl ether | 2-Methoxy-2-methylpropane | $(CH_3)_3COCH_3$ | Class 3 |
| Carbon tetrachloride | Tetrachloromethane | $CCl_4$ | Class 1 |
| Chlorobenzene | |  | Class 2 |
| Chloroform | Trichloromethane | $CHCl_3$ | Class 2 |
| Cumene | Isopropylbenzene; (1-Methylethyl)benzene |  | Class 2 |
| Cyclohexane | Hexamethylene |  | Class 2 |
| 1,2-Dichloroethane | *sym*-Dichloroethane; Ethylene dichloride; Ethylene chloride | $CH_2ClCH_2Cl$ | Class 1 |
| 1,1-Dichloroethene | 1,1-Dichloroethylene; Vinylidene chloride | $H_2C=CCl_2$ | Class 1 |

## Appendix 2: Additional Background

### ENVIRONMENTAL REGULATION OF ORGANIC VOLATILE SOLVENTS

Several of the residual solvents frequently used in the production of pharmaceuticals are listed as toxic chemicals in *Environmental Health Criteria* (EHC) monographs and in the *Integrated Risk Information System* (IRIS) and other similar reference material. The approach to risk assessment described therein relates primarily to long-term or lifetime exposure of the general population via the ambient environment (i.e., inhaled air, food, drinking water, and other sources). The objectives of such groups as the International Programme on Chemical Safety (IPCS), the U.S. Environmental Protection Agency (EPA), and the U.S. Food and Drug Administration (FDA) include the determination of acceptable exposure levels. The goal is maintenance of environmental integrity and protection of human health against the possible deleterious effects of chemicals resulting from long-term environmental exposure. The procedures involved in the estimation of maximum safe exposure limits are usually based on long-term studies. When long-term study data are unavailable, shorter-term study data can be used with modification of the approach, such as use of larger safety factors.

### RESIDUAL SOLVENTS IN PHARMACEUTICALS

Exposure limits in this chapter were established by referring to methodologies and toxicity data described in EHC and IRIS monographs. However, the following specific assumptions about residual solvents to be used in the synthesis and formulation of pharmaceutical products should be taken into account in establishing exposure limits.

1. Patients (not the general population) use pharmaceuticals to treat their diseases or for prophylaxis to prevent infection or disease.
2. The assumption of lifetime patient exposure is not necessary for most pharmaceutical products but may be appropriate as a working hypothesis to reduce risk to human health.
3. Residual solvents are unavoidable components in pharmaceutical production and will often be a part of pharmaceutical drug products.
4. Residual solvents should not exceed recommended levels except in exceptional circumstances.
5. Data from toxicological studies that are used to determine acceptable levels for residual solvents should have been generated using appropriate protocols such as those described by the Organization for Economic Cooperation and Development (OECD), the EPA, and the FDA *Redbook* or derived from alternative sources also considered to be adequate to support PDE limit setting.

## Appendix 3: Procedures for Establishing Exposure Limits

The Gaylor–Kodell method of risk assessment (Gaylor, DW, Kodell, RL. Linear interpolation algorithm for low dose risk assessment of toxic substances. *J Environ Pathol, Toxicol*, 1980;4:305–312) is appropriate for Class 1 carcinogenic solvents. Only in cases where reliable carcinogenicity data are available should extrapolation by the use of mathematical models be applied to setting exposure limits. Exposure limits for Class 1 residual solvents could be determined with the use of a large safety factor (i.e., 10,000–100,000) with respect to the no-observed-effect level (NOEL). Detection and quantification of these residual solvents should be performed using state-of-the-art analytical techniques.

Acceptable exposure levels in this chapter for Class 2 residual solvents were established by calculation of PDE values according to the procedures for setting exposure limits in pharmaceuticals (page 5748 of *Pharmacopeial Forum* [Nov.–Dec. 1989]), and the method adopted by IPCS for *Assessing Human Health Risks of Chemicals* (*Environmental Health Criteria 170*, WHO, 1994), detailed calculations are published in *Pharmeuropa*, Vol. 9, No. 1, Supplement, April 1997. These procedures are similar to those used by the U.S. EPA (IRIS) and the U.S. FDA (*Redbook*) and others. The method is outlined here to give a better understanding of the origin of the PDE values. It is not necessary to perform these calculations in order to use the PDE values presented in *Table 3* of this document.

PDE is derived from the NOEL, or the lowest-observed-effect level (LOEL), in the most relevant animal study as follows:

$$\text{PDE} = (\text{NOEL} \times \text{Weight Adjustment})/(F1 \times F2 \times F3 \times F4 \times F5)$$

The PDE is derived preferably from a NOEL. If no NOEL is obtained, the LOEL may be used. Modifying factors proposed here, for relating the data to humans, are the same kind of "uncertainty factors" used in *Environmental Health Criteria* (*Environmental Health Criteria 170*, WHO, 1994) and "modifying factors" or "safety factors" used in *Pharmacopeial Forum*. The assumption of 100% systemic exposure is used in all calculations regardless of the route of administration.

The modifying factors are as follows:

*F1* = A factor to account for extrapolation between species.
- *F1* = 5 for extrapolation from rats to humans
- *F1* = 12 for extrapolation from mice to humans
- *F1* = 2 for extrapolation from dogs to humans
- *F1* = 2.5 for extrapolation from rabbits to humans
- *F1* = 3 for extrapolation from monkeys to humans
- *F1* = 10 for extrapolation from other animals to humans

*F1* takes into account the comparative surface area to body weight ratios for the species concerned and for humans. Surface area (*S*) is calculated as:

$$S = kM^{0.67}$$

@2024 USPC

*k* = a constant that has been taken to be 10
*M* = body weight

The body weights used in the equation are those shown below in *Table A-2*:

*F2* = A factor of 10 to account for variability between individuals.

A factor of 10 is generally given for all organic solvents, and 10 is used consistently in this chapter.

*F3* = A variable factor to account for toxicity studies of short-term exposure

*F3* = 1 for studies that last at least one half lifetime (1 year for rodents or rabbits; 7 years for cats, dogs, and monkeys)

*F3* = 1 for reproductive studies in which the whole period of organogenesis is covered

*F3* = 2 for a 6-month study in rodents, or a 3.5-year study in non-rodents

*F3* = 5 for a 3-month study in rodents, or a 2-year study in non-rodents

*F3* = 10 for studies of a shorter duration

In all cases, the higher factor has been used for study durations between the time points (e.g., a factor of 2 for a 9-month rodent study).

*F4* = A factor that may be applied in cases of severe toxicity, e.g., nongenotoxic carcinogenicity, neurotoxicity, or teratogenicity. In studies of reproductive toxicity, the following factors are used:

*F4* = 1 for fetal toxicity associated with maternal toxicity

*F4* = 5 for fetal toxicity without maternal toxicity

*F4* = 5 for a teratogenic effect with maternal toxicity

*F4* = 10 for a teratogenic effect without maternal toxicity

*F5* = A variable factor that may be applied if the no-effect level was not established.

When only a LOEL is available, a factor of up to 10 can be used, depending on the severity of the toxicity. The weight adjustment assumes an arbitrary adult human body weight for either sex of 50 kg. This relatively low weight provides an additional safety factor against the standard weights of 60 or 70 kg that are often used in this type of calculation. It is recognized that some adult patients weigh less than 50 kg; these patients are considered to be accommodated by the built-in safety factors used to determine a PDE. If the solvent was present in a formulation specifically intended for pediatric use, an adjustment for a lower body weight would be appropriate.

As an example of the application of this equation, consider a toxicity study of acetonitrile in mice that is summarized in *Pharmeuropa*, 1997;9(1): S24. The NOEL is calculated to be 50.7 mg $kg^{-1}$ $day^{-1}$. The PDE for acetonitrile in this study is calculated as follows:

$$PDE = (50.7 \text{ mg kg}^{-1} \text{ day}^{-1} \times 50 \text{ kg})/(12 \times 10 \times 5 \times 1 \times 1) = 4.22 \text{ mg day}^{-1}$$

In this example,

*F1* = 12 to account for the extrapolation from mice to humans

*F2* = 10 to account for differences between individual humans

*F3* = 5 because the duration of the study was only 13 weeks

*F4* = 1 because no severe toxicity was encountered

*F5* = 1 because the no-effect level was determined

**Table A-2. Values Used in the Calculations in This Chapter**

| | |
|---|---|
| Rat body weight | 425 g |

**Table A-2. Values Used in the Calculations in This Chapter** *(continued)*

| | |
|---|---|
| Rat water consumption | 30 mL/day |
| Rat food consumption | 30 g/day |

The equation for an ideal gas, $PV = nRT$, is used to convert concentrations of gases used in inhalation studies from units of ppm to units of mg/L or mg/m$^3$. Consider as an example the rat reproductive toxicity study by inhalation of carbon tetrachloride (molecular weight, 153.84) summarized in *Pharmeuropa*, 1997:*9*(1):S9.

$$\frac{n}{V} = \frac{P}{RT} = \frac{300 \times 10^{-6}\text{atm} \times 153{,}840 \ \text{mg mol}^{-1}}{0.082\text{L atm K}^{-1}\text{mol}^{-1} \times 298 \ \text{K}} = \frac{46.15 \ \text{mg}}{24.45 \ \text{L}} = 1.89 \ \text{mg/L}$$

The relationship 1000 L = 1 m$^3$ is used to convert to mg/m$^3$.

# ⟨469⟩ ETHYLENE GLYCOL, DIETHYLENE GLYCOL, AND TRIETHYLENE GLYCOL IN ETHOXYLATED SUBSTANCES

The following procedure is used to determine the concentration of residual ethylene glycol, diethylene glycol, and triethylene glycol in ethoxylated products. Ethoxylated products may contain residual ethylene glycol, diethylene glycol, and triethylene glycol as a result of the manufacturing process. The procedure is suitable for the following substances:

1. Polyethylene glycol 200
2. Polyethylene glycol 300
3. Polyethylene glycol 400
4. Polyethylene glycol 600
5. Polyethylene glycol 1000
6. Polysorbate 20
7. Polysorbate 40
8. Polysorbate 60
9. Polysorbate 80
10. Polyethylene glycol monomethyl ether 350
11. Polyethylene glycol monomethyl ether 550
12. Polyoxyl 35 castor oil
13. Polyoxyl 15 hydroxystearate
14. Polyoxyl 20 cetostearyl ether
15. Polyoxyl 8 stearate
16. Octoxynol 9
17. Nonoxynol 9

## IMPURITIES

• **PROCEDURE**

**Diluent:** Acetone

**Standard solution:** 25 µg/mL of USP Ethylene Glycol RS, 40 µg/mL of USP Diethylene Glycol RS, 40 µg/mL of USP Triethylene Glycol RS, and 40 µg/mL of USP Butane-1,3-diol RS (internal standard) in *Diluent*

**Sample solution:** 40 mg/mL of the test substance and 40 µg/mL of USP Butane-1,3-diol RS (internal standard) in *Diluent*

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** GC

**Detector:** Flame ionization

**Column:** 0.53-mm × 30-m capillary column bonded with a 1.0-µm layer of phase G3

**Temperatures**

**Detector:** 290°

**Injection port:** 270°

**Column:** See *Table 1*.

**Table 1**

| Initial Temperature (°) | Temperature Ramp (°/min) | Final Temperature (°) | Hold Time at Final Temperature (min) |
|---|---|---|---|
| 40 | 10 | 60 | 5 |
| 60 | 10 | 170 | 0 |
| 170 | 15 | 280 | 0, 60[a] |

[a] Hold time was 0 min for the *Standard solution* and 60 min for the *Sample solution* and *Diluent*.

**Carrier gas:** Helium

**Flow rate:** 5.0 mL/min

**Injection volume:** 1.0 µL

**Injection type:** Split injection, split ratio is 2:1

**Liner:** General-purpose split/splitless, tapered, glass wool, deactivated

**Run time:** 26 min for the *Standard solution*; 86 min for the *Sample solution* and *Diluent*

**System suitability**

**Sample:** *Standard solution*

[NOTE—See *Table 2* for the relative retention times.]

Official

https://pharmacopeia.cn/v-gbook/411m7/

**Table 2**

| Name | Relative Retention Time |
|---|---|
| Ethylene glycol | 0.45 |
| Butane-1,3-diol (internal standard) | 1.00 |
| Diethylene glycol | 1.25 |
| Triethylene glycol | 1.70 |

**System suitability requirements**

**Resolution:** NLT 20 between ethylene glycol and butane-1,3-diol; NLT 20 between butane-1,3-diol and diethylene glycol; NLT 20 between diethylene glycol and triethylene glycol

**Tailing factor:** 0.8–1.8 for each of the four peaks assigned to ethylene glycol, butane-1,3-diol, diethylene glycol, and triethylene glycol

**Relative standard deviation:** NMT 5.0% for the peak response ratio of the respective glycol (ethylene glycol, diethylene glycol, or triethylene glycol) to the internal standard

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Identify the ethylene glycol, diethylene glycol, and triethylene glycol peaks in the *Sample solution* by comparison with those in the *Standard solution*.

Calculate the content of ethylene glycol, diethylene glycol, or triethylene glycol, in µg/g, in the portion of test substance taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times F$$

$R_U$ = peak response ratio of the respective glycol to the internal standard (peak response of the respective glycol/peak response of the internal standard) from the *Sample solution*

$R_S$ = peak response ratio of the respective glycol to the internal standard (peak response of the respective glycol/peak response of the internal standard) from the *Standard solution*

$C_S$ = concentration of the respective glycol (ethylene glycol, diethylene glycol, or triethylene glycol) in the *Standard solution* (µg/mL)

$C_U$ = concentration of the test substance in the *Sample solution* (mg/mL)

$F$ = conversion factor (1000 mg/g)

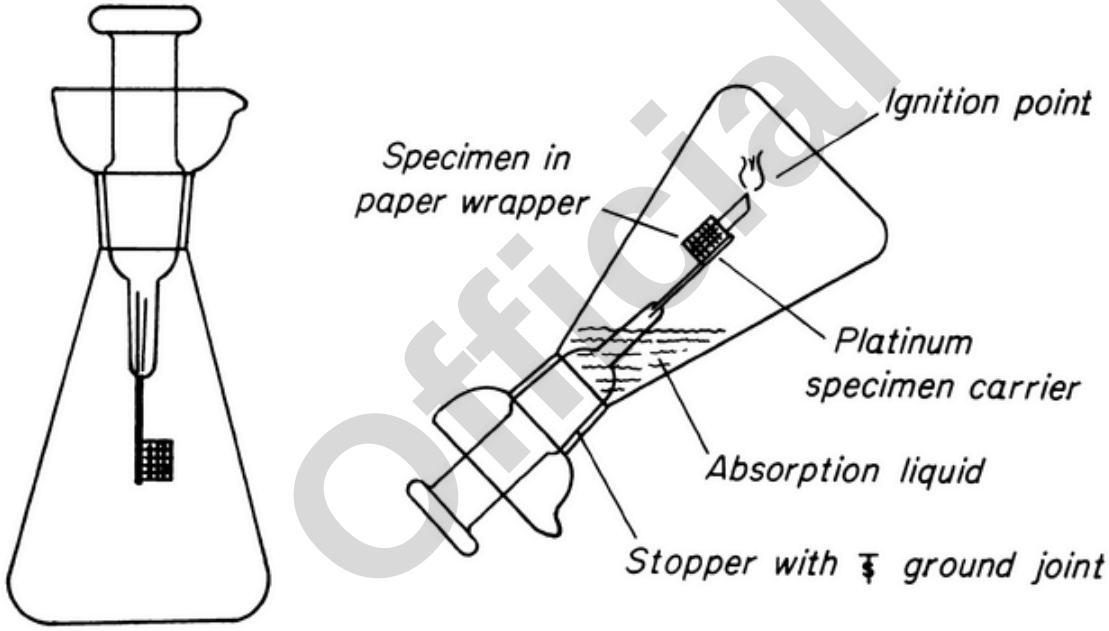
# ⟨471⟩ OXYGEN FLASK COMBUSTION

The oxygen flask combustion procedure is provided as the preparatory step in the determination of bromine, chlorine, iodine, selenium, and sulfur in some Pharmacopeial articles. Combustion of the material under test (usually organic) yields water-soluble inorganic products, which are analyzed for specific elements as directed in the individual monograph or general chapter.

The caution statement given for *Procedure* covers minimum safety precautions only, and serves to emphasize the need for exceptional care throughout.

## APPARATUS

The apparatus[1] consists of a heavy-walled conical, deeply lipped or cupped 500-mL flask (unless a larger flask is specified), fitted with a ground-glass stopper to which is fused a test specimen carrier consisting of heavy-gauge platinum wire and a piece of welded platinum gauze measuring about 1.5 × 2 cm.



Apparatus for Oxygen Flask Combustion

## PROCEDURE

[**CAUTION**—Wear safety glasses and use a suitable safety shield between yourself and the apparatus. Exercise care to ensure that the flask is scrupulously clean and free from even traces of organic solvents.]

Weigh the substance, if a solid, on a piece of halide-free filter paper measuring about 4 cm square, and fold the paper to enclose it. Liquid substances are weighed in tared capsules, polycarbonate capsules[1] being used for liquids in volumes not exceeding 200 µL, and gelatin capsules being satisfactory for use for larger volumes. [NOTE—Gelatin capsules may contain significant amounts of combined halide or sulfur. If such capsules are used, perform a blank determination, and make any necessary correction.] Place the specimen, together with a filter paper fuse-strip, in the platinum gauze specimen holder. Place the absorbing liquid specified in the individual monograph or general chapter in the flask, moisten the joint of the stopper with water, and flush the air from the flask with a stream of rapidly flowing oxygen, swirling the liquid to favor its taking up oxygen. [NOTE—Saturation of the liquid with oxygen is essential for the successful performance of the combustion procedure.] Ignite the fuse-strip by suitable means. If the strip is ignited outside the flask, immediately plunge the specimen holder into the flask, invert the flask so that the absorption solution makes a seal around the stopper, and hold the stopper firmly in place. If the

[1] A suitable apparatus [Catalog Nos. 6513-C20 (500-ml capacity) and 6513-C30 (1000-ml capacity)] and suitable capsules [Catalog No. 6513-84 (1000 capsules)] are obtainable from Thomas Scientific, 99 High Hill Road, Swedesboro, NJ 08085.

https://pharmacopeia.cn/v-choose/

ignition is carried out in a closed system, the inversion of the flask may be omitted. After combustion is complete, shake the flask vigorously, and allow to stand for not less than 10 minutes with intermittent shaking. Then proceed as directed in the individual monograph or general chapter.

# ▲⟨476⟩ CONTROL OF ORGANIC IMPURITIES IN DRUG SUBSTANCES AND DRUG PRODUCTS

## INTRODUCTION

This chapter covers requirements for controlling drug-related organic impurities in drug substances and drug products described in *USP* monographs. A threshold-based approach described in the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use (ICH) Q3A(R2) *Impurities in New Drug Substances* and Q3B(R2) *Impurities in New Drug Products* guidelines may be used for the control of organic impurities in drug substances or drug products generated during the manufacturing process and/or storage. (For additional information and definition of terms, see *Impurities in Drug Substances and Drug Products* ⟨1086⟩.)

This chapter applies to drug substances and drug products described in the *USP* when referenced in the individual monograph. This chapter addresses organic impurities arising during the manufacturing process and/or storage of the drug substance. Also the chapter covers those impurities in drug products classified as degradation products of the drug substance or reaction products of the drug substance with an excipient and/or immediate container–closure system (collectively referred to as "degradation products").

This chapter does not cover veterinary products, biological/biotechnological products, peptides, oligonucleotides, fermentation products and semisynthetic products derived from them, polymorphic forms, radiopharmaceuticals, herbal products, or crude products of animal or plant origin. In addition, inorganic/elemental impurities, residual solvents, impurities in excipients, and leachables from the container–closure system are out of the scope of this chapter.

This chapter does not cover mutagenic impurities as described in ICH Guideline M7(R1) *Assessment and Control of DNA Reactive (Mutagenic) Impurities in Pharmaceuticals to Limit Potential Carcinogenic Risk*.

## ANALYTICAL PROCEDURES FOR IMPURITIES

Manufacturers shall validate or verify, as appropriate, analytical procedures and must demonstrate their suitability for the detection and quantitation of impurities in drug substances and drug products. Manufacturers shall develop acceptance criteria for impurities that are justified by appropriate safety considerations and consistent with current applicable regulatory guidances.

For impurities known or suspected to be unusually toxic (e.g., mutagenic impurities) or to produce undesired pharmacological effects, the limit of detection and limit of quantitation of the analytical procedures shall be commensurate with the acceptance criteria and the current applicable regulatory guidances to ensure patient safety.

## REPORTING IMPURITIES

The reporting threshold can be established using current applicable regulatory guidances or other acceptable scientific means. The preferred terms applicable to organic impurities procedures are "impurity" and "total impurities" in the drug substance monographs and "degradation product" and "total degradation products" in the drug product monographs. Impurities presenting above the reporting threshold shall be reported according to the relevant analytical procedure.

Impurity results shall be reported as numerical values and rounded according to conventional rules (see *General Notices, 7.20. Rounding Rules*). All impurities at a level greater than (>) the reporting threshold shall be summed and reported as a value for total impurities, unless otherwise indicated in the monograph.

## IDENTIFICATION OF IMPURITIES

Impurities present above the identification threshold for drug substances and drug products at release and on storage shall be investigated and all reasonable attempts shall be made to identify these impurities. The identification threshold can be established using current applicable regulatory guidances or other acceptable scientific means. Lower thresholds may be required for impurities known or suspected to be unusually toxic (e.g., mutagenic impurities) or to produce undesired pharmacological effects. Higher thresholds may be applied if scientifically justified, according to ICH Q3A(R2) and ICH Q3B(R2).

## QUALIFICATION OF IMPURITIES

Qualification is the process of establishing the biological safety of impurities at the specified level(s). Qualification of impurities shall be based on a combination of factors including safety, intended use, applicable guidances, and scientific rationale.

## SETTING ACCEPTANCE CRITERIA FOR IMPURITIES

Acceptance criteria shall be set for all impurities present above the reporting thresholds for drug substances and drug products. Specified impurities/degradation products can be either identified or unidentified. Specified identified impurities/degradation products should be included along with specified unidentified impurities/degradation products estimated to be

@2024 USPC

present at a level greater than (>) the identification threshold. Unspecified impurities/degradation products are limited by a general acceptance criterion, which is NMT (≤) the identification threshold and NLT (>) the reporting threshold. A rationale for the inclusion or exclusion of impurities in the specification should be documented. The acceptance criteria shall be based on applicable guidances or other acceptable scientific means, with safety as the primary consideration and not solely based on process capability.

A monograph for a drug substance shall include acceptance criteria for the following, where applicable:

- Each specified identified impurity
- Each specified unidentified impurity
- Any unspecified impurity with an acceptance criterion of NMT the identification threshold
- Total impurities

Unless otherwise indicated, total impurities in the drug substance monographs are the sum of all specified (identified and unidentified) and unspecified impurities above the reporting threshold.

A monograph for a drug product shall include acceptance criteria for the following, where applicable:

- Each specified identified degradation product
- Each specified unidentified degradation product
- Any unspecified degradation product with an acceptance criterion of NMT the identification threshold
- Total degradation products

Unless otherwise indicated, total degradation products in the drug product monographs are the sum of all specified and unspecified degradation products above the reporting threshold.

The preferred terminology applicable to organic impurities procedures is “impurity” and “total impurities” in the drug substance monographs, and “degradation product” and “total degradation products” in the drug product monographs, respectively. Drug substance process impurities need not be controlled in the drug product unless they are also degradation products. However, in some cases drug substance process-related impurities may be included in the drug product specifications, if appropriate, and limited by appropriate acceptance criteria. Drug substance process-related impurities also detected in the drug product and included in its specification may have a note that certain drug substance process-related impurities are listed only for information and should not be included in the total degradation products. When this note is included, the total degradation products should only include all specified and unspecified impurities/degradation products above the reporting threshold, with the exception of these designated process-related impurities.

Acceptance criteria for impurities (including unusually toxic, for example, mutagenic impurities) should be supported by appropriate toxicological evaluation, using current applicable guidances. Lower thresholds may be required for impurities known or suspected to be unusually toxic.

## ORGANIC IMPURITIES IN DRUG SUBSTANCES

Organic impurities in drug substances arising from the manufacturing process and/or storage should be controlled. A rationale for the inclusion or exclusion of impurities in the specification should be documented. The organic impurities to be controlled in the drug substance are the process-related impurities and degradation products. They can be identified or unidentified. Process-related impurities are generated during drug substance manufacturing, such as byproducts, residual starting materials, intermediates, reagents, and ligands. Impurities that increase over time on storage are considered degradation products.

When there are changes to the chemistry, manufacturing, and/or controls of the drug substance (e.g., a different manufacturer or manufacturing site, scale/equipment, starting materials, synthetic pathways, and/or purification steps) described in a monograph, they should be evaluated to determine if the differences affect the impurity profile listed in the existing monograph. If the individual monograph does not include a procedure for quantifying an impurity or acceptance criterion for an observed impurity, the manufacturer is responsible for developing and validating analytical procedures and then establishing appropriate acceptance criterion. USP requests submission of the alternative/new procedure to evaluate for potential inclusion in the appropriate monograph(s).

A threshold-based approach as described in ICH Q3A(R2) may be used for the reporting, identification, and/or qualification of impurities in drug substances. Because toxicity is a dose-related phenomenon, the thresholds are set based on the amount of drug substance administered per day (see *Table 1*). Lower thresholds can be appropriate if the impurity is unusually toxic or produces undesirable pharmacological effects.

**Table 1. ICH Recommended Thresholds for Impurities in Drug Substances**

| Maximum daily dose | ≤2 g | >2 g |
|---|---|---|
| Reporting threshold | 0.05% | 0.03% |
| Identification threshold | 0.10% (1.0 mg)[a] | 0.05% |
| Qualification threshold | 0.15% (1.0 mg)[a] | 0.05% |

[a] The total daily intake (TDI; in parentheses) applies if it is lower than the calculated value.

*Principles for Setting Acceptance Criteria for Impurities* in drug substances are discussed in this chapter and also in ICH guidelines and FDA guidances for New Drug Applications (NDAs) and Abbreviated New Drug Applications (ANDAs). The acceptance criteria shall be based on applicable guidances or other acceptable scientific means, with safety as the primary consideration and not solely based on process capability.

# ORGANIC IMPURITIES IN DRUG PRODUCTS

Usually, the organic impurities to be controlled in the drug product are only the degradation products resulting from the degradation of the drug substance or the interaction of the drug substance with excipients and/or the primary packaging configuration. They can be identified or unidentified. A rationale for the inclusion or exclusion of impurities in the specification should be documented. Drug substance process-related impurities need not be monitored or specified in drug products unless they are also degradation products.

A threshold-based approach as described in ICH Q3B(R2) may be used for the reporting, identification, and/or qualification of impurities in drug products. Because the toxicity is dose-related, the thresholds are based on the amount of drug substance administered per day (see *Table 2*). The amount of drug substance administered per day is based upon the manufacturer's maximum recommended labeled dosage per day. Lower thresholds can be appropriate if the degradation product is unusually toxic or produces undesirable pharmacological effects.

**Table 2. ICH Recommended Thresholds for Degradation Products in Drug Products**

| Maximum daily dose | <1 mg | ≥1 to <10 mg | 10 mg | >10–100 mg | >100 mg–1 g | >1–2 g | >2 g |
|---|---|---|---|---|---|---|---|
| Reporting threshold | 0.1% | 0.1% | 0.1% | 0.1% | 0.1% | 0.05% | 0.05% |
| Identification threshold | 1.0% (5 µg)[a] | 0.5% (20 µg)[a] | 0.5% (20 µg) [a] | 0.2% (2 mg)[a] | 0.2% (2 mg)[a] | 0.2% (2 mg)[a] | 0.10% |
| Qualification threshold | 1.0% (50 µg)[a] | 1.0% (50 µg)[a] | 0.5% (200 µg)[a] | 0.5% (200 µg)[a] | 0.2% (3 mg)[a] | 0.2% (3 mg)[a] | 0.15% |

[a] Whichever is lower, calculated value or TDI (in parentheses).

*Principles for Setting Acceptance Criteria for Impurities* in drug products are discussed in this chapter and also in ICH guidelines and FDA guidances for NDAs and ANDAs. The acceptance criteria shall be based on applicable guidances or other acceptable scientific means, with safety as the primary consideration and not solely based on process capability. In cases of complex impurity profiles, limits may be established based on the grouping of impurities, if appropriate and scientifically justified [according to ICH Q3B(R2)].

For drug products that contain multiple drug substances, degradation products from each active ingredient should be controlled. Manufacturers should provide rationale and supporting data to justify the acceptance criteria for impurities associated with each drug substance, as applicable.▲ (USP 1-May-2021)

# ⟨481⟩ RIBOFLAVIN ASSAY

## ASSAY

• **Chemical Methods, Procedure 1**

The following procedure is suitable for preparations in which riboflavin is a constituent of a mixture of several ingredients. In using the procedure, keep the pH of solutions below 7.0, and protect the solutions from direct sunlight at all stages.

**Standard riboflavin stock solution:** To 50.0 mg of USP Riboflavin RS, previously dried and stored protected from light in a desiccator over phosphorus pentoxide, add about 300 mL of 0.02 N acetic acid, and heat the mixture on a steam bath with frequent agitation until the riboflavin has dissolved, then cool. To this solution add 0.02 N acetic acid to make 500 mL; then mix. Store the solution under toluene in a refrigerator.

Dilute an accurately measured portion of this solution by using 0.02 N acetic acid to a concentration of 10.0 µg/mL of the dried USP Riboflavin RS to obtain the *Standard riboflavin stock solution*. Store the solution under toluene in a refrigerator.

**Standard solution:** Dilute with water 10.0 mL of *Standard riboflavin stock solution* in a 100-mL volumetric flask to volume, and mix. Each mL represents 1.0 µg of USP Riboflavin RS. Prepare a fresh *Standard solution* for each assay.

**Sample solution:** Place an amount of the material to be assayed in a flask of suitable size, and add a volume of 0.1 N hydrochloric acid equal in mL to NLT 10 times the dry weight of the material in grams, but the resulting solution will contain NMT 100 µg/mL of riboflavin. If the material is not readily soluble, comminute the material so that it may be evenly dispersed in the liquid. Agitate vigorously, and wash down the sides of the flask with 0.1 N hydrochloric acid.

Heat the mixture in an autoclave at 121°–123° for 30 min, and cool. If clumping occurs, agitate the mixture until the particles are evenly dispersed. Adjust the mixture, with vigorous agitation, with sodium hydroxide solution[1] to a pH of 6.0–6.5, then add hydrochloric acid solution[1] immediately until no further precipitation occurs (usually at a pH of approximately 4.5, which is the isoelectric point of many of the proteins present). Dilute the mixture with water to make a measured volume that contains about 0.11 µg of riboflavin in each mL, and filter through paper known not to adsorb riboflavin. To an aliquot of the filtrate add, with vigorous agitation, sodium hydroxide solution[1] to produce a pH of 6.6–6.8, dilute the solution with water to make a final measured volume that contains approximately 0.1 µg of riboflavin in each mL, and if cloudiness occurs, filter again.

**Instrumental conditions**

(See *Fluorescence Spectroscopy* ⟨853⟩.)

**Mode:** Fluorescence

**Excitation wavelength:** 444 nm

**Emission wavelength:** 530 nm

**Analysis**

**Samples:** *Standard solution*, *Sample solution*, and *Blank*

To each of four or more tubes (or reaction vessels) add 10.0 mL of the *Sample solution*. To each of two or more of these tubes add 1.0 mL of the *Standard solution*, and mix; to each of two or more of the remaining tubes add 1.0 mL of water, and mix. To each tube add 1.0 mL of glacial acetic acid, mix, then add, with mixing, 0.50 mL of potassium permanganate solution (1 in 25), and allow to stand for 2 min. To each tube add, with mixing, 0.50 mL of hydrogen peroxide solution, whereupon the permanganate color is destroyed within 10 s. Shake the tubes vigorously until excess oxygen is expelled. Remove any gas bubbles remaining on the sides of the tubes after foaming has ceased by tipping the tubes so that the solution flows slowly from end to end.

Measure the fluorescence of all tubes, designating the average reading from the tubes containing only the *Sample solution* as $I_U$, and designating the average from the tubes containing both the *Sample solution* and the *Standard solution* as $I_S$. Then to each of one or more tubes of each kind add, with mixing, 20 mg of sodium hydrosulfite, and within 5 s again measure the fluorescence, designating the average reading as $I_B$.

Calculate the quantity, in mg, of riboflavin ($C_{17}H_{20}N_4O_6$) in each mL of the *Sample solution* taken:

$$\text{Result} = [0.0001 \times (I_U - I_B)]/(I_S - I_U)$$

$I_U$ = average reading of the tubes containing only the *Sample solution*
$I_B$ = average reading of fluorescence of the tubes after adding 20 mg of sodium hydrosulfite
$I_S$ = average reading of the tubes containing both the *Sample solution* and *Standard solution*

Calculate the quantity, in mg, of riboflavin ($C_{17}H_{20}N_4O_6$) in each capsule or tablet.

• **Chemical Methods, Procedure 2**

This procedure is suitable for the determination of riboflavin as a dietary ingredient or active pharmaceutical ingredient. [Note—Conduct the entire *Analysis* without exposure to direct sunlight.]

**Standard solution:** Transfer 50 mg of USP Riboflavin RS to a 1000-mL volumetric flask containing 50 mL of water. Add 5 mL of acetic acid and sufficient water to make 800 mL. Heat on a steam bath, protected from light, with frequent agitation until dissolved. Cool to 25°, and dilute with water to volume. Dilute this solution with water to bring it within the operating sensitivity of the fluorometer used.

**Sample solution:** Transfer 50 mg of Riboflavin to a 1000-mL volumetric flask containing 50 mL of water. Add 5 mL of acetic acid and sufficient water to make 800 mL. Heat on a steam bath, protected from light, with frequent agitation until

[1] The concentrations of the hydrochloric acid and sodium hydroxide solutions used are not stated in each instance, because these concentrations may be varied depending upon the amount of material taken for assay, volume of test solution, and buffering effect of material.

https://pharmacopeia.com/

dissolved. Cool to 25°, and dilute with water to volume. Dilute this solution with water to bring it to the same concentration as that of the *Standard solution*.

**Blank:** Prepare as directed for the *Sample solution*, except omit the test specimen.

**Instrumental conditions**

(See *Fluorescence Spectroscopy* ⟨853⟩.)

**Mode:** Fluorescence

**Excitation wavelength:** 444 nm

**Emission wavelength:** 530 nm

**Analysis**

**Samples:** *Standard solution*, *Sample solution*, and *Blank*

Measure the fluorescence intensity of the *Standard solution*. Immediately after the reading, add to the solution 10 mg of sodium hydrosulfite, stirring with a glass rod until dissolved, and at once measure the fluorescence again. [NOTE—Depending on the final concentration of riboflavin in the solution, it may be necessary to increase the amount of sodium hydrosulfite to suppress the fluorescence activity completely.] The difference between the two readings represents the fluorescence intensity ($I_S$) due to the *Standard solution*. Similarly, measure the fluorescence intensity ($I_U$) due to the *Sample solution*. Perform the blank determination, and make any necessary correction.

Calculate the percentage of riboflavin ($C_{17}H_{20}N_4O_6$) in the portion of Riboflavin taken:

$$\text{Result} = (I_U/I_S) \times (C_S/C_U) \times 100$$

$I_U$ = fluorescence of the *Sample solution*
$I_S$ = fluorescence of the *Standard solution*
$C_S$ = concentration of USP Riboflavin RS in the *Standard solution* (µg/mL)
$C_U$ = concentration of riboflavin in the *Sample solution* (µg/mL)

The following liquid chromatographic procedures are provided for the determination of riboflavin as an active pharmaceutical ingredient, a dietary supplement ingredient, or a component in the dietary supplements or pharmaceutical dosage forms. Use the appropriate USP Reference Standards.

Throughout these procedures, protect solutions containing and derived from the test specimen and the Reference Standards from the atmosphere and light, preferably by the use of low-actinic glassware.

**Chromatographic Methods, Procedure 1**

This procedure can be used to determine riboflavin in:

- *Oil- and Water-Soluble Vitamins Capsules*
- *Oil- and Water-Soluble Vitamins Tablets*
- *Oil- and Water-Soluble Vitamins with Minerals Capsules*
- *Oil- and Water-Soluble Vitamins with Minerals Tablets*
- *Water-Soluble Vitamins Capsules*
- *Water-Soluble Vitamins Tablets*
- *Water-Soluble Vitamins with Minerals Capsules*
- *Water-Soluble Vitamins with Minerals Tablets*

This is the procedure that involves the extraction of riboflavin from the formulation by the *Diluent*, heat, and mechanical shaking.

Unless specified in the individual monographs, the *Standard solution*, *Sample solutions*, and reagent solutions are prepared as follows.

**Diluent:** Acetonitrile, glacial acetic acid, and water (5:1:94)

**Mobile phase:** A mixture of methanol, glacial acetic acid, and water (27:1:73) containing 140 mg of sodium 1-hexanesulfonate per 100 mL

**Standard solution:** Transfer 20 mg of USP Riboflavin RS to a 200-mL volumetric flask, and add 180 mL of *Diluent*. Immerse the flask in a hot water bath maintained at 65°–70° for 10 min with regular shaking, or using a vortex mixer, until all of the solid materials are dissolved. Chill rapidly in a cold water bath for 10 min to room temperature, and dilute with *Diluent* to volume.

**Sample solution for capsules:** Weigh NLT 20 capsules in a tared weighing bottle. Open the capsules, without loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the shells by washing with several portions of ether. Discard the washings, and dry the capsule shells with the aid of a current of dry air until the odor of ether is no longer perceptible. Weigh the empty capsule shells in the tared weighing bottle, and calculate the average net weight per capsule. Transfer a portion of the capsule contents, equivalent to 2.5 mg of riboflavin, to a 50-mL centrifuge tube. Add 25.0 mL of *Diluent*, and mix using a vortex mixer for 30 s to completely suspend the powder. Immerse the centrifuge tube in a hot water bath maintained at 65°–70°, heat for 5 min, and mix on a vortex mixer for 30 s. Return the tube to the hot water bath, heat for another 5 min, and mix on a vortex mixer for 30 s. Filter a portion of the solution, cool to room temperature, and use the clear filtrate. [NOTE—Use the filtrate within 3 h of filtration.]

**Sample solution for tablets:** Finely powder NLT 30 tablets. Transfer a portion of the powder, equivalent to 2.5 mg of riboflavin, to a 50-mL centrifuge tube. Add 25.0 mL of *Diluent*, and mix using a vortex mixer for 30 s to completely suspend the powder. Immerse the centrifuge tube in a hot water bath maintained at 65°–70°, heat for 5 min, and mix on a vortex mixer for 30 s. Return the tube to the hot water bath, heat for another 5 min, and mix on a vortex mixer for 30 s. Filter a portion of the solution, cool to room temperature, and use the clear filtrate. [NOTE—Use the filtrate within 3 h of filtration.]

**Chromatographic system**
(See *Chromatography* ⟨621⟩, *System Suitability*.)
**Mode:** LC
**Detector:** UV 280 nm
**Column:** 4.6-mm × 25-cm; packing L1
**Flow rate:** 1 mL/min
**Injection volume:** 10 µL
**System suitability**
**Sample:** *Standard solution*
**Suitability requirements**
**Relative standard deviation:** NMT 3.0%
**Analysis**
**Samples:** *Standard solution* and appropriate *Sample solution*
Calculate the percentage of the labeled amount of riboflavin ($C_{17}H_{20}N_4O_6$) in the portion of sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of riboflavin from the appropriate *Sample solution*
$r_S$ = peak response of riboflavin from the *Standard solution*
$C_S$ = concentration of USP Riboflavin RS in the *Standard solution* (mg/mL)
$C_U$ = nominal concentration of riboflavin in the appropriate *Sample solution* (mg/mL)

- **Chromatographic Methods, Procedure 2**

This procedure can be used to determine riboflavin in:
- *Oil- and Water-Soluble Vitamins Capsules*
- *Oil- and Water-Soluble Vitamins Tablets*
- *Oil- and Water-Soluble Vitamins with Minerals Capsules*
- *Oil- and Water-Soluble Vitamins with Minerals Tablets*
- *Water-Soluble Vitamins Capsules*
- *Water-Soluble Vitamins Tablets*
- *Water-Soluble Vitamins with Minerals Capsules*
- *Water-Soluble Vitamins with Minerals Tablets*

This is the procedure that involves the extraction of riboflavin from the formulation by the *Extraction solvent*, heat, and mechanical shaking.
Unless specified in the individual monographs, the *Standard solution*, *Sample solutions*, and reagent solutions are prepared as follows.
**Extraction solvent:** Transfer 1 mL of glacial acetic acid and 2.5 g of edetate disodium to a 100-mL volumetric flask. Dissolve in and dilute with water to volume. Mix the resulting solution with methanol (3:1).
**Solution A:** 6.8 g of sodium acetate per 1000 mL of water
**Mobile phase:** Prepare a mixture of *Solution A* and methanol (13:7). Add 2 mL of triethylamine per L of the mixture, and adjust with glacial acetic acid to a pH of 5.2.
**Standard stock solution:** Transfer 20 mg of USP Riboflavin RS to a 200-mL volumetric flask, and add 180 mL of *Extraction solvent*. Immerse the flask for 5 min in a water bath maintained at 65°–75°. Mix well, and repeat if necessary until dissolved. Chill rapidly in a cold water bath to room temperature, and dilute with *Extraction solvent* to volume.
**Standard solution:** Dilute 5.0 mL of the *Standard stock solution* with *Extraction solvent* to 25.0 mL.
**Sample solution for capsules:** Weigh NLT 20 capsules in a tared weighing bottle. Open the capsules, without loss of shell material, and transfer the contents to a beaker. Remove any contents adhering to the shells by washing with several portions of ether. Discard the washings, and dry the capsule shells with the aid of a current of dry air. Weigh the empty capsule shells in the tared weighing bottle, and calculate the net weight of the capsule contents. Transfer a portion of the capsule contents, equivalent to 2 mg of riboflavin, to a 200-mL volumetric flask. Add 100.0 mL of *Extraction solvent*, and mix for 20 min using a wrist-action shaker. Immerse the flask in a water bath maintained at 70°–75°, and heat for 20 min. Mix on a vortex mixer for 30 s, cool to room temperature, and filter. Use the clear filtrate.
**Sample solution for tablets:** Finely powder NLT 20 tablets. Transfer a portion of the powder, equivalent to 2 mg of riboflavin, to a 200-mL volumetric flask. Add 100.0 mL of *Extraction solvent*, and mix for 20 min using a wrist-action shaker. Immerse the flask in a water bath maintained at 70°–75°, and heat for 20 min. Mix on a vortex mixer for 30 s, cool to room temperature, and filter. Use the clear filtrate.

- *Oil- and Water-Soluble Vitamins with Minerals Capsules*
- *Oil- and Water-Soluble Vitamins with Minerals Tablets*
- *Water-Soluble Vitamins Capsules*
- *Water-Soluble Vitamins Tablets*
- *Water-Soluble Vitamins with Minerals Capsules*
- *Water-Soluble Vitamins with Minerals Tablets*

This is the procedure that involves the extraction of riboflavin from the formulation by mixtures of organic solvents, heat, and mechanical shaking.

Unless specified in the individual monographs, the *Standard solutions*, *Sample solutions*, and reagent solutions are prepared as follows.

**Diluent:** 25 mg/mL of edetate disodium in water

**Mobile phase:** Transfer 0.4 mL of triethylamine, 15.0 mL of glacial acetic acid, and 350 mL of methanol to a 2000-mL volumetric flask. Dilute with 0.008 M sodium 1-hexanesulfonate to volume.

**Standard stock solution:** 0.08 mg/mL of USP Riboflavin RS in *Diluent*, with heating if necessary

**Standard solution for capsules/tablets:** Transfer 5.0 mL of *Standard stock solution* to a stoppered 125-mL flask. Add 10.0 mL of a mixture of methanol and glacial acetic acid (9:1) and 30.0 mL of a mixture of methanol and ethylene glycol (1:1). Insert the stopper, shake for 15 min in a water bath maintained at 60°, and cool. Filter, discarding the first few mL of the filtrate.

**Standard solution for oral solution:** 8 µg/mL of USP Riboflavin RS in *Diluent*, diluted from the *Standard stock solution*

**Sample solution for capsules:** Weigh NLT 20 capsules in a tared weighing bottle. Open the capsules, without the loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing, if necessary, with several portions of ether. Discard the washings, and dry the capsule shells with the aid of a current of dry air until the odor of ether is no longer perceptible. Weigh the empty capsule shells in the tared weighing bottle, and calculate the average net weight per capsule. Transfer a portion of the capsule contents, equivalent to 0.4 mg of riboflavin, to a stoppered 125-mL flask. Add 10.0 mL of a mixture of methanol and glacial acetic acid (9:1) and 30.0 mL of a mixture of methanol and ethylene glycol (1:1). Insert the stopper, shake for 15 min in a water bath maintained at 60°, and cool. Filter, discarding the first few mL of the filtrate.

**Sample solution for oral solution:** Equivalent to 8 µg/mL of riboflavin from oral solution in the *Diluent*

**Sample solution for tablets:** Weigh and finely powder NLT 20 tablets. Transfer a portion of the powder, equivalent to 0.4 mg of riboflavin, to a stoppered 125-mL flask. Add 10.0 mL of a mixture of methanol and glacial acetic acid (9:1) and 30.0 mL of a mixture of methanol and ethylene glycol (1:1). Insert the stopper, shake for 15 min in a water bath maintained at 60°, and cool. Filter, discarding the first few mL of the filtrate.

**Chromatographic system**

(See *Chromatography* ⟨621⟩*, System Suitability*.)

**Mode:** LC

**Detector:** UV 270 nm

**Column:** 4.6-mm × 25-cm; packing L7

**Column temperature:** 50°

**Flow rate:** 2 mL/min

**Injection volume:** 5 µL

**System suitability**

**Sample:** *Standard solution*

**Suitability requirements**

**Relative standard deviation:** NMT 2.0%

**Analysis**

**Samples:** Appropriate *Standard solution* and appropriate *Sample solution*

For capsules and tablets, calculate the percentage of the labeled amount of riboflavin ($C_{17}H_{20}N_4O_6$) in the portion of sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of riboflavin from the appropriate *Sample solution*

Official

https://nhathuocngocanh.com/

$r_S$ = peak response of riboflavin from the *Standard solution for capsules/tablets*
$C_S$ = concentration of USP Riboflavin RS in the *Standard solution for capsules/tablets* (mg/mL)
$C_U$ = nominal concentration of riboflavin in the appropriate *Sample solution* (mg/mL)

For oral solution, calculate the percentage of the labeled amount of riboflavin ($C_{17}H_{20}N_4O_6$) in the portion of sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of riboflavin from the *Sample solution for oral solution*
$r_S$ = peak response of riboflavin from the *Standard solution for oral solution*
$C_S$ = concentration of USP Riboflavin RS in the *Standard solution for oral solution* (mg/mL)
$C_U$ = nominal concentration of riboflavin in the *Sample solution for oral solution* (mg/mL)

- **Chromatographic Methods, Procedure 4**

This procedure can be used to determine riboflavin in:

- *Oil- and Water-Soluble Vitamins Capsules*
- *Oil- and Water-Soluble Vitamins Tablets*
- *Oil- and Water-Soluble Vitamins with Minerals Capsules*
- *Oil- and Water-Soluble Vitamins with Minerals Tablets*
- *Water-Soluble Vitamins Capsules*
- *Water-Soluble Vitamins Tablets*
- *Water-Soluble Vitamins with Minerals Capsules*
- *Water-Soluble Vitamins with Minerals Tablets*

This is a newly added procedure as part of the USP monograph modernization efforts. The procedure uses hydrophilic interaction liquid chromatography (HILIC), and the sample preparation involves the extraction of riboflavin from the formulation by the *Diluent*, heat, and mechanical shaking.

Unless specified in the individual monographs, the *Standard solution*, *Sample solutions*, and reagent solutions are prepared as follows.

**Diluent:** Methanol, glacial acetic acid, and water (50:1:49)
**Solution A:** 50 mM ammonium formate; adjust with ammonium hydroxide to a pH of 9.0.
**Solution B:** Acetonitrile
**Mobile phase:** Gradient elution. See *Table 1*.

**Table 1**

| Time (min) | Solution A (%) | Solution B (%) |
|---|---|---|
| 0 | 11 | 89 |
| 8 | 17 | 83 |
| 15 | 23 | 77 |
| 20 | 30 | 70 |
| 21 | 50 | 50 |
| 24 | 50 | 50 |
| 25 | 11 | 89 |
| 30 | 11 | 89 |

**Standard solution:** Transfer 20 mg of USP Riboflavin RS to a 200-mL volumetric flask, and add 160 mL of *Diluent*. Immerse the flask in a hot water bath maintained at 65°–70° for 10 min with regular shaking or using a vortex mixer, until all of the solid materials are dissolved. Chill rapidly in a cold water bath for 10 min to room temperature, and dilute with *Diluent* to volume.

**Sample solution for capsules:** Weigh NLT 20 capsules in a tared weighing bottle. Open the capsules, without the loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing, if necessary, with several portions of ether. Discard the washings, and dry the capsule shells with the aid of a current of dry air until the odor of ether is no longer perceptible. Weigh the empty capsule shells in the tared weighing bottle, and calculate the average net weight per capsule. Transfer a portion of the capsule contents, equivalent to 2.5 mg of riboflavin, to a 50-mL centrifuge tube. Add 25.0 mL of *Diluent*, and mix using a vortex mixer for 30 s to completely suspend the powder. Immerse the centrifuge tube in a hot water bath maintained at 68°, heat for 10 min, and mix on a vortex mixer for 30 s. Return the tube to the hot water bath, heat for another 10 min, and mix on a vortex mixer for 30 s. Filter a portion of the solution, cool to room temperature, and use the clear filtrate.

**Sample solution for tablets:** Finely powder NLT 30 tablets. Transfer a portion of the powder, equivalent to 2.5 mg of riboflavin, to a 50-mL centrifuge tube. Add 25.0 mL of *Diluent*, and mix using a vortex mixer for 30 s to completely suspend the powder. Immerse the centrifuge tube in a hot water bath maintained at 65°–70°, heat for 10 min, and mix on a vortex mixer for 30 s. Return the tube to the hot water bath, heat for another 10 min, and mix on a vortex mixer for 30 s. Filter a portion of the solution, cool to room temperature, and use the clear filtrate. [Note—Use the filtrate within 3 h of filtration.]

## ADDITIONAL REQUIREMENTS

• **USP Reference Standards** ⟨11⟩
USP Riboflavin RS

Official

https://pharmacopeia.cn/

# ⟨501⟩ SALTS OF ORGANIC NITROGENOUS BASES

## STANDARD PREPARATION

Unless otherwise directed, prepare a solution in dilute sulfuric acid (1 in 70) containing, in each mL, about 500 µg of the specified USP Reference Standard, calculated on the anhydrous basis, and accurately weighed.

## ASSAY PREPARATION

If the dosage form is a tablet, weigh and finely powder not less than 20 tablets, weigh accurately a portion of the powder, equivalent to about 25 mg of the active ingredient, and transfer to a 125-mL separator; or, if the dosage form is a liquid, transfer a volume of it, equivalent to about 25 mg of the active ingredient and accurately measured, to a 125-mL separator. Then to the separator add 20 mL of dilute sulfuric acid (1 in 350), and shake vigorously for 5 minutes. Add 20 mL of ether, shake carefully, and filter the acid phase into a second 125-mL separator. Shake the ether phase with two 10-mL portions of dilute sulfuric acid (1 in 350), filter each portion of acid into the second separator, and discard the ether. To the acid extract add 10 mL of sodium hydroxide TS and 50 mL of ether, shake carefully, and transfer the aqueous phase to a third 125-mL separator containing 50 mL of ether. Shake the third separator carefully, and discard the aqueous phase. Wash the two ether solutions, in succession, with a single 20-mL portion of water, and discard the water. Extract each of the two ether solutions with 20-, 20-, and 5-mL portions of dilute sulfuric acid (1 in 70), in the order listed, but each time extract first the ether solution in the third separator and then that in the second separator. Combine the acid extracts in a 50-mL volumetric flask, dilute with the acid to volume, and mix.

[NOTE—Hexane or heptane may be substituted for ether if the distribution ratio of the nitrogenous base between water and hexane, or between water and heptane, favors complete extraction by the organic phase.]

## PROCEDURE

Unless otherwise directed, dilute 5.0 mL each of the *Standard Preparation* and the *Assay Preparation* with dilute sulfuric acid (1 in 70) to 100.0 mL, and determine the absorbance of each solution at the specified wavelength, using dilute sulfuric acid (1 in 70) as the blank. Designate the absorbance of the solution from the *Standard Preparation* as $A_S$ and that from the *Assay Preparation* as $A_U$, and calculate the result of the assay as directed in the individual monograph.

# ⟨503.1⟩ TRIFLUOROACETIC ACID (TFA) IN PEPTIDES

## INTRODUCTION

The following procedures are to be used to determine the amount of trifluoroacetic acid (TFA) in peptides. TFA/Trifluoroacetate is a common residual process impurity in the preparation of peptides or a counter ion in active pharmaceutical ingredients (API).

- **PROCEDURE**

**Solution A:** Add 7.0 mL of phosphoric acid and 5.0 mL of ammonium hydroxide to 900 mL of water. Mix and dilute with water to 1000 mL. [NOTE—The pH of the solution is approximately 2.5.] Pass through a filter of 0.45-µm pore size and degas. Add 20 mL of methanol, mix, and degas for an additional 2 min.

**Solution B:** Acetonitrile and water (50:50). Mix and degas.

**Mobile phase:** See *Table 1*.

**Table 1**

| Time (min) | Solution A (%) | Solution B (%) |
|---|---|---|
| 0 | 100 | 0 |
| 5 | 100 | 0 |
| 6 | 0 | 100 |
| 14 | 0 | 100 |
| 15 | 100 | 0 |
| 25 | 100 | 0 |

**Diluent:** 0.5% phosphoric acid in water (v/v)

**TFA stock solution** (option 1): 12 mg/mL of USP Sodium Trifluoroacetate RS in water

Calculate the concentration ($C_S$), in mg/mL, of TFA in the *TFA stock solution* taken:

$$C_S = 0.838 \times C$$

0.838 = molecular weight conversion factor (114.02/136.01)

$C$ = concentration of USP Sodium Trifluoroacetate RS in the *TFA stock solution* (mg/mL)

**TFA stock solution** (option 2): 10 mg/mL of TFA in water prepared as follows. Add about 50 mL of water to a 100-mL volumetric flask with a stopper. Tare the stoppered flask on an analytical balance until there is no further significant drift in the reading. Transfer 670 µL of TFA to the flask, stopper immediately, and weigh. Dilute with water to volume.

**System suitability solution:** 0.025 mg/mL of TFA in *Diluent* prepared from the *TFA stock solution*

**Standard solution** (when TFA content is tested as a process impurity): 0.01 mg/mL of TFA in *Diluent* prepared from the *TFA stock solution*

**Standard solution** (when TFA content is tested as a counter ion in the API): 0.25 mg/mL of TFA in *Diluent* prepared from the *TFA stock solution*. [NOTE—The concentration can be adjusted depending on the amount of TFA expected to be present in the test material.]

**Sample solution:** NLT 4 mg/mL of test sample in *Diluent*. [NOTE—The sample concentration can be adjusted so that the limit (when TFA content is tested as a process impurity) or the mid-range (when TFA content is tested as a counter ion) of the amount of TFA stated in the specification for the test material corresponds to that of the *Standard solution*.]

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 210 nm

**Column:** 4.6-mm × 25-cm; 5-µm packing L1. [NOTE—A guard column of 4-mm × 2-cm; 5-µm packing L1 can be used.]

**Flow rate:** 1.5 mL/min

**Injection volume:** 20 µL

**System suitability**

**Sample:** *System suitability solution*

[NOTE—The retention time is about 3 min for TFA.]

**Suitability requirements**

**Relative standard deviation:** NMT 5%

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Calculate the percentage of TFA in the portion of sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = TFA peak responses from the *Sample solution*

$r_S$ = TFA peak responses from the *Standard solution*

Official

https://pharmacopeia.cn/

$C_S$ = concentration of TFA in the *Standard solution* (mg/mL)
$C_U$ = concentration of the *Sample solution* (mg/mL)

# ⟨503⟩ ACETIC ACID IN PEPTIDES

## INTRODUCTION

This chapter provides procedures to be used to determine the amount of acetic acid in peptides. Acetic acid/acetate is a common counter ion in peptide preparations.

• **METHOD 1**

**Strong sodium hydroxide solution:** Dissolve 42 g of sodium hydroxide in water, and dilute with water to 100 mL.

**Solution A:** Add 0.7 mL of phosphoric acid to 1000 mL of water, and adjust with *Strong sodium hydroxide solution* to a pH of 3.0.

**Solution B:** Methanol

**Mobile phase:** See *Table 1*.

**Table 1**

| Time (min) | Solution A (%) | Solution B (%) |
|---|---|---|
| 0 | 95 | 5 |
| 5 | 95 | 5 |
| 10 | 50 | 50 |
| 20 | 50 | 50 |
| 22 | 95 | 5 |

**Diluent:** Prepare a mixture of *Solution A* and *Solution B* (95:5).

**Standard solution:** Dissolve an accurately weighed quantity of USP Glacial Acetic Acid RS in *Diluent* to obtain a solution having a known concentration of about 0.1 mg/mL. [NOTE—The concentration can be adjusted, depending on the amount of acetate or acetic acid expected to be present in the test material.]

**Sample solution:** Prepare as directed in the individual monograph. If no direction is given in the individual monograph, the sample concentration can be adjusted so that the mid-range of the amount of acetic acid stated in the specification for the test material corresponds to that of the *Standard solution*.

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 210 nm

**Column:** 4.6-mm × 25-cm; 5-µm packing L1

**Flow rate:** 1.2 mL/min

**Injection volume:** 10 µL

**System suitability**

**Sample:** *Standard solution*

**Suitability requirements**

**Relative standard deviation:** NMT 5%

**Retention time of acetic acid:** 3–4 min

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Calculate the percentage of acetic acid in the portion of test material taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response from the *Sample solution*
$r_S$ = peak response from the *Standard solution*
$C_S$ = concentration of USP Glacial Acetic Acid RS in the *Standard solution* (mg/mL)
$C_U$ = concentration of the *Sample solution* (mg/mL)

• **METHOD 2**

**Solution A, Solution B, Mobile phase, Diluent,** and **Chromatographic system:** See *Trifluoroacetic Acid (TFA) in Peptides* ⟨503.1⟩.

**Standard solution:** 0.7 mg/mL of USP Sodium Acetate Trihydrate RS in *Diluent*

Calculate the concentration of acetic acid in the *Standard solution* ($C_S$), in mg/mL, taken:

$$C_S = 0.441 \times C$$

0.441 = molecular weight conversion factor (60.05/136.08)
$C$ = concentration of USP Sodium Acetate Trihydrate RS in the *Standard solution* (mg/mL)

**Sample solution:** About 4 mg/mL of the test sample in *Diluent*. [NOTE—The sample concentration can be adjusted so that the mid-range of the amount of acetic acid stated in the specification for the test material corresponds to that of the *Standard solution*.]

Official

https://pharmacopeia.cn/v29240/

[NOTE—Alternatively, the *Standard solution* and *Sample solution* can be prepared as described in *Method 1*.]

**System suitability**

**Sample:** *Standard solution*

**Suitability requirements**

**Relative standard deviation:** NMT 5%

**Analysis:** Proceed as described in *Method 1*.

# ⟨507⟩ PROTEIN DETERMINATION PROCEDURES

## INTRODUCTION

Several procedures exist to determine the total protein in pharmaceutical drug substances and products. Procedures may differ based on the physical characteristic of the protein, which serves as the basis of the measurement principle (e.g., absorbance of ultraviolet light by aromatic amino acid residues or by dye binding). Understanding the protein structure and sample matrix is important when selecting a total protein quantitation procedure. Users must verify that the chosen validated method below is suitable for their specific purposes (see *Verification of Compendial Procedures* ⟨1226⟩).

## PROCEDURE

Two options for Method I are presented: *Method IA*, using denaturing conditions; and *Method IB*, using native conditions. Depending on the protein structure and the nature of the protein sample (e.g., denaturing conditions may be more suitable for a strong coiled structure with most aromatic amino acids in the interior of the protein), one method may prove superior to the other, and users should select which is the most suitable method based on their protein and verify, as appropriate. At a minimum, both methods are dependent on the following conditions being met: 1) the amino acid sequence and molecular weight of the protein must be known; and 2) the protein must contain tyrosines or tryptophans, and no other chromophores (other than cystines) that absorb near 280 nm (including nucleic acids and diluent components) should be present.

- **Method IA. Ultraviolet Light Absorbance Under Denaturing Conditions**

**Sample buffer A:** Prepare 20 mM sodium phosphate, pH 6.5 by dissolving 0.24 g of sodium dihydrogen phosphate in about 80 mL of water. Adjust the pH with sodium hydroxide solution (10% w/w), and fill with water to 100 mL. Filter.

**Sample buffer B:** Prepare 7 M guanidine hydrochloride and 20 mM sodium phosphate, pH 6.5 by dissolving 0.24 g of sodium dihydrogen phosphate and 66.87 g of guanidine hydrochloride in about 50 mL of water. Adjust with sodium hydroxide solution (10% w/w), and fill with water to 100 mL. Filter.

**Reference solution:** Prepare 6 M guanidine hydrochloride in *Sample buffer A* by mixing 330 µL of *Sample buffer A* and 2000 µL of *Sample buffer B*.

**Sample preparation A:** Dilute the test sample by adding *Sample buffer A* and *Sample buffer B* to achieve a final concentration of 6 M guanidine hydrochloride and an absorbance of about 0.4–0.6. [Note—Gravimetric dilutions can be used and sometimes improve accuracy.] Prepare at least three replicates per test sample.

**Analysis**

**Samples:** *Sample buffer A*, *Sample buffer B*, *Reference solution*, and *Sample preparation A*

**Determination of the protein concentration in denaturing buffer:** Using a suitable spectrophotometer (see *Ultraviolet-Visible Spectroscopy* ⟨857⟩), measure the absorbance of *Sample preparation A* in 1-cm cuvettes at an optical density of 280 nm against the *Reference solution*, and subtract the absorbance value at 330 nm to obtain $A_{corrected}$.

Calculate the protein concentration ($c$) in the test sample:

$$c = A_{corrected} \times DF \times MW/(\varepsilon_{280\ nm} \times 1\ cm)$$

$A_{corrected}$ = absorbance at 280 nm minus the absorbance at 330 nm
$DF$ = dilution factor
$MW$ = calculated molecular weight of the protein
$\varepsilon_{280\ nm}$ = extinction coefficient of the test sample at 280 nm

$$\varepsilon_{280\ nm} = (n_{Trp} \times 5690 + n_{Tyr} \times 1280 + n_{Cys} \times 120)\ M^{-1} \times cm^{-1}$$

$n_{Trp}$ = number of tryptophans
$n_{Tyr}$ = number of tyrosines
$n_{Cys}$ = number of cystines

**System suitability**

The test sample UV spectra must show a maximum between 270 and 285 nm and must show a minimum between 243 and 257 nm. The measured absorbance at 280 nm must be NLT 0.4 and NMT 0.6. The relative standard deviation (RSD) of the calculated concentration of all replicates must be NMT 3.0%.

- **Method IB. Ultraviolet Light Absorbance Under Native Conditions**

**Sample buffer A:** Prepare 20 mM sodium phosphate, pH 6.5 by dissolving 0.24 g of sodium dihydrogen phosphate in about 80 mL of water. Adjust the pH with sodium hydroxide solution (10% w/w), and fill with water to 100 mL. Filter.

**Sample preparation A:** Dilute the test sample by adding *Sample buffer A* to achieve an absorbance of about 0.4–0.6. [Note—Gravimetric dilutions can be used and sometimes improve accuracy.] Prepare at least three replicates per test sample.

**Analysis**

**Samples:** ***Sample buffer A*** and ***Sample preparation A***

**Determination of the protein concentration in native buffer:** Using a suitable spectrophotometer (see ⟨857⟩), measure the absorbance of *Sample preparation A* in 1-cm cuvettes at 280 nm against *Sample buffer A* and subtract the absorbance value at 330 nm to obtain $A_{corrected}$.

Calculate the protein concentration ($c$) of the test sample:

$$c = A_{corrected} \times DF \times MW/(\varepsilon_{280\ nm\text{-}native2} \times 1\ cm)$$

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M7147_03_01
@2024 USPC

$A_{corrected}$ = absorbance at 280 nm minus the absorbance at 330 nm
$DF$ = dilution factor
$MW$ = calculated molecular weight of the protein
$\varepsilon_{280\ nm\text{-}native2}$ = extinction coefficient of the test sample at 280 nm

where the extinction coefficient $\varepsilon_{280\ nm\text{-}native2}$ is calculated as:

$$\varepsilon_{280\ nm\text{-}native2} = (n_{Trp} \times 5500 + n_{Tyr} \times 1490 + n_{Cys} \times 125)\ M^{-1} \times cm^{-1}$$

$n_{Trp}$ = number of tryptophans
$n_{Tyr}$ = number of tyrosines
$n_{Cys}$ = number of cystines

**System suitability**

The test sample UV spectra must show a maximum between 270 and 285 nm and must show a minimum between 243 and 257 nm. The measured absorbance at 280 nm must be NLT 0.4 and NMT 0.6. The RSD of the calculated concentration of all replicates must be NMT 3.0%.

- **Method II. Bicinchoninic Acid Method**

**BCA reagent solution:**[1] Prepare a solution of 10 g/L of bicinchoninic acid (BCA), 20 g/L of sodium carbonate monohydrate, 1.6 g/L of sodium tartrate, 4 g/L of sodium hydroxide, and 9.5 g/L of sodium bicarbonate in water to a pH of 11.25.

**Copper sulfate reagent solution:** Prepare a solution of 40 g/L of cupric sulfate pentahydrate in water.

**BCA working reagent solution:** Mix 50 volumes of *BCA reagent solution* with 1 volume of *Copper sulfate reagent solution*. Mix until the green solution is clear.

**Sample dilution buffer:** Water or another suitable, non-interfering buffer

**Standard solutions:** Ideally, use the USP Reference Standard for the protein under test. If the protein of interest is unknown, is a mixture, or is a specific USP Reference Standard that is unavailable, use USP BSA for Protein Quantitation RS. Dilute portions of this solution with the *Sample dilution buffer* to obtain NLT five evenly spaced *Standard solutions* in triplicate. The selected *Standard solution* concentrations should result in a linear curve, typically in the range of 25–1000 µg/mL of protein.

**Suitability standard solution:** Prepare an independent dilution of the same protein used to make the *Standard solutions* above using *Sample dilution buffer* to obtain a *Suitability standard solution* with a concentration near the midpoint of the standard curve. Prepare the *Suitability standard solution* in triplicate.

**Sample solution:** Prepare a *Sample solution* with an expected concentration within the standard curve by diluting with the *Sample dilution buffer*. Prepare triplicate samples.

**Analysis**

**Samples:** *Sample dilution buffer*, *Standard solutions*, *Suitability standard solution*, and *Sample solution*

Accurately transfer 100 µL of *Sample dilution buffer*, *Standard solutions*, *Suitability standard solution*, and *Sample solution* to individual test tubes. [Note—96-well, plate-based, and automated methods can also be used with suitable volume adjustments to the procedure below.] Add 2.0 mL of *BCA working reagent solution* to each tube, and mix well.

Cover and incubate the solutions at 37 ± 2° for 30 ± 1 min, then allow the samples to cool to room temperature for NLT 5 min and NMT 60 min. Determine the absorbances of the solutions at 562 nm with a suitable spectrophotometer (see ⟨857⟩). Autozero the instrument with the *Sample dilution buffer* sample.

Measure the absorbance of all *Sample dilution buffer*, *Standard solutions*, *Suitability standard solution*, and *Sample solution* samples within 10 min.

**Calculations:** Plot the absorbances of the *Standard solutions* versus the protein concentrations of the *Standard solutions*, and prepare a standard curve using the linear regression method. Use this standard curve and the absorbance of the *Sample solution* to determine the concentration of protein in each *Suitability standard solution* and *Sample solution*.

**System suitability**

**Samples:** *Standard solutions* and *Suitability standard solution*

**Suitability requirements**

**Linearity:** The coefficient of determination ($r^2$) for a linear fit of all *Standard solutions* is NLT 0.99.

**Relative standard deviation:** NMT 5% for triplicate results of the *Suitability standard solution*

**Accuracy:** The calculated concentration of the *Suitability standard solution* must be within 90%–110% of the theoretical concentration.

**Acceptance criteria**

**Relative standard deviation:** NMT 5% for triplicate *Sample solution* results

- **Method III. Bradford Method**

**Sample dilution buffer:** Water or another suitable, non-interfering buffer

**Standard solutions:** Use the USP Reference Standard for the protein under test or USP BSA for Protein Quantitation RS if the protein of interest is unknown, is a mixture, or is a specific USP Reference Standard that is unavailable. Dilute portions of this solution with the *Sample dilution buffer* to obtain NLT five evenly spaced *Standard solutions* in triplicate. Two standard curve ranges are provided for use: either 0.1–1.0 mg/mL of protein (see *Analysis* procedure *A*, below) or 5–25 µg/mL of protein (see *Analysis* procedure *B*, below).

**Suitability standard solution:** Dilute the USP Reference Standard for the protein under test or USP BSA for Protein Quantitation RS with *Sample dilution buffer* to obtain a *Suitability standard solution* having a concentration near the midpoint of the standard curve. Prepare the *Suitability standard solution* in triplicate.

[1] Suitable BCA reagents are available from Thermo Scientific catalog #23225 or equivalent.

@2024 USPC

**Sample solution:** Prepare a *Sample solution* with an expected concentration within one of the two concentration ranges in options *A* or *B* below by diluting with the *Sample dilution buffer*. Prepare triplicate samples.

**Coomassie reagent solution:** Dissolve 100 mg of brilliant blue G[2] in 50 mL of alcohol. Add 100 mL of phosphoric acid, dilute with water to 1 L, and mix. Pass the solution through filter paper (Whatman No. 1 or equivalent), and store the filtered reagent in an amber bottle at room temperature. [NOTE—Slow precipitation of the dye will occur during storage of the reagent. Filter the reagent before use.]

**Analysis:** Select one of the two concentration ranges listed below that is suitable for the expected concentrations of the *Sample solutions*.

**A. Protein concentration range:** 0.1–1.0 mg/mL

**Samples:** *Sample dilution buffer*, *Standard solutions*, and *Sample solution*

Add 1 mL of the *Coomassie reagent solution* to 20 µL of each *Sample dilution buffer*, *Standard solution*, and *Sample solution* sample. Mix by inversion, avoiding foaming. Incubate 10–30 min. By using a suitable spectrophotometer (see ⟨857⟩) [NOTE—Do not use quartz (silica) cuvettes.] , use the *Sample dilution buffer* to set the instrument to zero at 595 nm. Autozero the instrument with the *Sample dilution buffer* sample.

Measure the absorbance of all *Sample dilution buffer*, *Standard solutions*, *Suitability standard solution*, and *Sample solution* samples within 60 min.

**B. Protein concentration range:** 5–25 µg/mL

**Samples:** *Sample dilution buffer*, *Standard solutions*, and *Sample solution*

Add 0.5 mL of the *Coomassie reagent solution* to 0.5 mL each of *Sample dilution buffer*, *Standard solution*, and *Sample solution* sample. Mix by inversion, avoiding foaming. Incubate 10–30 min. By using a suitable spectrophotometer (see ⟨857⟩) [NOTE—Do not use quartz (silica) cuvettes.] , use the *Sample dilution buffer* to set the instrument to zero at 595 nm. Autozero the instrument with the *Sample dilution buffer* sample. Measure the absorbance of all *Sample dilution buffer*, *Standard solutions*, *Suitability standard solution*, and *Sample solution* samples within 60 min.

**Calculations:** [NOTE—The relationship of absorbance to protein concentration is nonlinear; however, if the standard curve concentration range is sufficiently small, it will approach linearity.] Plot the absorbances of the *Standard solutions* versus the protein concentrations, and determine the standard curve best fitting the plotted points. From this standard curve and the absorbance of the *Sample solution*, determine the concentration of protein in the *Sample solution*.

**System suitability**

**Samples:** *Standard solutions* and *Suitability standard solutions*

**Suitability requirements**

**Linearity:** $r^2$ for a fit of all *Standard solutions* is NLT 0.99.

**Relative standard deviation:** NMT 15% for triplicate results of the *Suitability standard solution*

**Recovery:** The calculated concentration of the *Suitability standard solution* must be within 90%–110% of the theoretical concentration.

**Acceptance criteria:** %CV of triplicates of the *Sample solution* is NMT 15%.

• **METHOD IV. LOWRY METHOD**

**SDS solution:** If required, prepare a solution of 50 g/L of sodium dodecyl sulfate (SDS).

**Lowry reagent A:** Prepare a solution of 10 g/L of sodium hydroxide in water, and prepare a solution of 50 g/L of sodium carbonate anhydrous in water. Mix equal volumes (2 volumes and 2 volumes) of each solution, and dilute with water or *SDS solution*, if required, to 5 volumes. [NOTE—SDS may be added to *Lowry reagent A* when the test protein contains detergents or lipids or is poorly soluble after treatment for interfering substances.]

**Lowry reagent B:** Prepare a fresh solution of 29.8 g/L of disodium tartrate dihydrate in water. Prepare a solution of 12.5 g/L of cupric sulfate pentahydrate in water. Mix equal volumes (2 volumes and 2 volumes) of each solution, and dilute with water to 5 volumes.

**Lowry reagent C:** Mix 50 volumes of *Lowry reagent A* with 1 volume of *Lowry reagent B*. [NOTE—Prepare fresh and protect from light.]

**Sample dilution buffer:** Purified water or other non-interfering buffer

**Standard solutions:** Use the USP Reference Standard for the protein under test or USP BSA for Protein Quantitation RS if the protein of interest is unknown, is a mixture, or is a specific USP Reference Standard that is unavailable. Dilute portions of this solution with the *Sample dilution buffer* to obtain NLT five evenly spaced *Standard solutions*. The standard concentrations should be selected to result in a linear curve, typically in the range of 10–200 µg/mL of protein.

**Suitability standard solution:** Dilute the USP Reference Standard for the protein under test or USP BSA for Protein Quantitation RS with *Sample dilution buffer* to obtain a *Suitability standard solution* having a concentration near the midpoint of the standard curve. Prepare and analyze the *Suitability standard solution* in triplicate.

**Sample solution:** Prepare a *Sample solution* with an expected concentration within the standard curve by diluting with the *Sample dilution buffer*. Prepare and analyze samples in triplicate.

**Diluted Folin–Ciocalteu's phenol reagent:** Dilute Folin–Ciocalteu's phenol reagent with water (1:1). Alternative dilutions may be used provided that the pH of the samples (i.e., *Standard solutions* and *Sample solutions* after addition of *Lowry reagent C* and the *Diluted Folin–Ciocalteu's phenol reagent*) is 10.0–10.6.

**Analysis**

**Samples:** *Sample dilution buffer*, *Standard solutions*, *Suitability standard solution*, and *Sample solution*

Accurately transfer 1.0 mL of *Sample dilution buffer*, *Standard solutions*, *Suitability standard solution*, and *Sample solution* samples to individual test tubes. To each test tube add 5.0 mL of *Lowry reagent C*. Allow to stand at room temperature for 10 min. Add 0.5 mL of *Diluted Folin–Ciocalteu's phenol reagent* to each test tube, mix immediately, and incubate at room temperature for 30 min. Determine the absorbance of each solution at 750 nm with a suitable spectrophotometer (see ⟨857⟩). Autozero the instrument with the *Sample dilution buffer*.

[2] Suitable brilliant blue G dye is available from Sigma–Aldrich, catalog #B0770.

**Linearity:** $r^2$ for a linear fit of all standards is NLT 0.995.

**Relative standard deviation:** NMT 5% for triplicate results of the *Suitability standard solution*

**Recovery:** The calculated concentration of the *Suitability standard solution* must be within 90%–110% of the theoretical concentration.

**Acceptance criteria**

**Relative standard deviation:** NMT 5% for triplicate sample results

• **Method V. Amino Acid Analysis**

Separation and determination of hydrolyzed amino acids by ion-exchange chromatography, followed by postcolumn ninhydrin derivatization, is described for protein samples containing a protein of known molecular weight and amino acid composition. [Note—For additional information, see *Biotechnology-Derived Articles—Amino Acid Analysis* ⟨1052⟩, which may be a helpful but not mandatory resource.]

**Hydrolysis solution:** 6 N hydrochloric acid

**Sample hydrolysate preparations:** Prepare a protein sample such that the content of amino acids is within the established linear working range of the procedure. [Note—Glassware used for hydrolysis must be clean.] Place suitable volumes of the sample and *Hydrolysis solution* in a hydrolysis tube. [Note—Common volumes range from 100 to 500 µL for the sample and from 1 to 2 mL for the *Hydrolysis solution* such that complete protein digestion is demonstrated within the hydrolysis incubation time.] Cool the mixture until solidification, and evacuate until the pressure is <0.2 bar. Flame-seal the hydrolysis tube in vacuum by melting the neck of the tube. [Note—Alternative commercially available hydrolysis vials also can be used.] Hydrolyze at 110° for 22 h. Allow the tube to cool, and remove the solvent by centrifugal vacuum concentrator.

**Chromatography**

**Solution A:** Sodium citrate buffer (0.2 N in sodium), containing 2.0% trisodium citrate dihydrate, 0.1% phenol, 0.2% thiodiglycol, and 2.0% propan-2-ol. Adjust with concentrated hydrochloric acid to a pH of 3.2.

**Solution B:** Sodium citrate buffer (0.2 N in sodium), containing 2.0% trisodium citrate dihydrate and 0.1% phenol. Adjust with concentrated hydrochloric acid to a pH of 4.25.

**Solution C:** Sodium citrate buffer (1.2 N in sodium), containing 2.0% trisodium citrate dihydrate, 0.1% phenol, and 5.8% sodium chloride. Adjust with concentrated hydrochloric acid to a pH of 6.45.

**Solution D:** 0.4 M sodium hydroxide containing 0.1% ethylenediaminetetraacetic acid

**Mobile phase:** See *Table 1*. Equilibrate the system before each run.

**Table 1**

| Time (min) | Solution (100%) | Column Temperature | Flow, Mobile Phase (mL/h) | Flow, Postcolumn Reagent (mL/h) |
|---|---|---|---|---|
| 0 | A | 49° | 35 | 25 |

**Loading buffer:** Sodium citrate buffer (0.2 N in sodium), containing 2.0% trisodium citrate dihydrate, 0.1% phenol, and 2.0% thiodiglycol. Adjust with concentrated hydrochloric acid to a pH of 2.2.

**Postcolumn reagent**

**Solution 1:** Solution containing 7.6% acetic acid, 47.7% ethylene glycol, 28.7% water, and 16.0% potassium acetate

**Solution 2:** Solution containing 9% methanol, 8% ninhydrin, 46.4% diethylene glycolmethyl ether, 36% ethylene glycol, and 0.6% hydrindantin. Prepare *Postcolumn reagent* by mixing 1.75 L of *Solution 1* and 0.25 L of *Solution 2*. Use nitrogen sparging during preparation and mixing. Keep the solution under nitrogen pressure.

**Standard solution:** Prepare a solution having known equimolar amounts of L-alanine, L-arginine, L-aspartic acid, L-glutamic acid, glycine, L-histidine, L-isoleucine, L-leucine, L-lysine, L-methionine, L-phenylalanine, L-proline, L-serine, L-threonine, L-tyrosine, and L-valine with half the equimolar amount of L-cystine. [NOTE—Suitable concentrations are 250 and 125 nmol/mL, respectively.]

**Sample solution:** Reconstitute the *Sample hydrolysate preparations* in a suitable volume of *Loading buffer*.

**Blank:** *Hydrolysis solution* that has been taken through analytical steps including hydrolysis

**Chromatographic system**

(See *Chromatography* ⟨621⟩*, System Suitability*.)

**Mode:** LC

**Detector:** 440 and 570 nm

**Columns**

**Prewash:** 4.6-mm × 10-cm; 20-µm sodium form, packing L58

**Analytical:** 4.6-mm × 20-cm; 8-µm sodium form, packing L58

**Injection volume:** 40 µL, at 1 min with baseline reset

**Postcolumn reaction:** As the amino acids are eluted from the column, *Postcolumn reagent* is added at a rate of 25 mL/h. After mixing, the column effluent and the *Postcolumn reagent* are passed through a reaction coil of approximately 10-m × 0.3-mm PTFE tubing at a temperature of approximately 135°, where a purple color is developed.

**Reaction coil temperature:** 135°

**System suitability**

**Sample:** *Standard solution*

**Suitability requirements:** All 17 amino acid peaks must be visible in the *Standard solution*.

**Resolution:** NLT 1.2 between the pairs of L-threonine and L-serine, L-cystine and L-valine, and L-isoleucine and L-leucine

**Tailing factor:** 0.8–1.5 for the peak of L-aspartic acid

**Relative standard deviation:** NMT 2.0% determined from the L-aspartic acid peak

**Analysis**

**Samples:** *Blank*, *Standard solution*, and *Sample solution*

Record and measure the responses for each amino acid peak in the *Standard solution* and *Sample solution*. Use the responses obtained from the *Standard solution* to calculate the content of each amino acid in the sample. Analyze the *Blank* to confirm purity of the reagent and diluent.

**Calculations:** Use well-recovered amino acids to quantify the protein. [NOTE—For additional information, see *Biotechnology-Derived Articles—Amino Acid Analysis* ⟨1052⟩*, Protein Hydrolysis*, which may be a helpful but not mandatory resource.] Divide the quantity, in nmol, of each of the well-recovered amino acids by the expected number of residues for that amino acid to obtain the protein content based on each well-recovered amino acid. Average the protein content results calculated. Discard protein content values that deviate >5% from the mean. Recalculate the mean protein content from the remaining values to obtain the protein content of the sample.

# ▲⟨509⟩ RESIDUAL DNA TESTING

## INTRODUCTION

The following method is suitable for measurement of residual host cell DNA in recombinant therapeutic products produced in either *Escherichia coli* (*E. coli*) or Chinese hamster ovary (CHO) cell lines. Also provided is an extraction procedure that is suitable to be used prior to a quantitative polymerase chain reaction (qPCR)-based method for the measurement of residual host cell DNA. For discussion of the principles and best practices for this type of testing, see *Nucleic Acid-Based Techniques—Approaches for Detecting Trace Nucleic Acids (Residual DNA Testing)* ⟨1130⟩, which may be a helpful resource.

## PROCEDURE

- **Sample Preparation**

There are several procedures for isolating DNA that may be appropriate for biopharmaceutical sample testing. One such procedure is described in detail below and validated for starting DNA concentrations ranging from 0.01 to 50 pg/µL.

**Resuspension solution:** Dissolve tris(hydroxymethyl)aminomethane hydrochloride (Tris-HCl) and ethylenediaminetetraacetic acid (EDTA) to obtain a solution of 10 mM and 1.0 mM, respectively. Add hydrochloric acid or sodium hydroxide to adjust to a pH of 8.0.

**DNA standard stock solution:** Dilute either the USP CHO Genomic DNA RS or the USP *E. coli* Genomic DNA RS, as appropriate, to a concentration of 1 µg/mL in *Resuspension solution*.

**Sample solutions:** Samples for testing may require dilution or reconstitution to: 1) overcome matrix interference affecting the DNA recovery, 2) yield an appropriate starting volume, or 3) bring the analyte concentration within the quantitative range of the qPCR method. *Sample solutions* may be diluted in water or in *Resuspension solution* if necessary. For drug substance samples, *Sample solutions* should contain sufficient starting material to allow determination of the residual DNA content, if present at the specification limit.

**Positive control solution:** Prepare by spiking *DNA standard stock solution* to *Sample solutions* at a concentration appropriate for the assay (specification, or otherwise justified).

**Negative control solution:** Water or *Resuspension solution* is used in place of *Sample solutions* in the extraction procedures and will be extracted with any samples (if extraction is necessary). The *Negative control solution* is tested using the qPCR-based method to determine the DNA content contributed by the background and to demonstrate that there is no potential cross-contamination during the assay.

**70% Ethanol:** Prepare by adding water to ethanol to give a final concentration of 70% (v/v).

**Proteinase K solution:** Dissolve Tris-HCl, EDTA, and sodium dodecyl sulfate (SDS) to obtain solutions of 100 mM (pH 8.0), 5 mM, and 100 mg/mL, respectively. Add proteinase K[1] to this solution to a final concentration of 10 mg/mL.

**Sodium iodide solution:** 6 M sodium iodide, 15 mM EDTA, 0.25% sodium sulfite, 0.5% sodium *N*-lauroyl sarcosinate, 25 mM Tris-HCl pH 8.0, and 35 µg/mL linear acrylamide. For 100 mL (scale as appropriate), while mixing with a stir bar on a magnetic plate, add in the following order: 50 mL of nuclease-free water, 0.25 g of sodium sulfite, 3.0 mL of 0.5 M EDTA solution, and 2.5 mL of 1 M Tris-HCl pH 8.0; then slowly add 89.93 g of sodium iodide. Add nuclease-free water to a final volume of 100 mL. Filter the solution using a 0.2-µm nylon membrane. [Note—This stock solution can be stored in the dark at 4° for up to 1 year.] On the day of use, add linear acrylamide and sodium *N*-lauroyl sarcosinate to final concentrations of 35 µg/mL and 0.5% (w/v), respectively. [Note—Addition of sodium *N*-lauroyl sarcosinate to sodium iodide solution may result in turbidity. If so, warming to 50–55° for 2–3 min is helpful before using for extraction.]

**Extraction:** Add 50 µL of *Proteinase K solution* to 450 µL of triplicate samples each of *Sample solutions* and *Positive control solution*, and at least one sample of *Negative control solution*, in a 2.0-mL centrifuge tube. Mix and incubate at 60 ± 2° for 1–24 h. Add 500 µL of *Sodium iodide solution* to each tube. Mix and incubate at 40° for 15 min. Add 900 µL of 100% ethanol, mix well, and incubate at room temperature for 15 min. Centrifuge at 10,000 × g for 15 min to pellet the DNA. [Note—Centrifugation at 2°–8° may be helpful to improve DNA recovery.] Remove and discard the supernatant. Wash the pellet by adding 1 mL of 70% ethanol containing 3 µg/mL linear acrylamide, centrifuge again, and discard the supernatant. Air dry the pellet for 5–10 min until no visible liquid is observed. Resuspend the pellet and record the volume of water or *Resuspension solution* used, which may be needed when reporting the final results in *Calculations.*

- **qPCR Analysis**

**2X Master mix:** A suitable buffer containing magnesium chloride, deoxyadenosine triphosphate, deoxyguanosine triphosphate, deoxycytidine triphosphate, deoxyuridine triphosphate, deoxythymidine triphosphate, and highly purified *Thermus aquaticus* DNA polymerase.[2] Mix well immediately before use.

**DNA stock primers and probes:** According to the DNA of the species tested, prepare individual 10-µM solutions of the following primer pairs and probe, using DNAse-free water (see *Table 1*).

**Table 1**

| | | |
|---|---|---|
| *E. coli* | Forward primer | 5′-CCTTACGACCAGGGCTACACA-3′ |
| | Reverse primer | 5′-CTCGCGAGGTCGCTTCTC-3′ |
| | Probe[a] | 5′-CGTGCTACAATGGCGCATACA-3′ |

[1] Sigma catalog #P2308 or a suitable alternative.
[2] ThermoFisher catalog #4440038 or a suitable alternative.

https://pharmacopeia.cn/v-download/

**Table 1** *(continued)*

| | | |
|---|---|---|
| CHO | Forward primer | 5′-CCTGAGTTCAATTCCCAGCAA-3′ |
| | Reverse primer | 5′-ACATTCTGCTTCCATGTATATCTGCA-3′ |
| | Probe[a] | 5′-TGGCTCACAACCATCCGTTATGAGACCT-3′ |

[a] The probe can be 5′-labeled with 6-carboxyfluorescein and 3′-labeled with 6-carboxytetramethylrhodamine or a suitable alternative.

**DNA probe solution:** Dilute *DNA stock probe* to 2.5 µM with DNAse-free water.

**Standard solutions:** Dilute the *DNA standard stock solution* to obtain five or more suitable standards within the concentration range of 0.001–100 pg/µL.

**Analysis**

**Samples:** *Sample solutions*, *Positive control solution*, *Negative control solution*, and *Standard solutions*

[NOTE—If samples are extracted, then extracted *Sample solutions* and extracted *Control solutions* will be used.]

Transfer 25 µL of the *2X Master mix* to each well of a 96-well qPCR plate. Add 5 µL each of the *DNA stock forward primer*, the *DNA stock reverse primer*, and the *DNA probe solution* of the appropriate species to each well. Add 10 µL of either (extracted) *Sample solutions*, *Standard solutions*, (extracted) *Negative control solution*, or (extracted) *Positive control solution* to their respective wells. [NOTE—The qPCR reaction volume may be scaled as appropriate to accommodate different instruments.] Mix, seal the plate tightly, and centrifuge for 1 min at 1000 × g. Place the plate in a suitable qPCR thermal cycler. Incubate for 2 min at 50°, then for 10 min at 95°, followed by 40 cycles, with each cycle consisting of 95° for 15 s and 60° for 1 min. [NOTE—Some instruments and reagents require a preincubation step. Carefully follow specific instrument/reagent recommendations.] Monitor the signal of the labeled probe using a suitable fluorescent detector. Determine the threshold value using the instrument-specific recommendations. Record the cycle thresholds ($C_t$) for each sample.

**Calculations**

Plot the log quantity of DNA of the *Standard solutions* versus the $C_t$.

Calculate the slope and the intercept.

Using these values and the following equation, calculate the quantity of DNA in each well:

$$\text{Result} = 10^{\left(\frac{C_t - b}{m}\right)}$$

$C_t$ = cycle threshold of the *Sample solutions*
$b$ = intercept of the line for the *Standard solutions*
$m$ = slope of the line for the *Standard solutions*

Calculate the quantity of DNA in each of the *Sample solutions*. Correct for any dilution or concentration of the sample.

**System suitability**

**Samples:** *Negative control solution* and *Standard solutions*

**Suitability requirements**

**Negative control solution:** The $C_t$ corresponding to the *Negative control solution*, if any, is NLT the $C_t$ of all of the lowest concentrations of the *Standard solutions*.

**Sensitivity:** The $C_t$ corresponding to the lowest concentration of the *Standard solutions* is NMT 39.

**Linearity:** The regression coefficient associated with the *Standard solutions* is NLT 0.98. The slope is between –3.1 and –3.8.

**Acceptance criteria**

Any measurable sample must fall within the standard curve.

**Accuracy:** The mean spike recovery of three replicates of *Positive control solution* is between 50% and 150%. [NOTE—If needed due to the extraction procedure, correct for the sample dilution.]

**Relative standard deviation:** NMT 30% for three replicates of the *Sample solutions*; NMT 30% for three replicates of *Positive control solution*

The limit of residual DNA is defined in the product monograph.

# ⟨511⟩ SINGLE-STEROID ASSAY

In the following procedure, the steroid to be assayed is separated from related foreign steroids and excipients by thin-layer chromatography and determined following recovery from the chromatogram.

## PREPARATION OF THE PLATE

Prepare a slurry from 30 g of chromatographic silica gel with a suitable fluorescing substance by the gradual addition, with mixing, of about 65 mL of a mixture of water and alcohol (5:2). Transfer the slurry to a clean, 20- × 20-cm plate, spread to make a uniform layer 250 µm thick, and allow to dry at room temperature for 15 minutes. Heat the plate at 105° for 1 hour, and store in a desiccator.

## SOLVENT A

Mix methylene chloride with methanol (180:16).

## SOLVENT B

Mix chloroform with acetone (4:1).

## STANDARD PREPARATION

Dissolve in a mixture of equal volumes of chloroform and alcohol a suitable quantity of the USP Reference Standard specified in the individual monograph, previously dried as directed (see *USP Reference Standards* ⟨11⟩) and accurately weighed, to obtain a solution having a known concentration of about 2 mg per mL.

## ASSAY PREPARATION

Prepare as directed in the individual monograph.

## PROCEDURE

Divide the area of the chromatographic plate into three equal sections, the left and right sections to be used for the *Assay Preparation* and the *Standard Preparation,* respectively, and the center section for the blank. Apply 200 µL each of the *Assay Preparation* and the *Standard Preparation* as streaks 2.5 cm from the bottom of the appropriate section of the plate. Dry the solution as it is being applied, with the aid of a stream of air. Using the *Solvent* specified in the individual monograph, develop the chromatogram in a suitable chamber, previously equilibrated and lined with absorbent paper, until the solvent front has moved 15 cm above the initial streaks.

Remove the plate, evaporate the solvent, and locate the principal band occupied by the *Standard Preparation* by viewing under UV light. Mark this band, as well as corresponding bands in the *Assay Preparation* and blank sections of the plate. Remove the silica gel from each band separately, either by scraping onto glazed weighing papers or by using a suitable vacuum collecting device, and transfer it to a glass-stoppered, 50-mL centrifuge tube. To each tube add 25.0 mL of alcohol, and shake for not less than 2 minutes. Centrifuge the tubes for 5 minutes, pipet 20 mL of the supernatant from each tube into a glass-stoppered, 50-mL conical flask, add 2.0 mL of a solution prepared by dissolving 50 mg of blue tetrazolium in 10 mL of methanol, and mix. Proceed as directed for *Procedure* under *Assay for Steroids* ⟨351⟩, beginning with "Then to each flask."

# ⟨525⟩ SULFUR DIOXIDE

The following methods are provided for the determination of sulfur dioxide in pharmaceutical excipients.

## METHOD I

### Procedure

Mix 20 g of the test specimen, accurately weighed, with 200 mL of an appropriate solvent as indicated in each individual monograph, and stir until a smooth suspension is obtained. Allow the test specimen mixture to remain undisturbed until most of the test specimen has settled, and filter the aqueous portion through paper (Whatman No. 1 or equivalent). To 100 mL of the clear filtrate add an additional solvent as indicated in each individual monograph, add 3 mL of starch TS, and titrate with 0.01 N iodine solution VS to the first permanent blue or purple color. Each 1.0 mL of 0.01 N iodine solution VS consumed corresponds to 0.003% of sulfur dioxide found.

## METHOD II

### Procedure

Transfer about 50 to 100 g of the substance to be tested, accurately weighed, to a 250-mL conical flask, add 100 to 150 mL of water, and mix. Cool to between 5° and 10°. While stirring with a magnetic stirrer, add 10 mL of cold 1.5 N sodium hydroxide (at a temperature between 5° and 10°). Stir for an additional 20 seconds, and add 10 mL of starch indicator solution, prepared as follows: mix 10 g of soluble starch with 50 mL of cold water, transfer to 1000 mL of boiling water, stir until completely dissolved, cool, and add 1 g of salicylic acid preservative.

[NOTE—Discard the solution after 1 month.]

Add 10 mL of 2.0 N sulfuric acid (at a temperature between 5° and 10°), and titrate immediately with 0.005 N iodine VS until a light blue color persists for 1 minute (see *Titrimetry* ⟨541⟩). Perform a blank determination, using 200 mL of water treated similarly to the solution under test, and make any necessary correction. Each mL of 0.005 N iodine is equivalent to 0.16 mg of $SO_2$.

## METHOD III

### Procedure

Dissolve 20.0 g of the test specimen in 150 mL of hot water in a flask having a round bottom and a long neck, add 5 mL of phosphoric acid and 1 g of sodium bicarbonate, and at once connect the flask to a condenser.

[NOTE—Excessive foaming can be alleviated by the addition of a few drops of a suitable antifoaming agent.]

Distill 50 mL, receiving the distillate under the surface of 50 mL of 0.1 N iodine. Acidify the distillate with a few drops of hydrochloric acid, add 2 mL of barium chloride TS, and heat on a steam bath until the liquid is nearly colorless. The precipitate of barium sulfate, if any, when filtered, washed, and ignited, weighs not more than 3 mg, corresponding to not more than 0.004% of sulfur dioxide, correction being made for any sulfate that may be present in 50 mL of the 0.1 N iodine.

## METHOD IV

In this test, sulfur dioxide is released from the test specimen in a boiling acid medium and is removed by a stream of carbon dioxide. The separated gas is collected in a dilute hydrogen peroxide solution, in which the sulfur dioxide is oxidized to sulfuric acid and titrated with standard alkali, using a pH meter to control the pH value and titration. This test is performed under conditions such that the requirements specified in the system suitability test are met.

### Special Reagents

#### CARBON DIOXIDE

Use carbon dioxide with a flow regulator that will maintain a flow of 100 ± 10 mL per minute.

#### HYDROGEN PEROXIDE SOLUTION

Dilute 30% hydrogen peroxide with water to obtain a 3% solution. Neutralize the 3% hydrogen peroxide solution with 0.01 N sodium hydroxide to a pH of 4.1 determined potentiometrically.

#### POTASSIUM METABISULFITE SOLUTION

Transfer 0.87 g of potassium metabisulfite ($K_2S_2O_5$) and 0.2 g of edetate disodium to a 1000-mL volumetric flask. Dilute with water to volume before mixing. [NOTE—Edetate disodium is used to protect sulfite ion from oxidation.]

## Apparatus

A suitable apparatus for sulfur dioxide determination is shown in the accompanying diagram (*Figure 1*).

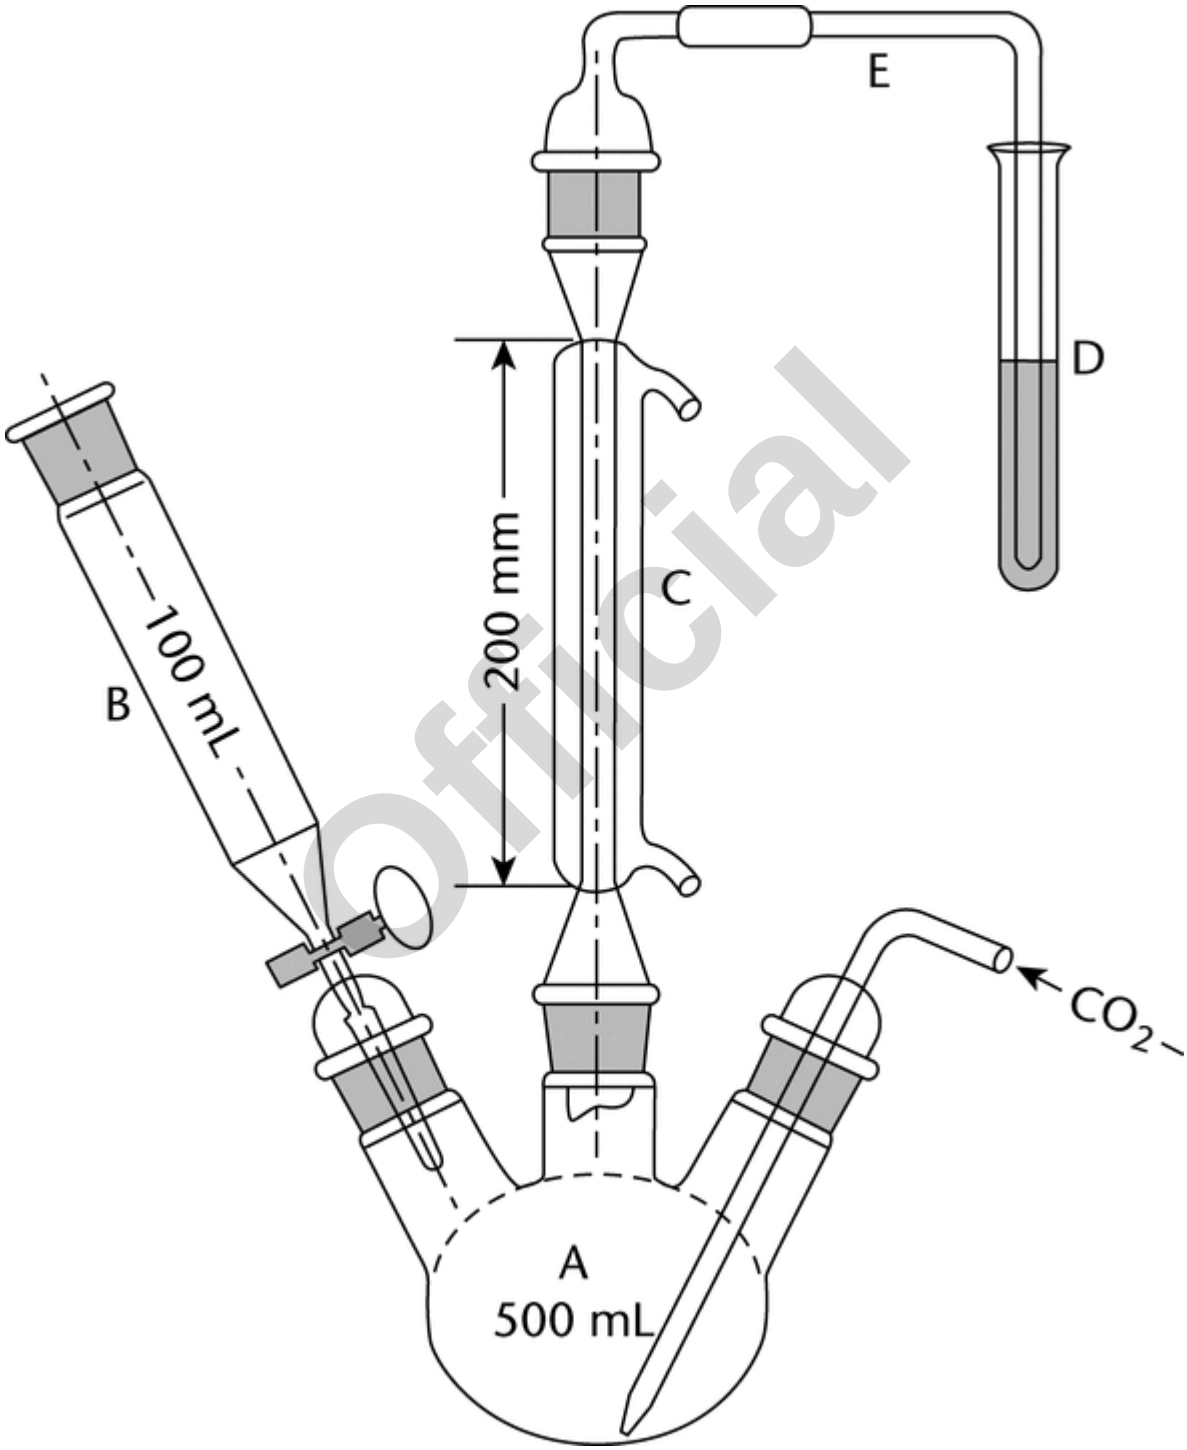

Figure 1. Apparatus for Method IV.

The apparatus consists of a 500-mL three-neck, round-bottom boiling flask, *A;* a separatory funnel, *B,* having a capacity of 100 mL or greater; a gas inlet tube of sufficient length to permit introduction of the carbon dioxide within 2.5 cm of the bottom of the boiling flask; a reflux condenser, *C,* having a jacket length of 200 mm; and a delivery tube, *E,* connecting the upper end of the reflux condenser to the bottom of a receiving test tube, *D.* Apply a thin film of stopcock grease to the sealing surfaces of all joints except the joint between the separatory funnel and the boiling flask, and clamp the joints to ensure tightness.

## System Suitability Test

TEST A

Using the *Potassium Metabisulfite Solution* as the standard, proceed as directed for *Procedure*, except replace the 25.0 g of test substance with 20 mL of *Potassium Metabisulfite Solution*. Calculate the content, in µg per mL, of sulfur dioxide in the *Potassium Metabisulfite Solution* taken by the formula:

$$1000(32.03)VN/V_P$$

in which the factor 1000 converts mg to µg; 32.03 is the milliequivalent weight of sulfur dioxide; V is the volume, in mL, of titrant consumed; N is the normality of the titrant; and $V_P$ is the volume, in mL, of the *Potassium Metabisulfite Solution* taken for the test.

TEST B

In a 100-mL conical flask, add 20 mL of 0.02 N iodine solution and 5 mL of 2 N hydrochloric acid. Add 1 mL of starch TS, and titrate with the *Potassium Metabisulfite Solution* until the first discoloration is observed. Calculate the content, in µg per mL, of sulfur dioxide in the *Potassium Metabisulfite Solution* by the formula:

$$1000(32.03)V_IN_I/V_P$$

in which 1000 and 32.03 are defined above; $V_I$ is the volume, in mL, of the iodine solution used in the test; $N_I$ is the normality of the iodine solution; and $V_P$ is the volume, in mL, of the *Potassium Metabisulfite Solution* consumed.

The difference between the sulfur dioxide contents obtained from *Test A* and *Test B* is not more than 5% of their mean value. *Test B* shall be performed within 15 minutes after completion of *Test A*. [NOTE—This avoids a potential variation of the sulfur dioxide content in the *Potassium Metabisulfite Solution* when stored at room temperature.]

## Procedure

Add 150 mL of water to the boiling flask (*A*). Close the stopcock of the separatory funnel, and begin the flow of carbon dioxide at a rate of 100 ± 5 mL per minute through the apparatus. Start the condenser coolant flow. Place 10 mL of *Hydrogen Peroxide Solution* in the receiving test tube (*D*). After 15 minutes, without interrupting the flow of carbon dioxide, remove the separatory funnel (*B*) from the boiling flask, and transfer 25.0 g of the test specimen to the boiling flask with the aid of 100 mL of water. Apply stopcock grease to the outer joint of the separatory funnel, and replace the separatory funnel in the boiling flask. Close the stopcock of the separatory funnel, and add 80 mL of 2 N hydrochloric acid to the separatory funnel. Open the stopcock of the separatory funnel to permit the hydrochloric acid solution to flow into the boiling flask, guarding against escape of sulfur dioxide into the separatory funnel by closing the stopcock before the last few mL of hydrochloric acid drain out. Boil the mixture for 1 hour. Open the stopcock of the funnel, stop the flow of carbon dioxide, discontinue heating the flask, and turn off the cooling water in the condenser. Remove the receiving test tube, and transfer its contents to a 200-mL wide-necked, conical flask. Rinse the receiving test tube with a small portion of water, add the rinsing to the 200-mL conical flask, and mix. Heat on a water bath for 15 minutes, and allow to cool. Add 0.1 mL of bromophenol blue TS, and titrate the contents with 0.1 N sodium hydroxide VS until the color changes from yellow to violet-blue, with the color change lasting for at least 20 seconds. Perform a blank determination and make any necessary correction (see *Titrimetry* ⟨541⟩). Calculate the content, in µg per g, of sulfur dioxide in the test specimen taken by the formula:

$$1000(32.03)VN/W$$

in which the factor 1000 converts mg to µg; 32.03 is the milliequivalent weight of sulfur dioxide; V is the volume, in mL, of titrant consumed; N is the normality of the titrant; and W is the weight, in g, of the test specimen taken.

# METHOD V

In this method, similar to *Method IV,* sulfur dioxide is released from the test specimen in a boiling acid medium and is removed by a stream of nitrogen. The separated gas is collected in a dilute hydrogen peroxide solution, in which the sulfur dioxide is oxidized to sulfuric acid and titrated with standard alkali, using methyl red as an indicator. This test is performed under conditions such that the requirements specified in the system suitability test are met.

## Special Reagents

HYDROGEN PEROXIDE SOLUTION

Dilute a portion of 30 percent hydrogen peroxide with water to obtain a 3% solution. Just before use, add 3 drops of methyl red TS, and neutralize to a yellow endpoint with 0.01 N sodium hydroxide. Do not exceed the endpoint.

@2024 USPC

NITROGEN

Use high-purity nitrogen with a flow regulator that will maintain a flow of 200 ± 10 mL per minute. Guard against the presence of oxygen by passing the nitrogen through a scrubber, such as alkaline pyrogallol, prepared as follows: add 4.5 g of pyrogallol to a gas-washing bottle, purge the bottle with nitrogen for 3 minutes, and add a solution containing 85 mL of water and 65 g of potassium hydroxide while maintaining an atmosphere of nitrogen in the bottle.

POTASSIUM METABISULFITE SOLUTION

Transfer 0.87 g of potassium metabisulfite ($K_2S_2O_5$) and 0.2 g of edetate disodium to a 1000-mL volumetric flask. Dilute with water to volume before mixing. [NOTE—Edetate disodium is used to protect sulfite ion from oxidation.]

## Apparatus

The apparatus (see *Figure 2*) is designed to effect the selective transfer of sulfur dioxide from the specimen in boiling aqueous hydrochloric acid to the *Hydrogen Peroxide Solution* in vessel *G*. The backpressure is limited to the unavoidable pressure due to the height of the *Hydrogen Peroxide Solution* above the tip of the bubbler, *F.* Keeping the backpressure as low as possible reduces the likelihood that sulfur dioxide will be lost through leaks. Preboil vinyl and silicone tubing. Apply a thin film of stopcock grease to the sealing surfaces of all joints, except the joint between the separatory funnel and the flask, and clamp the joints to ensure tightness. The separatory funnel, *B,* has a capacity of 100 mL or greater. The inlet adapter, *A,* with a hose connector, provides a means of applying headpressure over the solution.

[NOTE—A pressure-equalizing dropping funnel is not recommended because condensate, which may contain sulfur dioxide, is deposited in the funnel and the side arm.]

The round-bottom flask, *C,* is a 1000-mL flask with three 24/40 tapered joints. The gas inlet tube, *D,* is long enough to permit introduction of the nitrogen to within 2.5 cm of the bottom of the flask. The Allihn condenser, *E,* has a jacket length of 300 mm. The bubbler, *F* (see *Figure 3*), is fabricated from glass according to the dimensions given in *Figure 3*. The *Hydrogen Peroxide Solution* is contained in the vessel, *G*, having an inside diameter of about 2.5 cm and a depth of about 18 cm. Circulate coolant, such as a mixture of water and methanol (4:1) maintained at 5°, to chill the condenser.

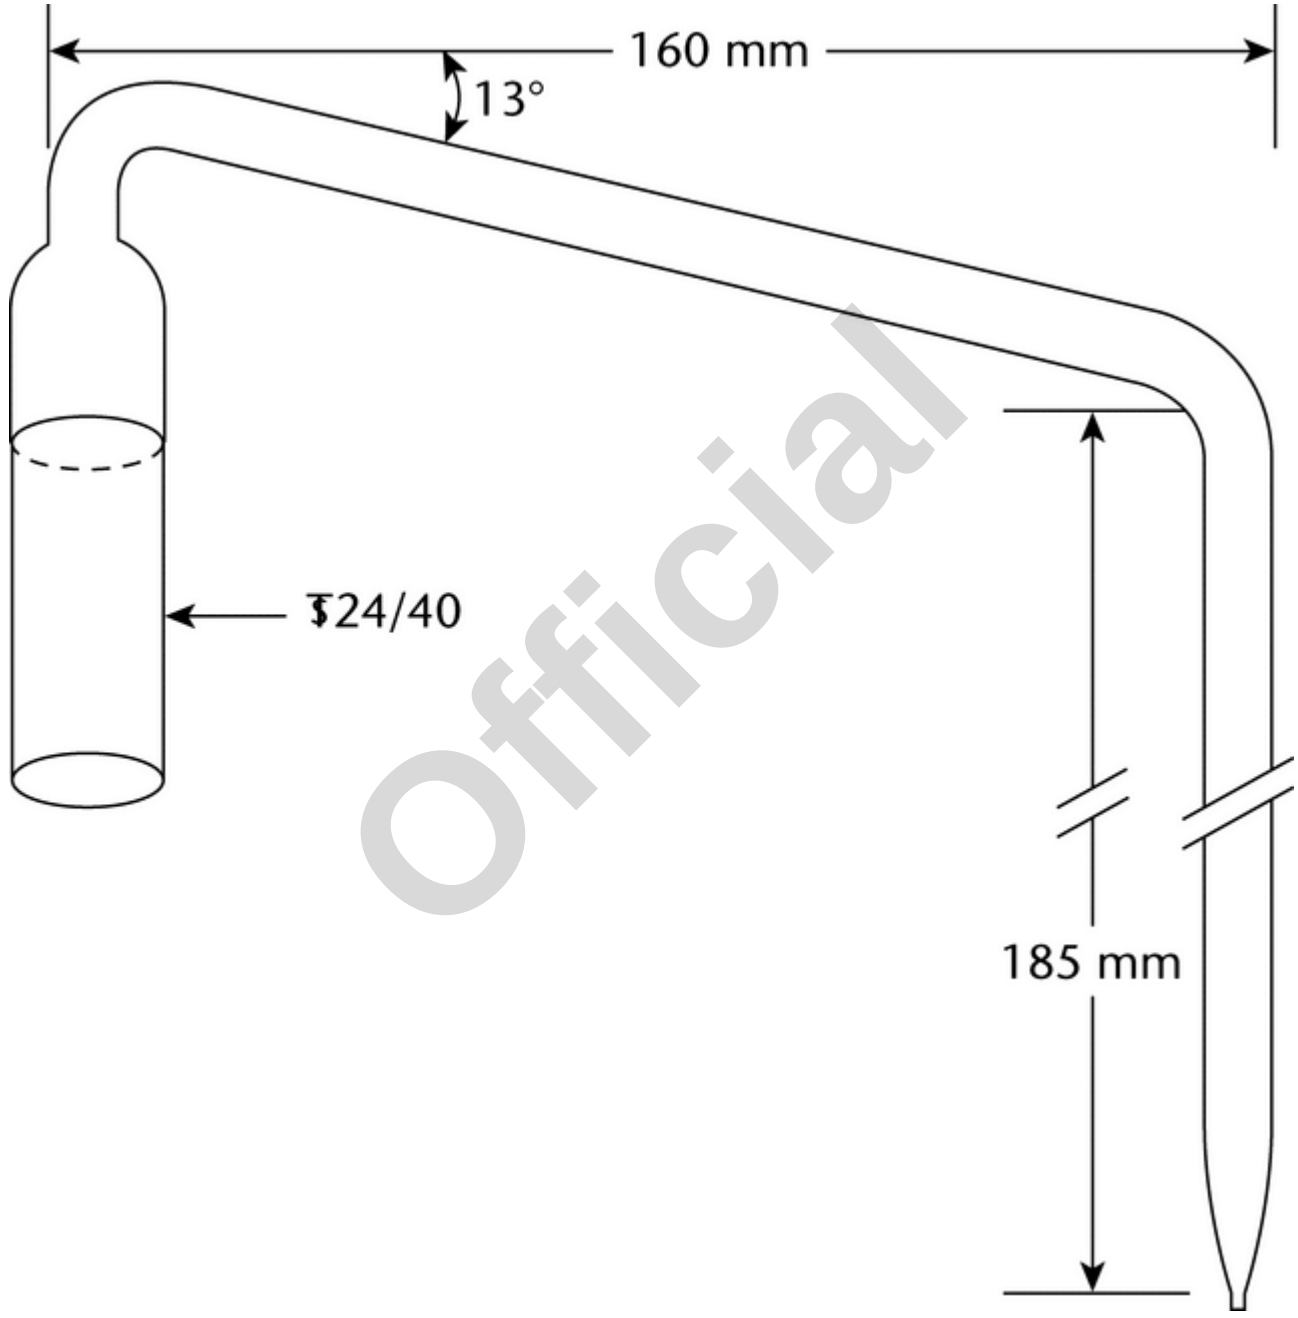

Figure 3. Bubbler (F) for apparatus in Method V.

## System Suitability Test

TEST A

Using the *Potassium Metabisulfite Solution* as the standard, proceed as directed for *Procedure*, except replace the 50.0 g of test substance with 20 mL of *Potassium Metabisulfite Solution*. Calculate the content, in µg per mL, of sulfur dioxide in the *Potassium Metabisulfite Solution* taken by the formula:

$$1000(32.03)VN/V_P$$

@2024 USPC

in which the factor 1000 converts mg to µg; 32.03 is the milliequivalent weight of sulfur dioxide; V is the volume, in mL, of titrant consumed; N is the normality of the titrant; and $V_P$ is the volume, in mL, of *Potassium Metabisulfite Solution* taken for the test.

TEST B

In a 100-mL conical flask, add 20 mL of 0.02 N iodine solution and 5 mL of 2 N hydrochloric acid. Add 1 mL of starch TS, and titrate with the *Potassium Metabisulfite Solution* until the first discoloration is observed. Calculate the content, in µg per mL, of sulfur dioxide in the *Potassium Metabisulfite Solution* by the formula:

$$1000(32.03)V_IN_I/V_P$$

in which 1000 and 32.03 are defined above; $V_I$ is the volume, in mL, of iodine solution used in the test; $N_I$ is the normality of the iodine solution; and $V_P$ is the volume, in mL, of *Potassium Metabisulfite Solution* consumed.

The difference between the sulfur dioxide contents obtained from *Test A* and *Test B* is not more than 5% of their mean value. *Test B* shall be performed within 15 minutes after completion of *Test A*. [NOTE—This avoids a potential variation of the sulfur dioxide content in the *Potassium Metabisulfite Solution* when stored at room temperature.]

## Procedure

Position the apparatus in a heating mantle controlled by a power-regulating device. Add 400 mL of water to the flask. Close the stopcock of the separatory funnel, and add 90 mL of 4 N hydrochloric acid to the separatory funnel. Begin the flow of nitrogen at a rate of 200 ± 10 mL per minute. Start the condenser coolant flow. Add 30 mL of *Hydrogen Peroxide Solution* to the vessel *(G)*. After 15 minutes, remove the separatory funnel, and transfer a mixture of 50.0 g of the test specimen, accurately weighed, and 100 mL of alcohol solution (5 in 100) to the flask. Apply stopcock grease to the outer joint of the separatory funnel, return the separatory funnel to the tapered joint flask, and concomitantly resume the nitrogen flow. Apply headpressure above the hydrochloric acid solution in the separatory funnel with a rubber bulb equipped with a valve. Open the stopcock of the separatory funnel to permit the hydrochloric acid solution to flow into the flask. Continue to maintain sufficient pressure above the hydrochloric acid solution to force it into the flask.

[NOTE—The stopcock may be temporarily closed, if necessary, to increase the pressure.]

To guard against escape of sulfur dioxide into the separatory funnel, close the stopcock before the last few mL of hydrochloric acid drain out. Apply power to the heating mantle sufficient to cause about 85 drops of reflux per minute. After refluxing for 1.75 hours, remove the vessel *(G)*, add 3 drops of methyl red TS, and titrate the contents with 0.01 N sodium hydroxide VS, using a 10-mL buret with an overflow tube and a hose connection to a carbon dioxide-absorbing tube, to a yellow endpoint that persists for at least 20 seconds. Perform a blank determination, and make any necessary correction (see *Titrimetry* ⟨541⟩). Calculate the quantity, in µg, of $SO_2$ in each g of the test specimen taken by the formula:

$$1000(32.03)VN/W$$

in which the factor 1000 converts mg to µg; 32.03 is the milliequivalent weight of sulfur dioxide; V is the volume, in mL, of titrant consumed; N is the normality of the titrant; and W is the weight, in g, of the test specimen taken.

# ⟨531⟩ THIAMINE ASSAY

## ASSAY

• **Chemical Methods, Procedure 1**

The following procedure is provided for the determination of thiamine as an ingredient of pharmacopeial preparations containing other active constituents. The procedure involves thiamine reacting with potassium ferricyanide and subsequently being determined by fluorescence detection. Throughout the procedure, protect solutions containing and derived from the test specimen and the Reference Standard from the atmosphere and light, preferably by the use of low-actinic glassware.

**Potassium ferricyanide solution:** Dissolve 1.0 g of potassium ferricyanide in water to make 100 mL. Prepare fresh on the day of use.

**Oxidizing reagent:** Mix 4.0 mL of *Potassium ferricyanide solution* with a sufficient amount of 3.5 N sodium hydroxide to make 100 mL. Use this solution within 4 h.

**Quinine sulfate stock solution:** Dissolve 10 mg of quinine sulfate in 0.1 N sulfuric acid to make 1000 mL. Preserve this solution, protected from light, in a refrigerator.

**Quinine sulfate standard solution:** Dilute 0.1 N sulfuric acid with *Quinine sulfate stock solution* (39:1). This solution fluoresces to approximately the same degree as the thiochrome obtained from 1 µg of thiamine hydrochloride and is used to correct the fluorometer at frequent intervals for variation in sensitivity from reading to reading within an assay. Prepare this solution fresh on the day of use.

**Standard thiamine hydrochloride stock solution:** Transfer about 25 mg of USP Thiamine Hydrochloride RS, accurately weighed, to a 1000-mL volumetric flask. Dissolve the weighed Standard in about 300 mL of dilute alcohol solution (1 in 5) adjusted with 3 N hydrochloric acid to a pH of 4.0, and add the acidified, dilute alcohol to volume. Store in a refrigerator in a light-resistant container. Prepare this stock solution fresh each month.

**Standard solution:** Dilute a portion of *Standard thiamine hydrochloride stock solution* quantitatively and stepwise with 0.2 N hydrochloric acid to obtain the *Standard solution*, each mL of which represents 0.2 µg of USP Thiamine Hydrochloride RS.

**Sample solution:** Place in a suitable volumetric flask a sufficient amount of the material to be assayed, accurately weighed or measured by volume as directed, such that when diluted with 0.2 N hydrochloric acid to volume, the resulting solution will contain about 100 µg of thiamine hydrochloride (or mononitrate) per mL. If the sample is difficult to dissolve, the solution may be heated on a steam bath, and then cooled and diluted with the acid to volume. Dilute 5 mL of this solution, quantitatively and stepwise, using 0.2 N hydrochloric acid, to an estimated concentration of 0.2 µg of thiamine hydrochloride (or mononitrate) per mL.

**Instrumental conditions**

(See *Fluorescence Spectroscopy* ⟨853⟩.)

**Mode:** Fluorescence

**Excitation wavelength:** 365 nm

**Emission wavelength:** 435 nm

**Analysis:** To each of three or more tubes (or other suitable vessels) of about 40-mL capacity, pipet 5 mL of *Standard solution*. To each of two of these tubes, add rapidly (within 1 to 2 s), with mixing, 3.0 mL of *Oxidizing reagent*, and within 30 s add 20.0 mL of isobutyl alcohol, then mix vigorously for 90 s by shaking the capped tubes manually, or by bubbling a stream of air through the mixture. Prepare a blank in the remaining tube of the standard by substituting for the *Oxidizing reagent* with an equal volume of 3.5 N sodium hydroxide and proceed in the same manner. Into each of three or more similar tubes, pipet 5 mL of the *Sample solution*. Treat these tubes in the same manner as directed for the tubes containing the *Standard solution*. Into each of the six tubes, pipet 2 mL of dehydrated alcohol, swirl for a few seconds, allow the phases to separate, and decant or draw off about 10 mL of the clear, supernatant isobutyl alcohol solution into the standardized cells; then measure the fluorescence in a suitable fluorometer, having an input filter of narrow transmittance range with a maximum at about 365 nm and an output filter of narrow transmittance range with a maximum at about 435 nm.

Calculate the quantity, in µg, of thiamine hydrochloride ($C_{12}H_{17}ClN_4OS \cdot HCl$) in each 5 mL of the *Sample solution*:

$$\text{Result} = (A - b)/(S - d)$$

$A$ = average fluorometer readings of the portions of the *Sample solution* treated with the *Oxidizing reagent*
$b$ = reading for the blank of the *Sample solution*
$S$ = average fluorometer readings of the portions of the *Standard solution* treated with the *Oxidizing reagent*
$d$ = reading for the blank of the *Standard solution*

Calculate the quantity, in mg, of thiamine hydrochloride ($C_{12}H_{17}ClN_4OS \cdot HCl$) in the assay material on the basis of the aliquots taken. Where indicated, the quantity, in mg, of thiamine mononitrate ($C_{12}H_{17}N_5O_4S$) may be calculated by multiplying the quantity of thiamine hydrochloride ($C_{12}H_{17}ClN_4OS \cdot HCl$) found by 0.9706.

The following liquid chromatographic procedures are provided for the determination of thiamine as an active pharmaceutical ingredient, a dietary supplement ingredient, or a component in dietary supplements or pharmaceutical dosage forms.

Throughout these procedures, protect solutions containing and derived from the test specimen and the Reference Standards from the atmosphere and light, preferably by the use of low-actinic glassware.

• **Chromatographic Methods, Procedure 1**

This procedure can be used to determine thiamine in:

- *Oil- and Water-Soluble Vitamins Capsules*
- *Oil- and Water-Soluble Vitamins Tablets*

- *Oil- and Water-Soluble Vitamins with Minerals Capsules*
- *Oil- and Water-Soluble Vitamins with Minerals Tablets*
- *Water-Soluble Vitamins Capsules*
- *Water-Soluble Vitamins Tablets*
- *Water-Soluble Vitamins with Minerals Capsules*
- *Water-Soluble Vitamins with Minerals Tablets*

This is the procedure that involves the extraction of thiamine from the formulation by the *Diluent*, heat, and mechanical shaking.

Unless specified in the individual monographs, the *Standard solution*, *Sample solutions*, and reagent solutions are prepared as follows.

**Diluent:** Acetonitrile, glacial acetic acid, and water (5:1:94)

**Mobile phase:** A mixture of methanol, glacial acetic acid, and water (27:1:73) containing 140 mg of sodium 1-hexanesulfonate per 100 mL

**Standard solution:** Transfer 20 mg of USP Thiamine Hydrochloride RS to a 200-mL volumetric flask, and add 180 mL of *Diluent*. Immerse the flask in a hot water bath maintained at 65°–70° for 10 min with regular shaking or using a vortex mixer until all of the solid materials are dissolved. Chill rapidly in a cold water bath for 10 min to room temperature, and dilute with *Diluent* to volume.

**Sample solution for capsules:** Weigh NLT 20 capsules in a tared weighing bottle. Open the capsules, without loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the shells by washing with several portions of ether. Discard the washings, and dry the capsule shells with the aid of a current of dry air until the odor of ether is no longer perceptible. Weigh the empty capsule shells in the tared weighing bottle, and calculate the average net weight per capsule. Transfer a portion of the capsule contents, equivalent to 2.5 mg of thiamine hydrochloride, to a 50-mL centrifuge tube. Add 25.0 mL of *Diluent*, and mix using a vortex mixer for 30 s to completely suspend the powder. Immerse the centrifuge tube in a hot water bath maintained at 65°–70°, heat for 5 min, and mix on a vortex mixer for 30 s. Return the tube to the hot water bath, heat for another 5 min, and mix on a vortex mixer for 30 s. Filter a portion of the solution, cool to room temperature, and use the clear filtrate. [NOTE—Use the filtrate within 3 h of filtration.]

**Sample solution for tablets:** Finely powder NLT 30 tablets. Transfer a portion of the powder, equivalent to 2.5 mg of thiamine hydrochloride, to a 50-mL centrifuge tube. Add 25.0 mL of *Diluent*, and mix using a vortex mixer for 30 s to completely suspend the powder. Immerse the centrifuge tube in a hot water bath maintained at 65°–70°, heat for 5 min, and mix on a vortex mixer for 30 s. Return the tube to the hot water bath, heat for another 5 min, and mix on a vortex mixer for 30 s. Filter a portion of the solution, cool to room temperature, and use the clear filtrate. [NOTE—Use the filtrate within 3 h of filtration.]

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 280 nm

**Column:** 4.6-mm × 25-cm; packing L1

**Flow rate:** 1 mL/min

**Injection volume:** 10 µL

**System suitability**

**Sample:** *Standard solution*

**Suitability requirements**

**Relative standard deviation:** NMT 3.0%

**Analysis**

**Samples:** *Standard solution* and appropriate *Sample solution*

For products containing thiamine hydrochloride, calculate the percentage of the labeled amount of thiamine hydrochloride ($C_{12}H_{17}ClN_4OS \cdot HCl$) in the portion of sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of thiamine from the appropriate *Sample solution*
$r_S$ = peak response of thiamine from the *Standard solution*
$C_S$ = concentration of USP Thiamine Hydrochloride RS in the *Standard solution* (mg/mL)
$C_U$ = nominal concentration of thiamine hydrochloride in the appropriate *Sample solution* (mg/mL)

For products containing thiamine mononitrate, calculate the percentage of the labeled amount of thiamine mononitrate ($C_{12}H_{17}N_5O_4S$) in the portion of sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times 100$$

$r_U$ = peak response of thiamine from the appropriate *Sample solution*
$r_S$ = peak response of thiamine from the *Standard solution*
$C_S$ = concentration of USP Thiamine Hydrochloride RS in the *Standard solution* (mg/mL)
$C_U$ = nominal concentration of thiamine mononitrate in the appropriate *Sample solution* (mg/mL)
$M_{r1}$ = molecular weight of thiamine mononitrate, 327.36
$M_{r2}$ = molecular weight of thiamine hydrochloride, 337.27

- **Chromatographic Methods, Procedure 2**

This procedure can be used to determine thiamine in:

- *Oil- and Water-Soluble Vitamins Capsules*
- *Oil- and Water-Soluble Vitamins Tablets*
- *Oil- and Water-Soluble Vitamins with Minerals Capsules*
- *Oil- and Water-Soluble Vitamins with Minerals Tablets*
- *Water-Soluble Vitamins Capsules*
- *Water-Soluble Vitamins Tablets*
- *Water-Soluble Vitamins with Minerals Capsules*
- *Water-Soluble Vitamins with Minerals Tablets*

This is the procedure that involves the extraction of thiamine from the formulation by dilute hydrochloric acid, heat, and mechanical shaking.

Unless specified in the individual monographs, the *Standard solution*, *Sample solutions*, and reagent solutions are prepared as follows.

**Solution A:** 1.88 g/L of sodium 1-hexanesulfonate in 0.1% phosphoric acid

**Mobile phase:** *Solution A* and acetonitrile (46:9)

**Standard stock solution:** 0.1 mg/mL of USP Thiamine Hydrochloride RS in 0.2 N hydrochloric acid

**Standard solution:** 0.02 mg/mL of USP Thiamine Hydrochloride RS from *Standard stock solution* diluted with 0.2 N hydrochloric acid

**Sample solution for capsules:** Weigh NLT 20 capsules in a tared weighing bottle. Open the capsules, without the loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing, if necessary, with several portions of ether. Discard the washings, and dry the capsule shells with the aid of a current of dry air until the odor of ether is no longer perceptible. Weigh the empty capsule shells in the tared weighing bottle, and calculate the average net weight per capsule. Mix a portion of the capsule contents with a volume of 0.2 N hydrochloric acid to obtain a concentration of 0.02 mg/mL of thiamine. Shake the solution for 15 min with a wrist-action shaker, and heat to boiling for 30 min. Cool to room temperature, and filter. Use the clear filtrate.

**Sample solution for tablets:** Weigh and finely powder NLT 20 tablets. Mix a portion of the powder with a volume of 0.2 N hydrochloric acid to obtain a concentration of 0.02 mg/mL of thiamine. Shake for 15 min with a wrist-action shaker, and heat to boiling for 30 min. Cool to room temperature, and filter. Use the clear filtrate.

**Chromatographic system**

$M_{r1}$ = molecular weight of thiamine mononitrate, 327.36
$M_{r2}$ = molecular weight of thiamine hydrochloride, 337.27

- **Chromatographic Methods, Procedure 3**

This procedure can be used to determine thiamine in:

- *Oil- and Water-Soluble Vitamins Capsules*

Official

https://pharmacopeia.cn/

- *Oil- and Water-Soluble Vitamins Oral Solution*
- *Oil- and Water-Soluble Vitamins Tablets*
- *Oil- and Water-Soluble Vitamins with Minerals Capsules*
- *Oil- and Water-Soluble Vitamins with Minerals Oral Solution*
- *Oil- and Water-Soluble Vitamins with Minerals Tablets*
- *Water-Soluble Vitamins Capsules*
- *Water-Soluble Vitamins Tablets*
- *Water-Soluble Vitamins with Minerals Capsules*
- *Water-Soluble Vitamins with Minerals Oral Solution*
- *Water-Soluble Vitamins with Minerals Tablets*

This is the procedure that involves the extraction of thiamine from the formulation by mixtures of organic solvents, heat, and mechanical shaking.

Unless specified in the individual monographs, the *Standard solutions*, *Sample solutions*, and reagent solutions are prepared as follows.

**Diluent:** 25 mg/mL of edetate disodium in water

**Mobile phase:** Transfer 0.4 mL of triethylamine, 15.0 mL of glacial acetic acid, and 350 mL of methanol to a 2000-mL volumetric flask. Dilute with 0.008 M sodium 1-hexanesulfonate to volume.

**Standard stock solution:** 0.24 mg/mL of USP Thiamine Hydrochloride RS in *Diluent*, with heating if necessary

**Standard solution for capsules/tablets:** Transfer 5.0 mL of *Standard stock solution* to a stoppered 125-mL flask. Add 10.0 mL of a mixture of methanol and glacial acetic acid (9:1) and 30.0 mL of a mixture of methanol and ethylene glycol (1:1). Insert the stopper, shake for 15 min in a water bath maintained at 60°, and cool. Filter, and discard the first few mL of the filtrate.

**Standard solution for oral solution:** 24 µg/mL of USP Thiamine Hydrochloride RS, diluted from the *Standard stock solution* with *Diluent*

**Sample solution for capsules:** Weigh NLT 20 capsules in a tared weighing bottle. Open the capsules, without the loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing, if necessary, with several portions of ether. Discard the washings, and dry the capsule shells with the aid of a current of dry air until the odor of ether is no longer perceptible. Weigh the empty capsule shells in the tared weighing bottle, and calculate the average net weight per capsule. Transfer a portion of the capsule contents, equivalent to 1.2 mg of thiamine hydrochloride, to a stoppered 125-mL flask. Add 10.0 mL of a mixture of methanol and glacial acetic acid (9:1) and 30.0 mL of a mixture of methanol and ethylene glycol (1:1). Insert the stopper, shake for 15 min in a water bath maintained at 60°, and cool. Filter, and discard the first few mL of the filtrate.

**Sample solution for oral solution:** Equivalent to 24 µg/mL of thiamine hydrochloride or thiamine mononitrate from oral solution in *Diluent*

**Sample solution for tablets:** Weigh and finely powder NLT 20 tablets. Transfer a portion of the powder, equivalent to 1.2 mg of thiamine, to a stoppered 125-mL flask. Add 10.0 mL of a mixture of methanol and glacial acetic acid (9:1) and 30.0 mL of a mixture of methanol and ethylene glycol (1:1). Insert the stopper, shake for 15 min in a water bath maintained at 60°, and cool. Filter, and discard the first few mL of the filtrate.

$M_{r1}$ = molecular weight of thiamine mononitrate, 327.36
$M_{r2}$ = molecular weight of thiamine hydrochloride, 337.27

- **Chromatographic Methods, Procedure 4**

This procedure can be used to determine thiamine in:

- An active pharmaceutical ingredient
- A dietary ingredient

This is the procedure that involves the dissolution of the sample directly into the *Mobile phase*. The procedure is applicable for the determination of thiamine hydrochloride or thiamine mononitrate as active pharmaceutical or dietary supplement ingredients.

Unless specified in the individual monographs, the *Standard solution*, *Sample solution*, and reagent solutions are prepared as follows.

**Solution A:** 0.005 M sodium 1-octanesulfonate in dilute glacial acetic acid (1 in 100)
**Solution B:** Methanol and acetonitrile (3:2)
**Mobile phase:** *Solution A* and *Solution B* (60:40)
**Internal standard solution:** 2% (v/v) of methylbenzoate in methanol
**Standard solution:** Prepare a 1-mg/mL solution of USP Thiamine Hydrochloride RS in *Mobile phase*. Transfer 20.0 mL of this solution and 5.0 mL of *Internal standard solution* to a 50-mL volumetric flask, and dilute with *Mobile phase* to volume. The *Standard solution* contains 400 µg/mL of thiamine hydrochloride.
**Sample solution:** Prepare a 2-mg/mL solution of thiamine hydrochloride or thiamine mononitrate in *Mobile phase*. Transfer 10.0 mL of this solution and 5.0 mL of *Internal standard solution* to a 50-mL volumetric flask, and dilute with *Mobile phase* to volume.
**Chromatographic system**
(See *Chromatography* ⟨621⟩, *System Suitability*.)
**Mode:** LC
**Detector:** UV 254 nm
**Column:** 4.6-mm × 25-cm; packing L1
**Flow rate:** 1 mL/min. [NOTE—The flow rate may be adjusted to obtain a retention time of about 12 min for thiamine.]
**Injection volume:** 10 µL
**System suitability**
**Sample:** *Standard solution*
**Suitability requirements**
**Resolution:** NLT 4.0 between the thiamine and methylbenzoate peaks
**Tailing factor:** NMT 2.0 for the thiamine peak
**Column efficiency:** NLT 1500 theoretical plates for thiamine
**Relative standard deviation:** NMT 2.0% for the ratios of thiamine peak response to the internal standard peak response
**Analysis**
**Samples:** *Standard solution* and *Sample solution*
Calculate the percentage of thiamine hydrochloride ($C_{12}H_{17}ClN_4OS \cdot HCl$) in the portion of sample taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

$R_U$ = peak response ratio of thiamine to methylbenzoate from the *Sample solution*
$R_S$ = peak response ratio of thiamine to methylbenzoate from the *Standard solution*
$C_S$ = concentration of USP Thiamine Hydrochloride RS in the *Standard solution* (mg/mL)
$C_U$ = concentration of thiamine hydrochloride in the *Sample solution* (mg/mL)

If the active pharmaceutical or dietary supplement ingredient is thiamine mononitrate, calculate the percentage of thiamine mononitrate ($C_{12}H_{17}N_5O_4S$) in the portion of sample taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times 100$$

$R_U$ = peak response ratio of thiamine to methylbenzoate from the *Sample solution*
$R_S$ = peak response ratio of thiamine to methylbenzoate from the *Standard solution*
$C_S$ = concentration of USP Thiamine Hydrochloride RS in the *Standard solution* (mg/mL)
$C_U$ = concentration of thiamine mononitrate in the *Sample solution* (mg/mL)
$M_{r1}$ = molecular weight of thiamine mononitrate, 327.36
$M_{r2}$ = molecular weight of thiamine hydrochloride, 337.27

- **Chromatographic Methods, Procedure 5**

This procedure can be used to determine thiamine in:

- *Thiamine Hydrochloride Oral Solution*
- *Thiamine Mononitrate Oral Solution*

This is the procedure that involves the dissolution of the sample directly into the *Mobile phase*. The procedure is applicable for the determination of thiamine hydrochloride or thiamine mononitrate as an active ingredient in the formulations such as those used in *Thiamine Hydrochloride Injection*, *Thiamine Hydrochloride Oral Solution*, and *Thiamine Mononitrate Oral Solution*.

Unless specified in the individual monographs, the *Standard solution*, *Internal standard solution*, and *Sample solution* are prepared as follows.

**Mobile phase:** Methanol and 0.04 M aqueous monobasic potassium phosphate (45:55)
**Internal standard solution:** 100 µg/mL of methylparaben in *Mobile phase*
**Standard stock solution:** 500 µg/mL of USP Thiamine Hydrochloride RS in *Mobile phase*
**Standard solution:** Dilute a mixture of equal volumes of the *Standard stock solution* and *Internal standard solution* with *Mobile phase* to obtain a concentration of USP Thiamine Hydrochloride RS of about 50 µg/mL.
**Sample stock solution:** Equivalent to 500 µg/mL of thiamine hydrochloride or thiamine mononitrate in *Mobile phase* from an accurately measured volume of oral solution or injection
**Sample solution:** Dilute a mixture of equal volumes of the *Internal standard solution* and *Sample stock solution* with *Mobile phase* to obtain a concentration of thiamine hydrochloride or thiamine mononitrate of about 50 µg/mL.
**Chromatographic system**
(See *Chromatography* ⟨621⟩, *System Suitability*.)
**Mode:** LC
**Detector:** UV 254 nm
**Column:** 4.6-mm × 25-cm; packing L1
**Flow rate:** 1 mL/min
**Injection volume:** 25 µL
**System suitability**
**Sample:** *Standard solution*
[NOTE—The relative retention times for thiamine and methylparaben are about 0.35 and 1.0, respectively.]
**Suitability requirements**
**Resolution:** NLT 6.0 between thiamine and methylparaben
**Column efficiency:** NLT 1500 theoretical plates for thiamine
**Relative standard deviation:** NMT 2.0% for the ratios of thiamine peak response to the methylparaben peak response
**Analysis**
**Samples:** *Standard solution* and *Sample solution*
Calculate the percentage of the labeled amount of thiamine hydrochloride ($C_{12}H_{17}ClN_4OS \cdot HCl$) in the portion of sample taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

$R_U$ = peak response ratio of thiamine to methylparaben from the *Sample solution*
$R_S$ = peak response ratio of thiamine to methylparaben from the *Standard solution*
$C_S$ = concentration of USP Thiamine Hydrochloride RS in the *Standard solution* (mg/mL)
$C_U$ = nominal concentration of thiamine hydrochloride in the *Sample solution* (mg/mL)

If the products contain thiamine mononitrate, calculate the percentage of the labeled amount of thiamine mononitrate ($C_{12}H_{17}N_5O_4S$) in the portion of sample taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times 100$$

$R_U$ = peak response ratio of thiamine to methylparaben from the *Sample solution*
$R_S$ = peak response ratio of thiamine to methylparaben from the *Standard solution*
$C_S$ = concentration of USP Thiamine Hydrochloride RS in the *Standard solution* (mg/mL)
$C_U$ = concentration of thiamine mononitrate in the *Sample solution* (mg/mL)
$M_{r1}$ = molecular weight of thiamine mononitrate, 327.36
$M_{r2}$ = molecular weight of thiamine hydrochloride, 337.27

• **CHROMATOGRAPHIC METHODS, PROCEDURE 6**

This procedure can be used to determine thiamine in the following:

- *Thiamine Hydrochloride Tablets*

This is the procedure that involves the dissolution of the sample directly into water. The procedure is applicable to the performance (dissolution) test for *Thiamine Hydrochloride Tablets*.

Unless specified in the individual monographs, the *Standard solution* and *Sample solution* are prepared as follows.
**Medium:** Water, 900 mL
**Apparatus 2:** 50 rpm
**Time:** 45 min
**Mobile phase:** A mixture of methanol, glacial acetic acid, and water (27:1:73) containing 140 mg of sodium 1-hexanesulfonate per 100 mL
**Standard solution:** A known concentration of USP Thiamine Hydrochloride RS in *Medium* (water)
**Sample solution:** Filtered portion of the solution under test, suitably diluted with *Medium* (water) if necessary

Calculate the percentage of the labeled amount of thiamine hydrochloride ($C_{12}H_{17}ClN_4OS \cdot HCl$) in the portion of sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S \times D \times V/L) \times 100$$

$r_U$ = peak response of thiamine from the *Sample solution*
$r_S$ = peak response of thiamine from the *Standard solution*
$C_S$ = concentration of USP Thiamine Hydrochloride RS in the *Standard solution* (mg/mL)
$D$ = dilution factor for the *Sample solution*
$V$ = volume of *Medium*, 900 mL
$L$ = labeled amount of thiamine hydrochloride (mg/Tablet)

• **Chromatographic Methods, Procedure 7**
This procedure can be used to determine thiamine in:
- *Oil- and Water-Soluble Vitamins Capsules*
- *Oil- and Water-Soluble Vitamins Oral Solution*
- *Oil- and Water-Soluble Vitamins Tablets*
- *Oil- and Water-Soluble Vitamins with Minerals Capsules*
- *Oil- and Water-Soluble Vitamins with Minerals Oral Solution*
- *Oil- and Water-Soluble Vitamins with Minerals Tablets*
- *Water-Soluble Vitamins Capsules*
- *Water-Soluble Vitamins Tablets*
- *Water-Soluble Vitamins with Minerals Capsules*
- *Water-Soluble Vitamins with Minerals Oral Solution*
- *Water-Soluble Vitamins with Minerals Tablets*

This is a newly added procedure as part of the USP monograph modernization efforts. The procedure uses hydrophilic interaction liquid chromatography (HILIC), and the sample preparation involves the extraction of thiamine from the formulation by the *Diluent*, heat, and mechanical shaking.
Unless specified in the individual monographs, the *Standard solution*, *Sample solutions*, and reagent solutions are prepared as follows.
**Diluent:** Methanol, glacial acetic acid, and water (50:1:49)
**Solution A:** 50 mM ammonium formate. Adjust with ammonium hydroxide to a pH of 9.0.
**Solution B:** Acetonitrile
**Mobile phase:** Gradient elution. See *Table 1*.

**Table 1**

| Time (min) | Solution A (%) | Solution B (%) |
|---|---|---|
| 0 | 11 | 89 |
| 8 | 17 | 83 |
| 15 | 23 | 77 |
| 20 | 30 | 70 |
| 21 | 50 | 50 |
| 24 | 50 | 50 |
| 25 | 11 | 89 |
| 30 | 11 | 89 |

**Standard solution:** Transfer 20 mg of USP Thiamine Hydrochloride RS to a 200-mL volumetric flask, and add 160 mL of *Diluent*. Immerse the flask in a hot water bath maintained at 65°–70° for 10 min with regular shaking or using a vortex

@2024 USPC

mixer, until all of the solid materials are dissolved. Chill rapidly in a cold water bath for 10 min to room temperature, and dilute with *Diluent* to volume.

**Sample solution for capsules:** Weigh NLT 20 capsules in a tared weighing bottle. Open the capsules, without the loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing, if necessary, with several portions of ether. Discard the washings, and dry the capsule shells with the aid of a current of dry air until the odor of ether is no longer perceptible. Weigh the empty capsule shells in the tared weighing bottle, and calculate the average net weight per capsule. Transfer a portion of the capsule contents, equivalent to 2.5 mg of thiamine hydrochloride, to a 50-mL centrifuge tube. Add 25.0 mL of *Diluent*, and mix using a vortex mixer for 30 s to completely suspend the powder. Immerse the centrifuge tube in a hot water bath maintained at 68°, heat for 10 min, and mix on a vortex mixer for 30 s. Return the tube to the hot water bath, heat for another 10 min, and mix on a vortex mixer for 30 s. Filter a portion of the solution, cool to room temperature, and use the clear filtrate.

**Sample solution for oral solution:** Equivalent to 0.1 mg/mL of thiamine hydrochloride in *Diluent*, from an accurately measured volume of oral solution. In an appropriate volumetric flask, dissolve the sample with *Diluent* to about 80% of the total volume, immerse the flask in a water bath maintained at 68° for 10 min, chill rapidly in a cold water bath to room temperature, and dilute with *Diluent*. Mix well, and filter a portion of the solution; finally, use the clear filtrate.

**Sample solution for tablets:** Finely powder NLT 30 tablets. Transfer a portion of the powder, equivalent to 2.5 mg of thiamine hydrochloride, to a 50-mL centrifuge tube. Add 25.0 mL of *Diluent*, and mix using a vortex mixer for 30 s to completely suspend the powder. Immerse the centrifuge tube in a hot water bath maintained at 65°–70°, heat for 10 min, and mix on a vortex mixer for 30 s. Return the tube to the hot water bath, heat for another 10 min, and mix on a vortex mixer for 30 s. Filter a portion of the solution, cool to room temperature, and use the clear filtrate. [NOTE—Use the filtrate within 3 h of filtration.]

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 267 nm

**Column:** 4.6-mm × 15-cm; 3.5-µm packing L68

**Column temperature:** 40°

**Flow rate:** 1.2 mL/min

**Injection volume:** 10 µL

**System suitability**

**Sample:** *Standard solution*

**Suitability requirements**

**Relative standard deviation:** NMT 2.0%

**Analysis**

**Samples:** *Standard solution* and appropriate *Sample solution*

For products containing thiamine hydrochloride, calculate the percentage of the labeled amount of thiamine hydrochloride ($C_{12}H_{17}ClN_4OS \cdot HCl$) in the portion of sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of thiamine from the appropriate *Sample solution*
$r_S$ = peak response of thiamine from the *Standard solution*
$C_S$ = concentration of USP Thiamine Hydrochloride RS in the *Standard solution* (mg/mL)
$C_U$ = nominal concentration of thiamine in the appropriate *Sample solution* (mg/mL)

For products containing thiamine mononitrate, calculate the percentage of the labeled amount of thiamine mononitrate ($C_{12}H_{17}N_5O_4S$) in the portion of sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times 100$$

$r_U$ = peak response of thiamine from the appropriate *Sample solution*
$r_S$ = peak response of thiamine from the *Standard solution*
$C_S$ = concentration of USP Thiamine Hydrochloride RS in the *Standard solution* (mg/mL)
$C_U$ = nominal concentration of thiamine mononitrate in the appropriate *Sample solution* (mg/mL)
$M_{r1}$ = molecular weight of thiamine mononitrate, 327.36
$M_{r2}$ = molecular weight of thiamine hydrochloride, 337.27

# ⟨541⟩ TITRIMETRY

## DIRECT TITRATIONS

Direct titration is the treatment of a soluble substance, contained in solution in a suitable vessel (the titrate), with an appropriate standardized solution (the titrant), the endpoint being determined instrumentally or visually with the aid of a suitable indicator.

The titrant is added from a suitable buret and is so chosen, with respect to its strength (normality), that the volume added is between 30% and 100% of the rated capacity of the buret.

[NOTE—Where less than 10 mL of titrant is required, a suitable microburet is to be used.]

The endpoint is approached directly but cautiously, and finally the titrant is added dropwise from the buret in order that the final drop added will not overrun the endpoint. The quantity of the substance being titrated may be calculated from the volume and the normality or molarity factor of the titrant and the equivalence factor for the substance given in the individual monograph.

## RESIDUAL TITRATIONS

Some Pharmacopeial assays require the addition of a measured volume of a volumetric solution, in excess of the amount actually needed to react with the substance being assayed, the excess of this solution then being titrated with a second volumetric solution. This constitutes a residual titration and is known also as a "back titration." The quantity of the substance being titrated may be calculated from the difference between the volume of the volumetric solution originally added, corrected by means of a blank titration, and that consumed by the titrant in the back titration, due allowance being made for the respective normality or molarity factors of the two solutions, and the equivalence factor for the substance given in the individual monograph.

## COMPLEXOMETRIC TITRATIONS

Successful complexometric titrations depend on several factors. The equilibrium constant for formation of the titrant-analyte complex must be sufficiently large that, at the endpoint, very close to 100% of the analyte has been complexed. The final complex must be formed rapidly enough that the analysis time is practical. When the analytical reaction is not rapid, a residual titration may sometimes be successful.

In general, complexometric indicators are themselves complexing agents. The reaction between metal ion and indicator must be rapid and reversible. The equilibrium constant for formation of the metal-indicator complex should be large enough to produce a sharp color change but must be less than that for the metal-titrant complex. Indicator choice is also restricted by the pH range within which the complexation reaction must be carried out and by interference of other ions arising from the sample or the buffer. Interfering ions may often be masked or "screened" via addition of another complexing agent. (The masking technique is also applicable to redox titrations.)

## OXIDATION-REDUCTION (REDOX) TITRATIONS

Determinations may often be carried out conveniently by the use of a reagent that brings about oxidation or reduction of the analyte. Many redox titration curves are not symmetric about the equivalence point, and thus graphical determination of the endpoint is not possible; but indicators are available for many determinations, and a redox reagent can often serve as its own indicator. As in any type of titration, the ideal indicator changes color at an endpoint that is as close as possible to the equivalence point. Accordingly, when the titrant serves as its own indicator, the difference between the endpoint and the equivalence point is determined only by the analyst's ability to detect the color change. A common example is the use of permanganate ion as an oxidizing titrant since a slight excess can easily be detected by its pink color. Other titrants that may serve as their own indicators are iodine, cerium (IV) salts, and potassium dichromate. In most cases, however, the use of an appropriate redox indicator will yield a much sharper endpoint.

It may be necessary to adjust the oxidation state of the analyte prior to titration through use of an appropriate oxidizing or reducing agent; the excess reagent must then be removed, e.g., through precipitation. This is nearly always the practice in the determination of oxidizing agents since most volumetric solutions of reducing agents are slowly oxidized by atmospheric oxygen.

## TITRATIONS IN NONAQUEOUS SOLVENTS

Acids and bases have long been defined as substances that furnish, when dissolved in water, hydrogen and hydroxyl ions, respectively. This definition, introduced by Arrhenius, fails to recognize the fact that properties characteristic of acids or bases may be developed also in other solvents. A more generalized definition is that of Brönsted, who defined an acid as a substance that furnishes protons, and a base as a substance that combines with protons. Even broader is the definition of Lewis, who defined an acid as any material that will accept an electron pair, a base as any material that will donate an electron pair, and neutralization as the formation of a coordination bond between an acid and a base.

Official

https://nhathuocngocanh.com/

The apparent strength of an acid or a base is determined by the extent of its reaction with a solvent. In water solution all strong acids appear equally strong because they react with the solvent to undergo almost complete conversion to oxonium ion and the acid anion (leveling effect). In a weakly protophilic solvent such as acetic acid the extent of formation of the acetate acidium ion shows that the order of decreasing strength for acids is perchloric, hydrobromic, sulfuric, hydrochloric, and nitric (differentiating effect).

Acetic acid reacts incompletely with water to form oxonium ion and is, therefore, a weak acid. In contrast, it dissolves in a base such as ethylenediamine, and reacts so completely with the solvent that it behaves as a strong acid. The same holds for perchloric acid.

This leveling effect is observed also for bases. In sulfuric acid almost all bases appear to be of the same strength. As the acid properties of the solvent decrease in the series sulfuric acid, acetic acid, phenol, water, pyridine, and butylamine, the bases become progressively weaker until all but the strongest have lost their basic properties. In order of decreasing strength, the strong bases are sodium 2-aminoethoxide, potassium methoxide, sodium methoxide, and lithium methoxide.

Many water-insoluble compounds acquire enhanced acidic or basic properties when dissolved in organic solvents. Thus the choice of the appropriate solvent permits the determination of a variety of such materials by nonaqueous titration. Furthermore, depending upon which part of a compound is the physiologically active moiety, it is often possible to titrate that part by proper selection of solvent and titrant. Pure compounds can be titrated directly, but it is often necessary to isolate the active ingredient in pharmaceutical preparations from interfering excipients and carriers.

The types of compounds that may be titrated as acids include acid halides, acid anhydrides, carboxylic acids, amino acids, enols such as barbiturates and xanthines, imides, phenols, pyrroles, and sulfonamides. The types of compounds that may be titrated as bases include amines, nitrogen-containing heterocyclic compounds, oxazolines, quaternary ammonium compounds, alkali salts of organic acids, alkali salts of weak inorganic acids, and some salts of amines. Many salts of halogen acids may be titrated in acetic acid or acetic anhydride after the addition of mercuric acetate, which removes halide ion as the unionized mercuric halide complex and introduces the acetate ion.

For the titration of a basic compound, a volumetric solution of perchloric acid in glacial acetic acid is preferred, although perchloric acid in dioxane is used in special cases. The calomel-glass electrode system is useful in this case. In acetic acid solvent, this electrode system functions as predicted by theory.

For the titration of an acidic compound, two classes of titrant are available: the alkali metal alkoxides and the tetraalkylammonium hydroxides. A volumetric solution of sodium methoxide in a mixture of methanol and toluene is used frequently, although lithium methoxide in methanol-benzene solvent is used for those compounds yielding a gelatinous precipitate on titration with sodium methoxide.

The alkali error limits the use of the glass electrode as an indicating electrode in conjunction with alkali metal alkoxide titrants, particularly in basic solvents. Thus, the antimony-indicating electrode, though somewhat erratic, is used in such titrations. The use of quaternary ammonium hydroxide compounds, e.g., tetra-*n*-butylammonium hydroxide and trimethylhexadecylammonium hydroxide (in benzene-methanol or isopropyl alcohol), has two advantages over the other titrants in that (a) the tetraalkylammonium salt of the titrated acid is soluble in the titration medium, and (b) the convenient and well-behaved calomel-glass electrode pair may be used to conduct potentiometric titrations.

Because of interference by carbon dioxide, solvents for acidic compounds need to be protected from excessive exposure to the atmosphere by a suitable cover or by an inert atmosphere during the titration. Absorption of carbon dioxide may be determined by performing a blank titration. The blank should not exceed 0.01 mL of 0.1 N sodium methoxide VS per mL of solvent.

The endpoint may be determined visually by color change, or potentiometrically, as indicated in the individual monograph. If the calomel reference electrode is used, it is advantageous to replace the aqueous potassium chloride salt bridge with 0.1 N lithium perchlorate in glacial acetic acid for titrations in acidic solvents or potassium chloride in methanol for titrations in basic solvents.

Where these or other mixtures are specified in individual monographs, the calomel reference electrode is modified by first removing the aqueous potassium chloride solution and residual potassium chloride, if any, by rinsing with water, then eliminating residual water by rinsing with the required nonaqueous solvent, and finally filling the electrode with the designated nonaqueous mixture.

In nearly all cases, except those where silver ion might interfere, a silver-silver chloride reference electrode may be substituted for the calomel electrode. The silver-silver chloride electrode is more rugged, and its use helps to eliminate toxic mercury salts from the laboratory. Generally, a salt bridge may be used to circumvent interference by silver ion.

The more useful systems for titration in nonaqueous solvents are listed in *Table 1*.

**Table 1. Systems for Nonaqueous Titrations**

| Type of Solvent | Acidic (for titration of bases and their salts) | Relatively Neutral (for differential titration of bases) | Basic (for titration of acids) | Relatively Neutral (for differential titration of acids) |
|---|---|---|---|---|
| Solvent[1] | Glacial Acetic Acid | Acetonitrile | Dimethylformamide | Acetone |

## INDICATOR AND POTENTIOMETRIC ENDPOINT DETECTION

The simplest and most convenient method by which the equivalence point, i.e., the point at which the stoichiometric analytical reaction is complete, may be determined is with the use of indicators. These chemical substances, usually colored, respond to changes in solution conditions before and after the equivalence point by exhibiting color changes that may be taken visually as the endpoint, a reliable estimate of the equivalence point.

A useful method of endpoint determination results from the use of electrochemical measurements. If an indicator electrode, sensitive to the concentration of the species undergoing titrimetric reaction, and a reference electrode, whose potential is insensitive to any dissolved species, are immersed in the titrate to form a galvanic cell, the potential difference between the electrodes may be sensed by a pH meter and used to follow the course of the reaction. Where such a series of measurements is plotted correctly (i.e., for an acid-base titration, pH versus mL of titrant added; for a precipitimetric, complexometric, or oxidation-reduction titration, mV versus mL of titrant added), a sigmoid curve results with a rapidly changing portion (the "break") in the vicinity of the equivalence point. The midpoint of this linear vertical portion or the inflection point may be taken as the endpoint. The equivalence point may also be determined mathematically without plotting a curve. However, it should be noted that in asymmetrical reactions, which are reactions in which the number of anions reacting is not the same as the number of cations reacting, the endpoint as defined by the inflection of the titration curve does not occur exactly at the stoichiometric equivalence point. Thus, potentiometric endpoint detection by this method is not suitable in the case of asymmetric reactions, examples of which are the precipitation reaction,

$$2Ag^{+} + CrO_4^{-2}$$

and the oxidation-reduction reaction,

$$5Fe^{+2} + MnO_4^{-}.$$

All acid-base reactions, however, are symmetrical. Thus, potentiometric endpoint detection may be employed in acid-base titrations and in other titrations involving symmetrical reversible reactions where an indicator is specified, unless otherwise directed in the individual monograph.

Two types of automatic electrometric titrators are available. The first is one that carries out titrant addition automatically and records the electrode potential differences during the course of titration as the expected sigmoid curve. In the second type, titrant addition is performed automatically until a preset potential or pH, representing the endpoint, is reached, at which point the titrant addition ceases.

Several acceptable electrode systems for potentiometric titrations are summarized in *Table 2*.

**Table 2. Potentiometric Titration Electrode Systems**

| Titration | Indicating Electrode | Equation[1] | Reference Electrode | Applicability[2] |
|---|---|---|---|---|
| Acid-base | Glass | $E = k + 0.0591\ pH$ | Calomel or silver–silver chloride | Titration of acids and bases |
| Precipitimetric (silver) | Silver | $E = E° + 0.0591 \log [Ag^{+}]$ | Calomel (with potassium nitrate salt bridge) | Titration with or of silver involving halides or thiocyanate |
| Complexometric | Mercury–mercury(II) | $E = E° + 0.0296(\log k' - pM)$ | Calomel | Titration of various metals (M), e.g., $Mg^{+2}$, $Ca^{+2}$ $Al^{+3}$, $Bi^{+3}$, with EDTA |

[2] Listing is representative but not exhaustive.

## BLANK CORRECTIONS

As previously noted, the endpoint determined in a titrimetric assay is an estimate of the reaction equivalence point. The validity of this estimate depends upon, among other factors, the nature of the titrate constituents and the concentration of the titrant. An appropriate *blank correction* is employed in titrimetric assays to enhance the reliability of the endpoint determination. Such a blank correction is usually obtained by means of a *residual blank titration*, wherein the required procedure is repeated in every detail except that the substance being assayed is omitted. In such instances, the actual volume of titrant equivalent to the substance being assayed is the difference between the volume consumed in the residual blank titration and that consumed in the titration with the substance present. The corrected volume so obtained is used in calculating the quantity of the substance being titrated, in the same manner as prescribed under *Residual Titrations*. Where potentiometric endpoint detection is employed, the blank correction is usually negligible.

# ⟨551⟩ VITAMIN E ASSAY

## INTRODUCTION

The following liquid chromatographic procedures are provided for the determination of vitamin E as an active pharmaceutical ingredient, as a dietary supplement ingredient, or as a component in compendial dosage forms in the forms of alpha tocopherol ($C_{29}H_{50}O_2$), alpha tocopheryl acetate ($C_{31}H_{52}O_3$), or alpha tocopheryl acid succinate ($C_{33}H_{54}O_5$).

Throughout this assay, protect solutions containing, and derived from, the test specimen and the Reference Standard from the atmosphere and light, preferably by the use of a blanket of inert gas and low-actinic glassware.

Where vitamin E (alpha tocopherol, alpha tocopheryl acetate, or alpha tocopheryl acid succinate) is specified in the following procedure, use the chemical form present in the formulation and the relevant USP Reference Standard.

## ASSAY

- **PROCEDURE 1**
  - This procedure can be used to determine vitamin E in:
    - Oil-Soluble Vitamins Tablets
    - Oil-Soluble Vitamins Capsules
    - Oil-Soluble Vitamins with Minerals Tablets
    - Oil-Soluble Vitamins with Minerals Capsules
    - Oil- and Water-Soluble Vitamins Tablets
    - Oil- and Water-Soluble Vitamins Capsules
    - Oil- and Water-Soluble Vitamins with Minerals Tablets
    - Oil- and Water-Soluble Vitamins with Minerals Capsules
  - This is a neutral procedure that involves the use of dimethyl sulfoxide to dissolve the excipients in the sample, followed by a liquid–liquid extraction of vitamin E with hexane. The hexane extract is then evaporated in vacuum to dryness, and the residue is reconstituted in methanol prior injection into the chromatograph.
  - Unless specified in the individual monographs, the *System suitability solution*, *Standard solution*, *Sample solutions*, and reagent solutions are prepared as follows.

**Solution A:** Phosphoric acid solution (1 in 100) in water

**Mobile phase:** Methanol and *Solution A* (19:1)

**System suitability solution:** Prepare a 0.65-mg/mL solution of USP Ergocalciferol RS in methanol. Transfer 1.0 mL of this solution to a 100-mL volumetric flask containing 100 mg of USP Alpha Tocopheryl Acetate RS. Dissolve in 30 mL of methanol, with the aid of sonication if necessary, and dilute with methanol to volume. Store this solution in a refrigerator.

**Standard solution:** 2 mg/mL of USP Alpha Tocopherol RS, USP Alpha Tocopheryl Acetate RS, or USP Alpha Tocopheryl Acid Succinate RS in methanol

**Sample solution for Tablets:** Finely powder NLT 20 Tablets. Transfer a portion of the powder typically equivalent to 20 mg of the vitamin E form under testing but not exceeding 7.5 g of the powder, to a centrifuge tube having a polytef-lined screw cap. Add about 2 mL of dimethyl sulfoxide per each g of powdered Tablets, and about 3 mL of *n*-hexane each per g of powdered Tablets, and shake for 45 min on a shaker in a water bath maintained at 60°. [NOTE—Set up the shaker to ensure that the contents of the container are mixed vigorously and thoroughly.] Centrifuge at 3000 rpm for 10 min, and transfer the hexane layer by means of a pipet to a volumetric flask. [NOTE—Volumetric flask size: NLT 20 mL.] Add 3 mL of *n*-hexane per each g of powdered Tablets to the dimethyl sulfoxide layer, shake thoroughly for 5 min, and transfer the hexane layer by means of a pipet to the same volumetric flask. Repeat this extraction with three additional portions of *n*-hexane. Dilute the extracts in the volumetric flask with *n*-hexane to volume. Transfer NLT 20 mL of this solution to a suitable container, and evaporate in vacuum at room temperature to dryness. Transfer the residue with the aid of methanol to a suitable volumetric flask, and dilute with methanol to volume to obtain a concentration of 2 mg/mL of alpha tocopherol, alpha tocopheryl acetate, or alpha tocopheryl acid succinate.

**Sample solution for Capsules:** Transfer the contents of NLT 20 Capsules to a suitable container, mix, and weigh. Transfer a portion of the mixture, typically equivalent to 20 mg of the vitamin E form under testing but not exceeding 7.5 g of the mixture, to a centrifuge tube having a polytef-lined screw cap. [NOTE—For hard gelatin Capsules, remove, as completely as possible, the contents of NLT 20 Capsules by cutting open the Capsule shells, transferring the shells and their contents to a suitable container, and triturating to a homogeneous mass. Transfer a portion of the mass, typically equivalent to 20 mg of the vitamin E form under testing but not exceeding 7.5 g of the mixture to a centrifuge tube having a polytef-lined screw cap.] Add about 2 mL of dimethyl sulfoxide per each g of Capsule contents, and about 3 mL of *n*-hexane per each g of Capsule contents, and shake for 45 min on a shaker in a water bath maintained at 60°. [NOTE—Set up the shaker to ensure that the contents of the container are mixed vigorously and thoroughly.] Centrifuge at 3000 rpm for 10 min, and transfer the hexane layer by means of a pipet to a volumetric flask. [NOTE—Volumetric flask size: NLT 20 mL.] Add 3 mL of *n*-hexane per each g of Capsule contents to the dimethyl sulfoxide layer, shake thoroughly for 5 min, and transfer the hexane layer by means of a pipet to the same volumetric flask. Repeat this extraction with three additional portions of *n*-hexane. Dilute the extracts in the volumetric flask with *n*-hexane to volume. Transfer NLT 20 mL of this solution to a suitable container, and evaporate in vacuum at room temperature to dryness. Transfer the residue with the aid of methanol to a suitable volumetric flask, and dilute with methanol to volume to obtain a concentration of 2 mg/mL of alpha tocopherol, alpha tocopheryl acetate, or alpha tocopheryl acid succinate.

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 254 nm

**Column:** 8-mm × 10-cm; 5-µm packing L1

**Flow rate:** 2 mL/min
**Injection volume:** 100 µL

**System suitability**

**Samples:** *System suitability solution* and *Standard solution*

[NOTE—The relative retention times for ergocalciferol and alpha tocopheryl acetate are about 0.5 and 1.0, respectively.]

**Suitability requirements**

**Resolution:** NLT 12 between ergocalciferol and alpha tocopheryl acetate, *System suitability solution*
**Tailing factor:** 0.8–1.2, *System suitability solution*
**Relative standard deviation:** NMT 3.0%, *Standard solution*

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of alpha tocopherol, alpha tocopheryl acetate, or alpha tocopheryl acid succinate in the portion of the sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of the relevant vitamin E form from the *Sample solution*
$r_S$ = peak response of the relevant vitamin E form from the *Standard solution*
$C_S$ = concentration of the relevant vitamin E form of the corresponding USP Reference Standard in the *Standard solution* (mg/mL)
$C_U$ = nominal concentration of the corresponding form of vitamin E in the *Sample solution* (mg/mL)

- **PROCEDURE 2**
  - This procedure can be used for the formulations containing vitamins A, D, and E. Application includes:
    - Oil-Soluble Vitamins Tablets
    - Oil-Soluble Vitamins Capsules
    - Oil-Soluble Vitamins with Minerals Tablets
    - Oil-Soluble Vitamins with Minerals Capsules
    - Oil- and Water-Soluble Vitamins Tablets
    - Oil- and Water-Soluble Vitamins Capsules
    - Oil- and Water-Soluble Vitamins with Minerals Tablets
    - Oil- and Water-Soluble Vitamins with Minerals Capsules
  - It involves the treatment of sample with methanolic sulfuric acid, followed by extraction with 2,2,4-trimethylpentane.
  - Unless specified in the individual monographs, the *System suitability solution*, *Standard solution*, *Sample solutions*, and reagent solutions are prepared as follows.

**Mobile phase:** Mix 240 mL of methanol with 10 mL of water, followed by 0.5 mL of 50% phosphoric acid, and dilute with acetonitrile to 1000 mL.

**3 N methanolic sulfuric acid solution:** Cautiously add 9 mL of sulfuric acid to 80 mL of methanol in a 100-mL volumetric flask. Cool, and dilute with methanol to volume.

**Sodium ascorbate–pyrogallol solution:** Transfer 10 g of sodium ascorbate and 5 g of pyrogallol to a 100-mL volumetric flask, and add sufficient water to dissolve. Add 1.7 mL of sulfuric acid, and dilute with water to volume.

**Lecithin solution:** 5 mg/mL of lecithin in 2,2,4-trimethylpentane

**System suitability solution:** 2 mg/mL each of USP Alpha Tocopherol RS, USP Alpha Tocopheryl Acetate RS, and USP Alpha Tocopheryl Acid Succinate RS in methanol

**Standard solution:** 2 mg/mL of USP Alpha Tocopherol RS, USP Alpha Tocopheryl Acetate RS, or USP Alpha Tocopheryl Acid Succinate RS in methanol

**Sample solution for Tablets:** [NOTE—This preparation is suitable for the determination of vitamin A, vitamin D, and vitamin E when present in the formulation. The sample amount may be adjusted depending on the presence or absence of the appropriate vitamins.] Finely powder NLT 20 Tablets. Use a portion of the powder nominally equivalent to an amount 90 mg of alpha tocopherol, alpha tocopheryl acetate, or alpha tocopheryl acid succinate. Add 0.5 g of sodium bicarbonate, 1.5 mL of *Lecithin solution*, and 12.5 mL of 2,2,4-trimethylpentane, and disperse on a vortex mixer. Add 6 mL of *Sodium ascorbate–pyrogallol solution*, shake slowly, and allow the solution to degas. Continue shaking until the evolution of gas has ceased, and then shake for an additional 12 min. Add 6 mL of dimethyl sulfoxide, mix on a vortex mixer to form a suspension, and shake for 12 min. Add 6 mL of *3 N methanolic sulfuric acid solution*, mix on a vortex mixer to form a suspension, and shake for 12 min. Add 12.5 mL of 2,2,4-trimethylpentane, mix on a vortex mixer to form a suspension, and shake for 10 min. Centrifuge for 10 min to break up the emulsion and to clarify the supernatant. Transfer a volume of the supernatant 2,2,4-trimethylpentane layer to a suitable volumetric flask, the volume of the specimen withdrawn from the 2,2,4-trimethylpentane layer and the size of the volumetric flask being such that the final concentration of the *Sample solution* is equivalent to that of the *Standard solution*. Evaporate nearly to dryness, add several mL of methanol, and evaporate the remaining 2,2,4-trimethylpentane. Dilute with methanol to volume.

**Sample solution for Capsules:** [NOTE—This preparation is suitable for the determination of vitamin A, vitamin D, and vitamin E when present in the formulation. The sample amount may be adjusted depending on the presence or absence of the appropriate vitamins.] Weigh NLT 20 Capsules in a tared weighing bottle. Using a sharp blade if necessary, carefully open the Capsules, without loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing with several portions of ether. Discard the washings, and dry the Capsule shells with the aid of a current of dry air. Weigh the empty Capsule shells in the tared weighing bottle, and calculate the net

weight of the Capsule contents. Transfer a portion of the Capsule contents, equivalent to 55 mg of vitamin E, to a container having a polytef-lined screw cap. Add 0.5 g of sodium bicarbonate, 1.5 mL of *Lecithin solution*, and 12.5 mL of 2,2,4-trimethylpentane, and disperse on a vortex mixer. Add 6 mL of *Sodium ascorbate–pyrogallol solution*, shake slowly, and allow the solution to degas. Continue shaking until the evolution of gas has ceased, and then shake for an additional 12 min. Add 6 mL of dimethyl sulfoxide, mix on a vortex mixer to form a suspension, and shake for 12 min. Add 6 mL of *3 N methanolic sulfuric acid solution*, mix on a vortex mixer to form a suspension, and shake for 12 min. Add 12.5 mL of 2,2,4-trimethylpentane, mix on a vortex mixer to form a suspension, and shake for 10 min. Centrifuge for 10 min to break up the emulsion and to clarify the supernatant layer. Transfer a volume of the supernatant 2,2,4-trimethylpentane layer to a suitable volumetric flask, the volume of the specimen withdrawn from the 2,2,4-trimethylpentane layer and the size of the volumetric flask being such that the final concentration of the *Sample solution* is equivalent to that of the *Standard solution*. Evaporate nearly to dryness, add several mL of methanol, and evaporate the remaining 2,2,4-trimethylpentane. Dilute with methanol to volume.

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 280 nm

**Column:** 4.6-mm × 25-cm; 5-µm packing L1

**Flow rate:** 1.5 mL/min

**Injection volume:** 25 µL

**System suitability**

**Samples:** *System suitability solution* and *Standard solution*

[NOTE—The relative retention times for alpha tocopheryl acid succinate, alpha tocopherol, and alpha tocopheryl acetate are about 0.6, 0.8, and 1.0, respectively]

**Suitability requirements**

**Resolution:** NLT 4.0 between alpha tocopheryl acid succinate and alpha tocopherol; NLT 3.0 between alpha tocopherol and alpha tocopheryl acetate, *System suitability solution*

**Relative standard deviation:** NMT 3.0%, *Standard solution*

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of alpha tocopherol, alpha tocopheryl acetate, alpha tocopheryl acid succinate in the portion of the sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of the relevant vitamin E form from the *Sample solution*

$r_S$ = peak response of the relevant vitamin E form from the *Standard solution*

$C_S$ = concentration of the relevant vitamin E form of the corresponding USP Reference Standard in the *Standard solution* (mg/mL)

$C_U$ = nominal concentration of the corresponding form of vitamin E in the *Sample solution* (mg/mL)

[NOTE—Account for the initial extraction volume of 26.5 mL of 2,2,4-trimethylpentane and the dilution factor to exchange the solvent from 2,2,4-trimethylpentane to methanol to calculate the nominal concentration.]

- **PROCEDURE 3**
  - This procedure can be used for the determination of vitamin E in:
    - Oil-Soluble Vitamins Tablets
    - Oil-Soluble Vitamins Capsules
    - Oil-Soluble Vitamins with Minerals Tablets
    - Oil-Soluble Vitamins with Minerals Capsules
    - Oil- and Water-Soluble Vitamins Tablets
    - Oil- and Water-Soluble Vitamins Capsules
    - Oil- and Water-Soluble Vitamins with Minerals Tablets
    - Oil- and Water-Soluble Vitamins with Minerals Capsules
    - Oil- and Water-Soluble Vitamins Oral Solution
    - Oil- and Water-Soluble Vitamins with Minerals Oral Solution
  - It involves the saponification of the sample, followed by a liquid–liquid extraction of vitamin E from the sample with *n*-hexane. Evaporate the hexane extract to dryness, and reconstitute the residue in a mixture of acetonitrile and ethyl acetate (1:1).
  - Unless specified in the individual monographs, the *Standard solution*, *Sample solutions*, and reagent solutions are prepared as follows.

**Mobile phase:** Methanol, acetonitrile, and *n*-hexane (46.5: 46.5: 7.0)

**Diluent:** Acetonitrile and ethyl acetate (1:1)

**Potassium hydroxide solution:** [NOTE—Used for the Oral Solution sample.] Transfer 90 g of potassium hydroxide pellets to a 100-mL volumetric flask containing 60 mL of water. Mix to dissolve, cool, and dilute with water to volume.

**Standard solution:** 0.3 mg/mL of USP Alpha Tocopherol RS in *Diluent*

**Sample solution for Tablets:** Finely powder NLT 20 Tablets. Transfer a portion of the powder, equivalent to 8 mg of alpha tocopherol, to a 125-mL flask fitted with a ground-glass joint. Add 25.0 mL of water, 25.0 mL of dehydrated alcohol, and 3.5 g of potassium hydroxide pellets. Shake for 1 h in a water bath maintained at 55°. Cool, and transfer with the aid of a

@2024 USPC

minimum volume of water to a 125-mL separatory funnel. Rinse the flask with 50 mL of *n*-hexane, and add the rinsing to the separatory funnel. Insert the stopper, shake vigorously for 60 s, and allow the layers to separate. Drain the aqueous layer into a second 250-mL separatory funnel, and repeat the extraction with 50 mL of *n*-hexane. Discard the aqueous layer, and combine the hexane extracts. Wash the combined extracts with 25 mL of water, allow the layers to separate, and discard the aqueous layer. Add 3 drops of glacial acetic acid, and repeat the washing procedure two more times. Filter the washed hexane layer through anhydrous sodium sulfate into a 250-mL round-bottom flask. Rinse the funnel and sodium sulfate with a few mL of *n*-hexane, and add the rinsing to the hexane solution in the flask. Place the flask in a water bath maintained at 50°, and evaporate the hexane solution with the aid of a rotary evaporator to dryness. Immediately add 25.0 mL of *Diluent*, and swirl to dissolve the residue.

**Sample solution for Capsules:** Weigh NLT 20 Capsules in a tared weighing bottle. Open the Capsules, without loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing with several portions of ether. Discard the washings, and dry the Capsule shells with the aid of a current of dry air. Weigh the empty Capsule shells in the tared weighing bottle, and calculate the net weight of the Capsule contents. Transfer a portion of the Capsule contents, equivalent to an amount of 8.0 mg of alpha tocopherol, to a glass-stoppered conical flask. Add 25.0 mL of water, 25.0 mL of dehydrated alcohol, and 3.5 g of potassium hydroxide pellets. Shake for 1 h in a water bath maintained at 55°. Cool, and transfer with the aid of a minimum volume of water to a 125-mL separatory funnel. Rinse the flask with 50 mL of *n*-hexane, and add the rinsing to the separatory funnel. Insert the stopper, shake vigorously for 60 s, and allow the layers to separate. Drain the aqueous layer into a second 250-mL separatory funnel, and repeat the extraction with 50 mL of *n*-hexane. Discard the aqueous layer, and combine the hexane extracts. Wash the combined extracts with 25 mL of water, allow the layers to separate, and discard the aqueous layer. Add 3 drops of glacial acetic acid, and repeat the washing procedure two more times. Filter the washed hexane layer through anhydrous sodium sulfate into a 250-mL round-bottom flask. Rinse the funnel and sodium sulfate with a few mL of *n*-hexane, and add the rinsing to the hexane solution in the flask. Place the flask in a water bath maintained at 50°, and evaporate the hexane solution with the aid of a rotary evaporator to dryness. Immediately add 25.0 mL of *Diluent*, and swirl to dissolve the residue.

**Sample solution for Oral Solution:** Transfer an amount of Oral Solution equivalent to 1.5 mg of alpha tocopherol to a 125-mL conical flask fitted with a ground-glass joint, and add 25.0 mL of dehydrated alcohol. Attach a reflux condenser, and reflux in a boiling water bath for 1 min. Cautiously add 3 mL of *Potassium hydroxide solution* through the condenser, and continue to reflux for 30 min. Remove the flask from the bath, and rinse the condenser with about 15 mL of water. Cool, and transfer with a minimum volume of water to a 250-mL separatory funnel. Rinse the flask with 50 mL of *n*-hexane, and add the rinsings to the separatory funnel. Insert the stopper, shake vigorously for 1 min, and allow the layers to separate. Drain the aqueous layer into a second 250-mL separatory funnel, and repeat the extraction with 50 mL of *n*-hexane. Discard the aqueous layer, and combine the hexane extracts. Wash the combined extracts with 25 mL of water, allow the layers to separate, and discard the aqueous layer. Add 3 drops of glacial acetic acid, and repeat the washing procedure two more times. Filter the washed hexane layer through anhydrous sodium sulfate into a 250-mL round-bottom flask. Rinse the funnel and sodium sulfate with *n*-hexane, and add the rinsing to the hexane solution in the flask. Evaporate the hexane solution to dryness with the aid of a rotary evaporator over a water bath maintained at about 50°. Immediately add 5.0 mL of *Diluent*, and swirl to dissolve the residue.

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC
**Detector:** UV 291 nm

**Column temperature:** 40°
**Flow rate:** 3 mL/min
**Injection volume:** 20 µL

**System suitability**

**Sample:** *Standard solution*
**Suitability requirements**
**Relative standard deviation:** NMT 0.5%

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of vitamin E, as alpha tocopherol, in the portion of the sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of alpha tocopherol from the *Sample solution*
$r_S$ = peak response of alpha tocopherol from the *Standard solution*
$C_S$ = concentration of USP Alpha Tocopherol RS in the *Standard solution* (mg/mL)
$C_U$ = nominal concentration of vitamin E, as alpha tocopherol, in the *Sample solution* (mg/mL)

[NOTE—Calculate the alpha tocopherol equivalent of alpha tocopheryl acetate, or alpha tocopheryl acid succinate by multiplying their contents by the factors 0.91 or 0.81, respectively.]

- **PROCEDURE 4**
  - This gas chromatographic procedure is provided for the determination of vitamin E as an active pharmaceutical ingredient, as a dietary supplement ingredient, or as a component in compendial dosage forms. It can be used for:
    - Vitamin E
    - Vitamin E Capsules

- Vitamin E Preparation
- Unless specified in the individual monographs, the *Standard solutions*, *Sample solutions*, and reagent solutions are prepared and used appropriately as follows.

**Internal standard solution:** 10 mg/mL of squalane in cyclohexane

**System suitability solution:** 0.1 mg/mL each of USP Alpha Tocopherol RS and USP Alpha Tocopheryl Acetate RS in cyclohexane

**Standard solution 1:** 10 mg/mL of USP Alpha Tocopherol RS in *Internal standard solution*

**Standard solution 2:** 10 mg/mL of USP Alpha Tocopheryl Acetate RS in *Internal standard solution*

**Standard solution 3:** Transfer 30.0 mg of USP Alpha Tocopheryl Acid Succinate RS into a 20-mL vial. Add 2.0 mL of methanol, 1.0 mL of 2,2-dimethoxypropane, and 0.1 mL of hydrochloric acid to the vial. Cap tightly, and sonicate. Allow to stand in the dark for 1 h ± 5 min. Remove from the dark, uncap, and evaporate just to dryness on a steam bath with the aid of a stream of nitrogen. Add 3.0 mL of *Internal standard solution*, and mix on a vortex mixer to dissolve.

**Sample solutions for Active Pharmaceutical Ingredient**

**Sample solution 1** (vitamin E as alpha tocopherol or alpha tocopheryl acetate)**:** 10 mg/mL of Vitamin E (*d*- or *dl*-alpha tocopherol or *d*- or *dl*-alpha tocopheryl acetate) in *Internal standard solution*

**Sample solution 2** (vitamin E as alpha tocopheryl acid succinate)**:** Transfer 30.0 mg of Vitamin E (*d*- or *dl*-alpha tocopheryl acid succinate) into a 20-mL vial. Add 2.0 mL of methanol, 1.0 mL of 2,2-dimethoxypropane, and 0.1 mL of hydrochloric acid to the vial. Cap tightly, and sonicate. Allow to stand in the dark for 1 h ± 5 min. Remove from the dark, uncap, and evaporate just to dryness on a steam bath with the aid of a stream of nitrogen. Add 3.0 mL of *Internal standard solution*, and mix on a vortex mixer to dissolve.

**Sample solutions for Vitamin E Preparation**

**Sample solution 1** (vitamin E as alpha tocopherol or alpha tocopheryl acetate in liquid form)**:** Dissolve a portion of Preparation in *Internal standard solution* to prepare a Vitamin E (*d*- or *dl*-alpha tocopherol or *d*- or *dl*-alpha tocopheryl acetate) solution with nominal concentration of 10 mg/mL.

**Sample solution 2** (vitamin E as alpha tocopheryl acid succinate in liquid form)**:** Transfer a portion of Preparation, equivalent to 30.0 mg of Vitamin E (*d*- or *dl*-alpha tocopheryl acid succinate), into a 20-mL vial. Add 2.0 mL of methanol, 1.0 mL of 2,2-dimethoxypropane, and 0.1 mL of hydrochloric acid to the vial. Cap tightly, and sonicate. Allow to stand in the dark for 1 h ± 5 min. Remove from the dark, uncap, and evaporate just to dryness on a steam bath with the aid of a stream of nitrogen. Add 3.0 mL of *Internal standard solution*, and mix on a vortex mixer to dissolve.

**Sample solution 3** (vitamin E as alpha tocopherol or alpha tocopheryl acetate in solid form)**:** Transfer a portion of Preparation, equivalent to 50 mg of alpha tocopherol or alpha tocopheryl acetate, into a flask suitable for refluxing. Add 5 mL of water, and heat on a water bath at 60° for 10 min. Add 25 mL of alcohol, and reflux for 30 min. Cool, and transfer to a separator with the aid of 50 mL of water and 50 mL of ether. Shake vigorously, allow the layers to separate, and collect each layer in individual separators. Extract the aqueous layer with two 25-mL portions of ether, combining the extracts with the original ether layer. Wash the combined extract with one 25-mL portion of water, filter the ether solutions through 1 g of anhydrous sodium sulfate, and with the aid of a stream of nitrogen evaporate the ether solution on a water bath, controlled at a temperature that will not cause the ether solution to boil over. Remove the container from the water bath when 5 mL remains, and complete the evaporation without the application of heat. Dissolve the residue in *Internal standard solution* to prepare a Vitamin E (*d*- or *dl*-alpha tocopherol or *d*- or *dl*-alpha tocopheryl acetate) solution with nominal concentration of 10 mg/mL.

**Sample solution 4** (vitamin E as alpha tocopheryl acid succinate in solid form)**:** Transfer a portion of Preparation, equivalent to 30 mg of Vitamin E (*d*- or *dl*-alpha tocopheryl acid succinate), into a flask suitable for refluxing. Add 5 mL of water, and heat on a water bath at 60° for 10 min. Add 25 mL of alcohol, and reflux for 30 min. Cool, and transfer to a separator with the aid of 50 mL of water and 50 mL of ether. Shake vigorously, allow the layers to separate, and collect each layer in individual separators. Extract the aqueous layer with two 25-mL portions of ether, combining the extracts with the original ether layer. Wash the combined extract with one 25-mL portion of water, filter the ether solutions through 1 g of anhydrous sodium sulfate, and with the aid of a stream of nitrogen evaporate the ether solution on a water bath, controlled at a temperature that will not cause the ether solution to boil over. Remove the container from the water bath when 5 mL remains. Quantitatively transfer the remains into a 20-mL vial, and complete the evaporation without the application of heat. Add 2.0 mL of methanol, 1.0 mL of 2,2-dimethoxypropane, and 0.1 mL of hydrochloric acid to the vial. Cap tightly, and sonicate. Allow to stand in the dark for 1 h ± 5 min. Remove from the dark, uncap, and evaporate just to dryness on a steam bath with the aid of a stream of nitrogen. Add 3.0 mL of *Internal standard solution*, and mix on a vortex mixer to dissolve.

**Sample solutions for Vitamin E Capsules**

**Sample solution 1** (vitamin E as alpha tocopherol or alpha tocopheryl acetate)**:** Weigh NLT 10 Capsules in a tared weighing bottle. With a sharp knife or by other appropriate means, carefully open the Capsules, without loss of the shell material, and transfer the combined Capsule content to a 100-mL beaker. Remove any adhering substance from the emptied Capsules by washing with several small portions of *n*-hexane. Discard the washings, and allow the empty Capsules to dry in a current of dry air until the odor of *n*-hexane is no longer perceptible. Weigh the empty Capsules in the original tared weighing bottle, and calculate the average net weight per Capsule. Dissolve a portion of the combined Capsule contents in *Internal standard solution* to prepare a Vitamin E (*d*- or *dl*-alpha tocopherol or *d*- or *dl*-alpha tocopheryl acetate) solution with a nominal concentration of 10 mg/mL.

**Sample solution 2** (vitamin E as alpha tocopheryl acid succinate)**:** Weigh NLT 10 Capsules in a tared weighing bottle. With a sharp knife or by other appropriate means, carefully open the Capsules, without loss of the shell material, and transfer the combined Capsule content to a 100-mL beaker. Remove any adhering substance from the emptied Capsules by washing with several small portions of *n*-hexane. Discard the washings, and allow the empty Capsules to dry in a current of dry air until the odor of *n*-hexane is no longer perceptible. Weigh the empty Capsules in the original tared weighing bottle, and calculate the average net weight per Capsule. Transfer a portion of the combined Capsule contents, equivalent to 30.0 mg of Vitamin E (*d*- or *dl*-alpha tocopheryl acid succinate), into a 20-mL vial. Add 2.0 mL

**Chromatographic system**
(See *Chromatography* ⟨621⟩, *System Suitability*.)
**Mode:** GC
**Detector:** Flame ionization
**Column:** 0.25-mm × 30-m fused-silica capillary, bonded with a 0.25-µm film of phase G2
**Temperatures**
**Column:** 280°
**Injection port:** 290°
**Detector:** 290°
**Carrier gas:** Helium
**Flow rate:** 1 mL/min
**Split ratio:** 100:1
**Injection volume:** 1 µL
**System suitability**
**Samples:** *System suitability solution* and appropriate *Standard solution*
**Suitability requirements**
**Resolution:** NLT 3.5 between alpha tocopherol and alpha tocopheryl acetate, *System suitability solution*
**Relative standard deviation:** NMT 2.0% for ratios of relevant vitamin E form to internal standard peak responses from replicate injections, appropriate *Standard solution*
**Analysis**
**Samples:** Appropriate *Standard solution* and appropriate *Sample solution*
Calculate the percentage of vitamin E in terms of alpha tocopherol, alpha tocopheryl acetate, or alpha tocopheryl acid succinate in the portion of the sample taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

$R_U$ = internal standard ratio (peak response of relevant vitamin E form/peak response of the internal standard) from the appropriate *Sample solution*
$R_S$ = internal standard ratio (peak response of relevant vitamin E form/peak response of the internal standard) from the appropriate *Standard solution*
$C_S$ = concentration of the corresponding USP Reference Standard in the appropriate *Standard solution* (mg/mL)
$C_U$ = nominal concentration of the corresponding form of vitamin E in the appropriate *Sample solution* (mg/mL)

- **PROCEDURE 5**
  - This gas chromatographic procedure is provided for the determination of Vitamin E (as *d*- or *dl*-alpha tocopherol) in:
    - Vitamin E Polyethylene Glycol Succinate (Vitamin E polyethylene glycol succinate is a mixture formed by the esterification of *d*-alpha tocopheryl acid succinate and polyethylene glycol).
  - Unless specified in the individual monographs, the *Standard solutions*, *Sample solutions*, and reagent solutions are prepared as follows.

**Solvent:** 0.25 mL of phenolphthalein TS in 1 L of alcohol
**Internal standard solution:** 12 mg/mL of ethyl arachidate in isooctane
**Standard solution:** Transfer 32.5 mg of USP Alpha Tocopherol RS to a suitable reaction flask. Add 2 mL of pyridine and 0.5 mL of *N,O*-bis(trimethylsilyl)trifluoroacetamide with 1% trimethylchlorosilane, and heat the flask at 100° for 10 min. Cool the flask, add 5.0 mL of *Internal standard solution* followed by 20 mL of isooctane, and shake.
**Sample solution:** Transfer a quantity equivalent to 0.100–0.160 g of Vitamin E Polyethylene Glycol Succinate molten at 60° to a culture tube (about 20 cm long and 2.5 cm in diameter) equipped with a screw cap. Add 40–50 mg of ascorbic acid and a few boiling chips, followed by 20 mL of *Solvent*. [NOTE—Reflux the solution gently without emission of contents. Place the tube in a heating block set at 100°–150°.] When the sample is fully dissolved, add 0.25 g of potassium hydroxide, and continue to reflux for 30 min. Remove the tube from heat, and while contents are still hot, add 1–2 mL of hydrochloric acid dropwise until the pink coloration disappears. [**CAUTION**—Exothermic reaction. Allow the acid to trickle down the inside of the tube to prevent splashing.] Cool the tube, then wash the sides of the tube with 20 mL of water. Add 5.0 mL of *Internal standard solution*, cap, and shake to ensure thorough mixing. Allow the tube to stand until two distinct layers are formed. Transfer 2.5–3.5 mL of the upper layer into a suitable reaction flask, and add 2.0 mL of pyridine followed by 2.5 mL of *N,O*-bis(trimethylsilyl)trifluoroacetamide with 1% trimethylchlorosilane. Heat the flask at 100° for 10 min. Cool, and then add 12 mL of isooctane.
**Chromatographic system**
(See *Chromatography* ⟨621⟩, *System Suitability*.)
**Mode:** GC
**Detector:** Flame ionization

# ⟨561⟩ ARTICLES OF BOTANICAL ORIGIN

## SAMPLING

To reduce the effect of sampling bias in qualitative and quantitative results, it is necessary to ensure that the composition of the sample used be representative of the batch of drugs being examined. The following sampling procedures are the minimum considered applicable to vegetable drugs. Some articles, or some tests, may require more rigorous procedures involving more containers being sampled or more samples per container.

### Gross Sample

Where external examination of containers, markings, and labels indicates that the batch can be considered to be homogeneous, take individual samples from the number of randomly selected containers indicated below. Where the batch cannot be considered to be homogeneous, divide it into sub-batches that are as homogeneous as possible, and then sample each one as a homogeneous batch. It is recommended to include samples from the first, middle, and last containers where the *No. of Containers in Batch* (*N*) is 11 or more, and each container in the batch is numbered or lettered in order.

| No. of Containers in Batch (*N*) | No. of Containers to Be Sampled (*n*) |
|---|---|
| 1–10 | All |
| 11–19 | 11 |
| >19 | $n = 10 + (N/10)$ |

(Rounding was calculated as "*n*" to next highest whole number.)

Samples are taken from the upper, middle, and lower sections of each container. If the crude material consists of component parts that are 1 cm or less in any dimension, and in the case of all powdered or ground materials, withdraw the sample by means of a sampling device that removes a core from the top to the bottom of the container, NLT two cores being taken from different angles. For materials with component parts >1 cm in any dimension, withdraw samples by hand. In the case of large bales or packs, samples should be taken from a depth of 10 cm, because the moisture content of the surface layer may be different from that of the inner layers.

Prepare the gross sample by combining and mixing the individual samples taken from each opened container, taking care not to increase the degree of fragmentation or significantly affect the moisture content.

For articles in containers holding <1 kg, mix the contents, and withdraw a quantity sufficient for the tests. For articles in containers holding 1–5 kg, withdraw equal portions from the upper, middle, and lower parts of the container, each of the samples being sufficient to carry out the tests. Thoroughly mix the samples, and withdraw an amount sufficient to carry out the tests. For containers holding more than 5 kg, withdraw three samples, each weighing NLT 250 g, from the upper, middle, and lower parts of the container. Thoroughly mix the samples, and withdraw a portion sufficient to carry out the tests.

### Laboratory Sample

Prepare the *Laboratory Sample* by repeated quartering of the gross sample.

[NOTE—Quartering consists of placing the sample, adequately mixed, as an even and square-shaped heap and dividing it diagonally into four equal parts. The two opposite parts are then taken and carefully mixed. The process is repeated as necessary until the required quantity is obtained.]

The *Laboratory Sample* should be of a size sufficient for performing all the necessary tests.

### Test Sample

Unless otherwise directed in the individual monograph or test procedure below, prepare the *Test Sample* as follows.

Decrease the size of the *Laboratory Sample* by quartering, taking care that each withdrawn portion remains representative. In the case of unground or unpowdered drugs, grind the withdrawn sample so that it will pass through a No. 20 standard-mesh sieve, and mix the resulting powder well. If the material cannot be ground, reduce it to as fine a state as possible, mix by rolling it on paper or sampling cloth, spread it out in a thin layer, and withdraw the portion for analysis.

## METHODS OF ANALYSIS

### Foreign Organic Matter

TEST SAMPLE

Unless otherwise specified in the individual monograph, weigh the following quantities of the *Laboratory Sample*, taking care that the withdrawn portion is representative (quartering if necessary).

| | |
|---|---|
| Roots, rhizomes, bark, and herbs | 500 g |
| Leaves, flowers, seeds, and fruit | 250 g |
| Cut vegetable drugs (average weight of the pieces is <0.5 g) | 50 g |

Spread the sample out in a thin layer, and separate the foreign organic matter by hand as completely as possible. Weigh it, and determine the percentage of foreign organic matter in the weight of drug taken.

## Total Ash

Accurately weigh a quantity of the *Test Sample*, representing 2–4 g of the material, in a tared crucible and incinerate, gently at first, and gradually increase the temperature to 675 ± 25° until free from carbon, and determine the weight of the ash. [NOTE—For botanicals, a material in conformance with the *Loss on Drying* test in individual monographs should be used.] If a carbon-free ash cannot be obtained in this way, extract the charred mass with hot water, collect the insoluble residue on an ashless filter paper, incinerate the residue and filter paper until the ash is white or nearly so, then add the filtrate, evaporate it to dryness, and heat the whole to a temperature of 675 ± 25°. If a carbon-free ash cannot be obtained in this way, cool the crucible, add 15 mL of alcohol, break up the ash with a glass rod, burn off the alcohol, and again heat the whole to a temperature of 675 ± 25°. Cool in a desiccator, weigh the ash, and calculate the percentage of total ash from the weight of the drug taken.

## Acid-Insoluble Ash

Boil the ash obtained as directed in *Total Ash* with 25 mL of 3 N hydrochloric acid for 5 min, collect the insoluble matter on a tared filtering crucible or ashless filter, wash with hot water, ignite, and weigh. Determine the percentage of acid-insoluble ash calculated from the weight of drug taken.

## Water-Soluble Ash

Boil the ash obtained as directed in *Total Ash* with 25 mL of water for 5 min. Collect the insoluble matter in a sintered-glass crucible or on an ashless filter paper. Wash with hot water, and ignite for 15 min at a temperature not exceeding 450°. Subtract the weight of this residue, in mg, obtained in *Total Ash*, and calculate the percentage of water-soluble ash with reference to the weight of sample as determined in *Total Ash*.

## Alcohol-Soluble Extractives

### METHOD 1 (HOT EXTRACTION METHOD)

Transfer about 4 g of air-dried, coarsely powdered material, accurately weighed, to a glass-stoppered conical flask. Add 100 mL of alcohol, and weigh the flask. Shake, and allow to stand for 1 h. Attach a reflux condenser to the flask, boil gently for 1 h, cool, and weigh. Readjust to the original weight with alcohol. Shake, and filter rapidly through a dry filter. Transfer 25 mL of the filtrate to a tared flat-bottomed dish, and evaporate on a water bath to dryness. Dry at 105° for 6 h, cool in a desiccator for 30 min, and weigh without delay. Calculate the content, in mg/g, of alcohol-extractable matter in the test specimen.

### METHOD 2 (COLD EXTRACTION METHOD)

Transfer about 4 g of air-dried, coarsely powdered material, accurately weighed, to a glass-stoppered conical flask. Add 100 mL of alcohol, insert a stopper into the flask, and macerate for 24 h, shaking frequently during the first 8 h, and then allowing to stand. Filter rapidly, taking precautions against loss of alcohol. Evaporate 25 mL of the filtrate to dryness in a tared, flat-bottomed, shallow dish, and dry at 105° to constant weight. Calculate the content, in mg/g, of alcohol-extractable matter in the test specimen.

## Water-Soluble Extractives

### METHOD 1 (HOT EXTRACTION METHOD)

Proceed as directed in *Method 1 (Hot Extraction Method)* in *Alcohol-Soluble Extractives*, except use water in place of alcohol.

### METHOD 2 (COLD EXTRACTION METHOD)

Proceed as directed in *Method 2 (Cold Extraction Method)* in *Alcohol-Soluble Extractives*, except use water in place of alcohol.

## Crude Fiber

Exhaust a weighed quantity of the *Test Sample*, representing about 2 g of the material, with ether. Add 200 mL of boiling dilute sulfuric acid (1 in 78) to the ether-exhausted marc, in a 500-mL flask, and connect the flask to a reflux condenser. Reflux the mixture for 30 min, accurately timed, then pass through a linen or hardened-paper filter, and wash the residue on the filter with boiling water until the effluent washing is no longer acid. Rinse the residue back into the flask with 200 mL of boiling sodium hydroxide solution, adjusted to 1.25% by titration and free from sodium carbonate. Again reflux the mixture for 30 min,

Official

https://pharmacopeia.cn/v29240/

accurately timed, then rapidly pass through a tared filter, wash the residue with boiling water until the last washing is neutral, and dry it at 110° to constant weight. Incinerate the dried residue, ignite to constant weight, cool in a desiccator, and weigh the ash: the difference between the weight obtained by drying at 110° and that of the ash represents the weight of the crude fiber.

[NOTE—The boiling with acid and alkali should continue for 30 min, accurately timed, from the time that the liquid (which is cooled below the boiling point by being added to the cold flask) again boils. After the solution has been brought to boiling, the heat should be turned low enough just to maintain boiling. During the boiling, the flask should be gently rotated from time to time to wash down any particles that may adhere to the walls of the flask. A slow current of air introduced into the flask during the boiling operation aids in preventing excessive frothing.]

## Starch Content

### METHOD 1

The following is a general procedure for all reducing sugars and may be used to determine the starch content in botanical articles.

**Malt extract:** Use clean new barley malt of known efficacy, and grind just before use. Prepare malt extract just before use. For every 80 mL of malt extract needed, digest 5 g of ground malt with 100 mL of water at room temperature for 2 h. [NOTE—If an electric mixer is used, stir the mixture for 20 min.] Filter to obtain a clear extract, filtering again, if necessary, and mix the infusion well.

**Test solution:** Extract about 5 g of the finely ground test specimen with five 10-mL portions of ether, using a filter that will completely retain the smallest starch granule. Allow the ether to evaporate from the residue, and wash with 250 mL of aqueous alcohol solution (10 in 100). Carefully wash the residue from the paper into a 500-mL beaker with about 100 mL of water. Heat to about 60° (avoiding, if possible, gelatinizing starch), and allow to stand for about 1 h, stirring frequently to effect complete solution of sugars. Transfer to a wide-mouth bottle, rinse the beaker with a little warm water, and cool. Add an equal volume of alcohol, mix, and allow to stand for NLT 1 h.

Centrifuge until the precipitate is closely packed on the bottom of the bottle, and decant the supernatant. Wash the precipitate with successive 50-mL portions of alcohol solution (50 in 100) by centrifuging and decanting through a suitable filter until the washings are sugar free. [NOTE—To test for the presence of sugar, transfer a few drops of the washings to a test tube, and add 3 or 4 drops of a 20% solution of 1-naphthol in alcohol prepared by dissolving 200 mg of 1-naphthol in 1 mL of alcohol and 2 mL of water. Shake the test tube well to allow uniform mixing, allow 2–4 mL of sulfuric acid to flow down the sides of the test tube, and hold the test tube upright. If sugar is present, the interface of the two liquids is colored faint to deep violet, and on shaking, the whole solution becomes blue-violet.]

Transfer the residue from the bottle and hardened filter to a beaker with about 50 mL of water. Immerse the beaker in boiling water, and stir constantly for 15 min or until all of the starch is gelatinized. Cool the beaker to 55°, add 20 mL of *Malt extract*, and hold at this temperature for 1 h. Heat again to boiling for a few min, cool to 55°, add 20 mL of *Malt extract*, and hold at this temperature for 1 h or until the residue when treated with iodine TS shows no blue tinge upon microscopic examination. Cool, dilute with water to 250 mL, and filter.

**General procedure:** Transfer 200 mL of the *Test solution* to a flask fitted with a reflux condenser, add 20 mL of hydrochloric acid, and heat in a boiling water bath for 2.5 h. Cool, nearly neutralize with sodium hydroxide TS, complete neutralization with sodium carbonate TS, dilute with water to 500 mL, mix, and filter. The volume of aliquot taken depends on the starch content of the specimen under test (see *Table 1*). The aliquot should contain between 100 and 200 mg of dextrose. Transfer 50 mL of the filtrate to a 400-mL alkali-resistant glass beaker, add 50 mL of alkaline cupric tartrate TS, cover the beaker with a water glass, and heat. Adjust the flame in the burner so that the contents of the flask begin to boil in 4 min, and continue boiling for exactly 2 min. Pass the hot solution at once through a sintered-glass filter. Wash the precipitate of cuprous oxide thoroughly with water at about 60°, then with 10 mL of alcohol, and finally with 10 mL of ether.

**Table 1. Determination of the Optimum Aliquot**

| Expected Starch Content (%) | Aliquot (mL) |
|---|---|
| 60 | 25 |
| 50 | 35 |
| 40 | 50 |
| 30 | 50 |
| 20 | 50 |

For solutions of reducing sugars of comparatively high purity, proceed as directed in *Method 1A* to determine the amount of reduced copper obtained by weighing the dried cuprous oxide. For solutions of reducing sugars containing large amounts of organic impurities, including sucrose, proceed as directed in *Method 1B* to determine the amount of reduced copper obtained by titration with sodium thiosulfate.

*Method 1A:* Dry the precipitate obtained in *General procedure* for 30 min in an oven at 110 ± 2°, cool to room temperature in a desiccator, and weigh. Refer to *Table 2* to find the quantity of dextrose, in mg, corresponding to the weight of cuprous oxide found. Determine the percentage of dextrose and then the content of starch by the following formula:

$$\text{Percentage of dextrose} = (\text{wt. of dextrose in mg} \times 0.1 \times 500)/(\text{wt. of sample in g} \times \text{aliquot in mL})$$

*Method 1B*

SODIUM THIOSULFATE SOLUTION: Transfer 3.9 g of sodium thiosulfate, accurately weighed, to a 100-mL volumetric flask, dissolve in and dilute with water to volume, and mix.

POTASSIUM IODIDE SOLUTION: Dissolve 42 g of potassium iodide in 100 mL of water.

SODIUM ACETATE SOLUTION: Dissolve 5.74 g of sodium acetate in 10 mL of water.

COPPER SOLUTION: Transfer about 0.3 g of pure electrolytic copper, accurately weighed, to a 250-mL flask, add 5 mL of nitric acid to dissolve the copper, add about 25 mL of water, and boil to expel red fumes. Add about 5 mL of bromine TS, and boil until the bromine is completely removed. Cool, add 10 mL of *Sodium acetate solution* followed by 10 mL of *Potassium iodide solution*, and titrate with *Sodium thiosulfate solution* to a light yellow color. Add enough starch TS to produce a marked blue color, and continue the titration. As the endpoint nears, add 2 g of potassium thiocyanate, and stir until completely dissolved. Continue titration until the precipitate is completely white. One mL of *Sodium thiosulfate solution* is equivalent to about 10 mg of copper. [NOTE—It is essential that the concentration of *Potassium iodide solution* be carefully regulated. If the solution contains less than 320 mg of copper at the completion of titration, add 4.2–5 g of potassium iodide to make a total solution of 100 mL. If greater amounts of copper are present, add *Potassium iodide solution* slowly, with constant agitation, from the buret in amounts proportionately greater.]

PROCEDURE: Wash the precipitated cuprous oxide obtained in *General procedure* with water, cover this filter with a watch glass, and dissolve the cuprous oxide with 5 mL of nitric acid directed under the watch glass with a pipette. Collect the filtrate in a 250-mL flask, wash the watch glass, and the filter with water. Collect all the washings in the flask. Boil the contents of the flask to expel red fumes. Add about 5 mL of bromine TS, and boil until the bromine is completely removed. Cool, and proceed as directed in *Copper solution* beginning with "add 10 mL of *Sodium acetate solution*". From the volume of *Sodium thiosulfate solution* consumed, obtain the weight of copper, in mg, and multiply the weight of copper by 1.1259 to obtain the weight, in mg, of cuprous oxide. From *Table 2*, find the quantity of dextrose, in mg, corresponding to the weight of cuprous oxide. The content of starch is equivalent to the weight, in mg, of dextrose obtained times 0.9. Conduct a blank determination, using 50 mL of alkaline cupric tartrate TS and 50 mL of *Malt extract*. If the weight of the cuprous oxide so obtained exceeds 0.5 mg, correct the result of the determination accordingly. [NOTE—The alkaline cupric tartrate TS deteriorates on standing, and the quantity of cuprous oxide obtained in the blank determination increases.]

## METHOD 2

The following method is specific for dextrose (glucose), and because of its extreme sensitivity it may account for differences noted between values obtained from the same specimen. Duplicate determinations do not vary more than 2%.

**Glucoamylase solution:** Prepare a solution of glucoamylase in water containing 30 International Units (IU)/mL. Use glucoamylase obtained preferably from *Rhizopus delemar*. The total glucoamylase activity of the test specimen being used should be NLT 150 IU.

**Acetate buffer solution:** Dissolve 16.4 g of sodium acetate in 100 mL of water, add 12.0 mL of glacial acetic acid, and mix. The pH of this solution is 4.8.

**Phosphate buffer:** Dissolve 3.63 g of tris(hydroxymethyl) aminomethane and 5.0 g of monobasic sodium phosphate in 50.0 mL of water. At 37°, adjust with phosphoric acid to a pH of 7.0, dilute with water to 100.0 mL, and mix. [NOTE—The pH of the buffer medium is sensitive to temperature and should be adjusted to the desired pH at the temperature to be used during incubation.]

**Enzyme solution:** Dissolve 30 mg of glucose oxidase (Type II from *Aspergillus niger*), 3 mg of peroxidase (Type I from horseradish), and 10 mg of potassium ferrocyanide in 100 mL of *Phosphate buffer*. [NOTE—This mixture can be stored in a refrigerator for up to 10 days.]

**18 N sulfuric acid:** Add slowly, while stirring, 54 mL of sulfuric acid to 102 mL of water, allow to cool to 25°, and mix.

**Standard solutions:** Dissolve an accurately weighed quantity of USP Dextrose RS in water to obtain a solution containing 1.0 mg/mL of USP Dextrose RS. Quantitatively dilute a known volume of this solution with water to obtain *Standard solutions A*, *B*, *C*, *D*, and *E*, having known concentrations of 10, 20, 25, 40, and 50 µg/mL of USP Dextrose RS, respectively. [NOTE—Allow 4 h for complete mutarotation before use.]

**Test solutions:** Extract about 5 g of finely ground test specimen with five 25-mL portions of 80% alcohol, and filter. Remove all the alcohol from the residue by drying in an air oven at 105° for about 8 h. [NOTE—Any traces of alcohol remaining in the residue will inhibit glucoamylase.] Cool, and transfer the flask containing the dried test specimen to a desiccator. Transfer about 1 g, accurately weighed, of the test specimen to a previously tared flask, add 25 mL of water, and adjust with phosphoric acid to a pH of 5.0–7.0, if necessary. Boil the suspension for about 3 min, transfer the flask to an autoclave, and heat to 135° for 2 h. Remove the flask from the autoclave, maintain the temperature near 55°, and add 2.5 mL of *Acetate buffer solution* and sufficient water to adjust the total weight of the solution to 45 ± 1 g. Immerse the flask in a water bath maintained at 55 ± 1°, and add 5 mL of *Glucoamylase solution*. Continuously swirl the flask for 2 h to effect hydrolysis, pass through filter paper into a 250-mL volumetric flask, wash quantitatively with water, and collect all the washings in the flask. Dilute the contents of the flask with water to volume, and mix. Transfer 1 mL of an aliquot containing 20–60 µg of D-glucose to each of five test tubes.

@2024 USPC

[NOTE—To obtain the range of concentration of glucose in the hydrolysate, quantitatively dilute, if necessary, with water to volume.] Add 2 mL of *Enzyme solution* to each of the five test tubes, and place the test tubes in the dark at 37 ± 1° for exactly 30 min to develop the color. At the end of 30 min, add 2 mL of *18 N sulfuric acid* to each of the test tubes to stop the reaction, and mix.

**Control solution:** Transfer an accurately weighed quantity of about 0.4 g of starch to a previously tared flask, and proceed as directed in *Test solutions* beginning with "add 25 mL of water, and adjust the pH with phosphoric acid".

**Procedure:** Concomitantly determine the absorbances of the *Standard solutions* and the *Test solutions* at the wavelength of maximum absorbance at about 540 nm, with a suitable spectrophotometer, using the *Control solution* as the blank to set the instrument. Plot the absorbance values of the *Standard solutions* versus concentration, in µg/mL, of dextrose, and draw the straight line best fitting the five plotted points. From the graph, determine the concentration, *C*, in µg/mL, of dextrose in each of the *Test solutions*, and calculate the average concentration, in µg/mL, of the solution under test. The percentage of starch content in the weight of the test specimen taken is calculated by the formula:

$$(0.9C/10^6) \times V_1 \times (250/V_0)(100/E)(100/W) = 2.25CV_1/V_0EW$$

$C$ = average concentration of dextrose in the *Test solutions* (µg/mL)
$V_1$ = volume of the *Test solution* if extra dilution is done (mL) (see *Note 2* in *Test solutions*)
$V_0$ = volume of the aliquot taken from the 250-mL volumetric flask (mL)
$E$ = weight of the test specimen (g)
$W$ = percentage of dry weight of the test specimen

[NOTE—$V_0$ is 1.0 when no extra dilution is done.]

## Volatile Oil Determination

Set up a round-bottom, shortneck, 1-L flask in a heating mantle set over a magnetic stirrer. Insert an egg-shaped stirring bar magnet in the flask, and attach a cold-finger condenser and an appropriate volatile oil trap of the type illustrated (see *Figure 1)*).

@2024 USPC

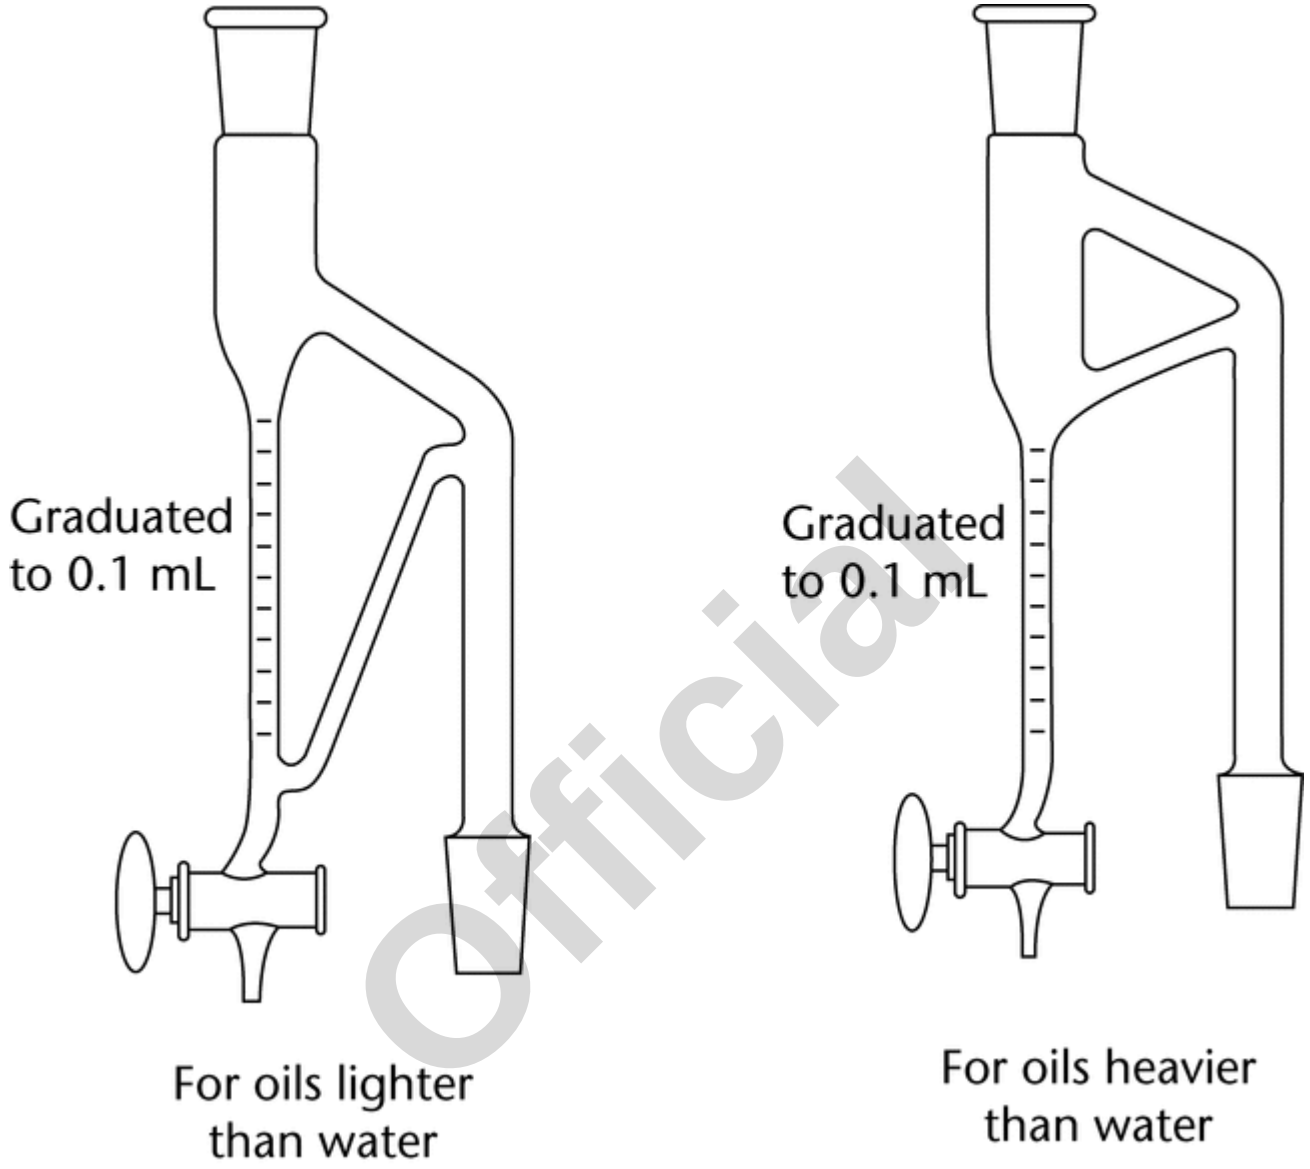

Figure 1. Traps for volatile oil apparatus.

Coarsely comminute a sufficient quantity of the material to yield from 1–3 mL of volatile oil. Small seeds, fruits, or broken leaves of herbs ordinarily do not need comminution. Very fine powders are to be avoided. If this is not possible, it may be necessary to mix them with purified sawdust or purified sand. Place a suitable quantity of the drug, accurately weighed, in the flask, and fill it one-half with water. Attach the condenser and the proper separator. Boil the contents of the flask, using a suitable amount of heat to maintain gentle boiling for 2 h, or until the volatile oil has been completely separated from the material and no longer collects in the graduated tube of the separator.

If a proper quantity of the volatile oil has been obtained in the graduated tube of the separator, it can be read to tenths of 1 mL, and the volume of volatile oil from each 100 g of material can be calculated from the weight of the drug taken. The graduations on the separator "for oils heavier than water" are so placed that oil remains below the aqueous condensate that automatically flows back into the flask.

## Water Content

For unground or unpowdered materials, prepare about 10 g of the *Laboratory Sample* by cutting, granulating, or shredding, so that the parts are about 3 mm in thickness. Seeds or fruits smaller than 3 mm should be cracked. Avoid the use of high-speed mills in preparing the sample, and exercise care that no appreciable amount of moisture is lost during the preparation and that the portion taken is representative of the *Laboratory Sample*. Determine the water content as directed in *Water Determination* ⟨921⟩, *Method III (Gravimetric), Procedure for Articles of Botanical Origin*.

# TEST FOR AFLATOXINS

[**CAUTION**—Aflatoxins are highly dangerous, and extreme care should be exercised in handling aflatoxin materials.]

Where the individual monograph calls for compliance with the limits for aflatoxins, the limits are NMT 5 ppb for aflatoxin $B_1$ ($AFB_1$) and NMT 20 ppb for the sum of aflatoxins $B_1$ ($AFB_1$), $B_2$ ($AFB_2$), $G_1$ ($AFG_1$), and $G_2$ ($AFG_2$). The extent of testing may be determined using a risk-based approach that considers the likelihood of contamination. The presence of unexpected contamination with aflatoxins is to be considered in determining compliance. The following analytical procedures are provided for determining compliance. Unless otherwise specified in the individual monograph, use *Method I*. If system suitability fails, use either *Method II* or *Method III*.

## Method I

This TLC test is provided to detect the possible presence of $AFB_1$, $AFB_2$, $AFG_1$, and $AFG_2$ in any material of plant origin.

### ZINC ACETATE–ALUMINUM CHLORIDE REAGENT

Dissolve 20 g of zinc acetate and 5 g of aluminum chloride in sufficient water to make 100 mL.

### SODIUM CHLORIDE SOLUTION

Dissolve 5 g of sodium chloride in 50 mL of water.

### TEST SOLUTION 1

Grind about 200 g of plant material to a fine powder. Transfer about 50 g of the powdered material, accurately weighed, to a glass-stoppered flask. Add 200 mL of a mixture of methanol and water (17:3). Shake vigorously by mechanical means for NLT 30 min, and filter. [NOTE—If the solution has interfering plant pigments, proceed as directed for *Test Solution 2*.] Discard the first 50 mL of the filtrate, and collect the next 40-mL portion. Transfer the filtrate to a separatory funnel. Add 40 mL of *Sodium Chloride Solution* and 25 mL of solvent hexane, and shake for 1 min. Allow the layers to separate, and transfer the lower aqueous layer to a second separatory funnel. Extract the aqueous layer in the separatory funnel twice, each time with 25 mL of methylene chloride, by shaking for 1 min. Allow the layers to separate each time, separate the lower organic layer, and collect the combined organic layers in a 125-mL conical flask. Evaporate the organic solvent on a water bath. Transfer the remaining extract to an appropriate sample tube, and evaporate to dryness on a water bath. Cool the residue. If interferences exist in the residue, proceed as directed for *Cleanup procedure* in *Test Solution 2*. Otherwise, dissolve the residue obtained above in 0.2 mL of a mixture of chloroform and acetonitrile (9.8: 0.2), and shake by mechanical means if necessary.

### TEST SOLUTION 2

Collect 100 mL of the filtrate from the start of the flow, and transfer to a 250-mL beaker. Add 20 mL of *Zinc Acetate–Aluminum Chloride Reagent* and 80 mL of water. Stir, and allow to stand for 5 min. Add 5 g of a suitable filtering aid, such as diatomaceous earth, mix, and filter. Discard the first 50 mL of the filtrate, and collect the next 80-mL portion. Proceed as directed for *Test Solution 1*, beginning with "Transfer the filtrate to a separatory funnel".

**Cleanup procedure:** Place a medium-porosity sintered-glass disk or a glass wool plug at the bottom of a 10-mm × 300-mm chromatographic tube. Prepare a slurry of 2 g of silica gel with a mixture of ethyl ether and solvent hexane (3:1), pour the slurry into the column, and wash with 5 mL of the same solvent mixture. Allow the absorbent to settle, and add to the top of the column a layer of 1.5 g of anhydrous sodium sulfate. Dissolve the residue obtained above in 3 mL of methylene chloride, and transfer it to the column. Rinse the flask twice with 1-mL portions of methylene chloride, transfer the rinses to the column, and elute at a rate NMT 1 mL/min. Add successively to the column 3 mL of solvent hexane, 3 mL of ethyl ether, and 3 mL of methylene chloride; elute at a rate NMT 3 mL/min; and discard the eluates. Add to the column 6 mL of a mixture of methylene chloride and acetone (9:1), and elute at a rate NMT 1 mL/min, preferably without the aid of vacuum. Collect this eluate in a small vial, add a boiling chip if necessary, and evaporate to dryness on a water bath. Dissolve the residue in 0.2 mL of a mixture of chloroform and acetonitrile (9.8: 0.2), and shake by mechanical means if necessary.

### TEST SOLUTION 3

If interferences still exist in the residue, proceed as directed for *Cleanup procedure with IAC* in *Test Solution* in *Method II*.

### AFLATOXIN STANDARD SOLUTION

[**CAUTION**—Aflatoxins are highly toxic. Handle with care.]

Prepare an *Aflatoxin Standard Solution* containing $AFB_1$, $AFB_2$, $AFG_1$, and $AFG_2$ at 2.0, 0.50, 2.0, and 0.50 µg/mL, respectively, in acetonitrile as follows. First prepare individual stock solutions of aflatoxins $AFB_1$, $AFB_2$, $AFG_1$, and $AFG_2$ in acetonitrile, each having a nominal concentration of 10 µg/mL.[1] Determine the concentration of each aflatoxin stock solution by measuring the absorbance (*A*) at a wavelength of maximum absorption close to 360 nm and using the equation:

[1] Suitable aflatoxin individual standards are available from Romer Labs, catalog #001012, 001013, 001014, 001015; and Sigma-Aldrich, catalog #A6636, A9887, A0138, A0263.

DOI Ref: z4zmq
DocId: GUID-E8A1366F-9657-41FC-9EDC-C20F4BE473B6_6_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99320_06_01
@2024 USPC

$$\text{Aflatoxin (µg/mL)} = (A \times M_r \times 1000)/\varepsilon$$

$A$ = absorbance
$M_r$ = molecular weight
$\varepsilon$ = molar absorptivity (see *Table 3*)

**Table 3. Molecular Weights and Molar Absorptivities for Aflatoxins**

| Aflatoxin | Molecular Weight ($M_r$) | Solvent | Molar Absorptivity ($\varepsilon$) |
|---|---|---|---|
| $AFB_1$ | 312 | Acetonitrile | 20700 |
| $AFB_2$ | 314 | Acetonitrile | 22500 |
| $AFG_1$ | 328 | Acetonitrile | 17600 |
| $AFG_2$ | 330 | Acetonitrile | 18900 |

Finally, to obtain the *Aflatoxin Standard Solution*, transfer an accurate volume of each aflatoxin stock solution to the same volumetric flask, and dilute with acetonitrile to volume. Calculate the concentration of each aflatoxin in the *Aflatoxin Standard Solution*:

$$C_{AF} = C'_{AF} \times V_{TS}/V_{AF}$$

$C_{AF}$ = concentration of the relevant aflatoxin in the *Aflatoxin Standard Solution*
$C'_{AF}$ = concentration of the relevant aflatoxin in the corresponding stock solution, as determined above
$V_{TS}$ = volume of the volumetric flask used to prepare the final *Aflatoxin Standard Solution*
$V_{AF}$ = volume of each individual aflatoxin stock solution transferred to the volumetric flask used to prepare the *Aflatoxin Standard Solution*

Store in a refrigerator. Equilibrate to room temperature before use.

### AFLATOXIN SOLUTION

Dilute the *Aflatoxin Standard Solution* with acetonitrile to obtain a solution having a concentration of 0.4 µg/mL each of $AFB_1$ and $AFG_1$, and 0.1 µg/mL each of $AFB_2$ and $AFG_2$.

### PROCEDURE

Separately apply 2.5, 5, 7.5, and 10 µL of the *Aflatoxin Solution* and three 10-µL applications of either *Test Solution 1*, *Test Solution 2*, or *Test Solution 3* to a suitable TLC plate (see *Chromatography* ⟨621⟩) coated with a 0.25-mm layer of chromatographic silica gel mixture. Superimpose 5 µL of the *Aflatoxin Solution* on one of the three 10-µL applications of the *Test Solution*. Allow the spots to dry, and develop the chromatogram in an unsaturated chamber containing a solvent system consisting of a mixture of chloroform, acetone, and isopropyl alcohol (85:10:5) until the solvent front has moved NLT 15 cm from the origin. Remove the plate from the developing chamber, mark the solvent front, and allow the plate to air-dry. Locate the spots on the plate by examination under UV light at 365 nm.

### SYSTEM SUITABILITY

The four applications of the *Aflatoxin Solution* appear as four clearly separated blue fluorescent spots. Observe any spot obtained from the *Test Solution* that coincides in hue and position with those of the *Aflatoxin Solution*. Any spot obtained from the *Test Solution* with the superimposed *Aflatoxin Solution* is not less intense than that of the corresponding *Aflatoxin Solution*.

### ACCEPTANCE CRITERIA

No spot from any of the other applications of the *Test Solution* corresponds to any of the spots obtained from the applications of the *Aflatoxin Solution*. If any spot of aflatoxins is obtained in the *Test Solution*, match the position of each fluorescent spot of the *Test Solution* with those of the *Aflatoxin Solution* to identify the type of aflatoxin present. The intensity of the aflatoxin spot, if present in the *Test Solution*, when compared with that of the corresponding aflatoxin in the *Aflatoxin Solution* will give an approximate concentration of aflatoxin in the *Test Solution*. Where the individual monograph calls for compliance with the limits for aflatoxins, the limits are NMT 5 ppb for $AFB_1$ and NMT 20 ppb for the sum of $AFB_1$, $AFB_2$, $AFG_1$, and $AFG_2$, except when otherwise indicated.

## Method II

### SODIUM CHLORIDE SOLUTION

See *Method I*.

### PHOSPHATE BUFFERED SALINE SOLUTION

Prepare 10 mM phosphate buffer solution containing 0.138 M sodium chloride and 0.0027 M potassium chloride in water, and adjust with 2 M sodium hydroxide to a pH of 7.4.[2]

### IMMUNOAFFINITY COLUMN

Before conditioning, adjust the immunoaffinity column (IAC) to room temperature. For conditioning, apply 10 mL of *Phosphate Buffered Saline Solution* onto the column and let it flow through the column by gravity force at a rate of 2–3 mL/min. Leave 0.5 mL of the *Phosphate Buffered Saline Solution* on top of the column until the *Test Solution* is applied.

### TEST SOLUTION

**Sample extraction:** Transfer about 5 g of a representative powdered sample, accurately weighed, to a glass-stoppered flask. Add 20 mL of a mixture of methanol and water (17:3). Shake vigorously by mechanical means for NLT 30 min, and filter. Discard the first 5 mL of the filtrate, and collect the next 4-mL portion. Transfer the filtrate to a separatory funnel. Add 4 mL of *Sodium Chloride Solution* and 2.5 mL of hexane, and shake for 1 min. Allow the layers to separate, and transfer the lower aqueous layer to a second separatory funnel. Extract the aqueous layer in the separatory funnel twice, each time with 2.5 mL of methylene chloride, by shaking for 1 min. Allow the layers to separate each time, separate the lower organic layer, and collect the combined organic layers in a 50-mL conical flask. Evaporate the organic solvent on a water bath. Transfer the remaining extract to an appropriate sample tube, and evaporate to dryness on a water bath. Cool the residue. If interferences exist in the residue, proceed as directed for *Cleanup procedure with IAC*. Otherwise, dissolve the residue obtained above in 200 µL of acetonitrile, and shake by mechanical means if necessary.
**Cleanup procedure with IAC:** The residue is dissolved in 5 mL of a mixture of methanol and water (6:4) and then diluted with 5 mL of water. This extract is applied onto a conditioned IAC. The IAC is rinsed twice with 10 mL of *Phosphate Buffered Saline Solution*, and the elution is performed slowly with 2 mL of methanol. Evaporate the eluate with nitrogen, and dissolve the residue in 200 µL of acetonitrile.

### AFLATOXIN SOLUTION

[**CAUTION**—Aflatoxins are highly toxic. Handle with care.]
Dilute the *Aflatoxin Standard Solution* with acetonitrile to obtain a solution containing 0.04 µg/mL each of $AFB_1$ and $AFG_1$, and 0.01 µg/mL each of $AFB_2$ and $AFG_2$.

### ANALYSIS

Separately apply 5, 7.5, and 10 µL of *Aflatoxin Solution* and three 10-µL applications of the *Test Solution* to a suitable HPTLC plate (see *Chromatography* ⟨621⟩) coated with a 200-µm layer of chromatographic silica gel mixture. Superimpose 5 µL of *Aflatoxin Solution* on one of the three 10-µL applications of the *Test Solution*. Allow the spots to dry, and develop the chromatogram in a saturated chamber containing a solvent system consisting of a mixture of chloroform, acetone, and water (140: 20: 0.3) until the solvent front has moved NLT 72 mm from the origin (80 mm from the lower edge of the plate). Remove the plate from the developing chamber, mark the solvent front, and allow the plate to air-dry for 5 min. Locate the spots on the plate by scanning fluorescence density (>400 nm) under UV light at 366 nm. Match the position of each fluorescent spot of the *Test Solution* with those of *Aflatoxin Solution* to identify the type of aflatoxin present. The concentration of aflatoxins in the *Test Solution* can be calculated from the calibration curve obtained from the scan data with *Aflatoxin Solution*.

### SYSTEM SUITABILITY

The four applications of *Aflatoxin Solution* appear as four clearly separated blue fluorescent spots. Observe any spot obtained from the *Test Solution* that coincides in hue and position with those of *Aflatoxin Solution*. Any spot obtained from the *Test Solution* with the superimposed *Aflatoxin Solution* is not less intense than that of the corresponding *Aflatoxin Solution*. The mean recovery of spiked $AFB_1$ and $AFG_1$ is NLT 70%.

### ACCEPTANCE CRITERIA

Where the individual monograph calls for compliance with the limits for aflatoxins, the limits are NMT 5 ppb for $AFB_1$ and NMT 20 ppb for the sum of $AFB_1$, $AFB_2$, $AFG_1$, and $AFG_2$, except when otherwise indicated.

## Method III

This test method is provided as an example for the detection of the possible presence of $AFB_1$ and total aflatoxins (AF: sum of $AFB_1$, $AFB_2$, $AFG_1$, and $AFG_2$). It has been shown to be suitable for powdered ginseng and ginger. Its suitability to other articles of botanical origin must be demonstrated.

[2] A suitable powder mixture is available from Sigma as PBS P-3813.

## 0.1 M PHOSPHATE BUFFER SOLUTION

Dissolve 8.69 g of anhydrous disodium phosphate and 4.66 g of anhydrous monosodium phosphate or 5.36 g of monosodium phosphate monohydrate in 800 mL of water, adjust with 2 M sodium hydroxide to a pH of 7.4, add 10 mL of polysorbate 20, and dilute with water to 1 L.

## PHOSPHATE BUFFERED SALINE SOLUTION

Prepare as directed in *Method II*.

## WORKING AFLATOXIN STANDARD SOLUTIONS

Prepare six solutions by diluting suitable volumes of *Aflatoxin Standard Solution* with methanol and water (1:1). The final aflatoxin concentrations in each *Working Aflatoxin Standard Solution* are shown in *Table 4*. Store in a refrigerator, and equilibrate to room temperature before use. Prepare the solutions daily.

**Table 4. Preparation of Working Aflatoxin Standard Solutions**

| Working Aflatoxin Standard Solutions | Aflatoxin Standard Solution (µL) | Final Aflatoxin Concentration of Working Aflatoxin Standard Solution (ng/mL) | | | | |
|---|---|---|---|---|---|---|
| | | $AFB_1$ | $AFB_2$ | $AFG_1$ | $AFG_2$ | ΣAF |
| 1 | 0 | 0 | 0 | 0 | 0 | 0 |
| 2 | 12.5 | 0.25 | 0.0625 | 0.25 | 0.0625 | 0.625 |
| 3 | 25 | 0.5 | 0.125 | 0.5 | 0.125 | 1.25 |
| 4 | 50 | 1 | 0.25 | 1 | 0.25 | 2.5 |
| 5 | 100 | 2 | 0.5 | 2 | 0.5 | 5 |
| 6 | 200 | 4 | 1 | 4 | 1 | 10 |

## IMMUNOAFFINITY COLUMN[3]

Use an IAC that contains monoclonal antibodies cross reactive toward $AFB_1$, $AFB_2$, $AFG_1$, and $AFG_2$. The immunoaffinity columns have a minimum capacity of NLT 100 ng of total aflatoxin and give a recovery of NLT 80% for $AFB_1$, $AFB_2$, $AFG_1$, and $AFG_2$ when 5 ng of each $AFB_1$, $AFB_2$, $AFG_1$, and $AFG_2$ is applied in 10 mL of 10% methanol in *Phosphate Buffered Saline Solution* (v/v).

## TEST SOLUTION

**Extraction:** Weigh 5 g of a representative test sample in a 50-mL centrifuge tube. Add 1 g of sodium chloride and 25 mL of a mixture of methanol and 0.5% sodium bicarbonate (7:3). Mix on a vortex mixer until sample particles and extract solvent are well mixed. Shake at 400 rpm for 10 min. Centrifuge for 10 min at 7000 rpm (*g* value = 5323 $mm/s^2$) or at a speed that can result in a firm pellet of residues. Immediately pipette 7 mL into a 50-mL centrifuge tube, add 28 mL of *0.1 M Phosphate Buffer Solution*, mix, and filter through glass microfiber paper. Collect 25 mL of filtrate (equivalent to 1 g of test sample) into a 25-mL graduated cylinder, and proceed immediately with IAC chromatography.
**IAC cleanup:** [NOTE—For IAC cleanup, columns must be kept at room temperature for at least 15 min before use.] Remove the top cap from the column, and connect it with the reservoir. Remove the end cap from the column, and attach it to the column manifold (the fit must be tight). Let the liquid in the column pass through until the liquid is about 2–3 mm above the column bed. Pass 25 mL of filtrate into the reservoir. Let the filtrate flow through the column by gravity force. Let the column run dry. To start the flow again easily, remove the column from the manifold, add about 2 mL of *Phosphate Buffered Saline Solution* into the column, reattach the column to the reservoir, and wash the column with an additional 3 mL of *Phosphate Buffered Saline Solution* and then with 5 mL of water (the 5 mL of *Phosphate Buffered Saline Solution* can be added directly to the column reservoir if other techniques are used to dislodge the air bubble at the end of the column and to start flow again easily). Let the column run dry, then force 3 mL of air through the column with a syringe. Elute with 1 mL of methanol, and collect the analytes in a 3-mL volumetric flask, letting the eluate drip freely. Let the column run dry. Let stand for 1 min, then elute with an additional 1 mL of methanol, and collect in the same volumetric flask. Let the column run dry, and force 10 mL of air through the column. Dilute the eluate with water to volume. Use this as the *Test Solution*, and perform the analysis of aflatoxins immediately.

## SYSTEM SUITABILITY SOLUTION

Prepare a spiked sample by adding 5 mL of *Working Aflatoxin Standard Solution 5* to a 5-g sample and repeating the procedure for the *Test Solution*, using 20 mL instead of 25 mL of the mixture of methanol and 0.5% sodium bicarbonate (700:300).

[3] AflaOchraTest column (G1017; Vicam, Watertown, MA, USA) or equivalent. Aflatoxin/OTA immunoaffinity columns are suitable.

## CHROMATOGRAPHIC SYSTEM

**Detector:** Fluorescence, excitation wavelength (Ex) 362 nm and emission wavelength (Em) 440 nm
**Column:** 4.6-mm × 15-cm; 3-µm packing L1
**Flow rate:** 0.8 mL/min
**Mobile phase:** Isocratic
*For post-column derivatization with PHRED cell:*[4] Water, methanol, and acetonitrile (60:25:15)
*For post-column derivatization with Kobra cell:*[5] A solution prepared by mixing 1 L of a mixture of water, methanol, and acetonitrile (60:25:15); 350 µL of 4 M nitric acid; and 120 mg of potassium bromide
**Post-column derivatization (PCD) systems**
*PHRED cell:* Post-column photochemical derivatization cell
*Kobra cell:* Electrochemical cell, post-column bromination derivatization cell

## ANALYSIS

**Post-column derivatization for aflatoxins:** Use a UV or Kobra cell. Inject 50 µL of reagent blank *(Working Aflatoxin Standard Solution 1)*, *Working Aflatoxin Standard Solutions 2–6*, or the *Test Solution* into the LC column. Identify the aflatoxin peaks in the *Test Solution* by comparing the retention times with those of the working standards. The aflatoxins elute in the order $AFG_2$, $AFG_1$, $AFB_2$, and $AFB_1$. After passing through the PHRED or Kobra cell, the $AFG_1$ and $AFB_1$ have been derivatized to form $AFG_{2a}$ (derivative of $AFG_1$) and $AFB_{2a}$ (derivative of $AFB_1$). [NOTE—The chemical structures of the derivatives resulting from electrochemical bromination and photolysis are not the same. The structures of $AFB_1$ and $AFG_1$ photolysis products have not been established.] The retention times of $AFG_2$, $AFG_{2a}$, $AFB_2$, and $AFB_{2a}$ are between about 14 and 27 min using the PHRED cell; retention times are shorter using the Kobra cell. The peaks should be baseline resolved. Construct standard curves for each aflatoxin. Determine the concentration of each aflatoxin in the *Test Solution* from the calibration curve.
**Aflatoxins calibration curves:** Calibration curves are prepared for each of the aflatoxins using the *Working Aflatoxin Standard Solutions* containing the four aflatoxins described. These solutions cover the range of 0.25–4 ng/mL for $AFB_1$ and $AFG_1$, and the range of 0.0625–1 ng/mL for $AFB_2$ and $AFG_2$. Make the calibration curves before analysis according to *Table 4*, and check the plot for linearity. If the test portion area response is outside (higher) the calibration range, then the *Test Solution* should be diluted with a mixture of methanol and water (1:1, v/v) and reinjected into the LC column.
**Quantitation of aflatoxins:** Quantitation of aflatoxins is performed by measuring peak areas at each aflatoxin retention time and comparing them with the corresponding calibration curve.

## SYSTEM SUITABILITY

The mean recovery of spiked $AFB_1$ (2 µg/kg) and the total of aflatoxins (5 µg/kg) is NLT 68% and 70%, respectively. The relative standard deviation (RSD) is NMT 10% for $AFB_1$ and for the total of aflatoxins.

## CALCULATIONS

Plot the peak area (response, *y*-axis) of each of the toxin standards against the concentration (ng/mL, *x*-axis) and determine the slope ($S$) and *y*-intercept ($a$). Calculate the level of toxin in the sample by the following formula:

$$\text{Toxin (µg/kg)} = \{[(R - a)/S] \times V/W\} \times F$$

$R$ = peak area of the *Test Solution*
$a$ = *y*-intercept of the calibration curve
$S$ = slope of the calibration curve
$V$ = final volume of the injected *Test Solution* (mL)
$W$ = 1 g of test sample passed through the immunoaffinity column
$F$ = dilution factor, 1 when $V = 3$ mL

The total of aflatoxins is the sum of $AFG_2$, $AFG_1$, $AFB_2$, and $AFB_1$.

## ACCEPTANCE CRITERIA

Where the individual monograph calls for compliance with the limits for aflatoxins, the limits are NMT 5 ppb for $AFB_1$ and NMT 20 ppb for the sum of $AFB_1$, $AFB_2$, $AFG_1$, and $AFG_2$, except when otherwise indicated.

[4] PHRED™ Photochemical Reactor (AURA Industries, New York, NY, USA) or equivalent. Avoid looking at the UV lamp.
[5] Kobra Cell™ (R-Biopharm Inc., Marshall, MI, USA) or equivalent. Set at 100 mA. Do not turn on the current until the LC pump is operating to avoid overheating the cell membrane.

# PESTICIDE RESIDUE ANALYSIS

## Definition

Where used in this Pharmacopeia, the designation “pesticide” applies to any substance or mixture of substances intended to prevent, destroy, or control any pest, unwanted species of plants, fungus, or animals causing harm during or otherwise interfering with the production, processing, storage, transport, or marketing of pure articles. The designation includes substances intended for use as growth regulators, defoliants, or desiccants, and any substance applied to crops before or after harvest to protect the product from deterioration during storage and transport.

## Limits

Within the United States, many botanicals are treated as dietary supplements and are subject to the statutory provisions that govern foods but not drugs in the Federal Food, Drug, and Cosmetic Act. Limits for pesticides in foods are determined by the Environmental Protection Agency (EPA) as indicated in the Code of Federal Regulations (40 CFR §180) or the Federal Register (FR). In addition, the FDA establishes action levels for unavoidable pesticide residues (21 CFR §109 and 21 CFR §509). For pesticide chemicals without EPA-established tolerance levels or FDA action levels, the residues should be below the detection limit of the specified method. Results less than the EPA detection limits are considered zero values. The limits contained herein, therefore, are not applicable in the United States when articles of botanical origin are labeled for food purposes. The limits, however, may be applicable in other countries. Unless otherwise indicated in the monograph, the article to be examined complies with the limits given in *Table 5*. The limits for suspected pesticides that are not listed in *Table 5* must comply with the regulations of the EPA. For instances in which a pesticide is not listed in *Table 5* or in EPA regulations, calculate the limit by the formula:

$$\text{Limit (mg/kg)} = AM/100B$$

where $A$ is the acceptable daily intake (ADI), as published by the Food and Agriculture Organization of the United Nations (FAO) and the World Health Organization (WHO), in mg/kg of body weight; $M$ is body weight, in kilograms (60 kg); and $B$ is the daily dose of the article, in kilograms.

If the article is intended for the preparation of extracts, tinctures, or other pharmaceutical forms of which the preparation method modifies the content of pesticides in the finished product, calculate the limits by the formula:

$$\text{Limit (mg/kg)} = AME/100B$$

where $E$ is the extraction factor of pesticide in the preparation method, determined experimentally as the ratio between the original pesticide content in the plant material and the final pesticide content in the preparation; $B$ is the daily dose of the preparation in kilograms; and $A$ and $M$ are as defined above.

A total or partial exemption from the test may be granted when the complete history (nature and quantity of the pesticides used, date of each treatment during cultivation and after harvest) of the treatment of the batch is known and can be checked precisely according to good agricultural and collection practices (GACP).

**Qualitative and Quantitative Analysis of Pesticide Residues** Use analytical procedures validated e.g., in accordance with the latest version of the EU guideline on analytical quality control and validation procedures for pesticide residue analysis [NOTE—Current version Document No. ▲SANTE/12682/2019, https://ec.europa.eu/food/system/files/2020-01/pesticides_mrl_guidelines_wrkdoc_2019-12682.pdf▲ (ERR 1-Nov-2021)] or the EPA method validation principles (OPPTS 860.1340) that satisfy the following criteria. The method, especially with respect to its purification steps, is suitable for the combination of pesticide residue and substance under test, and is not susceptible to interference from co-extractives; the limit of quantification for each pesticide matrix combination to be analyzed is NMT the corresponding tolerance limit: the method is shown to recover between 70% and 120% of each pesticide with a repeatability NLT 20% RSD [NOTE—lower recoveries may be acceptable in certain cases as discussed in SANTE/11813/2017] ; and the concentrations of test and reference solutions and the setting of the apparatus are such that a linear response is obtained from the analytical detector.

## LIMITS OF ELEMENTAL IMPURITIES

The levels of elemental impurities should be restricted as shown in *Table 6* unless otherwise stated in the individual monograph. Specific monographs may provide different limits for articles that are typically used in large quantities.

**Table 6. Limits of Elemental Impurities**

| Element | Limit (µg/g) |
|---|---|
| Arsenic (inorganic)[a] | 2 |
| Cadmium | 0.5 |
| Lead | 5 |
| Mercury (total) | 1 |
| Methylmercury (as Hg)[b] | 0.2 |

[a] Arsenic may be measured using a nonspeciation procedure under the assumption that all arsenic contained in the supplement is in the inorganic form. Where the limit is exceeded using a nonspeciation procedure, compliance with the limit for inorganic arsenic shall be demonstrated on the basis of a speciation procedure.
[b] Methylmercury determination is not necessary when the content for total mercury is less than the limit for methylmercury.

Articles are tested according to the procedures set forth in *Elemental Impurities—Procedures* ⟨233⟩. Where speciation is required, the procedures given in *Elemental Contaminants in Dietary Supplements* ⟨2232⟩ are used for testing.

# ⟨563⟩ IDENTIFICATION OF ARTICLES OF BOTANICAL ORIGIN

## INTRODUCTION

Identification of raw plant material intended for use in the manufacture of pharmaceuticals, excipients, or dietary supplements is carried out by examining the morphological and histological features of the article under test and by performing diagnostic chemical tests on the article. The botanical and chemical characteristics of the test article are then compared to the known botanical and chemical characteristics of the plant species. Reference articles may be specified to assist in the proper botanical and chemical identification of the plant and plant part. A reference article may be either a USP Authenticated Reference Material, which may be used for both botanical and chemical identification, or a USP Reference Standard, which is used for chemical identification only.

## USP AUTHENTICATED REFERENCE MATERIALS

USP Authenticated Reference Materials are plant organs or tissues certified to have come from a plant that has been properly identified as belonging to the species listed on the label. The authentication is performed by botanical taxonomists, plant anatomists, phytochemists, or other plant scientists contracted by USP. A USP Authenticated Reference Material is typically a dried, pulverized plant organ or tissue, and it may be obtained from USP. Herbarium samples that may include roots, stems, leaves, flowers, fruits, and seeds of the authenticated plants are archived and made available for examination upon request. Standard herbarium samples usually consist of the entire mature plant. USP Authenticated Reference Materials undergo the same botanical and chemical diagnostic tests as those applied to test raw materials. A test article must have all botanical and chemical characteristics specified and found in the USP Authenticated Reference Material. To serve its intended purpose, each USP Authenticated Reference Material is properly stored, handled, and used. Generally, USP Authenticated Reference Materials are stored in their original containers under cool and dry conditions and protected from light and insect infestation. Where special storage conditions are necessary, directions are given on the label. Active principles and marker compounds typically degrade with time; therefore, expiration dates are assigned to USP Authenticated Reference Materials for their use in chemical identification. USP Authenticated Reference Materials are not intended for use in the manufacture of pharmaceuticals, excipients, or dietary supplements.

## BOTANICAL IDENTIFICATION

The botanical identification of raw plant materials used in the manufacture of pharmaceuticals, excipients, or dietary supplements consists of ascertaining the macroscopic characteristics of the plant part, such as root, stem, leaf, flower, fruit, or seed, used in the manufacture of the article, as well as ascertaining its histological (microscopic) features. It may also include the inspection of organoleptic features of the botanical tissue such as the presence or absence of a characteristic odor. Individual compendial monographs may include botanical information on possible adulterant species to help ensure their absence in the raw material. For a proper identification of the plant, plant organ, or plant tissue, it is necessary to have a basic knowledge of plant anatomy.

### Diagnostic Plant Morphology and Anatomy

This section exclusively addresses the diagnostic morphological and anatomical features of vascular plants and the various plant parts, such as roots, stems, leaves, flowers, fruits, and seeds, from which pharmaceuticals, excipients, or dietary supplements are derived. Vascular plants include pteridophytes (ferns and fern allies; for example, genera *Aspidium*, *Equisetum*, and *Lycopodium*), gymnosperms (seed plants, in which the seed is not enclosed within a fruit; for example, genera *Ephedra*,*Gingko*, and *Pinus*), and angiosperms (seed plants, in which the seed is enclosed within a fruit; for example, genera *Allium*, *Digitalis*, *Panax*, *Matricaria*, and *Rauwolfia*). Anatomical diagnostic features that are specified in an individual monograph (see *Botanic characteristics* in individual monographs) may include, but are not limited to, the presence of a particular tissue within an organ; the arrangement and type of cells within a tissue; the presence and type of secretory canal, oil, or resin duct or laticifers within an organ; the number of epithelial cells surrounding a secretory canal; and the presence and type of ergastic substances such as starch, inulin, fat globules, essential oils, calcium oxalate crystals, cystoliths, polyphenols, fluids, or other materials occurring in the cytoplasm, organelles, vacuoles, cavities, or cell wall.

#### ROOTS

The tissues present in young roots, starting with the most external tissue, include an epidermis with root hairs, cortex, endodermis, pericycle, phloem, xylem, and, in some species, pith. In some species, the outermost layer or layers of cortex are distinct from the inner layers, in which case they are referred to as a hypodermis. In species that undergo secondary growth in the roots, it is typical for all tissues external to the pericycle to be sloughed off. Roots that exhibit secondary growth have a periderm or bark, composed of a phellum (cork), phellogen (cork cambium), and phelloderm as the outermost tissue. Underneath the periderm, remnants of primary phloem, secondary phloem, vascular cambium, primary xylem, and secondary xylem can be found. Secondary vascular tissues have medullary rays separating clusters of the principal conducting cells of phloem (sieve elements or sieve cells) and the principal conducting cells of xylem (vessels and tracheids). Most species of plants that undergo secondary growth lack pith in the root. The type and arrangement of the principal conducting cells of the vascular tissues may be diagnostic of the species. Roots of many species develop into food storage organs. Abundant parenchyma and

DOI: https://doi.org/10.31003/USPNF_M99323_03_01

large amounts of starch or other polysaccharides characterize these types of roots. The presence, type, and arrangement of fibers, sclereids, and other tissues, and the presence and location of ergastic material, may also be diagnostic features. Morphologically, roots may be distinguished from rhizomes (the underground stems) primarily by the absence of nodes and internodes, which are present in rhizomes.

## STEMS

Several external macroscopic features of stems that may be diagnostic of the species include the attributes of the nodes, internodes, leaf scars, vascular bundle scars, lenticles, and buds; the growth pattern of the buds; position and arrangement of the leaves along the stem; and the presence of tendrils, spines, thorns, or prickles. Starting with the outermost tissue, the internal arrangement of tissues in the young stems of most species is epidermis, cortex, a concentric ring of vascular bundles separated from each other by parenchymatous medullary rays, and pith. Depending on the species, stomata or trichomes or both structures may be present in the epidermis. The cortex of some species may include a hypodermis or an endodermis or both. In most monocotyledons, the vascular bundles are not arranged concentrically; instead, they are scattered throughout a mass of parenchyma tissue internal to the epidermis. Because of this arrangement, neither cortex, medullary rays, nor pith can be discerned. In woody plant stems that undergo secondary growth, it is typical for the epidermis to be sloughed off and replaced by a periderm composed of a phellum, phellogen, and phelloderm. Some species are characterized by having multiple periderms (rhytidome). Lenticles may be present in the periderm and their attributes may serve as diagnostic features. Underneath the periderm are the remnants of the cortex, primary phloem, secondary phloem, vascular cambium, secondary xylem, primary xylem, and pith. Medullary rays are also present. As in the root, the type and arrangement of the principal conducting cells of the vascular tissues; the presence, type, and arrangement of fibers, sclereids, and other tissues; and the presence and location of ergastic material may also be diagnostic features. Rhizomes may have some morphological characteristics similar to those of roots and therefore they may be mistaken for roots. However, rhizomes can be correctly identified as stems because they have distinct nodes and internodes.

## LEAVES

Several macroscopic features of leaves that may be diagnostic of the species include the attributes of the leaf blade, petiole, and stipules and the phyllotaxy. The outermost tissue of a leaf blade is the epidermis, followed by mesophyll and vascular tissues. Microscopic diagnostic features of epidermal cells include the cuticle thickness and markings, the shape and arrangement of stomata and guard cells, the arrangement and size of subsidiary cells, stomatal number (number of stomata per unit area), and stomatal index (number of stomata per unit number of epidermal cells). Additional features useful in the identification of leaf material include types and arrangement of trichomes (plant hairs) present; type and arrangement of mesophyll and vascular tissues; palisade mesophyll ratio; presence and appearance of accessory tissues such as parenchymatous or sclerenchymatous bundle sheaths, paraveinal mesophyll, endodermis, and transfusion tissue; type and arrangement of the principal conducting cells of the vascular tissues; presence, type, and arrangement of fibers, sclereids, and other tissues; and presence, location, and physical appearance of ergastic material.

## FLOWERS

Flowers are the best diagnostic morphological features of any flowering plant, and the floral structure is the principal criterion used in plant taxonomy. The diagnostic features of flowers include type of inflorescence; presence, number, and appearance of the primary floral parts (sepals, petals, stamens, and carpels); type of symmetry displayed by the floral parts; relative position of the ovaries in regard to the other parts of the flower; the number of ovules per ovary; type of placentation of the ovary; physical appearance of the pollen grains; presence of nectaries; presence of covering or glandular trichomes; and physical features of accessory structures such as the receptacle and bracts. The histological features and the presence of ergastic materials in the tissues of floral parts are also diagnostic of the species.

## FRUITS

The identification of the species of plant from which a fruit was derived may be determined by observing several macroscopic criteria. These criteria include the number of pistils found in the fruit; the number of carpels within each pistil; the number of seeds within each carpel; the placentation of the fruit; and the determination of whether the fruit is dehiscent, indehiscent, or fleshy. Additional diagnostic features include the number of sutures in a dehiscent fruit, the determination of whether the seeds are fused to or free from the pericarp wall, physical features of the three layers of the pericarp of fleshy fruits (epicarp, mesocarp, and endocarp), and presence and physical appearance of accessory tissues such as the receptacle and bracts. Histological features of fruit tissues may aid in identification. The characteristics of the seeds within the fruit are also diagnostic features of the species.

## SEEDS

The macroscopic features of seeds used in identification include the shape and size of the seed; appearance of the seed-coat surface; placement of the hilum and micropyle; and presence of accessory structures of the seed coat such as the arils, caruncle, or oil bodies. Physical features of the embryo, such as its size, shape, position, and the number and appearance of the cotyledons, as well as the presence and appearance of accessory nutritive tissues such as the remnants of a megagametophyte (in gymnosperms), perisperm (nucellus), or endosperm, are also diagnostic of the species. Histological features of the seed coat and other structures and tissues of the seed may also be used for species identification.

## Microtechnique

Histological analysis of botanical specimens can be performed on whole plant material or plant powder. The use of cytological stain or other reagents may be necessary to visualize certain histological features. Crossed polarizers can be used to detect structures that rotate plane-polarized light. These structures include starch grains, calcium oxalate crystals, some fibers, and grains of sand (present as a contaminant) that can be observed as bright objects against a dark background. One polarizer is commonly placed in the condenser or the light source, and the second polarizer is placed in the ocular. Light entering the slide from below is plane polarized, permitting only some light waves in a specific plane to pass through. When the two polarizers are aligned, the field becomes bright; when the two polarizers are crossed, the field becomes dark.

### PROCEDURE FOR TEMPORARY MOUNTS AND POWDERED MATERIAL

**General procedure:** Plant samples are observed under the microscope by employing different mounting media, stains, or other solutions to assist in the correct identification of the test article. If a USP Authenticated Reference Material is available, prepare it with the same mounting media or reagent solutions used for the test article. Place 1 or 2 drops of water, *Glycerin–alcohol solution*, *Chloral hydrate solution*, or another reagent solution (see *Preparation and use of reagent solutions, optical devices, and mountants*) in the center of a clean slide. Transfer a small plant tissue section or a portion of plant powder into the mountant or reagent solution, and cover with a clean coverslip. (For specific preparation techniques, see *Preparation of temporary mounts and hand sections*, *Maceration*, or *Preparation of powdered materials*, as appropriate.) To prevent the formation of air bubbles, the coverslip may be carefully placed at an appropriate angle with its edge making the first contact with the slide and then pressed until it covers the specimen. Using a piece of filter paper, remove excess fluid from the margin of the coverslip. Air bubbles can be removed by placing the slide in a vacuum desiccator. When using chloral hydrate, air bubbles can be removed by gently boiling the sample over a small flame such as that from an alcohol lamp. To replace the mountant or reagent solution, place drops of the new mountant or reagent solution on one edge of the coverslip. Place a strip of filter paper at the opposite edge of the coverslip to remove the old mountant or reagent solution and to cause the new mountant or reagent solution to be drawn over the powdered material or tissue. Plant oils can be also washed away from the tissue in this manner when solvent hexane or acetone are washed through the slide followed by water and, if necessary, *Chloral hydrate solution*. Do not use *Chloral hydrate solution* immediately after treating the plant tissue with flammable solvents without thoroughly washing the tissue with water. This is to avoid setting fire to residual solvent when the microscope slide is later placed over a small flame to boil the tissue. Care must be taken when using reagent solutions that are volatile or corrosive to the microscope. To prevent drying of aqueous or chloral hydrate solutions during observation, add a small drop of glycerin to the slide. Observe the mounted sample under an optical microscope (see *Optical Microscopy* ⟨*776*⟩), and examine for histological features.

**Preparation and use of reagent solutions, optical devices, and mountants:** The following reagents, optical devices, and mounting media are used to assist in the identification of cells, tissues, structural features, and ergastic substances in the tissue or powdered material (see *Table 1* and *Table 2*).

**Table 1. The Use of Reagent Solutions and Optical Devices** *(continued)*

| Detection | Reagent Solutions and Optical Devices |
|---|---|
| Saponin | *Blood–gelatin mixture*<br>*Iodine–glycerin solution* (confirm by testing with *Blood–gelatin mixture*) |
| Starch | *Crossed polarizers*<br>*Iodine solution*<br>*Universal reagent* |
| Tannins and other polyphenols | *Ferric chloride solution*<br>*Osmium tetroxide solution* |

**Table 2. Bleaching and Clarifying Agents and Mountants**

| Use | Mountants and Agents |
|---|---|
| Bleaching agents | *Sodium hypochlorite solution* |
| Clarifying agents | *Chloral hydrate solution*<br>*Lactochloral solution*<br>*Lactophenol solution* |
| Mountants | *Glycerin*<br>*Glycerin–alcohol solution*<br>*Glycerin–gelatin mixture*<br>*Water* |

*Alcoholic picric acid solution*—Prepare a 1% solution of picric acid in alcohol. Picric acid is useful to stain cells having dense cytoplasm such as aleurone cells in seeds. Place a small amount of powdered plant material in a test tube, and shake with about 1 mL of solvent hexane to remove plant oils, which would interfere with the reaction. Centrifuge, and discard solvent hexane. Soak the plant powder in *Alcoholic picric acid solution* for about 30 min. Transfer a portion of the powder to a microscope slide, and observe under a microscope. Cytoplasm and protein bodies turn bright yellow. [**CAUTION**—Picric acid is explosive when dry. Handle appropriately.]

*Blood–gelatin mixture*—Add 4.5 g of gelatin powder to 100 mL of a 0.9% sodium chloride solution, and allow to swell for 30 min. Heat the gel, while stirring, to about 80° in a water bath. Cool to 40°, and add 6 mL of defibrinated bovine blood. Heat to 45°–50°, and pour onto a microscope slide in a thin layer of about 1 mm while the slide is in a horizontal position. To prevent loss of blood-gelatin mixture from the sides, seal the microscope slide edge with a 1-cm wide adhesive tape to form a tray. After cooling and solidification, it is ready for use. [NOTE—Store in a humid chamber for NMT 1–2 days at 3°–4°.] To test for saponins, place small clusters of the powdered plant material on the blood–gelatin layer, spacing them a few mm apart from each other, transfer to a humidifier for a few h, and observe. Saponin-containing particles will cause light-transparent zones to appear in the blood–gelatin.

*Carmine alum–methyl green solution*—Boil 1.5 g of carmine for 30 min in a 15% solution of aluminum potassium sulfate. Cool, filter, and add 10 mL of a 0.75% methyl green solution while stirring. Add 1–2 drops to the plant material. Lignin and suberin turn green and cellulose turns red-violet.

*Chloral hydrate solution*—Use chloral hydrate TS. When using the solution as a clarifying agent, add a few drops to the plant material, and boil briefly over a small flame. Chloral hydrate dissolves cellular contents and intercellular substances and allows cell walls and shapes to be easily observed. It can be used to assist in the identification of cork, fibers, vessels, calcium oxalate crystals (with the aid of crossed polarizers), trichomes, stomata, and pollen.

*Crossed polarizers*—This optical device is used to detect calcium oxalate crystals and starch grains (amyloplasts). In polarized light, calcium oxalate crystals and starch grains appear as bright, birefringent objects on a dark background. Starch grains observed under polarized light will also have a Maltese-cross effect with the arms of the cross intersecting at the hilum. Calcium oxalate crystals are usually best viewed after the sample has been clarified with *Chloral hydrate solution* or another clarifying agent.

*Diluted acetic acid*—Add 1–2 drops to the plant material, and immediately observe under a microscope. Calcium carbonate deposits dissolve with effervescence.

*Ferric chloride solution*—Dilute 1 mL of ferric chloride TS with 9 mL of water. For the detection of phenol hydroxyl groups, such as tannins and flavonoids, from the side of the coverslip add the solution to the aqueous sample. Tannins and other polyphenols become blue-black to green.

*Glycerin*—Use as a mountant to prevent the drying of aqueous and chloral hydrate solutions.

*Glycerin–alcohol solution*—Mix equal volumes of glycerin and alcohol. Use as a mounting medium.

*Glycerin–gelatin mixture*—Add 10.0 g of powdered gelatin to 60 mL of water. Allow to stand for 2 h, and add 70 mL of glycerin containing 1.5 g of dissolved phenol. Heat in a water bath, and filter through a preheated funnel containing glass wool. The filtered mixture is liquefied before use, and it serves as a mounting medium. Add a few drops to the cut or powdered plant material, and cover with a heated coverslip. This preparation is used for long-term storage of specimen mounts. The margins of the coverslip may be sealed with Canada balsam after a few months of drying.

*Hydriodic acid*—Add 1–2 drops to plant material. Cellulosic cell walls become blue to blue-violet.

*Iodine solution*—Add 1–2 drops of 0.1 N iodine VS to the plant material. Starch particles become dark-blue to blue-violet; this reaction is reversible on heating. [NOTE—Proteins, lipids, and cellulose turn yellow to brown; guaiac powder particles become green to blue, but this reagent is not used for diagnostic identification of these features.]

*Iodine–glycerin solution*—Dissolve 0.3 g of iodine and 1.0 g of potassium iodide in a small quantity of water, and add 10 mL of a mixture of glycerin and water (1:1). Add 1–2 drops to the powdered plant material. Samples containing saponins form

@2024 USPC

yellow lumps or aggregates. If a sample tests positive for saponin, the result has to be confirmed by testing the sample with *Blood–gelatin mixture* as well.

*Lactochloral solution*—Dissolve 50.0 g of chloral hydrate in 50 mL of lactic acid with gentle heating. Add a few drops to the plant material. Place the microscope slide in a small vacuum desiccator if it is necessary to eliminate air bubbles. *Chloral hydrate solution* and *Lactochloral solution* are used for the same type of identification, except that *Lactochloral solution* is a stronger clarifying agent and it is used for plant material that is more difficult to clarify.

*Lactophenol solution*—Mix 20 g of lactic acid, 40 g of glycerin, and 20 mL of water. Add 20 g of phenol, and mix. This is a strong clarifying agent suitable for the examination of pollen grains.

*Naphthol–sulfuric acid solution*—Prepare a 20% solution of 1-naphthol in alcohol. To the plant material add 1 drop of 1-napthol solution and 1 drop of sulfuric acid. Inulin crystals turn brownish red and then dissolve.

*Osmium tetroxide solution*—Dissolve 0.1 g of osmium tetroxide in 5 mL of distilled water. Add 1–2 drops of the solution so obtained to the plant material. Essential oils, fatty oils and other lipids, tannins, and protein bodies become brown to black.

*Phloroglucinol–hydrochloric acid solution*—This solution is used for the identification of lignin and other hydroxyphenylpropane derivatives; lignified tissues, such as sclereids, vessels, fibers, and stone cells; and lignified parenchyma. Moisten the powder or the cut sample with phloroglucinol TS, and allow to dry for 2–3 min before placing the coverslip. Add a few drops of a 25% hydrochloric acid solution, and cover with the coverslip. Lignified cell walls turn carmine red. [NOTE—This stain is not stable.] Cells with hydroxyphenylpropane derivatives, such as vanillin and ferulic acid, also turn red. Alternatively, hydroxyphenylpropane derivatives can be extracted from the plant material and the plant material then examined. To extract hydroxyphenylpropane derivatives repeatedly immerse the untreated material in alcohol, mix on a vortex mixer, centrifuge, and discard the alcohol between washings. Then treat the plant material as specified previously, beginning with the addition of phloroglucinol TS.

*1 M Potassium hydroxide solution*—Add 1 drop to plant material. Cells containing 1,8-dihydroxyanthraquinones will stain red.

*Ruthenium red solution*—Add a few drops of ammonium hydroxide to ruthenium red TS. [NOTE—Store the solution protected from light.] Add 1–2 drops to the plant material. Pectin-containing cell membranes, acidic mucilage, and phytoglycogen turn red.

*Sodium hypochlorite solution*—This solution is used to bleach deeply colored sections. Immerse the plant material in the solution for a few min until sufficiently bleached. Wash the tissue with water, and mount with a suitable mounting agent. [NOTE—Sodium hypochlorite will extract lignin; plant tissue so treated will test negative for lignin.]

*Sudan III solution*—Dissolve 0.5 g of sudan III in 50 mL of alcohol or isopropyl alcohol with reflux boiling. Cool, filter, and add 50 mL of glycerin. Add 1–2 drops of this solution to plant powder. Essential oils, waxes, cutin, suberin, and fatty oils and other lipids combine with this lipophilic colorant and become orange-red to red after a short time.

*Thionine solution*—Prepare a 0.2% thionine acetate solution in 25% alcohol. Immerse the dry sample in this solution. After about 15 min, wash out the excess of stain with 25% alcohol. Mucilage will have swollen into spherical globules and turned red-violet, while cellulose, pectin, and lignified septa will turn blue or blue-violet.

*Toluidine blue solution*—Using toluidine blue, proceed as directed for *Thionine solution*.

*Universal reagent*

SOLUTION A: Dilute 20 mL of a lactic acid-saturated solution of sudan III with 30 mL of lactic acid.

SOLUTION B: Dissolve 0.55 g of aniline sulfate in 35 mL of water.

SOLUTION C: Dissolve 0.55 g of potassium iodide and 0.05 g of iodine in 5 mL of water, and add 5 mL of alcohol.

PROCEDURE: Combine *Solution A*, *Solution B*, and *Solution C*, and add 2.5 mL of hydrochloric acid while stirring. [NOTE—The solution is used without filtering.] For identification, add 2–3 drops to the sample, and gently boil over a small flame. If necessary, small amounts of *Universal reagent* may be added during boiling. Cover with the coverslip. Lignified elements turn yellow, suberin turns red-brown, lipids turn red, and starch turns blue-violet.

*Water*—Use as a mounting medium. [NOTE—All grades of water are acceptable for this purpose.]

*Zinc chloride–iodine solution*—Dissolve 20.0 g of zinc chloride and 6.5 g of potassium iodide in 10.5 mL of water. Add 0.5 g of 0.1 N iodine VS, and shake for 15 min. Filter if necessary. Store in low-actinic glassware. Add 1–2 drops to the plant material, and allow to stand for a few min. Cellulosic cell walls are stained blue to blue-violet.

**Preparation of temporary mounts and hand sections:** When using the dry plant tissue, soak or gently boil in water until soft. Do not soften too much. Material can then be treated like fresh plant material. When appropriate, use the mountants or reagent solutions listed for use with plant powder to help visualize features of the tissue (see *Preparation and use of reagent solutions, optical devices, and mountants*).

To make an epidermal peel of the leaf, petal, sepal, bract, and other leaf-like appendages, roll the tissue into a cylinder, and nick with a sharp, polytef-coated razor blade that has been wetted with water. Grasp the nicked piece of tissue with forceps, and strip back removing a clear section of the epidermis. Mount in water on a microscope slide, place a coverslip over the tissue, and examine under a microscope.

If it is difficult to obtain an epidermal peel using the previous procedure, proceed as follows. Soak the tissue in a 40%–60% nitric acid solution at 60° for 3–4 min or until the epidermis can be easily peeled. The peel is then washed 3–5 times in water to remove the excess of nitric acid. Neutralize the tissue in a 1% potassium hydroxide solution or a 1% sodium hydroxide solution. Wash the tissue again with water, mount in water on a microscope slide, place a coverslip over the tissue, and examine under a microscope.

An alternative method of preparing leaf tissue for the examination of the epidermis is to heat a leaf fragment (about 5 mm × 5 mm) for 15 min in *Chloral hydrate solution* on a water bath. Transfer the tissue to a microscope slide, add a drop of water, and cover with a coverslip. These procedures can be used to determine the stomatal type, distribution, number, and index.

Stomatal number is determined by counting the number of stomata per unit area of a microscopic field. Determine the stomatal number on at least 10 different sites of the specimen, and calculate a mean value. Keep track of which leaf surface is being observed, abaxial or adaxial, as the stomatal number for different surfaces is frequently significantly different.

To calculate the stomatal index, the specimen is observed under a microscope at a low magnification. The size of the surface is determined with a calibrated micrometer ocular, and the number of stomata and the number of epidermal cells for that area are determined. The stomatal index is calculated:

@2024 USPC

$$\text{Result} = (100 \times S)/(E + S)$$

$S$ = number of stomata for a given area
$E$ = number of epidermal cells of the same area

Determine the stomatal index on at least 10 different sites of the specimen, and calculate a mean value. Again, keep track of which leaf surface is being observed, abaxial or adaxial, as the stomatal indices for different surfaces is frequently significantly different.

To make a cross section of a leaf or thin roots, stems, or other thin appendages, lay the appendage to be sectioned on a microscope slide. Place another microscope slide over the appendage with a portion of the tissue exposed. Using a sharp, polytef-coated razor blade that has been wetted, cut straight down along the edge of upper slide. Without moving the upper slide, cut down again with the razor blade at an angle. Some practice may be necessary to be able to get sections thin enough so that when they are mounted and covered with a coverslip, these sections can be used to determine tissue arrangements (for instance, the number of palisade layers in leaf, thickness of cuticle, types of trichomes, types of vascular bundles, and the like). Because razor blades dull quickly, they have to be replaced frequently.

Use the cross section of leaf tissue so obtained to determine the palisade mesophyll ratio. Alternatively, boil leaf fragments of about 2 $mm^2$ in *Chloral hydrate solution*, mount, cover with a coverslip, and observe under a microscope. Identify groups of four adaxial epidermal cells, and count the palisade mesophyll cells that are lying below and are at least 50% covered by the epidermal cells. This value divided by 4 is the palisade mesophyll ratio. Determine the palisade mesophyll ratio of at least 10 groups of epidermal cells, and calculate a mean value. Palisade mesophyll ratio can also be determined on powdered leaf material.

To make a cross section of thick stems, roots, or other plant parts, including woody tissues, hold the tissue in one hand and using a sharp, polytef-coated razor blade that has been wetted with water, shave a cross section from the appendage. Mount in water, another medium, or reagent solution, place a coverslip over the material, and examine under a microscope. Sections thin enough to determine vascular tissue arrangement, ray type, parenchyma distribution, presence of crystals, and the like can usually be made with a little practice.

**Maceration:** For the proper identification of a plant material, it is sometimes necessary to macerate the tissue into its individual cells before microscopic examination. This can be an especially useful technique for woody or other hard tissues. The material is cut into small pieces of about 2-mm thickness and 5-mm length or sliced into pieces of about 1-mm thickness. Depending on the nature of the cell wall, one of the following methods is used. For hard or highly lignified tissues, use *Method I*. For tissues that are not extensively lignified, use *Method II*.

*Method I*

SOLUTION A: Use 4 N nitric acid solution.

SOLUTION B: Prepare a mixture of 1.2 M chromium trioxide solution and sulfuric acid (7:4).

PROCEDURE: Place the plant material in a test tube containing about 5 mL of a mixture of *Solution A* and *Solution B* (1:1). Heat in a water bath for 20 min. Wash the tissue repeatedly with water, and transfer to a microscope slide. Tease the tissue apart with a dissecting needle, add 1–2 drops of mountant, cover with a coverslip, and examine under a microscope. If necessary, cells can be further separated from each other by pressing down on the coverslip with a gentle, sliding motion. The macerated tissue will test negative for lignin.

*Method II*

PROCEDURE: Place the plant material in a test tube containing about 5 mL of 2 M potassium hydroxide solution. Heat in a water bath for 30 min. Wash the tissue repeatedly with water, and transfer to a microscope slide. Add 1–2 drops of mountant. Place a coverslip over the tissue, press down, squashing the tissue, and examine under a microscope. The macerated tissue will test negative for lignin.

**Preparation of powdered materials:** Place 1 or 2 drops of water, another mountant, or a reagent solution in the center of a clean slide. Moisten the tip of a dissecting needle with water, and dip into the powder under test. Transfer a small amount of material that adheres to the needle into the fluid on the slide, and stir thoroughly and carefully. Cover with a clean coverslip. Because the arrangement of the tissue structures within the plant tissue has been destroyed, the important features for observation of the powdered plant material are the chemical and physical features of tissues and cell types, as well as the presence and chemical and physical features of ergastic substances. The specific tissues, cells, and ergastic substances to be examined are specified in the individual monograph.

## PROCEDURE FOR THIN, PERMANENT MOUNTS

When it is necessary to reveal detailed histological features of a plant specimen, thin tissue sections have to be obtained. The sections need to be thin enough to transmit light, and they have to be cut in such a plane that the desired features are exposed. The plant material is properly killed, fixed, dehydrated, and embedded in paraffin or other embedding media. The embedding medium is used as a solid-support matrix during tissue sectioning. After sectioning and mounting, staining of the specimen is frequently performed to aid in the differentiation of certain structures. [NOTE—The process of fixing, dehydration, embedding, and staining can be significantly expedited by utilizing a microwave oven specifically designed for histological work.]

**Killing and fixation:** As a first step in preparing plant material for sectioning, living cells are killed, and the tissue is preserved. This is most frequently done by employing a chemical fixative. A good general purpose fixative for plant material is a mixture of formaldehyde, acetic acid, and alcohol (FAA).

*FAA solution*—Mix 50 mL of alcohol, 5 mL of glacial acetic acid, 10 mL of formaldehyde solution, and 35 mL of water. [NOTE—Periodically prepare fresh solution, as it loses effectiveness with storage.]

*Procedure*—Completely immerse the plant material in the *FAA solution*. Allow the material to remain immersed for 18–24 h at room temperature. Plant material can be kept indefinitely in *FAA solution*, as long as it remains completely immersed and is not allowed to dry out. Certain plant tissues may require vacuum infiltration to facilitate the penetration of the fixative. Vacuum infiltration is required if the tissue has abundant air spaces or epidermal hairs or if it floats on top of the fixative solution. Place the tissue in a small vial containing the fixative. Place the uncapped vial into a bell jar or desiccator that is connected to a vacuum

DOI: https://doi.org/10.31003/USPNF_M99323_03_01
@2024 USPC

source, preferably an oil-sealed vacuum pump. The vacuum is vented into a fume hood to prevent fixative vapors from filling the room. Slowly turn on the vacuum. Do not use a strong vacuum because the fixative may start to boil and damage the tissue. As residual air is pulled from the tissue, it will rise to the surface. Turn the vacuum on and off through several cycles until the tissue stays at the bottom of the container during an "on" cycle.

**Tissue dehydration:** Paraffin and other embedding media are hydrophobic; thus, water must be removed from the plant tissue after fixation. This is accomplished by immersing the fixed tissue in dehydration solutions, which are a series of mixtures of alcohol and water with increasing alcohol concentration. The final solution in the series is dehydrated alcohol. Begin by washing the fixed tissue once or twice with fresh 50% alcohol to remove traces of FAA. Remove this solution, and subsequently remove any other dehydration solution, by decanting the solution or removing it with the aid of a glass pipet. Add the first dehydration solution (70% alcohol) to the vial, completely immersing the tissue. The graded alcohol–water series and the suggested times for tissue immersion are listed in *Table 3*.

**Table 3**

| Dehydration Solution | Time (h) |
|---|---|
| 50% alcohol | 1–2 |
| 70% alcohol | 1–2 |
| 90% alcohol | 1–2 |
| 95% alcohol | 1–2 |
| Dehydrated alcohol containing 0.1% of safranin O | 2–4 |
| Dehydrated alcohol | 1 |

Safranin O is added to the penultimate dehydration solution in the series to visualize the tissue when it has become embedded in paraffin. If the tissue to be sectioned is hard or woody, the time for each step in the series may need to be increased to up to 24 h. If necessary, the tissue can be stored for several days in 70% alcohol or in solutions of even higher alcohol concentrations.

**Embedding**

*Preparation for embedding*

ALCOHOL REMOVAL: Paraffin is the most common embedding medium, although other embedding media are available. After dehydration, alcohol is removed from the tissue by using a graded series of dehydrated alcohol–xylene solutions, because paraffin is not soluble in alcohol. The graded dehydrated alcohol–xylene series and the suggested times for tissue immersion are listed in *Table 4*.

**Table 4**

| Alcohol Removal Solution | Time (h) |
|---|---|
| A mixture of dehydrated alcohol and xylene (3:1) | 1 |
| A mixture of dehydrated alcohol and xylene (1:1) | 1 |
| A mixture of dehydrated alcohol and xylene (1:3) | 1 |
| Xylene | 1 |
| Xylene | 1 |

XYLENE REMOVAL: Once xylene has completely replaced alcohol, paraffin is added slowly to infiltrate the tissue and remove xylene. Proceed as follows:

1. For each mL of xylene add about 1 paraffin chip to the tissue vial, cap, and allow to stand at room temperature for 4 h. Add additional paraffin chips until no more chips dissolve.
2. Place the tissue in an oven maintained at 42°–45°. Add 2–3 paraffin chips every h until no more chips dissolve at that temperature.
3. Pour off one-third of the volume, and replace with an equal volume of melted paraffin. Do not cap, and transfer the vial to an oven maintained at 58°–60°.
4. After the paraffin remelts (about 4 h later) pour off one-half of the volume, and replace with an equal volume of melted paraffin. Transfer the vial to the oven maintained at 58°–60° if the paraffin begins to solidify.
5. Repeat the fourth step twice more, then pour off the entire volume of paraffin–xylene. Replace with pure melted paraffin. About 4 h later, pour off the paraffin, and replace with fresh pure melted paraffin. Repeat the pouring off and replacement 4 h later, and allow to stand overnight. [NOTE—Transfer the vial to the oven maintained at 58°–60° if the paraffin begins to solidify at any point.]

*Embedding procedure*—Pour the tissue with the paraffin to an embedding boat. Paraffin has to completely cover the tissue by about 3–5 mm. Place the embedding boat on top of a preheated warming platform that is designed for histology work. Adjust the tissue in the boat to its proper orientation for sectioning. Slowly cool the paraffin by sliding the boat down to the cool side of the platform until the paraffin has solidified. Immerse the paraffin block in ice water to rapidly cool the block and to prevent paraffin crystals from forming. Store the paraffin block at 4°.

**Sectioning and mounting:** Cut the paraffin block into pieces, each containing one tissue sample. Trim the paraffin block, as close to the tissue mass as possible, to form a rectangle or a slight trapezoid. Such trimming will prevent sectioning problems due to excess paraffin around the tissue. To make transverse sections, orient the tissue at a right angle to a wooden tissue block

@2024 USPC

of which the face has been soaked in melted paraffin. Affix the paraffin block to the face of the tissue block. Add a small amount of melted paraffin to the base of the paraffin block to help form a tighter seal. Cool the block to 4°.

Properly mount and adjust the tissue and paraffin block in a microtome. Use a sharp stainless-steel microtome knife that has been properly honed. Set the microtome to cut sections 8–15 μm thick (10-μm thickness is optimal for most tissues). Cut individual or serial sections. Prepare a microscope slide as follows. An adhesive may be prepared as a solution containing 1% of gelatin and 0.5% of sodium benzoate that is heated to 30°–35° to dissolve the gelatin. Smear a thin film of the adhesive so obtained onto the slide, allow to dry, rinse with a 4% solution of formaldehyde TS, and add a small amount of water. Plate the cut sections upside down on the slide, so that they float on water, and flood with a 4% solution of formaldehyde TS. The sections will immediately spread out and wrinkles will disappear.

Place the slide on a warming platform, maintained at 42°, to relax the sections. Pipet, and blot the excess water and formaldehyde solution. Dry overnight in an oven at 42° to ensure adherence of the tissue section to the slide.

**Staining**

*Preparation for staining*—Immerse the microscope slide with the affixed tissue twice into xylene, each time for 10–15 min, to remove paraffin. Then immerse the slide into the following sequence of solutions, leaving it in each solution for 5 min and taking care not to dislodge the tissue: a mixture of dehydrated alcohol and xylene (1:1), dehydrated alcohol, alcohol, and a 70% alcohol solution. The tissue is bleached prior to staining if it is opaque because of the presence of tannins or other ergastic materials. To bleach, dip the slide into a 1% potassium permanganate solution for 1 min, rinse with water, dip into a 5% oxalic acid solution for 1 min, and rinse thoroughly with water. The material is ready for staining. One of the following two staining procedures is recommended for most botanical identification work. The first staining procedure uses safranin O counterstained with fast green. An alternative staining procedure uses safranin O counterstained with orange G.

*Safranin O–fast green staining*

SAFRANIN O STAINING SOLUTION: Prepare a mixture of methoxyethanol, dehydrated alcohol, water, and formaldehyde solution (50:25:25:2). Add a sufficient quantity of sodium acetate to obtain a solution containing 1% of sodium acetate, and mix. Add a sufficient quantity of safranin O to obtain a solution containing 1% of safranin O, and mix.

FAST GREEN STAINING SOLUTION: Prepare a mixture of methoxyethanol, dehydrated alcohol, and methyl salicylate (1:1:1) containing 0.05% of fast green FCF.

PROCEDURE: Once the tissue has been rehydrated to 70% alcohol as described in *Preparation for staining*, immerse for 2–24 h, depending on the tissue, in *Safranin O staining solution*. Remove excess stain by immersing the slide in water several times. Transfer the slide to an alcohol solution containing 0.5% of picric acid for 2–10 s to further remove excess stain from the section and to assist in differentiation of the tissue structures. To stop the action of the picric acid, transfer the slide for 10 s to 1 min to an alcohol solution containing 4 drops of ammonium hydroxide in each 100 mL of alcohol. Transfer the slide to dehydrated alcohol for 10 s. Visually inspect the stained tissue under a microscope to see if further destaining with picric acid is necessary. Counterstain for 10–15 s in *Fast green staining solution*. Transfer slide through two changes of a mixture of methyl salicylate, dehydrated alcohol, and xylene (2:1:1), each change lasting for 5–10 s. Then transfer the slide to a mixture of xylene and dehydrated alcohol (95:5) for 1 min. Transfer through two changes of xylene. Store in xylene until ready to mount the coverslip. Chromosomes, nuclei, and lignified, cutinized, or suberized cell walls will be stained red. Cytoplasm and cellulosic cell walls will be stained green to blue, depending on the pH of the tissue.

*Safranin O–orange G staining*

SAFRANIN O STAINING SOLUTION: Prepare a 0.004% solution of safranin O.

ORANGE G STAINING SOLUTION: Dissolve 2 g of orange G, 5 g of tannic acid, and 4 drops of hydrochloric acid in water, and dilute with water to 100 mL.

PROCEDURE: Once the tissue has been rehydrated to 70% alcohol as described in *Preparation for staining*, sequentially transfer the slide through the series of solutions in *Table 5*.

**Table 5**

| Solution | Time |
|---|---|
| 35% alcohol | 5 min |
| A filtered 2% zinc chloride solution | 1 min |
| Water | 5 s |
| *Safranin O staining solution* | 5 min |
| Water | 5 s |
| *Orange G staining solution* | 1 min |
| Water | 5 s |
| A filtered 5% tannic acid solution | 5 min |
| Water | 3 s |
| A 1% ferric ammonium sulfate solution | 2 min |
| Water | 15 s |
| 45% alcohol | 10 s |
| 90% alcohol | 10 s |
| Dehydrated alcohol | 10 s |
| A mixture of dehydrated alcohol and xylene (1:1) | 1–2 min |

Finally, store in xylene until ready to mount the coverslip. Cellulosic cell walls will stain blue-black, nuclei will stain yellow, starch grains will stain black, and lignified cell walls will stain red.

**Mounting the coverslip:** The mounting of a coverslip over the tissue completes the preparation of the slide. Canada balsam, diluted with a small portion of xylene, can be used as an adhesive. Other mountants are also commercially available. Upon drying of the mountant, the slide can then be examined under a microscope. The entire process of making permanent microscope slides can be expected to take 5 or more days.

**Scanning electron microscopy:** Botanicals in commerce are often encountered in the form of powder or in pieces, thus making authentication by the routine method of cross-sectioning of the article difficult and often impossible. Structures such as xylem vessels and trachids may be broken into smaller bits, making detection of pitting and lignifications on the walls difficult if not impossible using an optical microscope. Structures that are resistant to these processes are most useful in identification. Scanning electron microscopy (SEM) is useful for characterizing the size and morphology of microscopic specimens. The more detailed differential characteristics in the structure of trichomes and peculiar elements in the epidermis, along with superficial granular material containing specific compounds, can be observed and identified with SEM, which assists in the identification of particular species. SEM has been used extensively to investigate surface topology of a wide variety of plant materials. It can play a vital role in authentication of an entire botanical, those in powder form, distinguishing between closely related species, and can be used to examine a mixture of powders.

Introduction and general information about SEM as applied to pharmacopeial articles can be found in general information chapter *Scanning Electron Microscopy* ⟨1181⟩.

SEM produces a higher resolution compared to that possible using an optical microscope, and the images obtained are three-dimensional. SEM has the advantage of providing images with a large depth of field, which allows a substantial thickness of the sample to be in focus at one time. It allows the analysis of specimens as large as 50 mm, making it possible to produce detailed topographical electron micrographs of an object clearly visible to the naked eye. The maximum resolution for SEM (minimum distance by which the two objects can be separated and observed as distinct objects) is 10–20 nm compared to 200–300 nm for optical microscopy. Typical SEM magnification ranges from ×10 to ×300,000. Commercial SEM instruments also are available with magnifications as low as ×5 and as high as ×2,000,000. In comparison, typical modern optical microscopes have a magnification range of ×10 to ×2000. At low magnification, images obtained with SEM provide more information than those of optical microscopy. SEM can produce images for which contrast is based on compositional variations of specimens.

## CHEMICAL IDENTIFICATION

To help ensure the authenticity of the article, chemical identification is performed in conjunction with the botanical identification outlined previously. Chemical identification typically employs chromatographic procedures to detect the presence of marker compounds specified in the individual monograph. Spectroscopic or chromatographic profiles can be used to achieve chemical identification by fingerprint comparison against that of a reference sample or standard. Examples of spectroscopic methods include ultraviolet (UV), infrared (IR), and Fourier transformed IR (see ▲*Spectroscopic Identification Tests* ⟨197⟩▲ (CN 1-May-2020)). Examples of chromatographic methods include high-pressure liquid chromatography (HPLC), thin-layer chromatography (TLC), two-dimensional-TLC, and gas chromatography (GC) (see *Chromatography* ⟨621⟩). Analytical methods used for fingerprinting should be capable of detecting as many chemical constituents as possible. Multiple fingerprints, using a combination of analytical methods with different separation principles and test conditions, may be useful. In addition to the spectroscopic chromatographic methods, qualitative wet-chemistry methods may also be specified in the individual monograph.

### Chemotaxonomy

Chemotaxonomy is the classification of the plants based on their chemical constituents and it may be useful in botanical articles identification. Metabolic compounds found within plant tissues can be divided into two broad categories based on their functions. The first category comprises primary metabolites—metabolites involved in the physiological plant processes that are absolutely necessary for life and ubiquitous throughout the plant kingdom. These processes include photosynthesis; respiration; and nucleic acid, protein, carbohydrate, and lipid metabolism. The second category comprises secondary metabolites—compounds that are thought not to be absolutely necessary for plant processes, although they may have important functions in the plant's interactions with other organisms, such as allelopathic interactions; in chemical defense against herbivores and plant pathogens; and in signaling to attract pollinating and seed-dispersing animals. Many secondary metabolites are known to have pharmacological activity. They are also the basis for the chemotaxonomy of plants. Secondary metabolites fall into several different chemical classes such as nonprotein amino acids, flavonoids, xanthones, coumarins, polyacetylenes, cyclic polyketides, monoterpenes, sesquiterpenes, iridoids, triterpenes, sterols, nitrogen-containing terpenes, and alkaloids. These chemical classes are not ubiquitous throughout the plant kingdom, but tend to be specific to certain botanical classes, orders, and families. Moreover, many chemical subclasses and individual secondary compounds are specific to certain subfamilies, genera, or species. It is these chemical subclasses and individual compounds that can be used as marker compounds to aid in the proper identification of plant material.

### Active Principles and Marker Compounds

For chemical identification of botanical articles, extracts are prepared. Such extracts are usually complex mixtures of several chemical constituents. For a large majority of botanical extracts it is not known with certainty which of the various components is responsible for the reported pharmacological effect. It is generally believed that several constituents act synergistically to provide the reported effect. For articles for which compendial monographs are provided, certain chemical constituents of the

https://pharmacopeia.cn/v29240/

article are chosen and quantitative test procedures for determining their content are provided. The choice of such constituents, known generally as marker compounds, is based on certain considerations. Currently, the following types of marker compounds are specified in compendial monographs and may be identified in raw materials:

ACTIVE PRINCIPLES: These are constituents that have proven clinical activity. A minimum content or range for the active principles is usually specified in the individual monograph. A quantitative determination of active principles during stability studies of botanical dosage forms provides necessary information for arriving at suitable expiration dates.

ACTIVE MARKERS: These are constituents that have known pharmacological activity contributing in some extent to efficacy. However, the clinical efficacy for these constituents may not be proven. A minimum content or range for active markers is usually specified in individual monographs. A quantitative determination of active markers during stability studies of botanical dosage forms provides necessary information for arriving at suitable expiration dates.

ANALYTICAL MARKERS: Where neither defined active principles nor active markers are known, other constituents of the botanical extract amenable to quantitative determination are chosen. These markers aid in the positive identification of the article under test. In addition, maintaining a minimum content or a specified range of the analytical markers helps to achieve standardization of the plant extract and to arrive at a suitable expiration date during stability studies.

NEGATIVE MARKERS: These are constituents that may have allergenic or toxic properties, rendering their presence in the botanical extract undesirable. For example, ginkgolic acids from ginkgo belong to this category. A stringent limit for these negative markers may be specified in individual monographs.

### Use of USP Reference Articles

Reference articles are used to assist in the identification of marker compounds within the test article. Reference articles are either USP Authenticated Reference Materials or USP Reference Standards (see *USP Reference Standards* ⟨11⟩), whichever is specified in the individual monograph. USP Reference Standards used to identify marker compounds in the test articles may be a single purified chemical entity, a mixture of purified chemical entities, or a standardized extract prepared from the authenticated plant article. USP Reference Standards may also be used to quantitate marker compounds, as specified in the individual monograph.

A pulverized test article undergoes a specified extraction procedure (see *Methods of Extraction* in *Botanical Extracts* ⟨565⟩) and is prepared for chromatographic or wet-chemistry analysis. If a USP Authenticated Reference Material is available, then it undergoes the same extraction procedure as the test article. The test preparation and reference articles then undergo the same chromatographic or wet-chemistry procedure specified in the individual monograph. The response of the test preparation is compared to the response of reference articles to determine the presence of the marker compounds in the test article.

## DNA-BASED METHODS FOR AUTHENTICATION OF ARTICLES OF BOTANICAL ORIGIN

Because morphological identification often is not possible when the original plant material consists of dried, cut and shifted, or processed plant parts or when the material consists only of a whole, single plant part containing no taxonomic characters, additional identification methods, such as DNA-based identification, often are required for these sample types. DNA-based methods have been shown to be efficient in distinguishing genuine plant materials from adulterants in complex botanical matrixes and can complement traditional botanical identification methods that rely on morphological features or chemistry. In addition, DNA-based methods often are more reliable than traditional methods, especially when applied to single-organ specimens that lack diagnostic taxonomic characters, to powdered materials in which the distinguishing characteristics are no longer visible, or when it is difficult to distinguish among closely related or morphologically similar species.

### DNA Barcoding

DNA barcoding is a particular type of DNA sequence-based identification method that uses short sequences of specific nuclear or plastid DNA loci for identification of plant species. The assays rely on comparison of nucleotide sequences from a specific stretch of DNA (DNA sequences or DNA barcode) to perform DNA sequence-based identification. Further, DNA-based methods, such as next-generation sequencing (NGS) technologies, are able to identify multiple species in a mixture, including expected and unexpected species.

### Botanical Identification Using DNA (Sanger) Sequencing

The process for botanical identification using DNA (Sanger) sequencing includes marker selection, DNA extraction, polymerase chain reaction (PCR) primers and amplification, DNA sequencing, and comparison with reference materials, as described in the following sections. See *Nucleic Acid-Based Techniques—Extraction, Detection, and Sequencing* ⟨1126⟩, *Nucleic Acid-Based Techniques—Amplification* ⟨1127⟩, and *Nucleic Acid-Based Techniques—Genotyping* ⟨1129⟩ for additional information.

#### MARKER SELECTION

The chosen sequence must be sufficiently specific to capture any potential primary and adulterant species in the sample but also sufficiently universal to avoid false-negative reactions for closely related species. For example, a species-specific primer is not appropriate for most identification procedures because adulterants cannot be detected and amplification failure can result because of either the absence of the species or degraded DNA. In many cases, a single marker may be sufficient for identification, but multiple markers from different parts of the genome (e.g., plastid or nuclear material) ensure that hybrids can be detected.

https://pharmacopeia.cn/v-prod/

Typically, regions used for DNA sequence identification range from 100–1500 base pairs in length. Smaller DNA fragments may be less susceptible to DNA degradation.

## DNA EXTRACTION

Before amplification of the desired marker can be performed, the total genomic DNA must be extracted. The suitability of a procedure for genomic extraction depends on the starting material and the purity of the DNA required for downstream applications. The principal procedures are described as follows, and several commercial kits are available to accommodate different sample types and applications.

Total genomic DNA must be extracted from ground plant material. Plant materials can be homogenized manually using a mortar and pestle, mechanical grinder, or other apparatus depending on the nature of the material. Total genomic DNA extraction and purification can be challenging because of the abundance of secondary metabolites (polysaccharides, tannins, essential oils, phenolics, alkaloids, and waxes) in many medicinal plant species. Some of the secondary metabolites may coprecipitate with DNA during extraction and may inhibit further enzymatic reactions, including restriction digestion and PCR. In particular, large amounts of complex polysaccharides can make extraction of usable DNA impossible, rendering the aqueous portion of the extract too viscous to allow efficient separation of DNA from the contaminating polysaccharides. This type of contamination can lead to poor DNA yield and can prevent access by modifying enzymes.

Numerous commonly used DNA extraction methods are appropriate for a wide range of fresh and dried plant materials, including cetyl trimethylammonium bromide, silica-based methods, and a variety of commercially available kits that use silica columns or glass-coated magnetic beads. Although many of these methods work well on both fresh and dried materials and on any plant part, those that are degraded or contain significant levels of secondary compounds or other PCR inhibitors may require minor adjustments to standard extraction protocols.

## PCR PRIMERS AND AMPLIFICATION

Typically, PCR primers are between 18 and 30 bases in length and amplify a region between 100 and 1500 base pairs in length. As noted, PCR primers may be universal, meaning they are capable of amplifying all potential organisms that are present in a test sample (including fungi, plants, and animals or an important and predicable subset), or they are taxon specific, meaning they have been designed to amplify only organisms in a targeted set (i.e., family, genus, species, or subspecies). A number of nuclear, mitochondrial, and plastid gene regions are used for universal amplification, including nrITS, nrITS1, nrITS2, *matK*, *rbcL*, *psbA–trnH* intergenic spacer, *cox3*, *COI* (also known as *cox1*), external transcribed spacer, 18S, 5S, *trnL–trnF* intergenic spacer, and *trnL* intron. Taxon-specific primers may be designed on the basis of proteins found in specific plant groups (e.g., the soy lectin gene found in soy) or by obtaining sequences of any variable DNA region for the target taxon and designing primers that specifically bind only to sequences from the taxon of interest.

## DNA SEQUENCING

Most commonly, DNA sequencing is conducted using the Sanger protocol that has been modified to use fluorescent dye terminators on a capillary electrophoresis apparatus, although a number of emerging sequencing technologies [e.g., next-generation sequencing (NGS)] are now taking root. Once fluorescent dye has been incorporated into the amplified DNA, the bases are identified by their emission of light at different wavelengths. The resulting data are a chromatogram that can be visualized and analyzed by several sequence-analysis computer programs.

## COMPARISON WITH REFERENCE MATERIALS

DNA sequences of test articles are compared to sequences obtained from multiple reference materials in an aligned matrix (commonly referred to as an alignment), which allows the sequences to be visually inspected to identify diagnostic nucleotide positions. Although numerous computer programs are able to automate comparisons between sequences from test articles and reference sequences, performance varies widely. Investigators should always manually check the results suggested by computer programs to confirm identity. Positive identifications are not possible when the sequences from test articles fall outside the range of known variation represented in the reference sequences. If a sufficiently large number of reference materials have been used to develop the assay, most test materials should be identified without ambiguity based on DNA sequence data.

Official

# ⟨565⟩ BOTANICAL EXTRACTS

In the extraction practice for articles of botanical origin, the constituents of interest are completely or partially separated from other components with the aid of water, alcohol, alcohol-water mixtures, or other suitable solvents. This extraction process involves the removal of the desired constituents from the plant matter with suitable menstrua, the evaporation of all or nearly all of the solvent, and the adjustment of the residual fluids, masses, or powders to the prescribed standards. Suitable inert substances may be added as carriers or diluents to improve physical characteristics. Suitable antimicrobials and other preservatives may be added to preserve the integrity. Extracts may be subjected to processes that increase the content of characterized constituents, decrease the content of unwanted constituents, or both. Extracts with no added inert substances and no processing beyond the extraction are called native extracts. In some preparations, the plant matter may be pretreated by inactivation of enzymes and microbial contaminants, grinding, defatting, or a similar procedure.

Extracts may be defined as preparations with liquid, solid, or semisolid consistency. The products obtained by extraction are fluidextracts, powdered extracts, semisolid extracts, and tinctures.

## METHODS OF EXTRACTION

### Percolation

In the manufacture of extracts, percolation is a commonly used method. The crude material being extracted is reduced to pieces of suitable size, if necessary, then mixed thoroughly with a portion of the specified solvent, and allowed to stand for about 15 minutes. The mixture is transferred to a percolator, sufficient amount of the specified solvent is added to cover the entire solid mass, and the mixture is allowed to percolate slowly (at a rate of not more than 1 mL per minute for 1000 g of material), the matter to be extracted being always covered with a layer of solvent. The residue may be pressed, and the obtained fluid is combined with the percolate. The entire percolates are concentrated, generally by distillation under reduced pressure, so as to subject the constituents of interest in the article under extraction to as little heat as possible.

### Maceration

Unless otherwise specified, the crude material being extracted is reduced to pieces of suitable size, mixed thoroughly with the specified extracting solvent, and allowed to stand at room temperature in a closed container for an appropriate time, with frequent agitation until soluble matter is dissolved. The mixture is filtered, the insoluble material is washed with the same solvent used for maceration, and the filtrates are combined and concentrated, usually under reduced pressure, to the desired consistency.

***Change to read:***

## PREPARATIONS

### Fluidextracts

FLUIDEXTRACTS, also known as liquid extracts, are preparations of plant matter, containing alcohol as a solvent or as a preservative, or both, and are so made that each mL contains the extracted constituents of 1 g of the crude material that it represents, unless otherwise specified in the individual monograph. They may be prepared from suitable extracts and may contain suitable antimicrobial or other preservatives.

Pharmacopeial fluidextracts are made by percolation, often following a period of maceration. The required solvent is specified in the individual monograph. The common manufacturing procedure includes concentration of the more diluted portion of percolate by evaporation or distillation under vacuum at temperatures below 60°. The time of maceration and the rate of flow during percolation may be varied to adjust for the quantity and nature of the crude material under extraction, provided that the composition of the extracted constituents of interest is not adversely affected.

The rate of flow of the percolate can be slow, moderate, or rapid. With reference to the extraction of 1000 g of the starting material, at a slow rate, not more than 1 mL of percolate is produced per minute; at a moderate rate, between 1 and 3 mL per minute is produced; and at a rapid rate, between 3 and 5 mL per minute is produced. A fluidextract that tends to deposit sediment may be aged and filtered, or the clear portion may be decanted, provided that the resulting clarified liquid conforms to the Pharmacopeial standards.

### Powdered Extracts

POWDERED EXTRACTS are solid preparations having a powdery consistency obtained by evaporation of the solvent used for extraction. They may contain suitable added substances such as excipients, stabilizers, and preservatives. Standardized powdered extracts are adjusted to the defined content of constituents, using suitable inert materials or a powdered extract of the plant matter used for preparation. Where applicable, a limit for the solvent used for extraction is specified in the individual monograph.

Official

https://nhathuocngocanh.com/

## Semisolid Extracts

SEMISOLID EXTRACTS, also known as soft extracts or pillular extracts, are preparations having consistencies between those of fluidextracts and those of powdered extracts, and are obtained by partial evaporation of the solvent, water, alcohol, or hydroalcoholic mixtures being used as extracting solvents. They may contain suitable antimicrobial or other preservatives. A semisolid extract and a powdered extract obtained from the same material are interchangeable as drugs or as supplements, but each has its own advantages.

## General Pharmacopeial Requirements

Unless otherwise specified in the individual monographs, Pharmacopeial requirements for the fluidextracts, powdered extracts, and semisolid extracts are as follows.

PACKAGING AND STORAGE—Store in tight, light-resistant containers. [NOTE—See *Packaging and Storage Requirements* ⟨659⟩*, General Definitions*.]

LABELING—Label it to indicate the name of the plant part used; the names of solvents, other than the hydroalcoholic solvents, used in preparation; the content, in percentage, of active principles or marker compounds identified in the individual monograph; and the name and concentration of any added antimicrobial or other preservative. Where active principles are unknown, the ratio of starting material to final product is stated. For semisolid extracts and powdered extracts, the identity and quantity of any added excipient is also indicated. In such cases the percentage of native extract may also be stated.

RESIDUE ON EVAPORATION—Transfer promptly about 2 mL, accurately measured, of Fluidextract, about 0.5 g of Powdered Extract, or about 2 g of Semisolid Extract to a suitable tared, round-bottom flask. Evaporate to dryness on a water bath, and dry the residue at 100° to 105° for 3 hours. Allow to cool in a desiccator over phosphorus pentoxide, and determine the weight of the residue obtained: not less than 95% of Powdered Extract specimen remains as residue; or not less than 70% of Semisolid Extract specimen remains as residue. [NOTE—Limits for Fluidextracts are specified in the individual monographs.]

RESIDUAL SOLVENTS—If prepared with solvents other than alcohol, water, or alcohol-water mixtures, it meets the requirements for *Residual Solvents* ⟨467⟩. [NOTE—See ICH document *Impurities: Residual Solvents* for related information.]

PESTICIDE RESIDUES—Botanical extracts, tinctures, or other pharmaceutical forms might contain pesticide residues at either enriched or reduced levels compared to their native form as plant materials. Unless otherwise indicated in the monograph, the limits for pesticides in extracts of botanical articles are calculated by the following formula:

$$\text{If } E \leq 10\text{: Limit (mg/kg)} = L \times E$$

$$\text{If } E > 10\text{: Limit (mg/kg)} = AM/100B$$

where $L$ is the limit in the original article as listed in ▲*Table 5*▲ (ERR 1-Jun-2022) (see *Pesticide Residue Analysis* under *Articles of Botanical Origin* ⟨561⟩), or EPA tolerance or the FDA action level; $E$ is the plant to extract ratio (i.e. the ratio between the quantity of botanical article used in the manufacture of the extract and the quantity of the extract obtained); $A$ is the acceptable daily intake (ADI), as published by FAO-WHO, in mg/kg of body weight; $M$ is body weight, in kg (60 kg); and $B$ is the daily dose of the extract, in kg.

[NOTE—The higher pesticide limits for extracts of botanical ingredients may be justified if the suggested intake or dose of the extract is reduced by a factor which is higher than $E$.]

A total or partial exemption from the test may be granted when the complete history (nature and quantity of the pesticides used, date of each treatment during cultivation and after harvest) of the treatment of the batch is known and can be checked precisely according to good agricultural and collection practice (GACP).

ALCOHOL DETERMINATION, *Method II* ⟨611⟩ (IF PRESENT): Between 90% and 110% of the labeled amount of $C_2H_5OH$ is found in Fluidextract and Semisolid Extract.

## Tinctures

TINCTURES are liquid preparations usually prepared by extracting plant materials with alcohol or hydroalcoholic mixtures. Traditionally, tinctures of potent articles of botanical origin represent the activity of 10 g of the drug in each 100 mL of tincture, the strength being adjusted following the test for content of active principles or marker compounds. Most other plant tinctures represent 20 g of the respective plant material in each 100 mL of tincture.

Different tinctures are not always diluted to obtain the same ratio of starting plant material to final tincture. This ratio will depend on the requirements prescribed in the specific tests for content of active principles or marker compounds included in the individual monographs. As tinctures are being prepared, they are assayed in accordance with these content tests. Using the values obtained from such assays, the final concentration of a tincture is adjusted by adding more solvent or by evaporating part of the solvent.

Unless otherwise specified, tinctures are usually prepared from coarse powder or fine cuttings of plant materials either by a percolation process or a maceration process.

### PERCOLATION PROCESS

Carefully mix the ground mixture of ingredients with a sufficient quantity of the prescribed extracting solvent to render it evenly and distinctly damp, allow it to stand for 15 minutes, transfer it to a suitable percolator, and pack the mass firmly. Pour on enough of the specified extracting solvent to saturate the drug, and cover the top of the percolator. When the liquid is about to drip from the percolator, close the lower orifice, and allow the drug to macerate for 24 hours or for the time specified in the

Official

https://pharmacopeia.com/

monograph. If the test for content of active principles or marker compounds is not required in the individual monograph, allow the percolation to proceed slowly or at the specified rate (for definitions of flow rates, see under *Fluidextracts*), gradually adding sufficient quantity of extracting solvent to produce 1000 mL of tincture, and mix. If a test for content of active principles or marker compounds is required, collect only 950 mL of percolate, mix, and test a portion of it as directed in the individual monograph. Dilute the remainder of the percolate with as much of the prescribed extracting solvent as calculation from the content test indicates is necessary to produce a tincture that conforms to the requirements, and mix.

## MACERATION PROCESS

Macerate the drug with 750 mL of the prescribed extracting solvent in a closed container, and put in a warm place. Agitate it frequently during 3 days or until the soluble matter is dissolved. Transfer the mixture to a filter. When most of the liquid has drained, wash the residue on the filter with a sufficient quantity of the prescribed extracting solvent, combining the filtrates, to produce 1000 mL of tincture, and mix.

## GENERAL PHARMACOPEIAL REQUIREMENTS

Unless otherwise specified in the individual monographs, Pharmacopeial requirements for the tinctures are as follows.
**Packaging and Storage—**Store in tight, light-resistant containers, and avoid exposure to direct sunlight and excessive heat. [NOTE—See *Packaging and Storage Requirements* ⟨659⟩*, General Definitions*.]
**Labeling—**Label it to indicate the name of the plant part used for preparation; the name of the solvent or solvent mixture used for extraction; and the content of the constituents of interest and the ratio of starting material to final product.

# ⟨571⟩ VITAMIN A ASSAY

## ASSAY

### Chemical Methods

- **PROCEDURE 1**

The following procedure is provided for the determination of vitamin A in dietary ingredients or pharmaceutical ingredients. It conforms to the procedure that was adopted in 1956 for international use by the International Union of Pure and Applied Chemistry.

Complete the assay promptly, and exercise care throughout the procedure to keep to a minimum the exposure to actinic light and to atmospheric oxygen and other oxidizing agents, preferably by the use of low-actinic glassware and an atmosphere of an inert gas.

For the test articles that contain tocopherol, an appropriate chromatographic method should be used.

**Sample solution:** Accurately weigh, count, or measure a portion of the test specimen expected to contain the equivalent of NLT 0.15 mg of retinol but containing NMT 1 g of fat. If in the form of capsules, tablets, or other solid, so that it cannot be saponified efficiently by the ensuing instructions, reflux the portion taken in 10 mL of water on a steam bath for about 10 min, crush the remaining solid with a blunt glass rod, and warm for about 5 min longer.

Transfer to a suitable borosilicate glass flask, and add 30 mL of alcohol, followed by 3 mL of potassium hydroxide solution (9 in 10). Reflux in an all-borosilicate glass apparatus for 30 min. Cool the solution, add 30 mL of water, and transfer to a conical separator. Add 4 g of finely powdered sodium sulfate decahydrate. Extract by shaking with one 150-mL portion of ether for 2 min, and then, if an emulsion forms, with three 25-mL portions of ether. Combine the ether extracts, if necessary, and wash by swirling gently with 50 mL of water. Repeat the washing more vigorously with three additional 50-mL portions of water. Transfer the washed ether extract to a 250-mL volumetric flask, add ether to volume, and mix.

Evaporate a 25.0-mL portion of the ether extract to about 5 mL. *Without applying heat and with the aid of a stream of inert gas or vacuum,* continue the evaporation to about 3 mL. Dissolve the residue in sufficient isopropyl alcohol to give an expected concentration of the equivalent of 3 µg–5 µg of vitamin A per mL or to give an absorbance in the range 0.5–0.8 at 325 nm.

**Instrumental conditions**

(See *Ultraviolet-Visible Spectroscopy* ⟨857⟩.)

**Mode:** UV

**Analytical wavelengths:** 310, 325, and 334 nm

**Cell:** 1 cm

**Blank:** Isopropyl alcohol

**Analysis**

**Sample:** *Sample solution*

Determine the absorbances of the *Sample solution* at 310, 325, and 334 nm. Calculate the vitamin A, as retinol ($C_{20}H_{30}O$) content, in mg, in the portion of sample taken, using one of the following formulas:

$$\text{Result} = (0.549 \times A_{325})/(L \times C)$$

or

$$\text{Result} = (0.549 \times [A_{325}])/(L \times C)$$

$L$ = length of the absorption cell (cm)

$C$ = concentration in the final isopropyl alcohol solution of test specimen (g/100 mL) or capsules or tablets (units/100 mL)

$[A_{325}]$ = *corrected* absorbance at 325 nm, calculated:

$$\text{Result} = (6.815 \times A_{325}) - (2.555 \times A_{310}) - (4.260 \times A_{334})$$

Each mg of vitamin A, as retinol ($C_{20}H_{30}O$), represents 3333 USP Units of vitamin A.

Use the first formula when $A_{325}$, the observed absorbance at 325 nm, is between $[A_{325}]/1.030$ and $[A_{325}]/0.970$. Use the second formula when $[A_{325}]$ has a value less than $A_{325}/1.030$.

[NOTE—The range of the limits of error for this analytical procedure, indicating the extent of discrepancy to be expected in the results of different laboratories at $P = 0.05$, is approximately ±8%.]

- **PROCEDURE 2**

This procedure is used for dietary ingredients or pharmaceutical ingredients in the form of pure retinyl esters or prepared from pure retinyl esters into a vehicle excipient.

**Sample solution:** Dissolve 25–100 mg, accurately weighed, in 5 mL of pentane, and dilute with isopropyl alcohol to give an expected concentration of the equivalent of 3–4.5 µg/mL of retinol.

**Instrumental conditions**

(See *Ultraviolet-Visible Spectroscopy* ⟨857⟩.)

**Mode:** UV

**Analytical wavelength:** 326 nm

**Cell:** 1 cm

**Blank:** Isopropyl alcohol

Official

https://pharmacopeia.cn/

**Analysis**

**Sample:** *Sample solution*

Calculate the vitamin A, as retinol ($C_{20}H_{30}O$) content, in mg, in the portion of sample taken. Each mg of vitamin A, as retinol ($C_{20}H_{30}O$), represents 3333 USP Units of vitamin A.:

$$\text{Result} = (0.570 \times A_{326})/(L \times C)$$

$A_{326}$ = absorbance at 326 nm
$L$ = length of the absorption cell (cm)
$C$ = concentration of the *Sample solution* (g/100 mL)

**Chromatographic Methods**

The following liquid chromatographic procedures are provided for the determination of vitamin A as an active pharmaceutical ingredient, a dietary supplement ingredient, or a component in the dietary supplements or pharmaceutical dosage forms.

Throughout these procedures, protect solutions containing and derived from the test specimen and the Reference Standards from the atmosphere and light, preferably by the use of a blanket of inert gas and low-actinic glassware.

Where an ester form of vitamin A (retinyl acetate or retinyl palmitate) is specified in the following procedure, use the chemical form present in the formulation and the relevant USP Reference Standard.

• **PROCEDURE 1**

This is a neutral procedure that involves either simply dissolving the sample directly into hexane and injecting into the liquid chromatograph or sample extraction by first dissolving the sample in dimethyl sulfoxide, followed by a liquid–liquid extraction of the vitamin A with hexane. Although its chromatographic system can separate the 13-*cis* and all-*trans*-isomers of vitamin A, only the all-*trans*-isomer peak is used for the quantitation of vitamin A. The procedure can be used to determine vitamin A in raw material, Oil-Soluble Vitamins Tablets, Oil-Soluble Vitamins Capsules, Oil- and Water-Soluble Vitamins Tablets, Oil- and Water-Soluble Vitamins Capsules, Oil- and Water-Soluble Vitamins with Minerals Tablets, and Oil- and Water-Soluble Vitamins with Minerals Capsules.

Unless specified in the individual monographs, the *Standard solutions*, *Sample solutions*, and *System suitability solution* are prepared as follows.

**Mobile phase:** *n*-Hexane

**Standard solution 1:** 15 µg/mL of retinol[1] from USP Retinyl Acetate RS in *n*-hexane

**Standard solution 2:** 15 µg/mL of retinol[2] from USP Retinyl Palmitate RS in *n*-hexane

**System suitability solution:** Mix equal volumes of *Standard solution 1* and *Standard solution 2*.

**Sample solution for raw materials:** Transfer retinyl acetate or retinyl palmitate, accurately weighted, equivalent to 15 mg of retinol, to a 100-mL volumetric flask, dissolve in and dilute with *n*-hexane to volume, and mix. Pipet 5.0 mL of this solution into a 50-mL volumetric flask, dilute with *n*-hexane to volume, and mix.

**Sample solution for tablets:** Finely powder NLT 20 Tablets. Transfer a portion of the powder, not exceeding 7.5 g, equivalent to NLT 1 mg of vitamin A, as retinol ($C_{20}H_{30}O$), to a centrifuge tube having a polytef-lined screw cap. Add about 2 mL of dimethyl sulfoxide and about 3 mL of *n*-hexane per each g of powdered Tablets, and shake for 45 min on a shaker in a water bath maintained at 60°. [NOTE—Set up the shaker to ensure that the contents of the container are mixed vigorously and thoroughly.] Centrifuge at 3000 rpm for 10 min, and transfer the hexane layer by means of a pipet to a volumetric flask. Add 3 mL of *n*-hexane per each g of powdered Tablets to the dimethyl sulfoxide layer, shake thoroughly for 5 min, and transfer the hexane layer by means of a pipet to the same volumetric flask. Repeat this extraction with three additional portions of *n*-hexane. Dilute the extracts in the volumetric flask with *n*-hexane to volume. Dilute a volume of this solution with *n*-hexane to obtain a solution having a nominal concentration of 15 µg/mL of vitamin A, as retinol ($C_{20}H_{30}O$). [NOTE—Dilution may not be necessary.]

**Sample solution for capsules:** Transfer the contents of NLT 20 Capsules to a suitable container, mix, and weigh. Transfer a portion of the mixture, not exceeding 7.5 g equivalent to NLT 1 mg of vitamin A, as retinol ($C_{20}H_{30}O$), to a centrifuge tube having a polytef-lined screw cap. [NOTE—For hard gelatin Capsules, remove, as completely as possible, the contents of NLT 20 Capsules by cutting open the Capsule shells, transferring the shells and their contents to a suitable container, and triturating to a homogeneous mass. Transfer a portion of the mass, equivalent to NLT 1 mg of vitamin A, as retinol ($C_{20}H_{30}O$), to a centrifuge tube having a polytef-lined screw cap.] Add about 2 mL of dimethyl sulfoxide and about 3 mL of *n*-hexane per each g of Capsule contents, and shake for 45 min on a shaker in a water bath maintained at 60°. [NOTE—Set up the shaker to ensure that the contents of the container are mixed vigorously and thoroughly.] Centrifuge at 3000 rpm for 10 min, and transfer the hexane layer by means of a pipet to a volumetric flask. Add 3 mL of *n*-hexane per each g of Capsule contents to the dimethyl sulfoxide layer, shake thoroughly for 5 min, and transfer the hexane layer by means of a pipet to the same volumetric flask. Repeat this extraction with three additional portions of *n*-hexane. Dilute the extracts in the volumetric flask with *n*-hexane to volume. Dilute a volume of this solution with *n*-hexane to obtain a solution with a concentration of 15 µg/mL of vitamin A, as retinol ($C_{20}H_{30}O$). [NOTE—Dilution may not be necessary.]

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 325 nm

**Column:** 4.6-mm × 15-cm; 3-µm packing L8

**Flow rate:** 1 mL/min

[1] Use the value of 0.872 to convert retinyl acetate to its retinol equivalent.
[2] Use the value of 0.546 to convert retinyl palmitate to its retinol equivalent.

https://pharmacopeia.cn/

**Injection volume:** 40 µL

**System suitability**

**Samples:** *System suitability solution* and *Standard solution 1* or *Standard solution 2*

**Suitability requirements**

**Resolution:** NLT 10 between all-*trans*-retinyl acetate and all-*trans*-retinyl palmitate, *System suitability solution*

**Relative standard deviation:** NMT 3.0%, *Standard solution 1* or *Standard solution 2*

**Analysis**

**Samples:** *Standard solution 1* or *Standard solution 2* and appropriate *Sample solution*

Calculate the percentage of the labeled amount of vitamin A, as retinol ($C_{20}H_{30}O$), in the portion of sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of all-*trans* retinyl ester from the appropriate *Sample solution*
$r_S$ = peak response of all-*trans* retinyl ester from *Standard solution 1* or *Standard solution 2*
$C_S$ = concentration of retinol ($C_{20}H_{30}O$) in *Standard solution 1* or *Standard solution 2* (µg/mL)
$C_U$ = concentration of vitamin A, as retinol ($C_{20}H_{30}O$), in the *Sample solution* (µg/mL)

- **PROCEDURE 2**

This procedure involves the treatment of sample with methanolic sulfuric acid, followed by extraction with 2,2,4-trimethylpentane. Sample preparation can be used for the formulation containing vitamins A, D, and E. Application includes Oil-Soluble Vitamins Tablets, Oil-Soluble Vitamins Capsules, Oil- and Water-Soluble Vitamins Tablets, Oil- and Water-Soluble Vitamins Capsules, Oil- and Water-Soluble Vitamins with Minerals Tablets, and Oil- and Water-Soluble Vitamins with Minerals Capsules.

Unless specified in the individual monographs, the *Standard solutions*, *Sample solutions*, *System suitability solution,* and reagent solutions are prepared as follows.

**Mobile phase:** *n*-Hexane and ethyl acetate (99.7: 0.3)

**3 N methanolic sulfuric acid solution:** Cautiously add 9 mL of sulfuric acid to 80 mL of methanol in a 100-mL volumetric flask. Cool, and dilute with methanol to volume.

**Sodium ascorbate–pyrogallol solution:** Transfer 10 g of sodium ascorbate and 5 g of pyrogallol to a 100-mL volumetric flask, and add sufficient water to dissolve. Add 1.7 mL of sulfuric acid, and dilute with water to volume.

**Lecithin solution:** 5 mg/mL of lecithin in 2,2,4-trimethylpentane

**Standard solution 1:** 15 µg/mL of retinol[1] from USP Retinyl Acetate RS in 2,2,4-trimethylpentane

**Standard solution 2:** 15 µg/mL of retinol[2] from USP Retinyl Palmitate RS in 2,2,4-trimethylpentane

**System suitability solution:** Mix equal volumes of *Standard solution 1* and *Standard solution 2*.

**Sample solution for tablets:** [NOTE—This preparation is suitable for the determination of vitamin A, vitamin D, and vitamin E when present in the formulation. The sample amount may be adjusted depending on the presence or absence of the appropriate vitamins.] Finely powder NLT 20 Tablets. Use a portion of the powder nominally equivalent to an amount between 0.4 mg and 2.5 mg of retinol. Add 0.5 g of sodium bicarbonate, 1.5 mL of *Lecithin solution*, and 12.5 mL of 2,2,4-trimethylpentane, and disperse on a vortex mixer. Add 6 mL of *Sodium ascorbate–pyrogallol solution*, shake slowly, and allow the solution to degas. Continue shaking until the evolution of gas has ceased, and then shake for an additional 12 min. Add 6 mL of dimethyl sulfoxide, mix on a vortex mixer to form a suspension, and shake for 12 min. Add 6 mL of *3 N methanolic sulfuric acid solution*, mix on a vortex mixer to form a suspension, and shake for 12 min. Add 12.5 mL of 2,2,4-trimethylpentane, mix on a vortex mixer to form a suspension, and shake for 10 min. Centrifuge for 10 min to break up the emulsion and to clarify the supernatant. If necessary, quantitatively dilute a volume of the supernatant with 2,2,4-trimethylpentane to obtain a concentration close to that of the *Standard solution*.

**Sample solution for capsules:** [NOTE—This preparation is suitable for the determination of vitamin A, vitamin D, and vitamin E when present in the formulation. The sample amount may be adjusted depending on the presence or absence of the appropriate vitamins.] Weigh NLT 20 Capsules in a tared weighing bottle. Using a sharp blade if necessary, carefully open the Capsules, without loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing with several portions of ether. Discard the washings, and dry the Capsule shells with the aid of a current of dry air. Weigh the empty Capsule shells in the tared weighing bottle, and calculate the net weight of the Capsule contents. Transfer a portion of the Capsule contents, equivalent to 2.5 mg of the labeled amount of vitamin A, as retinol. Add 0.5 g of sodium bicarbonate, 1.5 mL of *Lecithin solution*, and 12.5 mL of 2,2,4-trimethylpentane, and disperse on a vortex mixer. Add 6 mL of *Sodium ascorbate–pyrogallol solution*, shake slowly, and allow the solution to degas. Continue shaking until the evolution of gas has ceased, and then shake for an additional 12 min. Add 6 mL of dimethyl sulfoxide, mix on a vortex mixer to form a suspension, and shake for 12 min. Add 6 mL of *3 N methanolic sulfuric acid solution*, mix on a vortex mixer to form a suspension, and shake for 12 min. Add 12.5 mL of 2,2,4-trimethylpentane, mix on a vortex mixer to form a suspension, and shake for 10 min. Centrifuge for 10 min to break up the emulsion and to clarify the supernatant. If necessary, quantitatively dilute a volume of the supernatant with 2,2,4-trimethylpentane to obtain a concentration close to that of the *Standard solution*.

**Suitability requirements**

**Resolution:** NLT 8.0 between all-*trans* retinyl acetate and all-*trans* retinyl palmitate

**Relative standard deviation:** NMT 3.0%

**Analysis**

**Samples:** *Standard solution 1* or *Standard solution 2* and *Sample solution*

Calculate the percentage of the labeled amount of vitamin A, as retinol ($C_{20}H_{30}O$), in the portion of sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of all-*trans* retinyl ester from the *Sample solution*
$r_S$ = peak response of the all-*trans* retinyl ester from *Standard solution 1* or *Standard solution 2*
$C_S$ = concentration of retinol ($C_{20}H_{30}O$) in *Standard solution 1* or *Standard solution 2* (µg/mL)
$C_U$ = nominal concentration of vitamin A, as retinol ($C_{20}H_{30}O$), in the *Sample solution* (µg/mL).

[NOTE—Use 26.5 mL as the final volume of the *Sample solution* to calculate the nominal concentration.]

- **PROCEDURE 3**

This procedure involves the saponification of both the standard and sample, followed by a liquid–liquid extraction of vitamin A from the sample with a mixture of *n*-hexane and methylene chloride (3:1). The 13-*cis*- and all-*trans*- isomers of vitamin A can be characterized and quantitated. The procedure can be used for Oil-Soluble Vitamins Tablets, Oil-Soluble Vitamins Capsules, Oil- and Water-Soluble Vitamins Tablets, Oil- and Water-Soluble Vitamins Capsules, Oil- and Water-Soluble Vitamins with Minerals Tablets, and Oil- and Water-Soluble Vitamins with Minerals Capsules.

Unless specified in the individual monographs, the *Standard solution*, *Sample solutions*, and reagent solutions are prepared as follows.

**Mobile phase:** *n*-Hexane and isopropyl alcohol (92:8)

**Extraction solvent:** *n*-Hexane and methylene chloride (3:1)

**Potassium hydroxide solution:** 800 mg/mL of potassium hydroxide in water. [NOTE—Cautiously add potassium hydroxide in water. Mix, and cool.]

**Diluent:** 10 mg/mL of pyrogallol in alcohol

**Standard solution:** Dilute USP Retinyl Acetate RS or USP Retinyl Palmitate RS with *Diluent* to obtain a concentration of 8.5 µg/mL of retinol[1,2] ($C_{20}H_{30}O$). Transfer 10.0 mL of this solution to a stoppered 125-mL flask, and add 5 mL of water, 5 mL of *Diluent*, and 3 mL of *Potassium hydroxide solution*. Insert the stopper tightly, shake for 15 min over a water bath maintained at 60 ± 5°, and cool to room temperature. Add 7 mL of water and 25.0 mL of *Extraction solvent*. Insert the stopper tightly, and shake vigorously for 60 s. Rinse the sides of the flask with 60 mL of water, and allow to stand for 10 min until the layers separate. Withdraw a portion of the organic layer for injection into the chromatograph. This *Standard solution* contains 3.4 µg/mL of retinol.

**Sample solution for capsules:** Weigh NLT 20 Capsules in a tared weighing bottle. Open the Capsules, without loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing with several portions of ether. Discard the washings, and dry the Capsule shells with the aid of a current of dry air. Weigh the empty Capsule shells in the tared weighing bottle, and calculate the net weight of the Capsule contents. Transfer a portion of the Capsule contents, equivalent to 1.3 mg of retinol, to a stoppered 125-mL flask. Add 5 mL of water, 15 mL of *Diluent*, and 3 mL of *Potassium hydroxide solution*. Insert the stopper tightly, shake for 15 min over a water bath maintained at 60 ± 5°, and cool to room temperature. Add 7 mL of water and 25.0 mL of *Extraction solvent*. Insert the stopper tightly, and shake vigorously for 60 s or longer, if necessary, for complete extraction. Rinse the sides of the flask with 60 mL of water, and allow to stand for 10 min until the layers separate. [NOTE—Do not shake, because an emulsion may form.] Withdraw a portion of the organic layer, and dilute quantitatively and stepwise if necessary, with *Extraction solvent*, to obtain a concentration of 3.4 µg/mL of retinol.

**Sample solution for tablets:** Finely powder a counted number of Tablets. Transfer a portion of the powder, equivalent to 1.3 mg of retinol, to a stoppered 125-mL flask. Add 5 mL of water, 15 mL of *Diluent*, and 3 mL of *Potassium hydroxide solution*. Insert the stopper tightly, shake for 15 min over a water bath maintained at 60 ± 5°, and cool to room temperature. Add 7 mL of water and 25.0 mL of *Extraction solvent*. Insert the stopper tightly, and shake vigorously for 60 s or longer, if necessary, for complete extraction. Rinse the sides of the flask with 60 mL of water, and allow to stand for 10 min until the layers separate. [NOTE—Do not shake, because an emulsion may form.] Withdraw a portion of the organic layer, and dilute with *Extraction solvent* to obtain a concentration of 3.4 µg/mL of retinol.

$$\text{Result} = (r_{T1}/r_{T2}) \times (C_S/C_U) \times 100$$

$r_{T1}$ = sum of peak responses of all-*trans* retinyl ester and 13-*cis*-retinyl ester peaks from the *Sample solution*
$r_{T2}$ = sum of peak responses of all-*trans* retinyl ester and 13-*cis*-retinyl ester peaks from the *Standard solution*
$C_S$ = concentration of retinol ($C_{20}H_{30}O$) in the *Standard solution* (µg/mL)
$C_U$ = nominal concentration of vitamin A, as retinol ($C_{20}H_{30}O$), in the *Sample solution* (µg/mL)

• **PROCEDURE 4**

This procedure involves a liquid–liquid extraction of vitamin A from the sample with hexane, followed by the evaporation of hexane and reconstitution of the residue in tetrahydrofuran and acetonitrile mixture (1:1). It can be used for the determination of vitamin A in Oil- and Water-Soluble Vitamins Oral Solution and Oil- and Water-Soluble Vitamins with Minerals Oral Solution.

Unless specified in the individual monographs, the *Standard solution*, *Sample solution*, and *Diluent* are prepared as follows.

**Mobile phase:** Methanol, acetonitrile, and *n*-hexane (46.5: 46.5: 7.0)

**Diluent:** Tetrahydrofuran and acetonitrile (1:1)

**Standard solution:** 0.33 mg/mL of retinol[1,2] ($C_{20}H_{30}O$) from USP Retinyl Acetate RS or USP Retinyl Palmitate RS in *Diluent*

**Sample solution for liquid dosage forms:** Transfer an accurately measured volume of Oral Solution, equivalent to 3.3 mg of retinol, to a 500-mL separatory funnel containing 10 mL of water and 20 mL of dehydrated alcohol. Add 150 mL of solvent hexane, insert the stopper, and shake for 1 min. Add another 150 mL of solvent hexane, insert the stopper, shake, and allow the layers to separate. Discard the aqueous layer, and filter the solvent hexane extract through anhydrous sodium sulfate into a 500-mL, round-bottom flask. Evaporate the solution to dryness with the aid of a rotary evaporator over a water bath maintained at about 65°. Immediately add 10.0 mL of *Diluent*, swirl to dissolve the residue, and filter.

# ⟨580⟩ VITAMIN C ASSAY

## INTRODUCTION

The following procedures are provided for analysis of different forms of vitamin C as ascorbic acid ($C_6H_8O_6$), sodium ascorbate ($C_6H_7NaO_6$), and calcium ascorbate dihydrate ($C_{12}H_{14}CaO_{12} \cdot 2H_2O$) or their mixtures in finished dosage forms, as Capsules, Tablets, or Oral Solutions.

### METHOD I—TITRIMETRIC METHOD

• **PROCEDURE**

Unless specified in the individual monographs, proceed as follows.

**Sample solution for Capsules:** Weigh NLT 20 Capsules in a tared weighing bottle. Open the Capsules, without the loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing, if necessary, with several portions of ether. Discard the washings, and dry the Capsule shells with the aid of a current of dry air until the odor of ether is no longer perceptible. Weigh the empty Capsule shells in the tared weighing bottle, and calculate the average net weight per Capsule. Transfer a portion of the Capsule contents, equivalent to 100 mg of ascorbic acid, to a 200-mL volumetric flask, and add 75 mL of metaphosphoric–acetic acids TS. Insert a stopper into the flask, and shake by mechanical means for 30 min. Dilute with water to volume.

**Sample solution for Oral Solutions:** Transfer a volume of Oral Solution equivalent to 50 mg of ascorbic acid, previously diluted with water if necessary, to a 100-mL volumetric flask. Add 20 mL of metaphosphoric–acetic acid TS, dilute with water to volume, and mix.

**Sample solution for Tablets:** Finely powder NLT 20 Tablets. Transfer a portion of the powder, equivalent of 100 mg of ascorbic acid, to a 200-mL volumetric flask, and add 75 mL of metaphosphoric–acetic acids TS. Insert a stopper into the flask, and shake by mechanical means for 30 min. Dilute with water to volume.

**Blank:** A mixture of 5.5 mL of metaphosphoric–acetic acids TS and 15 mL of water.

**Titrimetric system**

(See *Titrimetry* ⟨541⟩.)

**Mode:** Direct titration

**Titrant:** Standard dichlorophenol–indophenol solution VS

**Endpoint detection:** Visual

**Analysis:** Transfer a portion of the *Sample solution* to a centrifuge tube, and centrifuge until a clear supernatant is obtained. Transfer a volume of the *Sample solution*, equivalent to 2 mg of ascorbic acid into a 50-mL conical flask, and add 5 mL of metaphosphoric–acetic acids TS. Titrate with *Titrant* to a rose-pink color that persists for at least 5 s. Correct for the volume of *Titrant* consumed by the *Blank*.

Calculate the percentage of ascorbic acid ($C_6H_8O_6$) in the portion of sample taken:

$$\text{Result} = \{[(V_S - V_B) \times F]/W\} \times 100$$

$V_S$ = *Titrant* volume consumed by the *Sample solution* (mL)
$V_B$ = *Titrant* volume consumed by the *Blank*
$F$ = concentration of *Titrant* in terms of its equivalent of ascorbic acid (mg/mL)
$W$ = nominal amount of ascorbic acid taken for *Analysis* (mg)

### METHOD II—CHROMATOGRAPHIC METHOD

• **PROCEDURE 1**

Unless specified in the individual monographs, the *Diluent*, *Standard solution*, and *Sample solutions* are prepared as follows. [NOTE—Protect samples from air, light, and heat.]

**Buffer:** 2.04 g/L of monobasic potassium phosphate in water. Adjust with phosphoric acid to a pH of 3.0.

**Mobile phase:** *Buffer*

**Diluent:** 0.56 g of edetate disodium dihydrate and 2.04 g of monobasic potassium phosphate per 1000 mL of water. Adjust with phosphoric acid to a pH of 3.0.

**Standard solution:** 0.25 mg/mL of USP Ascorbic Acid RS in *Diluent*

**Sample solution for Capsules:** Weigh NLT 20 Capsules in a tared weighing bottle. Open the Capsules, without the loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing, if necessary, with several portions of ether. Discard the washings, and dry the Capsule shells with the aid of a current of dry air until the odor of ether is no longer perceptible. Weigh the empty Capsule shells in the tared weighing bottle, and calculate the average net weight per Capsule. Transfer a portion of the Capsule contents, equivalent to about 25 mg of ascorbic acid, into a 100-mL volumetric flask. Add 60 mL of *Diluent*, shake mechanically for 15 min, dilute with *Diluent* to volume, mix well, and pass through a membrane filter of 0.45-µm pore size, discarding the first 4 mL.

**Sample solution for Oral Solutions:** Dilute an accurately measured volume of Oral Solution with *Diluent* to obtain a solution with a concentration of 0.25 mg/mL of ascorbic acid. Mix carefully.

**Sample solution for Tablets:** Transfer a portion from NLT 20 finely powdered Tablets, nominally equivalent to about 25 mg of ascorbic acid, into a 100-mL volumetric flask. Add 60 mL of *Diluent*, shake mechanically for 15 min, dilute with *Diluent* to volume, mix well, and pass through a membrane filter of 0.45-µm pore size, discarding the first 4 mL.

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 245 nm

**Analysis**
**Samples:** *Standard solution* and *Sample solution*
Calculate the percentage of vitamin C, as ascorbic acid ($C_6H_8O_6$), in the portion of sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak area of ascorbic acid from the *Sample solution*
$r_S$ = peak area of ascorbic acid from the *Standard solution*
$C_S$ = concentration of USP Ascorbic Acid RS in the *Standard solution* (mg/mL)
$C_U$ = nominal concentration of ascorbic acid in the *Sample solution* (mg/mL)

- **PROCEDURE 2**

Unless specified in the individual monographs, the *Diluent*, *Standard solution*, and *Sample solutions* are prepared as follows. [NOTE—Protect samples from air, light, and heat. All prepared samples must be analyzed within 4 h.]
**Buffer:** 7.8 g/L of sodium dihydrogen phosphate dihydrate in water. Adjust with phosphoric acid to a pH of 2.5.
**Mobile phase:** *Buffer* and methanol. See *Table 1* for gradient.

**Table 1**

| Time (min) | Buffer (%) | Methanol (%) |
|---|---|---|
| 0 | 100 | 0 |
| 3 | 100 | 0 |
| 5 | 0 | 100 |
| 6 | 50 | 50 |
| 7 | 100 | 0 |
| 10 | 100 | 0 |

**Diluent:** Dissolve 73 g of metaphosphoric acid in 800 mL of water, add 84 mL of glacial acetic acid, and dilute with water to 1000 mL.
**Standard stock solution:** 1 mg/mL of USP Ascorbic Acid RS in *Diluent*. [NOTE—Sonicate with intermittent shaking to help dissolve, if necessary. Prepare fresh every time.]
**Standard solution:** Dilute *Standard stock solution* with *Diluent* to obtain a solution containing 0.05 mg/mL of USP Ascorbic Acid RS.
**Sample solution for Capsules:** Weigh NLT 20 Capsules in a tared weighing bottle. Open the Capsules, without the loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing, if necessary, with several portions of ether. Discard the washings, and dry the Capsule shells with the aid of a current of dry air until the odor of ether is no longer perceptible. Weigh the empty Capsule shells in the tared weighing bottle, and calculate the average net weight per Capsule. Transfer a portion of the Capsule contents, equivalent to about 25 mg of ascorbic acid, into a 50-mL centrifuge tube. Add 25.0 mL of *Diluent*, sonicate for 15 min, and centrifuge at about 2000 rpm for 5 min. Quantitatively dilute the clear supernatant with *Diluent* to obtain a solution containing 0.05 mg/mL of ascorbic acid. Mix and pass through a membrane filter of 0.45-µm pore size.
**Sample solution for Oral Solutions:** Dilute an accurately measured volume of Oral Solution with *Diluent* to obtain a solution with a concentration of 0.05 mg/mL of ascorbic acid. Mix carefully.
**Sample solution for Tablets:** Transfer a portion from NLT 20 ground Tablets, nominally equivalent to about 25 mg of ascorbic acid, into a 50-mL centrifuge tube. Add 25.0 mL of *Diluent*, sonicate for 15 min, and centrifuge at about 2000 rpm for 5 min. Quantitatively dilute the clear supernatant with *Diluent* to obtain a solution containing 0.05 mg/mL of ascorbic acid. Mix and pass through a membrane filter of 0.45-µm pore size.
**Chromatographic system**
(See *Chromatography* ⟨621⟩, *System Suitability*.)
**Mode:** LC
**Detector:** UV 245 nm
**Column:** 4.6-mm × 15-cm; 3.5-µm packing L7
**Flow rate:** 0.8 mL/min
**Injection volume:** 10 µL
**System suitability**
**Sample:** *Standard solution*
**Suitability requirements**
**Relative standard deviation:** NMT 2.0%

# ⟨581⟩ VITAMIN D ASSAY

***Change to read:***

## ASSAY

### Chromatographic Methods

The following liquid chromatographic procedures are provided for the determination of vitamin D as an active pharmaceutical ingredient, as a dietary supplement ingredient, or as a component in compendial dosage forms.

Throughout this assay, protect solutions containing and derived from the test specimen and the Reference Standard from the atmosphere and light, preferably by the use of a blanket of inert gas and low-actinic glassware.

Where vitamin D (cholecalciferol or ergocalciferol) is specified in the following procedure, use the chemical form present in the formulation and the relevant USP Reference Standard.

- **PROCEDURE 1**

This procedure uses a sample preparation without pH adjustment and involves the use of dimethyl sulfoxide to dissolve the excipients in the sample, followed by a liquid–liquid extraction of the vitamin D with hexane. The chromatographic separation is achieved using normal phase on an L8 column. It can be used to determine vitamin D alone or in combination with other vitamins and minerals in compendial dosage forms.

Unless specified in the individual monographs, the *Standard solution*, *Sample solution*, and *System suitability solution* are prepared as follows.

**Mobile phase:** *n*-hexane and isopropyl alcohol (99:1)

**Standard solution:** 2 µg/mL of USP Cholecalciferol RS or USP Ergocalciferol RS in *n*-hexane

**System suitability solution:** Heat a volume of the *Standard solution* at 60° for 1 h to partially isomerize vitamin D (cholecalciferol or ergocalciferol) to its corresponding precursor.

**Sample solution for tablets:** Finely powder NLT 20 Tablets. Transfer a portion of the powder, not exceeding 7.5 g, equivalent to NLT 0.1 mg of vitamin D as cholecalciferol or ergocalciferol, to a centrifuge tube having a polytef-lined screw cap. Add about 2 mL of dimethyl sulfoxide and about 3 mL of *n*-hexane per each g of powdered Tablets, and shake for 45 min on a shaker in a water bath maintained at 60°. [NOTE—Set up the shaker to ensure that the contents of the container are mixed vigorously and thoroughly in order to achieve accurate recoveries.] Centrifuge at 3000 rpm for 10 min, and transfer the hexane layer by means of a pipet to a volumetric flask. Add 3 mL of *n*-hexane per each g of powdered Tablets to the dimethyl sulfoxide layer, shake thoroughly for 5 min, and transfer the hexane layer by means of a pipet to the same volumetric flask. Repeat this extraction with three additional portions of *n*-hexane. Dilute the extracts in the volumetric flask with *n*-hexane to volume. Dilute a volume of this solution with *n*-hexane to obtain a solution with a concentration of 2 µg/mL of cholecalciferol or ergocalciferol. [NOTE—Dilution may not be necessary.]

**Sample solution for capsules:** Transfer the contents of NLT 20 Capsules to a suitable container, mix, and weigh. Transfer a portion of the mixture, not exceeding 7.5 g equivalent to NLT 0.1 mg of vitamin D as cholecalciferol or ergocalciferol, to a centrifuge tube having a polytef-lined screw cap. [NOTE—For hard gelatin Capsules, remove, as completely as possible, the contents of NLT 20 Capsules by cutting open the Capsule shells, transferring the shells and their contents to a suitable container, and triturating to a homogeneous mass. Transfer a portion of the mass, equivalent to NLT 0.1 mg of vitamin D as cholecalciferol or ergocalciferol, to a centrifuge tube having a polytef-lined screw cap.] Add about 2 mL of dimethyl sulfoxide and about 3 mL of *n*-hexane per each g of Capsule contents, and shake for 45 min on a shaker in a water bath maintained at 60°. [NOTE—Set up the shaker to ensure that the contents of the container are mixed vigorously and thoroughly in order to achieve accurate recoveries.] Centrifuge at 3000 rpm for 10 min, and transfer the hexane layer by means of a pipet to a volumetric flask. Add 3 mL of *n*-hexane per each g of Capsule contents to the dimethyl sulfoxide layer, shake thoroughly for 5 min, and transfer the hexane layer by means of a pipet to the same volumetric flask. Repeat this extraction with three additional portions of *n*-hexane. Dilute the extracts in the volumetric flask with *n*-hexane to volume. Dilute a volume of this solution with *n*-hexane to obtain a solution with a concentration of 2 µg/mL of vitamin D as cholecalciferol or ergocalciferol. [NOTE—Dilution may not be necessary.]

**Chromatographic system**

(See *Chromatography* ⟨621⟩*, System Suitability*.)

**Mode:** LC

**Detector:** UV 265 nm

**Column:** 4.6-mm × 15-cm; 3-µm packing L8

**Flow rate:** 1 mL/min

**Injection volume:** 100 µL

**System suitability**

**Samples:** *Standard solution* and *System suitability solution*

**Suitability requirements**

**Resolution:** NLT 10 between the vitamin D form present and its corresponding precursor, *System suitability solution*

**Relative standard deviation:** NMT 3.0%, *Standard solution*

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of cholecalciferol ($C_{27}H_{44}O$) or ergocalciferol ($C_{28}H_{44}O$) in the portion of the sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times F \times 100$$

$r_U$ = peak response of cholecalciferol or ergocalciferol from the *Sample solution*

$r_S$ = peak response of cholecalciferol or ergocalciferol from the *Standard solution*

$C_S$ = concentration of USP Cholecalciferol RS or USP Ergocalciferol RS in the *Standard solution* (µg/mL)
$C_U$ = nominal concentration of cholecalciferol or ergocalciferol in the *Sample solution* (µg/mL)
$F$ = correction factor to account for the average amount of previtamin D present in the *Sample solution*, 1.09

- **PROCEDURE 2**

This procedure involves the treatment of sample with sodium bicarbonate, an antioxidant acid solution generating gas evolution; lecithin as a surfactant; and dimethyl sulfoxide, followed by methanolic sulfuric acid to create a dispersion and efficiently extract vitamin D from the matrix components into the 2,2,4-trimethylpentane phase. Separation is achieved in normal-phase mode on an L24 column. The sample preparation and *Chromatographic system* used in this procedure also are suitable to determine vitamins A and E when present in the formulation; analysts should make corresponding adjustments in sample size and detection wavelength.

Unless specified in the individual monographs, the *Standard solution*, *Sample solution*, *System suitability solution*, and reagent solutions are prepared as follows.

**Mobile phase:** *n*-hexane and tertiary butyl alcohol (98.75: 1.25)

**3 N methanolic sulfuric acid solution:** Cautiously add 9 mL of sulfuric acid to 80 mL of methanol in a 100-mL volumetric flask. Cool, and dilute with methanol to volume.

**Sodium ascorbate–pyrogallol solution:** Transfer 10 g of sodium ascorbate and 5 g of pyrogallol to a 100-mL volumetric flask, and add sufficient water to dissolve. Add 1.7 mL of sulfuric acid, and dilute with water to volume.

**Lecithin solution:** 5 mg/mL of lecithin in 2,2,4-trimethylpentane

**Standard solution:** 1 µg/mL of USP Cholecalciferol RS or USP Ergocalciferol RS in 2,2,4-trimethylpentane

**System suitability solution:** Heat a volume of the *Standard solution* at 60° for 1 h to partially isomerize vitamin D (cholecalciferol or ergocalciferol) to its corresponding precursor.

**Sample solution for tablets:** ▲▲ (USP 1-Dec-2023) Finely powder NLT 20 Tablets. Use a portion of the powder nominally equivalent to an amount NLT 0.1 mg of vitamin D. Add 0.5 g of sodium bicarbonate, 1.5 mL of *Lecithin solution*, and 12.5 mL of 2,2,4-trimethylpentane, and disperse on a vortex mixer. Add 6 mL of the *Sodium ascorbate–pyrogallol solution*, shake slowly, and allow the solution to degas. Continue shaking until the evolution of gas has ceased, and then shake for an additional 12 min. Add 6 mL of dimethyl sulfoxide, mix on a vortex mixer to form a suspension, and shake for 12 min. Add 6 mL of the *3 N methanolic sulfuric acid solution*, mix on a vortex mixer to form a suspension, and shake for 12 min. Add 12.5 mL of 2,2,4-trimethylpentane, mix on a vortex mixer to form a suspension, and shake for 10 min. Centrifuge for 10 min to break up the emulsion and to clarify the supernatant. If necessary, quantitatively dilute a volume of the supernatant with 2,2,4-trimethylpentane to obtain a concentration close to that of the *Standard solution*.

**Sample solution for capsules:** ▲▲ (USP 1-Dec-2023) Weigh NLT 20 Capsules in a tared weighing bottle. Using a sharp blade if necessary, carefully open the Capsules, without loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing with several portions of ether. Discard the washings, and dry the Capsule shells with the aid of a current of dry air. Weigh the empty Capsule shells in the tared weighing bottle, and calculate the net weight of the Capsule contents. Transfer a portion of the Capsule contents, equivalent to NLT 0.1 mg of the labeled amount of vitamin D, as cholecalciferol or ergocalciferol. Add 0.5 g of sodium bicarbonate, 1.5 mL of *Lecithin solution*, and 12.5 mL of 2,2,4-trimethylpentane, and disperse on a vortex mixer. Add 6 mL of the *Sodium ascorbate–pyrogallol solution*, shake slowly, and allow the solution to degas. Continue shaking until the evolution of gas has ceased, and then shake for an additional 12 min. Add 6 mL of dimethyl sulfoxide, mix on a vortex mixer to form a suspension, and shake for 12 min. Add 6 mL of the *3 N methanolic sulfuric acid solution*, mix on a vortex mixer to form a suspension, and shake for 12 min. Add 12.5 mL of 2,2,4-trimethylpentane, mix on a vortex mixer to form a suspension, and shake for 10 min. Centrifuge for 10 min to break up the emulsion and to clarify the supernatant. If necessary, quantitatively dilute a volume of the supernatant with 2,2,4-trimethylpentane to obtain a concentration close to that of the *Standard solution*.

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 265 nm

**Column:** 4.6-mm × 25-cm; 5-µm packing L24

**Flow rate:** 1 mL/min

**Injection volume:** 40 µL

**System suitability**

**Samples:** *Standard solution* and *System suitability solution*

**Suitability requirements**

**Resolution:** NLT 4.0 between the vitamin D form present and its corresponding precursor, *System suitability solution*

**Relative standard deviation:** NMT 3.0%, *Standard solution*

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of cholecalciferol ($C_{27}H_{44}O$) or ergocalciferol ($C_{28}H_{44}O$) in the portion of the sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of cholecalciferol or ergocalciferol from the *Sample solution*
$r_S$ = peak response of cholecalciferol or ergocalciferol from the *Standard solution*
$C_S$ = concentration of USP Cholecalciferol RS or USP Ergocalciferol RS in the *Standard solution* (µg/mL)
$C_U$ = nominal concentration of cholecalciferol or ergocalciferol in the *Sample solution* (µg/mL)

- **PROCEDURE 3**

This procedure is suitable for matrices with excipients that are soluble or degradable in alkaline conditions. It involves the saponification of the sample solution, followed by a liquid–liquid extraction with hexane and clean-up on a solid phase extraction (SPE) using a mixture of methylene chloride and isopropyl alcohol (99.8: 0.2) as eluent. The *Standard solution* undergoes similar treatment to compensate for losses in recovery due to isomerization. The eluate then is evaporated, and the residue is reconstituted in acetonitrile before injection into the chromatograph. Separation is achieved in reversed phase mode.

Unless specified in the individual monographs, the *Standard solution*, *Sample solution*, and reagent solutions are prepared as follows.

**Mobile phase:** Acetonitrile and methanol (91:9)

**Diluted acetic acid:** Glacial acetic acid solution (1 in 10) in water

**Phenolphthalein solution:** 10 mg/mL of phenolphthalein in alcohol

**Potassium hydroxide solution:** Slowly dissolve 14 g of potassium hydroxide in a mixture of 31 mL of dehydrated alcohol and 5 mL of water. Prepare fresh daily.

**Extraction solvent:** Methylene chloride and isopropyl alcohol (99.8: 0.2)

**Extraction column:** Silica packing with a sorbent mass-to-column volume ratio of 500 mg to 2.8 mL or equivalent. [NOTE—Condition the column by initially washing with 4.0 mL of a mixture of methylene chloride and isopropyl alcohol (4:1), followed by 5.0 mL of the *Extraction solvent*. Do not allow the column to dry.]

**Standard stock solution:** 0.2 mg/mL of USP Cholecalciferol RS or USP Ergocalciferol RS in dehydrated alcohol. [NOTE—Prepare fresh every 4 weeks. Store in a freezer.]

**Standard solution:** Dilute a volume of the *Standard stock solution* with dehydrated alcohol to obtain a concentration of 5 µg/mL of USP Cholecalciferol RS or USP Ergocalciferol RS. Prepare this solution fresh daily. Transfer 2.0 mL of this solution to a stoppered 125-mL flask. Add 15.0 mL of water and 15.0 mL of the *Potassium hydroxide solution*, insert the stopper, and shake for 30 min in a water bath maintained at 60°. Allow to cool to room temperature, and transfer the contents of the flask to a 250-mL separatory funnel. Add 15.0 mL of water to the flask, insert the stopper, shake vigorously, and transfer this solution to the separatory funnel. Rinse the flask with 60 mL of *n*-hexane, and transfer the rinsing to the separatory funnel. Insert the stopper, shake vigorously for 90 s, and allow to stand for 15 min until the layers separate. Drain, and discard the aqueous layer. Add 15.0 mL of water to the hexane layer in the separatory funnel, insert the stopper, and shake vigorously. Allow to stand for 10 min until the layers separate, and discard the aqueous layer. Add 1 drop of *Phenolphthalein solution* and 15.0 mL of water to the separatory funnel. Add *Diluted acetic acid* dropwise, with shaking, until the washing is neutral. Allow to stand for 10 min until the layers separate. Drain, and discard the aqueous layer. Filter the hexane layer through anhydrous sodium sulfate supported by a small pledget of cotton into a 100-mL, round-bottom flask. Rinse the funnel and sodium sulfate with a few milliliters of *n*-hexane, and collect the rinsings in the same flask. Evaporate the hexane in the flask on a rotary evaporator at 50° to dryness. Immediately add 2.0 mL of the *Extraction solvent* to dissolve the residue. Transfer this solution to a freshly conditioned solid-phase *Extraction column*, rinse the round-bottom flask with 1.0 mL of the *Extraction solvent*, and transfer to the column. Elute the *Extraction column* with 2.0 mL of the *Extraction solvent*, and discard this fraction. Elute the column with 7.0 mL of the *Extraction solvent*, and collect the eluate in a suitable flask. Place the flask in a warm water bath maintained at 42°, and evaporate the solvent with the aid of a stream of nitrogen. Immediately add 2.0 mL of acetonitrile to the residue, and use the solution for injection into the chromatograph.
