**Sample solution for tablets:** Finely powder NLT 20 Tablets. Transfer a portion of the powder, equivalent to 10 µg of cholecalciferol or ergocalciferol, to a stoppered 125-mL flask. Add 15.0 mL of water and 15.0 mL of the *Potassium hydroxide solution*, insert the stopper, and shake for 30 min in a water bath maintained at 60°. Allow to cool to room temperature, and transfer the contents of the flask to a 250-mL separatory funnel. Add 15.0 mL of water to the flask, insert the stopper, shake vigorously, and transfer this solution to the separatory funnel. Rinse the flask with 60 mL of *n*-hexane, and transfer the rinsing to the separatory funnel. Insert the stopper, shake vigorously for 90 s, and allow to stand for 15 min until the layers separate. Drain and discard the aqueous layer. Add 15.0 mL of water to the hexane layer in the separatory funnel, insert the stopper, and shake vigorously. Allow to stand for 10 min until the layers separate, and discard the aqueous layer. Add 1 drop of *Phenolphthalein solution* and 15.0 mL of water to the separatory funnel. Add *Diluted acetic acid* dropwise, with shaking, until the washing is neutral. Allow to stand for 10 min until the layers separate. Drain, and discard the aqueous layer. Filter the hexane layer through anhydrous sodium sulfate supported by a small pledget of cotton into a 100-mL, round-bottom flask. Rinse the funnel and sodium sulfate with a few milliliters of *n*-hexane, and collect the rinsings in the same flask. Evaporate the hexane in the flask on a rotary evaporator at 50° to dryness. Immediately add 2.0 mL of the *Extraction solvent* to dissolve the residue. Transfer this solution to a freshly conditioned solid-phase *Extraction column*, rinse the round-bottom flask with 1.0 mL of the *Extraction solvent*, and transfer to the column. Elute the *Extraction column* with 2.0 mL of the *Extraction solvent*, and discard this fraction. Elute the column with 7.0 mL of the *Extraction solvent*, and collect the eluate in a suitable flask. Place the flask in a warm water bath maintained at 42°, and evaporate the solvent with the aid of a stream of nitrogen. Immediately add 2.0 mL of acetonitrile to the residue, and use the solution for injection into the chromatograph.

**Sample solution for capsules:** Weigh NLT 20 Capsules in a tared weighing bottle. Open the Capsules, without loss of shell material, and transfer the contents to a 100-mL beaker. Remove any contents adhering to the empty shells by washing with several portions of ether. Discard the washings, and dry the Capsule shells with the aid of a current of dry air. Weigh the empty Capsule shells in the tared weighing bottle, and calculate the net weight of the Capsule contents. Transfer a portion of the Capsule contents, equivalent to 10 µg of ergocalciferol or cholecalciferol, to a stoppered 125-mL flask. Add 15.0 mL of water and 15.0 mL of the *Potassium hydroxide solution*, insert the stopper, and shake for 30 min in a water bath maintained at 60°. Allow to cool to room temperature, and transfer the contents of the flask to a 250-mL separatory funnel. Add 15.0 mL of water to the flask, insert the stopper, shake vigorously, and transfer this solution to the separatory funnel. Rinse the flask with 60 mL of *n*-hexane, and transfer the rinsing to the separatory funnel. Insert the stopper, shake vigorously for 90 s, and allow to stand for 15 min until the layers separate.

**Relative standard deviation:** NMT 4.0%

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of cholecalciferol ($C_{27}H_{44}O$) or ergocalciferol ($C_{28}H_{44}O$) in the portion of the sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \text{ ▲(USP 1-Dec-2023)} \times 100$$

$r_U$ = peak response of cholecalciferol or ergocalciferol from the *Sample solution*

$r_S$ = peak response of cholecalciferol or ergocalciferol from the *Standard solution*

$C_S$ = concentration of USP Cholecalciferol RS or USP Ergocalciferol RS in the *Standard solution* (µg/mL)

$C_U$ = nominal concentration of cholecalciferol or ergocalciferol in the *Sample solution* (µg/mL)

▲ (USP 1-Dec-2023)

- **PROCEDURE 4**

This procedure is applicable to liquid dosage forms. It involves a liquid–liquid extraction of the sample with hexane, followed by the evaporation of hexane, and reconstitution of the residue in a tetrahydrofuran and acetonitrile mixture (1:1). Separation is achieved in reversed-phase mode.

Unless specified in the individual monographs, the *Standard solution*, *Sample solution*, and *Diluent* are prepared as follows.

**Mobile phase:** Methanol, acetonitrile, and *n*-hexane (46.5: 46.5: 7.0)

**Diluent:** Tetrahydrofuran and acetonitrile (1:1)

**Standard solution:** 5 µg/mL of USP Cholecalciferol RS or USP Ergocalciferol RS in *Diluent*

**Sample solution:** Transfer an accurately measured volume of the sample, equivalent to 50 µg of cholecalciferol or ergocalciferol, to a 500-mL separatory funnel containing 10 mL of water and 20 mL of dehydrated alcohol. Add 150 mL of solvent hexane, insert the stopper, and shake for 1 min. Add another 150 mL of solvent hexane, insert the stopper, shake, and allow the layers to separate. Discard the aqueous layer. Drain the solvent hexane extract through anhydrous sodium sulfate into a 500-mL, round-bottom flask. Evaporate the solution to dryness with the aid of a rotary evaporator over a water bath maintained at about 65°. Immediately add 10.0 mL of *Diluent*, swirl to dissolve the residue, and filter.

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times F \times 100$$

$r_U$ = peak response of cholecalciferol or ergocalciferol from the *Sample solution*
$r_S$ = peak response of cholecalciferol or ergocalciferol from the *Standard solution*
$C_S$ = concentration of USP Cholecalciferol RS or USP Ergocalciferol RS in the *Standard solution* (µg/mL)
$C_U$ = nominal concentration of cholecalciferol or ergocalciferol in the *Sample solution* (µg/mL)
$F$ = correction factor to account for the average amount of previtamin D present in the *Sample solution*, 1.09

- **PROCEDURE 5**

This procedure involves the dissolution of vitamin D in toluene, and the solution is injected into the liquid chromatograph. It is applicable to simple matrices such as pure vitamins and ingredients that do not require saponification and that are soluble in toluene. Separation is achieved in normal-phase mode.

Unless specified in the individual monographs, the *Standard solution*, *Sample solution*, and *System suitability solution* are prepared as follows.

**Dehydrated hexane:** Prepare a chromatographic column by packing a chromatographic tube, 8-cm × 60-cm, with 500 g of 50- to 250-µm chromatographic siliceous earth, activated by drying at 150° for 4 h. (See *Chromatography* ⟨621⟩, *Column Chromatography*.) Pass 500 mL of hexane through the column, and collect the eluate in a glass-stoppered flask.

**Mobile phase:** *n*-Amyl alcohol in *Dehydrated hexane* (3 in 1000)

**System suitability solution:** 250 mg of USP Vitamin D Assay System Suitability RS in 10 mL of a mixture of toluene and *Mobile phase* (1:1). Heat this solution, under reflux, at 90° for 45 min, and cool. [NOTE—This solution contains cholecalciferol, precholecalciferol, and *trans*-cholecalciferol. For the stock solutions, follow these procedures: use low-actinic glassware, dissolve the samples without heating, and prepare the solutions fresh daily.]

**Standard stock solution:** 0.6 mg/mL of USP Cholecalciferol RS or USP Ergocalciferol RS in toluene

**Standard solution:** 120 µg/mL of USP Cholecalciferol RS or USP Ergocalciferol RS in *Mobile phase*, prepared from the *Standard stock solution*

**Sample stock solution:** 0.6 mg/mL of cholecalciferol or ergocalciferol in toluene

**Sample solution:** 120 µg/mL of cholecalciferol or ergocalciferol in *Mobile phase*, prepared from the *Sample stock solution*

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 254 nm

**Column:** 4.6-mm × 25-cm; packing L3

**Column temperature:** 40°

**Flow rate:** Can be varied to meet the *System suitability requirements*

**Injection volume:** 5–10 µL

**System suitability**

**Sample:** *System suitability solution*

[NOTE—The relative retention times for precholecalciferol, *trans*-cholecalciferol, and cholecalciferol are 0.4, 0.5, and 1.0, respectively.]

**Suitability requirements**

**Resolution:** NLT 1.0 between *trans*-cholecalciferol and precholecalciferol

**Relative standard deviation:** NMT 2.0% for the peak response of cholecalciferol

**Analysis**

**Samples:** *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of cholecalciferol ($C_{27}H_{44}O$) or ergocalciferol ($C_{28}H_{44}O$) in the portion of the sample taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

$r_U$ = peak response of cholecalciferol or ergocalciferol from the *Sample solution*
$r_S$ = peak response of cholecalciferol or ergocalciferol from the *Standard solution*
$C_S$ = concentration of USP Cholecalciferol RS or USP Ergocalciferol RS in the *Standard solution* (µg/mL)
$C_U$ = nominal concentration of cholecalciferol or ergocalciferol in the *Sample solution* (µg/mL)

- **PROCEDURE 6**

The procedure involves the dissolution of the sample in *Mobile phase*, and the solution is injected into the liquid chromatograph. The application includes cholecalciferol and ergocalciferol dissolved in edible vegetable oil, polysorbate 80, or propylene glycol, none of which will interfere with the corresponding precursor so that it can be quantitated. Separation is achieved in normal-phase mode on an L3 column, and *System suitability* requires separation of the *trans* forms from the vitamin D precursors.

Unless specified in the individual monographs, the *Standard solutions* and *Sample solution* are prepared as follows.

**Mobile phase:** Hexane and pentanol (997:3)

**Standard stock solution:** Dissolve USP Cholecalciferol RS or USP Ergocalciferol RS in toluene, and dilute with *Mobile phase* to 50 µg/mL. [NOTE—Prepare this solution fresh daily.]

**Standard solution A:** 5 µg/mL from the *Standard stock solution* in *Mobile phase*. [NOTE—Store at a temperature not above 0°.]

**Standard solution B:** Transfer 5.0 mL of the *Standard stock solution* to a round-bottom flask fitted with a reflux condenser. Displace the air with nitrogen, and reflux for 1 h in a water bath under a nitrogen atmosphere to obtain a solution

**Column:** 4.6-mm × 25-cm; packing L3

**Flow rate:** 1–2 mL/min

**Injection volume:** 10–20 µL

**System suitability**

**Sample:** *Standard solution B* (USP Cholecalciferol RS or USP Ergocalciferol RS)

[NOTE—The relative retention times for precholecalciferol and cholecalciferol are about 0.4 and 1.0, respectively. Those for pre-ergocalciferol and ergocalciferol are about 0.8 and 1.0, respectively.]

**Suitability requirements**

**Resolution:** NLT 1.0 between precholecalciferol and cholecalciferol; NLT 1.0 between pre-ergocalciferol and ergocalciferol

**Relative standard deviation:** NMT 2.0% for the peak response of cholecalciferol or ergocalciferol

**Analysis**

**Samples:** *Standard solution A*, *Standard solution B*, and *Sample solution*

**Cholecalciferol or ergocalciferol response factor**

Calculate the cholecalciferol or ergocalciferol response factor, $F_C$:

$$F_C = C_S / r_S$$

$C_S$ = concentration of USP Cholecalciferol RS or USP Ergocalciferol RS in *Standard solution A* (µg/mL)
$r_S$ = peak area of cholecalciferol or ergocalciferol from *Standard solution A*

**Precholecalciferol or pre-ergocalciferol response factor**

Calculate the concentration, $C'_S$, in µg/mL, of cholecalciferol or ergocalciferol in *Standard solution B*:

$$C'_S = F_C \times r'_S$$

$F_C$ = response factor for cholecalciferol or ergocalciferol
$r'_S$ = peak area of cholecalciferol or ergocalciferol from *Standard solution B*

Calculate the concentration, $C'_{pre}$, in µg/mL, of precholecalciferol or pre-ergocalciferol:

$$C'_{pre} = C_S - C'_S$$

$C_S$ = concentration of USP Cholecalciferol RS or USP Ergocalciferol RS in *Standard solution A* (µg/mL)
$C'_S$ = concentration of cholecalciferol or ergocalciferol in *Standard solution B* (µg/mL)

Calculate the response factor, $F_{pre}$, for precholecalciferol or pre-ergocalciferol:

$$F_{pre} = C'_{pre} / r_p$$

$C'_{pre}$ = concentration of precholecalciferol or pre-ergocalciferol (µg/mL)
$r_p$ = peak response of precholecalciferol or pre-ergocalciferol from *Standard solution B*

**Content of vitamin D**

Calculate the percentage of the labeled amount of vitamin D as cholecalciferol ($C_{27}H_{44}O$) or as ergocalciferol ($C_{28}H_{44}O$) in the portion of the sample taken:

$$\text{Result} = \{[(F_C \times r_C) + (F_{pre} \times r_{pre})]/C_U\} \times 100$$

$F_C$ = response factor for cholecalciferol or ergocalciferol
$r_C$ = peak area of cholecalciferol or ergocalciferol from the *Sample solution*
$F_{pre}$ = response factor for precholecalciferol or pre-ergocalciferol
$r_{pre}$ = peak area of precholecalciferol or pre-ergocalciferol from the *Sample solution*
$C_U$ = nominal concentration of cholecalciferol or ergocalciferol in the *Sample solution* (µg/mL)

- **PROCEDURE 7**

This procedure involves the saponification of the sample, followed by a liquid–liquid extraction with ether–solvent hexane, and by the evaporation of ether–hexane and reconstitution of the residue in a mixture of toluene and *Mobile phase* (1:4). It is applicable to solutions in oil and capsules containing vitamin D solutions in oil, in which the oil does not interfere with the corresponding precursor so that it can be quantitated. Separation is achieved in normal-phase mode on an L3 column, and *System suitability* requires separation of the *trans* forms from the vitamin D precursors.

Unless specified in the individual monographs, the *Standard solutions*, *Sample solution*, and reagent solutions are prepared as follows.

**Dehydrated hexane:** Prepare a chromatographic column by packing a chromatographic tube, 8-cm × 60-cm, with 500 g of 50- to 250-µm chromatographic siliceous earth, activated by drying at 150° for 4 h. (See *Chromatography* ⟨621⟩, *Column Chromatography*.) Pass 500 mL of hexane through the column, and collect the eluate in a glass-stoppered flask.

**Mobile phase:** *n*-Amyl alcohol in *Dehydrated hexane* (3 in 1000)

**Butylated hydroxytoluene solution:** 10 mg/mL of butylated hydroxytoluene in chromatographic hexane

**Aqueous potassium hydroxide solution:** 1 g/mL of potassium hydroxide in freshly boiled water. [NOTE—Prepare this solution fresh daily.]

**Alcoholic potassium hydroxide solution:** 3 g of potassium hydroxide in 50 mL of freshly boiled water. Add 10 mL of alcohol, and dilute with freshly boiled water to 100 mL. [NOTE—Prepare this solution fresh daily.]

**Sodium ascorbate solution:** 175 mg/mL of ascorbic acid in 1 N sodium hydroxide. [NOTE—Prepare fresh daily.]

**Sodium sulfide solution:** 12 g of sodium sulfide in 20 mL of water. Dilute with glycerin to 100 mL.

**Standard stock solution:** 0.5 mg/mL of USP Ergocalciferol RS or USP Cholecalciferol RS in toluene. [NOTE—Prepare this solution fresh daily.]

**Standard solution A:** 20 µg/mL from the *Standard stock solution* in *Mobile phase*. [NOTE—Store this solution at a temperature not above 0°.]

**Standard solution B:** Pipet 4 mL of the *Standard stock solution* into a round-bottomed flask fitted with a reflux condenser, and add 2 or 3 crystals of butylated hydroxytoluene. Displace the air with nitrogen, and heat in a water bath maintained at a temperature of 90° in subdued light under a nitrogen atmosphere for 45 min to obtain a solution containing vitamin D and previtamin D. Cool, transfer with the aid of several portions of *Mobile phase* to a 100-mL volumetric flask, and dilute with *Mobile phase* to volume.

**System suitability solution:** Add 100 mg of USP Vitamin D Assay System Suitability RS to a 10-mL volumetric flask. Add a mixture (1 in 5) of toluene and *Mobile phase* to volume, and mix. Heat a portion of this solution under reflux at 90° for 45 min, and cool.

**Sample solution:** Reflux NLT 10 Capsules with a mixture of 10 mL of the *Sodium ascorbate solution* and 2 drops of the *Sodium sulfide solution* on a steam bath for 10 min, crush any remaining solids with a blunt glass rod, and continue heating for 5 min. Cool, and add 25 mL of alcohol and 3 mL of the *Aqueous potassium hydroxide solution*. Reflux the mixture on a steam bath for 30 min. Cool rapidly under running water, and transfer the saponified mixture to a conical separator, rinsing the saponification flask with two 15-mL portions of water, 10 mL of alcohol, and two 50-mL portions of ether. [NOTE—Use ether within 24 h after opening the container.] Shake the combined saponified mixture and rinsings vigorously for 30 s, and allow to stand until both layers are clear. Transfer the aqueous phase to a second conical separator, add a mixture of 10 mL of alcohol and 50 mL of solvent hexane, and shake vigorously. Allow to separate, transfer the aqueous phase to a third conical separator, and transfer the solvent hexane phase to the first separator, rinsing the second separator with two 10-mL portions of solvent hexane and adding the rinsings to the first separator. Shake the aqueous phase in the third separator with 50 mL of solvent hexane, and add the solvent hexane phase to the first separator. Wash the combined ether–solvent hexane extracts by shaking vigorously with three 50-mL portions of the *Alcoholic potassium hydroxide solution*, and wash with 50-mL portions of water vigorously until the last washing is neutral to phenolphthalein. Drain any remaining drops of water from the combined ether–solvent hexane extracts, add 2 sheets of 9-cm filter paper, in strips, to the separator, and shake. Transfer the washed ether–solvent hexane extracts to a round-bottom flask, rinsing the separator and paper with solvent hexane. Combine the solvent hexane rinsings with the ether–solvent hexane extracts, add 100 µL of the *Butylated hydroxytoluene solution*, and mix. Evaporate under vacuum to dryness by swirling in a water bath maintained at a temperature not higher than 40°. Cool under running water, and introduce nitrogen sufficient to restore atmospheric pressure. Without delay, dissolve and dilute the residue in an accurately measured volume of a mixture (1 in 5) of toluene and *Mobile phase*, until the concentration of vitamin D is about 25 µg/mL.

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Resolution:** NLT 1.0 between *trans*-cholecalciferol and precholecalciferol

**Relative standard deviation:** NMT 2.0% for the peak response of cholecalciferol

**Analysis**

**Samples:** *Standard solution A*, *Standard solution B*, and *Sample solution*

**Cholecalciferol and ergocalciferol response factor**

Calculate the cholecalciferol or ergocalciferol response factor, $F_D$:

$$F_D = C_S / r_S$$

$C_S$ = concentration of USP Ergocalciferol RS in *Standard solution A* (µg/mL)

$r_S$ = peak area of cholecalciferol or ergocalciferol from *Standard solution A*

Official

https://nhathuocngocanh.com/

**Precholecalciferol and pre-ergocalciferol response factor**

Calculate the concentration, $C'_S$, in µg/mL, of cholecalciferol or ergocalciferol in *Standard solution B*:

$$C'_S = F_D \times r'_S$$

$F_D$ = response factor for cholecalciferol or ergocalciferol
$r'_S$ = peak area of cholecalciferol or ergocalciferol from *Standard solution B*

Calculate the concentration, $C'_{pre}$, in µg/mL, of pre-ergocalciferol:

$$C'_{pre} = C_S - C'_S$$

$C_S$ = concentration of USP Ergocalciferol RS in *Standard solution A* (µg/mL)
$C'_S$ = concentration of cholecalciferol or ergocalciferol in *Standard solution B* (µg/mL)

Calculate the response factor, $F_{pre}$, for precholecalciferol or pre-ergocalciferol:

$$F_{pre} = C'_{pre}/r_p$$

$C'_{pre}$ = concentration of precholecalciferol or pre-ergocalciferol (µg/mL)
$r_p$ = peak response of precholecalciferol or pre-ergocalciferol from *Standard solution B*

**Content of vitamin D**

Calculate the percentage of the labeled amount of vitamin D as ergocalciferol ($C_{28}H_{44}O$) or as cholecalciferol ($C_{27}H_{44}O$) in the portion of the sample taken:

$$\text{Result} = \{[(F_D \times r_C) + (F_{pre} \times r'_{pre})]/C_U\} \times 100$$

$F_D$ = response factor for cholecalciferol or ergocalciferol
$r_C$ = peak area of cholecalciferol or ergocalciferol from the *Sample solution*
$F_{pre}$ = response factor for precholecalciferol or pre-ergocalciferol
$r'_{pre}$ = peak area of precholecalciferol or pre-ergocalciferol from the *Sample solution*
$C_U$ = nominal concentration of cholecalciferol or ergocalciferol in the *Sample solution* (µg/mL)

- **PROCEDURE 8**

This procedure is suitable for the determination of cholecalciferol in oils or fatty matrices. It involves two chromatographic systems, one for sample clean-up and the other for vitamin D determination. The *Standard*, *Internal standard*, and *Sample solutions* are subjected to saponification, followed by a liquid–liquid extraction with a mixture of ether and hexane (1:1). The extract is evaporated and reconstituted in the *Butylated hydroxytoluene solution*.

Unless specified in the individual monographs, the *Standard solution*, *Sample solutions*, *Internal standard solution*, and reagent solutions are prepared as follows.

**Solution A:** *n*-Amyl alcohol and dehydrated hexane (3:997)

**Solution B:** Acetonitrile, water, and phosphoric acid (96: 3.8: 0.2)

**Butylated hydroxytoluene solution:** 10 mg/mL of butylated hydroxytoluene in chromatographic hexane

**Aqueous potassium hydroxide solution:** Dissolve 800 g of potassium hydroxide in 1000 mL of freshly boiled water, mix, and cool. [NOTE—Prepare this solution fresh daily.]

**Alcoholic potassium hydroxide solution:** Dissolve 3 g of potassium hydroxide in 50 mL of freshly boiled water, add 10 mL of alcohol, and dilute with freshly boiled water to 100 mL. [NOTE—Prepare this solution fresh daily.]

**Ascorbic acid solution:** 100 mg/mL of ascorbic acid in water. [NOTE—Prepare this solution fresh daily.]

**Internal standard solution:** 5 µg/mL of USP Ergocalciferol RS in alcohol

**Standard stock solution:** 5 µg/mL of USP Cholecalciferol RS in alcohol

**Standard solution:** Transfer 2.0 mL of the *Standard stock solution* and 2.0 mL of the *Internal standard solution* to a round-bottom flask. Proceed as directed for *Sample solution 1* beginning with "Add 5 mL of…".

**Sample solution 1:** Transfer 4.00 g of oil to a round-bottom flask. Add 5 mL of the *Ascorbic acid solution*, 100 mL of alcohol, and 10 mL of the *Aqueous potassium hydroxide solution*, and mix. Reflux the mixture on a steam bath for 30 min. Add 100 mL of a 10-mg/mL sodium chloride solution. Cool rapidly under running water, and transfer the saponified mixture to a 500-mL separator, rinsing the saponification flask with 75 mL of a 10-mg/mL sodium chloride solution, and then with 150 mL of a mixture of ether and hexane (1:1). Shake the combined saponified mixture and rinsings vigorously for 30 s, and allow to stand until both layers are clear. Discard the lower layer. Wash the ether–hexane extracts by shaking vigorously with 50 mL of the *Alcoholic potassium hydroxide solution*, and then washing with three 50-mL portions of a 10-mg/mL sodium chloride solution. Filter the upper layer through 5 g of anhydrous sodium sulfate on a fast filter paper into a 250-mL flask suitable for a rotary evaporator. Wash the filter with 10 mL of a mixture of ether and hexane (1:1), and combine with the extract. Evaporate the solvent at reduced pressure at a temperature not exceeding 30°, and fill with nitrogen when the evaporation is complete. Alternatively evaporate the solvent under a gentle stream of nitrogen at a temperature not exceeding 30°. Dissolve the residue in 1.5 mL of the *Butylated hydroxytoluene solution*. [NOTE—Gentle heating in an ultrasonic bath may be required. A large fraction of the white residue is cholesterol.]

**Sample solution 2:** To 4.00 g of oil add 2.0 mL of the *Internal standard solution*, and proceed as directed for *Sample solution 1* beginning with "Add 5 mL of…".

# ⟨591⟩ ZINC DETERMINATION

## INTRODUCTION

A quantitative determination of zinc in drug substance and drug product monographs containing zinc is achieved by the *Dithizone Method*, *Ion Chromatographic Method*, or *Atomic Absorption Method*. Unless a specific method is indicated in the individual monograph, any of these methods can be used.

## PROCEDURE

### • Dithizone Method

Select all reagents for this test to have as low a content of heavy metals as practicable. If necessary, distill water and other solvents into a hard or borosilicate glass apparatus. Rinse thoroughly all glassware with warm diluted nitric acid (1 in 2) followed by water. Avoid using on the separator any lubricants that dissolve in chloroform.

**Special solutions and solvents**

**Alkaline ammonium citrate solution:** Dissolve 50 g of dibasic ammonium citrate in water to make 100 mL. Add 100 mL of ammonium hydroxide. Remove any heavy metals that may be present by extracting the solution with 20-mL portions of the *Dithizone extraction solution* (see *Lead* ⟨251⟩) until the *Dithizone extraction solution* retains a clear green color, then extract any dithizone remaining in the citrate solution by shaking with chloroform.

**Chloroform:** Distill chloroform in a hard or borosilicate glass apparatus, receiving the distillate in sufficient dehydrated alcohol to make the final concentration 1 mL of alcohol for each 100 mL of distillate.

**Dithizone solution:** Use the *Standard dithizone solution* (see ⟨251⟩), prepared with the distilled *Chloroform*.

**Standard zinc solution:** Dissolve 625 mg of zinc oxide, accurately weighed and previously gently ignited to constant weight, in 10 mL of nitric acid, and add water to make 500.0 mL. This solution contains 1.0 mg/mL of zinc.

**Diluted standard zinc solution:** Dilute 1 mL of the *Standard zinc solution*, accurately measured, with 2 drops of nitric acid and sufficient water to make 100.0 mL. This solution contains 10 µg/mL of zinc. Use this solution within 2 weeks.

**Trichloroacetic acid solution:** Dissolve 100 g of trichloroacetic acid in water to make 1000 mL.

**Procedure:** Transfer 1–5 mL of the preparation to be tested, accurately measured, to a centrifuge tube graduated at 40 mL. If necessary, add 0.25 N hydrochloric acid, dropwise, to obtain a clear solution. Add 5 mL of the *Trichloroacetic acid solution* and sufficient water to make 40.0 mL. Mix and centrifuge.

Transfer to a hard-glass separator an accurately measured volume of the supernatant believed to contain 5–20 µg of zinc, and add water to make about 20 mL. Add 1.5 mL of the *Alkaline ammonium citrate solution* and 35 mL of the *Dithizone solution*. Shake vigorously 100 times. Allow the chloroform phase to separate. Insert a cotton plug in the stem of the separator to remove any water emulsified with the chloroform. Collect the chloroform extract (discarding the first portion that comes through) in a test tube, and determine the absorbance at 530 nm, with a suitable spectrophotometer.

Calculate the amount of zinc present by reference to a standard absorbance–concentration curve obtained by using 0.5, 1.0, 1.5 mL, and, if the zinc content of the sample extracted exceeds 15 µg, 2.0 mL of the *Diluted standard zinc solution*, corrected as indicated by a blank determination run concomitantly, using all of the reagents but no added zinc.

### • Ion Chromatographic Method

The following ion chromatographic general procedure is provided for the determination of zinc in compendial articles. See *Ion Chromatography* ⟨1065⟩ for discussion of the theory and principles of measurements using ion chromatography.

Use water with a resistivity of not less than 18 megohm-cm to prepare the solutions.

**Diluent:** 0.2% (w/v) hydrochloric acid

**Mobile phase:** 7.0 mM dipicolinic acid, 66.0 mM potassium hydroxide, 5.6 mM potassium sulfate, and 74.0 mM formic acid in water; adjust with 2 N potassium hydroxide TS to a pH of 4.2. Pass through a suitable filter of 0.2-µm pore size.

**Post-column derivatization reagent:** 0.5 mM 4-(2-pyridylazo)resorcinol monosodium salt, 1.0 M 2-dimethylaminoethanol, 0.50 M ammonium hydroxide, and 0.30 M sodium bicarbonate in water. Stir and sonicate until the solid is completely dissolved. Pass through a suitable filter of 0.2-µm pore size.

**Standard stock solution:** 1500 µg/mL of zinc from USP Zinc Oxide RS prepared as follows. Transfer an appropriate portion of USP Zinc Oxide RS to a suitable volumetric flask. Add 6 N hydrochloric acid to about 10% of the final flask volume to dissolve. Dilute with water to volume.

**Standard solution:** 15.0 µg/mL of zinc in *Diluent* from the *Standard stock solution*

**Sample stock solution:** Prepare as directed in the monograph.

**Sample solution:** Equivalent to 15.0 µg/mL of zinc in *Diluent* from the *Sample stock solution*, unless otherwise stated in the monograph

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** Vis 530 nm

**Columns**

**Guard:** 4.0-mm × 5-cm; 9-µm packing L100

**Analytical:** 4.0-mm × 25-cm; 9-µm packing L100

**Column temperature:** 30°

**Flow rate:** 1.2 mL/min

**Flow rate of post-column reagent:** 0.6 mL/min. Introduce using a pulseless flow of reagent through a 375-µL polymeric mixing coil or other suitable volume coil.[1]

**Injection volume:** 10 µL

**Run time:** Not less than 2 times the retention time of zinc

[1] A knitted reaction coil, part number 043700, available from ThermoFisher Scientific (www.thermofisher.com), may be suitable.

https://nhathuocngocanh.com/

**System suitability**
**Sample:** *Standard solution*
**Suitability requirements**
**Tailing factor:** Not more than 2.0
**Relative standard deviation:** Not more than 0.73%, unless otherwise stated in the monograph
**Analysis**
**Samples:** *Standard solution* and *Sample solution*
Unless otherwise stated in the monograph, calculate the concentration of zinc in the portion of *Sample solution* taken:

$$\text{Result} = (r_U/r_S) \times C_S$$

$r_U$ = peak response from the *Sample solution*
$r_S$ = peak response from the *Sample solution*
$C_S$ = concentration of zinc in the *Standard solution* (µg/mL)

***Change to read:***

• **Atomic Absorption Method**
The following atomic absorption general procedure is provided for the determination of zinc in compendial articles.
**Diluent:** 0.01 N hydrochloric acid
**Zinc stock standard solution:** Use a certified 1000-µg/mL standard.
▲▲ (USP 1-May-2022)
**Zinc calibration standard solutions:** Prepare not less than 3 calibration standard solutions within the range of 0.2–1.6 µg/mL, or suitable concentrations to span anticipated zinc concentrations in the sample(s). Prepare these solutions by two-step dilutions of the *Zinc stock standard solution* with the *Diluent*.
**Drug substance sample solution:** Accurately weigh an amount of the sample and dissolve in *Diluent*. Dilute with *Diluent* to volume in a volumetric flask; dilute the solution such that the zinc concentration is within the concentration range of the prepared *Zinc calibration standard solutions*.
**Drug product sample solution:** If the sample is a suspension, resuspend and add 4–7 µL of 6 N hydrochloric acid,▲to each milliliter of the suspension▲ (USP 1-May-2022) as needed to dissolve prior to dilution. Dilute the sample with *Diluent* to a zinc concentration within the concentration range of the prepared *Zinc calibration standard solutions*.
**Instrumental conditions**
(See *Atomic Absorption Spectroscopy* ⟨852⟩.)
**Mode:** Atomic absorption spectrophotometry
**Analytical wavelength:** 213.9 nm
**Lamp:** Zinc hollow-cathode, 5–15 mA
**Flame:** Air–acetylene of suitable composition
**Blank:** 0.01 N hydrochloric acid
**Analysis:** Zero the instrument using the *Blank*. Determine the absorbance in triplicate, of the *Blank*, ▲▲ (USP 1-May-2022)the *Zinc calibration standard solutions*, and the *Sample solutions*.
**Calibration:** Prepare a calibration curve from the mean of the readings of the absorbance of the *Blank* and the *Zinc calibration standard solutions* (linear or quadratic fit).
**System suitability**
▲**Samples:** *Zinc calibration standard solutions*
**Suitability requirements**
**Correlation coefficient:** NLT 0.997, determined from the standard curve
**Relative standard deviation:** NMT 2.5%, for the triplicate measurements for each aspiration of the *Zinc calibration standard solutions* with the highest concentration▲ (USP 1-May-2022)
**Calculations:** Read the concentration of zinc in the sample solution using the calibration curve and calculate the concentration of zinc in the sample.

C.5 Next Generation Impactor with Pre-separator for Inhalation Powders and Nasal Powders

## INTRODUCTION

The major performance measures for inhalation and nasal aerosols, sprays, and powders relate to dose delivery to the patient, including *Delivered Dose Uniformity* (DDU) and relevant measures of particle size (optical and/or aerodynamic) depending on the dosage form. [NOTE—The word "dose" should not be confused with the clinical term but is used for quality purposes to refer to the minimum amount required to make the test functional.] Each of these is described in the following sections. A nomenclature table appears in *Inhalation and Nasal Drug Products—General Information and Product Quality Tests* ⟨5⟩ from which the descriptive terms for various dosage forms can be obtained. [NOTE—Typically, the word "spray" is used for spray drug products (e.g., inhalation and nasal spray drug products), and "actuation" is used for inhalation aerosol and powder drug products. However, actuation(s) and spray(s) are used interchangeably in the methods in this chapter.]

## A. DELIVERED DOSE UNIFORMITY

### A.1 Inhalation Aerosols and Inhalation Sprays

The following tests are applicable to inhalation aerosols [commonly known as (pressurized) metered-dose inhalers] and inhalation sprays. Inhalation aerosols are formulated as suspensions or solutions of one or more drug substances in propellant(s) and possibly other suitable excipients and are presented as multidose units. Inhalation sprays typically are aqueous-based liquid formulations packaged in a compact container–closure system containing an integral spray pump unit. Refer to ⟨5⟩ for additional information. The following performance quality test methods are specific to these products and may require modification when alternative inhalation products (for example, breath-actuated inhalation aerosols or inhalation sprays) are tested. However, pharmacopeial requirements for all metered inhalation dosage forms require determination of the DDU and *Aerodynamic Particle Size Distribution* (APSD). In all cases and for all tests, prepare and test the product as directed on the label and the instructions for use. When these directions are not provided by the product manufacturer, follow the precise discharge directions included in the following tests.

#### A.1.1 DELIVERED DOSE UNIFORMITY OF INHALATION AEROSOLS AND INHALATION SPRAYS

The test for *Delivered Dose Uniformity* is required for inhalation aerosols and inhalation sprays containing drug formulation either in device-metered or in premetered unit presentations. The test for *Delivered Dose Uniformity* includes dose uniformity over the entire unit life. (For products packaged in premetered dosage units, see also *Uniformity of Dosage Units* ⟨905⟩.) A dose in this test is defined as the minimum recommended number of actuations/sprays specified in the product labeling or instructions for use but NMT 2 actuations/sprays per determination. For inhalation aerosols and inhalation sprays, the drug delivered from the mouthpiece is specified by the label claim. Its value reflects the expected mean drug content for a large number of delivered actuations/sprays collected from many units of the product using the method specified in the monograph. For drug products equipped with an integral spacer, it should be emphasized that the quantity to be measured (label claim) is the drug delivered at the mouthpiece of the spacer, under specified in vitro test conditions.

Unless otherwise directed in the individual monograph, the drug content of the delivered dose collected at the beginning of unit life (after priming as described on the label or instructions for use) and end of unit life of the label claim, will be determined from each of 10 separate containers (i.e., a total of 20 determinations).

**A.1.1.1 Sampling the delivered dose from inhalation aerosols and inhalation sprays**

***DDU sampling apparatus A procedure:*** To determine the content of active ingredient in the discharged plume from an inhalation aerosol and inhalation spray, use DDU sampling apparatus A (see *Figure 1a* and *Table 1*).

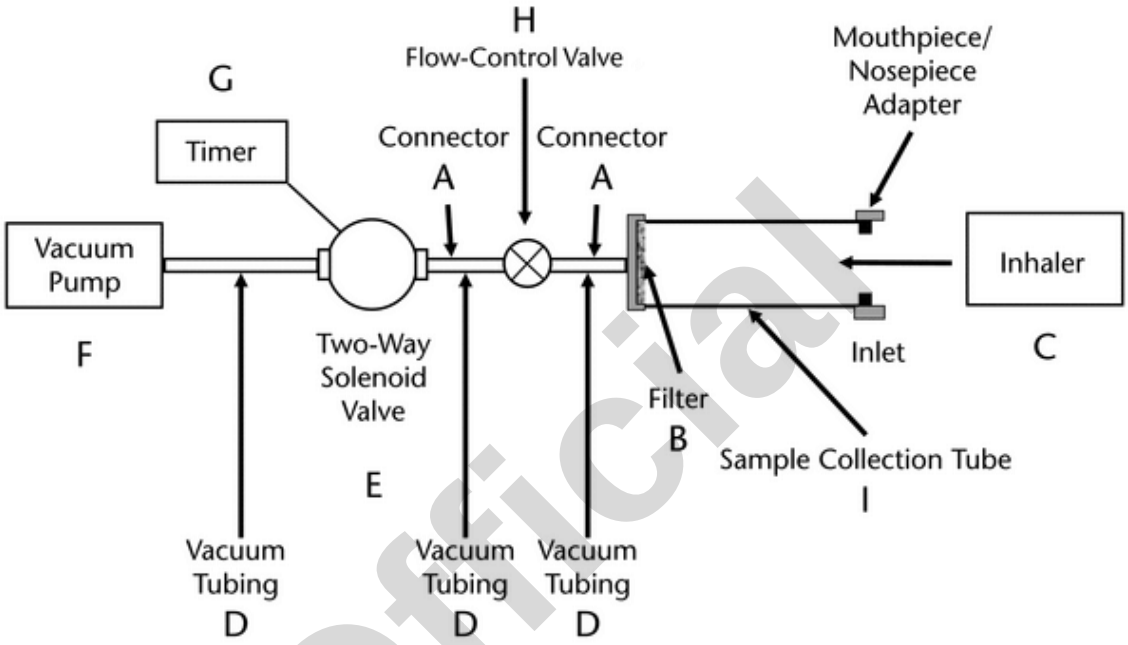

Figure 1a. DDU sampling apparatus for inhalation aerosol, inhalation spray, nasal aerosol, and nasal spray drug products. (See *Table 1* for component specifications for DDU sampling apparatus A.) [Note—The volumetric flow rate must be determined and fixed before the inhaler is inserted in *Figure 1a*.]

Unless otherwise specified in the individual monograph, with the vacuum pump running, ensure an airflow rate through the device of 28.3 L of air/min (±5%) or 30 L/min (±5%) as applicable for the apparatus selected for APSD determination. Prepare the product for use according to the label instructions for shaking, priming, and firing. Collect the minimum recommended number of actuations following priming. Discharge the first actuation of the minimum recommended actuations into the sampling apparatus through the mouthpiece adapter by actuating the metering system for a duration sufficient to ensure that the dose has been completely discharged. The volume of air sampled per actuation should not exceed 2.0 L (e.g., a timer solenoid valve can be used to achieve the required volume). If the minimum recommended dose consists of more than one actuation, wait for 5 s and collect the next actuation. The actuations between the two test samples (i.e., beginning and end of unit life) should be disposed of appropriately. Note that for inhalation aerosols the rate of discharges (number of discharges per unit time) to waste should not cause canister cooling that may affect subsequent test results. This should be evaluated for each drug product. Following each collection of the minimum number of actuations from each unit at each sequential test sample (NMT 2 actuations), detach the product from DDU sampling apparatus A (see *Figure 1a*), and disconnect the vacuum.

Separately assay the contents of the apparatus for drug for each delivered dose at the beginning and end of sequential test samples after rinsing the filter and the interior of the collection tube with a suitable solvent. A validated analytical method is employed to determine the amount of drug in each delivered dose, and data are reported as amount delivered and as a percentage of label claim.

***DDU sampling apparatus A:*** The DDU sampling apparatus is presented in *Figure 1a*. DDU Sampling Apparatus A consists of different accessories (see *Figure 1a* and *Table 1*) and a sample collection tube assembly (*Figure 2*). The latter includes a filter support base with an open mesh filter support such as a stainless steel screen. The sample collection tube is clamped or screwed to the filter support base, with a mouthpiece adapter to ensure an airtight seal between the sample collection tube and the mouthpiece. Use a mouthpiece adapter that ensures that the opening of the product's mouthpiece is flush with the front face

or 2.5-mm indented shoulder in the sample collection tube to make an airtight seal. The sample collection tube is connected to a system comprising a vacuum pump and flow-control valve (see *Figure 1a*).

The vacuum pump should be capable of pulling air through the complete assembly, including the filter and the product to be tested, at the desired flow rate. Connect the flowmeter to set the flow rate for DDU analysis (e.g., 28.3 L/min (±5%) or 30 L/min (±5%) as applicable). Replace the flowmeter with the inhaler for DDU determination. The flow rate should be in accordance with the test requirements of the drug product being evaluated.

During tests of inhalation aerosols and sprays, air should be drawn continuously through the system to avoid loss of drug into the atmosphere. The filter support base is designed to accommodate 25-mm diameter filter disks (see *Figure 2*). At the flow rate used, the sample collection tube and the filter must be capable of quantitatively collecting the delivered dose. The filter and other materials used in the construction of the apparatus must be compatible with the drug and the solvents that are used to extract the drug from the filter. One end of the sample collection tube is designed to hold the filter tightly against the filter support base using an O-ring as needed. When assembled, the joints between the components of the apparatus are airtight so that when a vacuum is applied to the base of the filter, all of the air drawn through the DDU sampling apparatus passes through the device component. The description for *Figure 1b* appears in *A.3.1.1. Sampling the delivered dose from inhalation powders*.

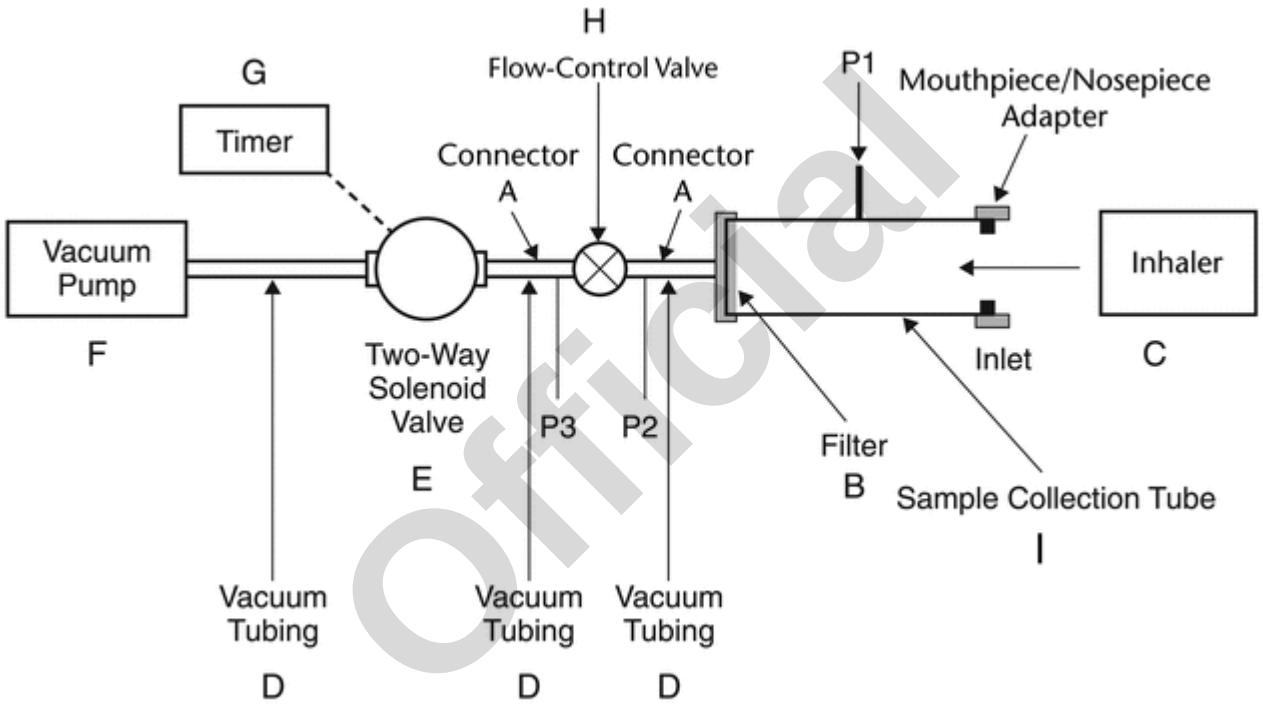

Figure 1b. DDU sampling apparatus for inhalation powder and nasal powder drug products. (See *Table 1* for component specifications for DDU sampling apparatuses A and B.) [Note—The volumetric flow rate must be determined and fixed before the inhaler is inserted.]

**Table 1. DDU Sampling Apparatuses A and B** (see *Figure 1a* and *Figure 1b*)

## A.2 Nasal Aerosols and Nasal Sprays

The following test is applicable to nasal aerosols and sprays formulated, respectively, as nonaqueous and aqueous suspensions or solutions of drug, presented typically in multidose containers, and fitted with dose-metering valves or pumps. In all cases and for all tests, prepare and test the spray as directed in the labeling and the instructions for use.

### A.2.1 DELIVERED DOSE UNIFORMITY OF NASAL AEROSOLS AND NASAL SPRAYS

Unless otherwise directed in the individual monograph, the drug content of the delivered dose collected at the beginning of unit life (after priming as described on the label or instructions for use) and end of unit life of the label claim, will be determined from each of 10 separate containers (i.e., a total of 20 determinations). This represents a total of 20 determinations. Sampling and measurements shall be made after priming as described in the labeling or instructions for use. A dose in this test is defined as the minimum recommended number of actuations/sprays specified in the product labeling or instructions for use but NMT 2 actuations per determination. For single-use products, *Delivered Dose Uniformity* of 10 dosage units should be determined separately.

**A.2.1.1 Sampling the delivered dose from nasal aerosols:** See *A.1.1.1 Sampling the delivered dose from inhalation aerosols and inhalation sprays*.

**A.2.1.2 Sampling the delivered dose from nasal sprays**

*Procedure:* To determine the content of active ingredient in the discharged plume from a nasal spray, use DDU sampling apparatus A (see *Figure 1a* and *Table 1*) described above. The use of a mechanical means of actuating the metering system or pump assembly to deliver doses for collection is recommended to ensure reproducible in vitro dose collection. The mechanical actuation procedure should have adequate controls for the critical mechanical actuation parameters (e.g., actuation force, actuation speed, stroke length, and rest periods). The test must be performed on units that have been thoroughly shaken and primed according to the instructions for patient use. The test unit should be actuated in a vertical or near-vertical, pump up position. The sprays at the beginning of each of the 10 test containers should be the sprays immediately following priming and the sprays at the end (label claim) of each from the same container. This represents a total of 20 determinations. The doses between the beginning and end sequential test samples must be disposed of appropriately. A validated analytical method is employed to determine the amount of drug in each delivered dose, and data are reported as amount delivered and as a percentage of label claim.

## A.3 Inhalation Powders

The following tests are applicable to inhalation powders (commonly known as dry powder inhalers (DPIs)) presented as premetered or device-metered units. Pharmacopeial requirements for all of these drug products require determination of each of the delivered doses and *Aerodynamic Particle Size Distribution*. In all cases and for all tests, prepare and test the product as directed in the labeling and the instructions for use. When these directions are not provided by the product manufacturer, follow the precise dose-discharge directions included in the following tests.

### A.3.1 DELIVERED DOSE UNIFORMITY OF INHALATION POWDERS

Where specified in the individual monograph, perform this test under conditions of controlled temperature and humidity.

The test for *Delivered Dose Uniformity* is required for inhalation powders in premetered (including ordered multiple dose) and device-metered presentations as labeled for use with the specified delivery system. The test for *Delivered Dose Uniformity* over the entire unit life is required for drug products packaged in device-metered or in ordered multiple-dose metering units of nominal premetered dosage units that have a predetermined dose sequence. For formulations packaged in premetered dosage units, an additional test, *Uniformity of Dosage Units* ⟨905⟩ is also required. Note that the target-delivered dose is determined by the mean drug content for a large number of delivered doses collected from many units under defined experimental conditions as specified in the product labeling. In many cases, the target value may depend on the manner in which the test for delivered dose uniformity is performed. For inhalation powders, where the label claim usually is the nominal premetered or device-metered dose of drug, the target-delivered dose and the method are specified in the individual monograph, and usually the target-delivered dose is less than the label claim.

Unless otherwise directed in the individual monograph, the drug content of the delivered dose from each of 10 separate units is determined separately.

The drug content of the delivered dose from each unit will be collected at the beginning and end of unit life per the label claim. Thus, two determinations will be obtained from each of 10 separate drug product units. This represents a total of 20 determinations.

For single-use products and for inhalation powders packaged in premetered single dosage form units, *Delivered Dose Uniformity* of 10 dosage units should be determined separately.

**A.3.1.1 Sampling the delivered dose from inhalation powders:** DDU sampling apparatus B should be used to determine the content of active ingredient emitted from the mouthpiece of an inhalation powder (see *Figure 1b* and *Table 1*). This apparatus is capable of sampling the emitted dose at a variety of flow rates.

***DDU sampling apparatus B procedure:*** Adjust the flow-control valve to provide the flow that has been determined to induce a 4-kPa pressure drop across the product to be tested and for a period of *T* seconds consistent with the withdrawal of 2.0 L of air from the mouthpiece of the product. [NOTE—If the flow rate and duration are defined otherwise in the monograph, adjust the system to within 5% of those values.] The volume of air sampled should not exceed 2.0 L. This flow rate should be fixed for all determinations for a specific drug product, established and validated during development studies as the suitable flow rate through the device to produce such pressure drop on the average. The flow rate should not be changed to compensate for device-to-device variability in flow resistance for the same product.

Determine the test flow rate using DDU sampling apparatus B as follows. Insert the product into the mouthpiece adapter to ensure an airtight seal. For premetered products, use a device loaded with an empty capsule or blister. For device-metered products, use an unused device. In both cases, the flow path should be free of drug. Connect one port of a differential pressure transducer to the pressure tap, P1 (in *Figure 1b*), and leave the other open to the atmosphere. Switch on the pump, and open the two-way solenoid valve. Adjust the flow-control valve until the pressure drop across the product is 4.0 kPa. Ensure that critical (sonic) flow occurs in the flow-control valve by measuring the individual values for absolute pressure, P2 and P3, so that their ratio P3/P2 is ≤0.5. If this ratio of P3/P2 is not achieved, switch to a more powerful pump and remeasure the test flow rate. Critical (sonic) flow conditions in the flow-control valve are required in order to ensure that the volumetric flow rate drawn from the mouthpiece is unaffected by pump fluctuations and changes in flow resistance of the product. Remove the product and the mouthpiece adapter, and without disturbing the flow-control valve, measure the flow rate drawn from the mouthpiece, $Q_{out}$. A flowmeter is connected in an airtight fashion at the inlet to the sampling apparatus (see *Figure 1b*) using a suitable adapter. Use a flowmeter calibrated for the volumetric flow leaving the meter in an airtight fashion to directly determine $Q_{out}$. If the flow rate is >100 L of air/min, adjust the flow-control valve until $Q_{out}$ equals 100 L/min; otherwise, record the value of $Q_{out}$, and leave the flow-control valve undisturbed. Define the test flow duration in seconds, e.g., at 60 L/min, $T = 120/Q_{out}$, so that a volume of 2.0 L of air (±5%) is withdrawn from the product at the test flow rate $Q_{out}$, and adjust the timer controlling the operation of the two-way solenoid valve accordingly.

Prepare the device with powder for inhalation according to the labeled instructions. With the vacuum pump running and the solenoid valve closed, insert the product's mouthpiece horizontally into the mouthpiece adapter. Discharge the powder into DDU sampling apparatus B by activating the timer controlling the solenoid valve and withdrawing 2.0 L of air from the product at the previously defined flow rate. Repeat the whole operation $n - 1$ times beginning with the text, "Prepare the device with powder," where $n$ is the number of actuations defined in the labeling as the minimum recommended dose, but NMT 2 actuations per determination. Detach the inhalation powder device container from DDU sampling apparatus B, and disconnect the vacuum tubing, D (*Figure 1b*). *Assay*the contents of the apparatus for drug after rinsing the filter and the interior of the apparatus with a suitable solvent.

***DDU sampling apparatus B:*** The sample collection tube assembly is similar to that described in *Figure 2* for testing inhalation aerosols. In this case, however, the filter and sample collection tube have a larger internal diameter to accommodate a 47-mm diameter filter (*Table 1*). This feature enables dosage collection at higher flow rates—up to 100 L of air/min—when necessary. A mouthpiece adapter ensures an airtight seal between the sample collection tube and the mouthpiece of the inhalation powder being tested. The mouthpiece adapter must ensure that the tip of the product's mouthpiece is flush with the open end of the sample collection tube. Tubing connectors, if they are used, should have an internal diameter of ≥10 mm to preclude their own internal diameters from creating significant flow resistance. A vacuum pump with excess capacity must be selected in order to draw air at the designated volumetric flow rate through both the sampling apparatus and the product simultaneously. A timer-controlled, low-resistance, solenoid-operated, two-way valve is interposed between the vacuum pump and the flow-control valve to control the duration of flow. Flow control is achieved by ensuring that critical (sonic) flow occurs in the flow-control valve (absolute pressure ratio P3/P2 is ≤0.5 under conditions of steady-state flow).

A validated analytical method is employed to determine the amount of drug in each delivered dose, and data are reported as amount delivered and as a percentage of target-delivered label claim.

## A.4 Nasal Powders

The following test is applicable to nasal powders presented in premetered and device-metered units. In all cases and for all tests, prepare and test the powder as directed in the labeling and the instructions for use, but NMT two actuations per determination.

### A.4.1 DELIVERED DOSE UNIFORMITY OF NASAL POWDERS

Unless otherwise directed in the individual monograph, the drug content of the minimum number of delivered dose(s) will be determined at the beginning of unit life and also at the end of unit life from each of 10 separate containers. This represents a total of 20 determinations. For nasal powders packaged in single-dose units, *Delivered Dose Uniformity* can be applied on 10 dosage units.

**A.4.1.1 Sampling the delivered dose from nasal powders:** To ensure reproducible dose collection, it is recommended that appropriate means of operating the device assembly be used to deliver doses for collection. (See *A.3.1 Delivered Dose Uniformity of Inhalation Powders*, *A.3.1.1 Sampling the delivered dose from inhalation powders* for additional information regarding the sampling procedure.) The two separate determinations (NMT 2 actuations) include samples of the beginning and end of the unit life corresponding to the label claim from each of 10 units. The discharges between the two sequential beginning and end test samples for each unit must be disposed of appropriately. A validated analytical method is used to determine the amount of drug in each delivered dose. Data are reported as amount delivered and as a percentage of target-delivered label claim. DDU sampling apparatus B (*Figure 1b* and *Figure 2*) is recommended for nasal powders.

# B. DROPLET/PARTICLE SIZE DISTRIBUTION—NASAL AEROSOLS AND NASAL SPRAYS

For suspension or solution nasal aerosols and nasal sprays, the emitted droplet/particle size distribution should be determined for the delivered plume subsequent to delivery under specified experimental conditions. Assuming that the density of the liquid under investigation is constant irrespective of droplet size, the volume-based size distributions may be treated as mass-based size distributions for the purpose of data interpretation. If a laser diffraction method is used (for more detail, refer to the description of this method in *B.1 Droplet/Particle Size Determination by Laser Diffraction*), droplet size distribution can be estimated in terms of ranges for the 10th ($D_{10}$), 50th ($D_{50}$), and 90th ($D_{90}$) percentiles of the cumulative volume-based size

distribution, as well as the span of the distribution, expressed as $[(D_{90} - D_{10})/D_{50}]$, and the percentage of droplets less than 10 µm. Note that $D_{50}$ is identical with the volume median diameter if the distribution is unimodal. Appropriate and validated or calibrated emitted droplet/particle size analytical procedures should be described in sufficient detail to allow accurate and reproducible assessment including the following:

- Complete information about the apparatus and accessories
- Theoretical model (Lorenz–Mie or Fraunhofer approximation)
- The application of a disabling option for one or more of the innermost detectors to mitigate beam steering effects (only applicable to nasal aerosols)
- Software version
- Sample placement with respect to the optical bench of the laser diffractometer
- Measurement range
- Beam width
- Laser trigger condition in connection with the initiation and termination of the measurement sequence
- Lower limit of detection (if laser triggering is not used)
- Obscuration limit (upper bound of detection range in terms of particle concentration)

## B.1 Droplet/Particle Size Determination by Laser Diffraction

Suspension and solution drug products intended for application to the nasal cavity produce liquid droplets that typically are much larger than the operating range for multistage inertial impactors. Thus, laser diffraction (sometimes referred to as low-angle laser light scattering) could be a complimentary and/or an alternative approach for determining the size distribution.

The theory and operating principles for laser diffraction are well described in the most recent version of ISO 13320. These systems use the light-scattering pattern produced by passage of a cloud of droplets through the measurement zone to develop the volume-based size distribution in an iterative process in which a theoretical model (either Fraunhofer or Lorenz–Mie) is used to interpret the data. The process is summarized schematically in *Figure 3*. [NOTE—If the Lorenz–Mie model option is chosen, it will be necessary to input values for the real (refraction) and imaginary (absorption) components of refractive index for the liquid being studied. Manufacturers of laser diffraction equipment provide this information for commonly encountered liquid media either on their website or upon inquiry.]

An apparatus that has the capability to assess aerosols or sprays is required. [NOTE—Not all commercially available laser diffractions possess this capability.] Set up the measurement system in accordance with the procedure outlined schematically in *Figure 4*.

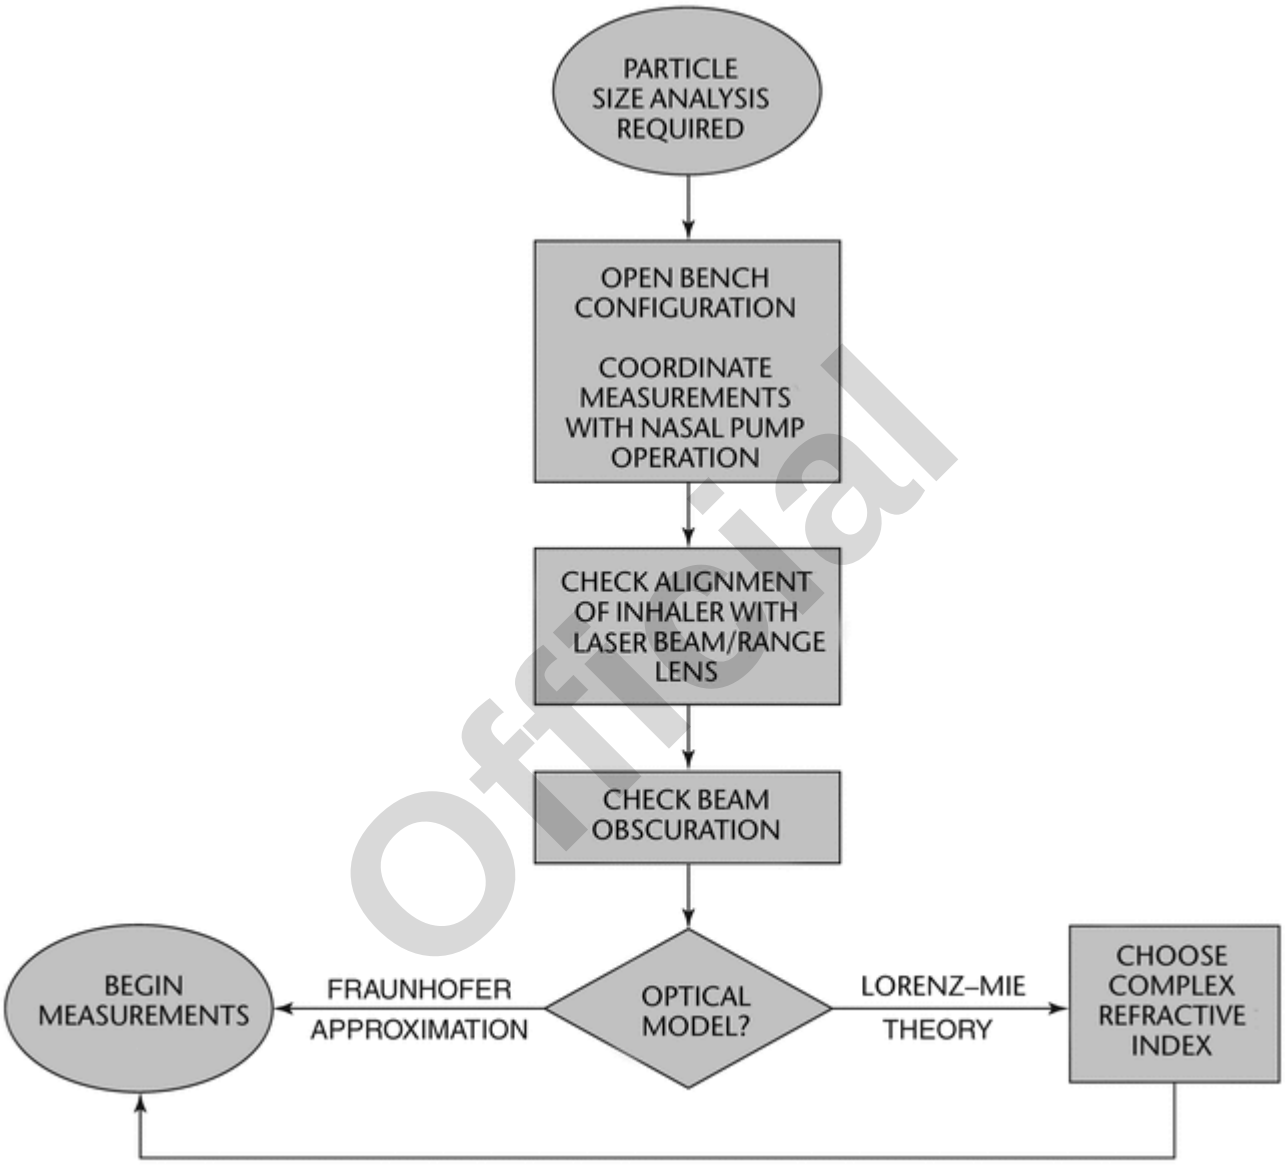

Figure 4. Setup for laser diffractometry with a nasal drug product.

Nasal spray drug products generally are determined with an open-bench arrangement with an automated actuation station setup so that reproducibility in nasal product operation from one actuation to the next can be optimized. Check the alignment of the inhaler plume intersecting with the optical configuration of the laser diffractometer using the tools provided by the manufacturer to optimize alignment of the optical bench. Check that the light beam obscuration is within the upper and lower limits specified by the manufacturer, consulting the operator's manual for the laser diffraction system being used. Vacuum extraction is required to efficiently remove droplets after they pass through the laser. An unrepresentative result may occur if this value is set too low (typically <5%). Unquantifiable error due to multiple scattering will happen if the obscuration is above the recommended upper limit. [NOTE—This limit varies from one manufacturer to another and may also vary from one laser diffractometer system to another from the same manufacturer.]

Conduct as many replicate measurements as needed to achieve a representative data set. Inspect each size distribution presented, ideally in differential volume-based format or equivalent to assess whether or not it is unimodal and symmetrical. A unimodal distribution is a requirement for data analysis.

### B.2 Aerodynamic Particle Size Distribution—Determination By Cascade Impaction

The particle or droplet size distribution in the plume discharged from nasal aerosols may be determined similar to inhalation aerosols as described in *C. Aerodynamic Particle/Droplet Size Distribution—Inhalation Aerosols, Inhalation Sprays, Inhalation Powders, Nasal Aerosols, and Nasal Powders*.

## C. AERODYNAMIC PARTICLE/DROPLET SIZE DISTRIBUTION—INHALATION AEROSOLS, INHALATION SPRAYS, INHALATION POWDERS, NASAL AEROSOLS, AND NASAL POWDERS

### C.1 General Principles of Aerodynamic Particle/Droplet Size Distribution Measurement

The particle or droplet size distribution in the plume discharged from inhalation aerosols, inhalation sprays, nasal aerosols, and the particle size distribution in the cloud discharged from inhalation powders and nasal powders are important characteristics used in judging product quality and performance. The aerodynamic diameter of an aerosol particle is equal to the diameter of a sphere of unit density whose gravimetric settling velocity is the same. The aerodynamic size distribution defines the manner in which aerosol droplets/particles deposit during inhalation. In use, many inhalers discharge drug in the form of large droplets or particles (the “ballistic fraction”) that leave the inhaler at high velocity and impact on and are captured by the moist surfaces in the mouth, throat, or nose. The remainder of the discharge from the inhaler is the "nonballistic fraction" that is inhaled into the remainder of the respiratory tract.

Cascade impaction devices classify aerosol particles and droplets on the basis of aerodynamic diameters. The principle of their operation whereby they separate aerosol particles and droplets from a moving airstream on the basis of particle or droplet inertia is shown in *Figure 5*. The internal geometry, surface smoothness, and dimensions of the induction port (and pre-separator if used) may affect the mass of the drug that enters the cascade impactor. These dimensions are carefully defined and are held constant for all apparatuses. The surface roughness of the inlet should be around 0.40 μm.

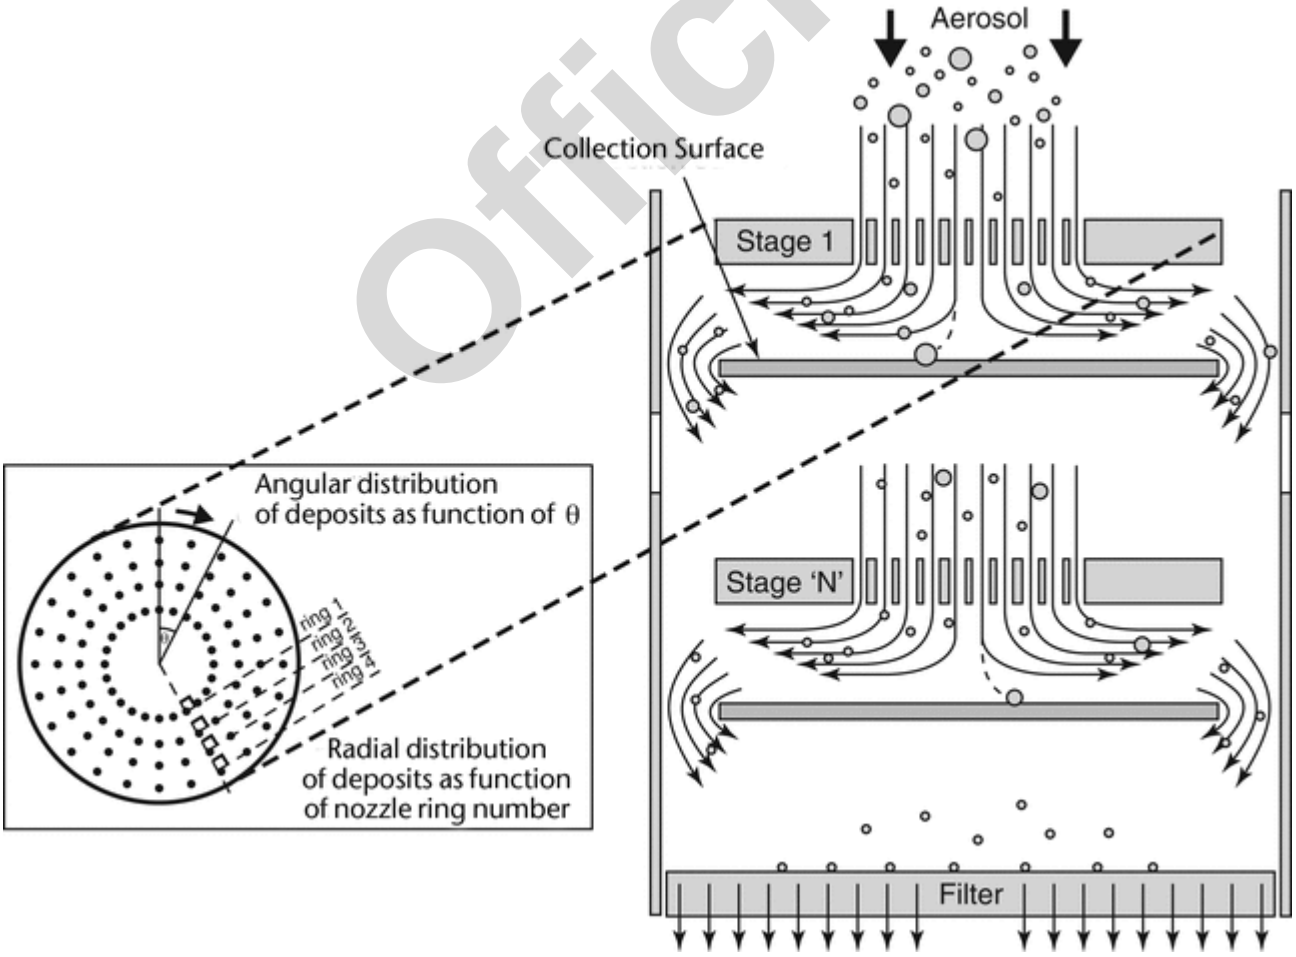

Figure 5. Schematic representation of the principle of operation of cascade impactors. [1]

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99360_05_01

### C.1.1 STAGE MENSURATION

Calibration of a cascade impactor is a property of the nozzle dimensions, the spatial arrangement of the nozzles and its collection surface, and the flow rate passing through it. Because nozzles can corrode and wear over time, the effective diameter of the nozzles of each stage, which are related to the impaction stage's cut-off size, must be measured precisely on a regular basis. This process, known as stage mensuration, replaces the need for repetitive calibration using standard aerosols and ensures that only impactors that conform to the manufacturer's specifications for the stage nozzles are used for testing product output.

### C.1.2 INTERSTAGE DRUG LOSSES (WALL LOSSES)

The selected *Aerodynamic Particle Size Distribution* determination procedure should ensure that NMT 5% of the product's total delivered drug mass (into the impactor) is subject to wall loss between the impaction apparatus's collection surfaces. In the event that interstage drug losses are predetermined to be >5% for a given drug product, either the procedure should be modified (e.g. coating of impactor plates should be explored) in such a way that wall losses are decreased below this level or an alternative apparatus should be used. Wall losses on a particular stage should not be combined with the plate deposition to assay the mass deposited on a specific stage. It is appropriate to include wall deposition in the determination of the mass balance.

### C.1.3 RE-ENTRAINMENT

Where method variations are possible, the selected method should seek to minimize particle re-entrainment (from an upper to a lower impaction stage) on stages that contribute to size fractions defined in the individual monograph, especially where this may affect the amounts of drug collected. Minimizing the number of actuations, using coated particle-collection surfaces, and proving that multiple-actuation procedures produce results that are statistically similar to those from smaller numbers of actuations are all methods that can be used for this purpose. The number of actuations collected, the time interval between actuations, and the total duration of flow through the cascade impactor should be standardized for the measurement program by appropriately validated approaches.

By using validated analytical methods and a suitable mensurated impaction device, analysts can determine aerodynamic particle size distributions for drugs leaving the mouthpiece/nosepiece of inhalation aerosols, inhalation sprays, inhalation powders, nasal aerosols, or nasal powders. If temperature or humidity limits for use of the product are stated on the label, it may be necessary to control the temperature and humidity of the air surrounding and passing through the device to conform to those limits. Ambient conditions are presumed unless otherwise specified in individual monographs.

### C.1.4 MASS BALANCE

In addition to the size distribution, good analytical practice dictates that a mass balance be performed in order to confirm that the amount of the drug discharged from the product and recovered from the mouthpiece/nosepiece adapter, the induction port through to the after-filter of the cascade impactor apparatus, is within an acceptable range around the target-delivered label claim. The result for the recovered mass can be expressed on a per-actuation basis as a percent of the labeled delivered dose, which represents the dose delivered from the mouthpiece/nosepiece.

The total mass of drug collected in all of the components (mass balance) divided by the total number of actuations discharged per determination typically is NLT 85% and NMT 115% of the target-delivered label claim. This is not a test of the product but serves to ensure that the test results are valid.

### C.1.5 PROCEDURE

Use one of the following multistage impaction apparatuses to determine aerodynamic particle size distributions of drug(s) leaving the mouthpiece/nosepiece of inhalation aerosols, inhalation sprays, inhalation powders, nasal aerosols, or nasal powders. An appropriate minimum number of drug product units (e.g. 5) should be tested individually, and the determination for each unit should be performed with the minimum number of actuations justified by the sensitivity of the analytical procedure used to quantitate the deposited drug. The Andersen Cascade Impactor and Next Generation Impactor without pre-separator are intended for use with inhalation aerosols, inhalation sprays, and nasal aerosols at a single flow rate. The Andersen Cascade Impactor and Next Generation Impactor with pre-separator are intended for use with inhalation powders and nasal powders, unless it has been shown to be unnecessary, at the appropriate flow rate, $Q_{out}$, determined earlier during testing for *Delivered Dose Uniformity*, see *C.3.1 Design—Andersen Cascade Impactor with Pre-Separator* and *C.5.1 Design—Next Generation Impactor with Pre-Separator*. The volume of total air sampled per actuation should be 4.0 L.

*Table 2* indicates the apparatuses used to determine aerodynamic particle size and the products that they are used to evaluate. *Table 3a* and *Table 3b* provide the cut-off diameters of the impactors listed in *Table 2* at specified flow rates.

**Table 2. Aerodynamic Particle Size Apparatuses: Description and the Products That They Can Be Used to Evaluate**

## C.2 Andersen Cascade Impactor without Pre-separator for Inhalation Aerosols, Inhalation Sprays, and Nasal Aerosols

Use the Andersen Cascade Impactor without pre-separator at a flow rate of 28.3 L/min (±5%) as specified by the manufacturer of the cascade impactor.

### C.2.1 DESIGN—ANDERSEN CASCADE IMPACTOR WITHOUT PRE-SEPARATOR

The design and assembly of this apparatus are shown in *Figure 6a*. The expanded view of the induction port and entrance cone to connect the impactor through the induction port to a drug product are shown, respectively, in *Figure 6b* and *Figure 6c*. The device is a cascade impactor with eight stages and an after filter. The material can be aluminum or stainless steel. Use this apparatus at a flow rate of 28.3 L/min (±5%) unless otherwise prescribed in the individual monograph.

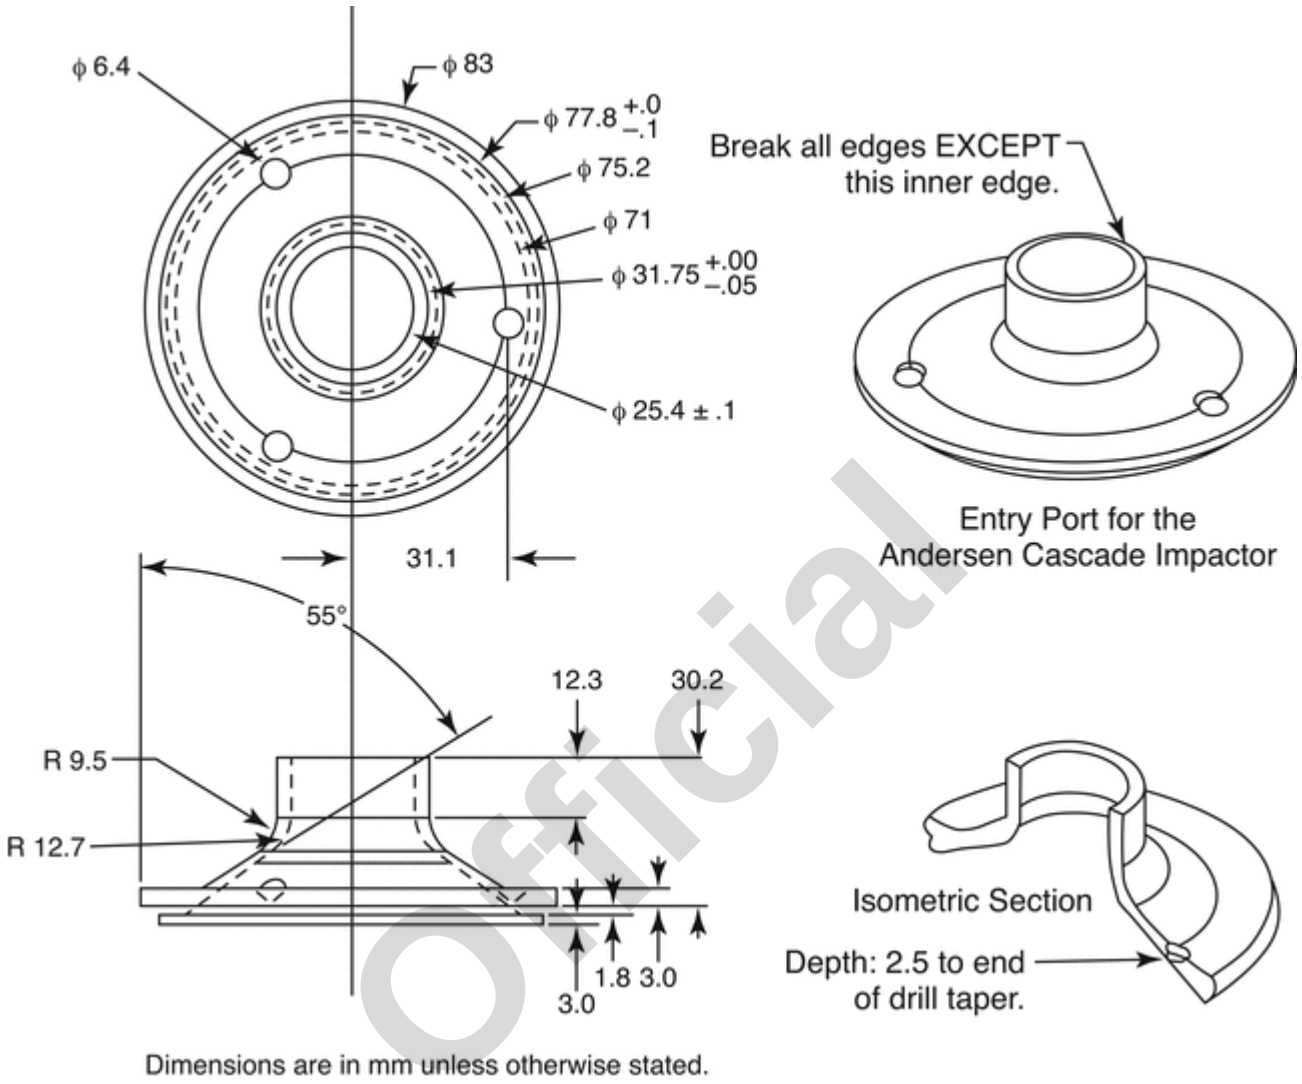

Figure 6c. Expanded view of the entrance cone for mounting induction port on the Andersen Cascade Impactor without pre-separator. Material can be aluminum or stainless steel. Surface roughness ($R_a$) should be approximately 0.40 µm.

Manufacturers' critical engineering dimensions for the stages of the Andersen Cascade Impactor are provided in *Table 4*. During use, some occlusion and blockage of nozzles may occur, and therefore, in-use mensuration tolerances must be justified.

**Table 4. Critical Dimensions for the Nozzles of the Andersen Cascade Impactor**

| Stage Number | Number of Nozzles | Nominal Nozzle Diameter (mm)[a] |
|---|---|---|
| 0 | 96 | 2.550 ± 0.025 |
| 1 | 96 | 1.890 ± 0.025 |
| 2 | 400 | 0.914 ± 0.013 |
| 3 | 400 | 0.711 ± 0.013 |
| 4 | 400 | 0.533 ± 0.013 |
| 5 | 400 | 0.343 ± 0.013 |
| 6 | 400 | 0.254 ± 0.013 |
| 7 | 201 | 0.254 ± 0.013 |

### C.2.2 PROCEDURE—ANDERSEN CASCADE IMPACTOR WITHOUT PRE-SEPARATOR

Set up the multistage cascade impactor as described in the manufacturer's literature with an after-filter below the final stage to capture any fine particles that otherwise would escape from the impactor. To ensure efficient particle capture, coat the particle collection surface of each stage appropriately with glycerol, silicone oil, or other suitable liquid unless this has been demonstrated to be unnecessary. Attach the mouthpiece/nosepiece adapter to the end of the induction port to produce an airtight seal between the product mouthpiece/nosepiece and the induction port as shown in *Figure 6a*. Use a mouthpiece adapter that ensures that the tip of the product's mouthpiece/nosepiece is flush with the open end of the induction port. Ensure that the various stages of the cascade impactor are connected with airtight seals to prevent leaks (seals should be periodically inspected for cracks and replaced as necessary). Turn on the vacuum pump to draw air through the cascade impactor, and calibrate the flow rate through the system with an appropriate flowmeter attached to the open end of the induction port.

Adjust the flow-control valve on the vacuum pump to achieve steady flow through the system at 28.3 L/min (±5%). Prepare the product for use according to the label instructions for shaking, priming, and firing. With the vacuum pump running, insert the mouthpiece/nosepiece of the inhaler into the mouthpiece/nosepiece adapter and immediately fire into the cascade impactor the first of the minimum recommended number of actuations. When testing, keep the valve depressed for a duration sufficient to ensure that the actuation has been completely discharged. If additional sprays are required for the sample, wait for 5 s before firing the next actuation. Repeat until the required number of actuations has been discharged. The number of minimum recommended actuations discharged per determination must be sufficient to ensure an accurate and precise determination of the *Aerodynamic Particle Size Distribution*, but not excessive to mask the variability of individual doses. After the last actuation has been discharged, remove the product from the mouthpiece/nosepiece adapter. Rinse the mouthpiece/nosepiece adapter and the induction port with a suitable solvent, and dilute quantitatively to an appropriate volume. Disassemble the cascade impactor, place each collection plate or filter in a separate container, and rinse the drug from each of them. [NOTE—Analyze all components separately. Only data from analysis of deposition on the collection plates should be used for the purpose of determination of stage deposition. The data from analysis of deposition on the other components should only be used for the purpose of establishing the determination of mass balance and should not be combined with the plate deposition for determination of aerodynamic particle size distribution.] Dilute each sample quantitatively to an appropriate volume. Using an appropriately validated method of analysis, determine the mass of drug collected in each of the components.

## C.3 Andersen Cascade Impactor with Pre-separator for Inhalation Powders and Nasal Powders

### C.3.1 DESIGN—ANDERSEN CASCADE IMPACTOR WITH PRE-SEPARATOR

The Andersen Cascade Impactor with pre-separator (*Figure 7a*) is identical to the Andersen Cascade Impactor without pre-separator (*Figure 6a*) except that the manufacturer's pre-separator is added atop modified Stage 0 (28.3 L/min), Stage –1 (60 L/min), or Stage –2 (90 L/min) to collect large particles of noninhalable powder prior to their entry into the impactor. (Note that there are different external fittings for the pre-separator for the 28.3, 60, and 90 L/min configurations of the Andersen Cascade Impactor.) To connect the pre-separator of the impactor to the induction port, use the top shown in *Figure 7b*. The impactor, therefore, has eight stages, a pre-separator, and an after-filter. A pre-separator may not be required for certain engineered powders, notably those of low bulk density. Connect the cascade impactor into the control system specified in *Figure 7c*.

[a] Flow coefficient, as defined by ISA S75.02 Control valve capacity test procedures in *Standards and Recommended Practices for Instrumentation and Control*, 10th ed., Vol. 2. Research Triangle Park, NC: Instrument Society of America; 1989.

For operation at flow rates of 60 and 90 L/min, use manufacturers' alternate stage configurations. To ensure efficient particle capture, coat the particle collection surface of each stage appropriately with glycerol, silicone oil, or other suitable liquid unless this has been demonstrated to be unnecessary. Assemble the impactor as described in the manufacturer's literature with an after-filter below the final stage to capture any fine particles that otherwise would escape from the impactor. Place an appropriate predefined volume (up to 10 mL) of an appropriate solvent into the pre-separator, or coat the particle collection surfaces of the pre-separator to prevent re-entrainment of impacted particles. [**CAUTION**—Some solvents form flammable vapor–air mixtures that may be ignited during passage through a vacuum pump. Take appropriate precautions (alternative solvents, use of vapor traps, minimal pump operating times, etc.) to ensure operator safety during testing.] Attach a mouthpiece/nosepiece adapter to the end of the induction port to produce an airtight seal between the product's mouthpiece/nosepiece and the induction port. Use a mouthpiece/nosepiece adapter that ensures that the tip of the product's mouthpiece/nosepiece is flush with the open end of the induction port. Ensure that the various stages of the cascade impactor are connected with airtight seals to prevent leaks.

For flow rate calibration, turn on the vacuum pump, open the two-way solenoid valve, and determine the flow rate testing through the system as follows. Connect a flowmeter to the induction port. Use a flowmeter calibrated for the volumetric flow leaving the meter to directly determine $Q_{out}$. Adjust the flow-control valve to achieve a steady flow through the system at the required rate, $Q_{out}$, so that $Q_{out}$ is within ±5% of the value determined during testing for *Delivered Dose Uniformity*. Under steady-state flow conditions at the valve and at the flow rate to be used during testing ensure critical flow exists, by using the following procedure. With the product in place and the intended flow running, measure the absolute pressure on both sides of the flow-control valve (P2 and P3 in *Figure 7c*). A ratio of P3/P2 $\leq$0.5 indicates critical flow. If this ratio of P3/P2 is not achieved, switch to a more powerful pump, and remeasure the test flow rate. Adjust the timer controlling the operation of the two-way solenoid valve so that it opens this valve for a duration of 2$T$ seconds based on determination of duration of $T$ seconds for testing of *Delivered Dose Uniformity*.

### C.3.2 PROCEDURE—ANDERSEN CASCADE IMPACTOR WITH PRE-SEPARATOR

Perform the test using the Andersen Cascade Impactor with pre-separator at the flow rate, $Q_{out}$ determined earlier during testing for *Delivered Dose Uniformity*. Connect the apparatus to a flow-control system that is based on critical (sonic) flow as specified in *Figure 7c* (see also *Table 5*). Coat the particle collection surface of each of the stages of the cascade impactor appropriately to ensure that particles that have impacted on a given stage are not re-entrained in the flowing airstream or to reduce particle bouncing unless this has been shown to be unnecessary.

Prepare the inhalation powder or nasal powder according to the labeled instructions. With the vacuum pump running and the two-way solenoid valve closed, insert the product's mouthpiece/nosepiece, held horizontally, into the mouthpiece/nosepiece adapter. Once the product is positioned, discharge the powder into the apparatus by opening the two-way solenoid valve for the required duration of 2$T$ s, to sample 4.0 L of air, based on determined duration of $T$ seconds for testing of *Delivered Dose Uniformity*. After the total volume of 4.0 L of air per actuation has been sampled, the two-way solenoid valve is closed and the product is removed. If additional actuations are required for a determination, reload the inhalation powder according to the labeled instructions while inserted into the induction port mouthpiece/nosepiece adapter, and repeat the operation until the required number of actuations has been discharged. Certain types of oral or nasal DPIs, e.g., capsule-based premetered or other DPI designs, may need removal of the DPI from the mouthpiece/nosepiece adapter after each discharged dose for reloading of the device according to the labeled instructions. After each reload, reinsert the mouthpiece of the DPI into the mouthpiece/nosepiece adapter. Repeat the same operation until the required minimum number of actuations has been discharged. After discharge of the last actuation, remove the product from the mouthpiece/nosepiece adapter, and switch off the vacuum pump.

Carefully disassemble the apparatus. Using a suitable solvent, rinse the drug from the mouthpiece/nosepiece adapter, induction port, pre-separator, each stage, and the collection plate of each stage and the filter immediately into appropriately sized flasks. [NOTE—Analyze all components separately. Only data from analysis of deposition on the collection plates should be used for the purpose of determination of stage deposition. The data from analysis of deposition on the other components should only be used for the purpose of establishing the determination of mass balance and should not be combined with the plate deposition for determination of aerodynamic particle size distribution.] Quantitatively dilute each flask to an appropriate volume. Using an appropriately validated method of analysis, determine the mass of drug collected in each of the samples.

## C.4 Next Generation Impactor without Pre-separator for Inhalation Aerosols, Inhalation Sprays, and Nasal Aerosols

### C.4.1 DESIGN—NEXT GENERATION IMPACTOR WITHOUT PRE-SEPARATOR

The design and assembly of the Next Generation Impactor without pre-separator are shown in *Figure 8a* and *Figure 8b*. The induction port used to connect the impactor to a product has the same internal dimensions as shown in *Figure 6b*. The device is a cascade impactor with seven stages and a micro-orifice collector (MOC). Use this apparatus at a flow rate of 30 L/min (±5%) unless otherwise prescribed in the individual monograph.

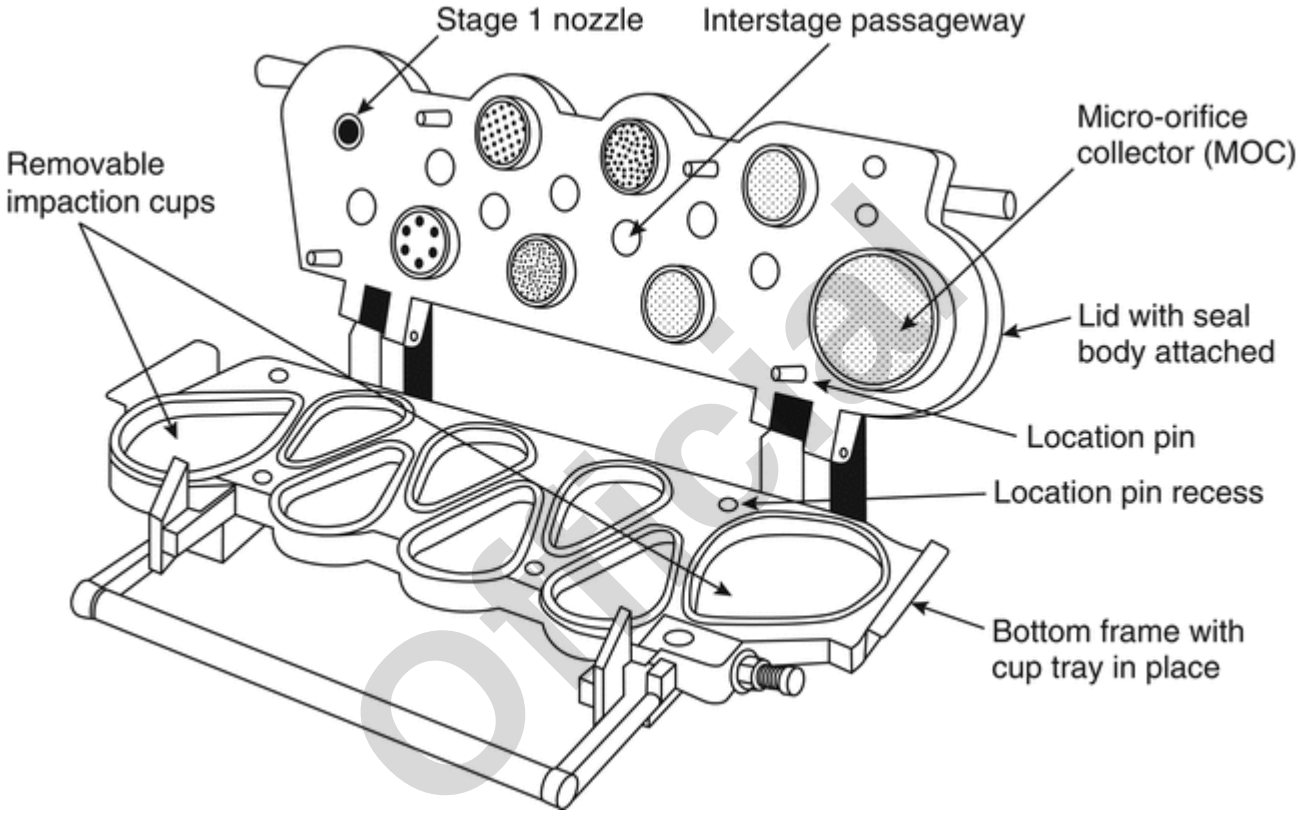

Figure 8a. Components and Nozzle Configuration of the Next Generation Impactor.

@2024 USPC

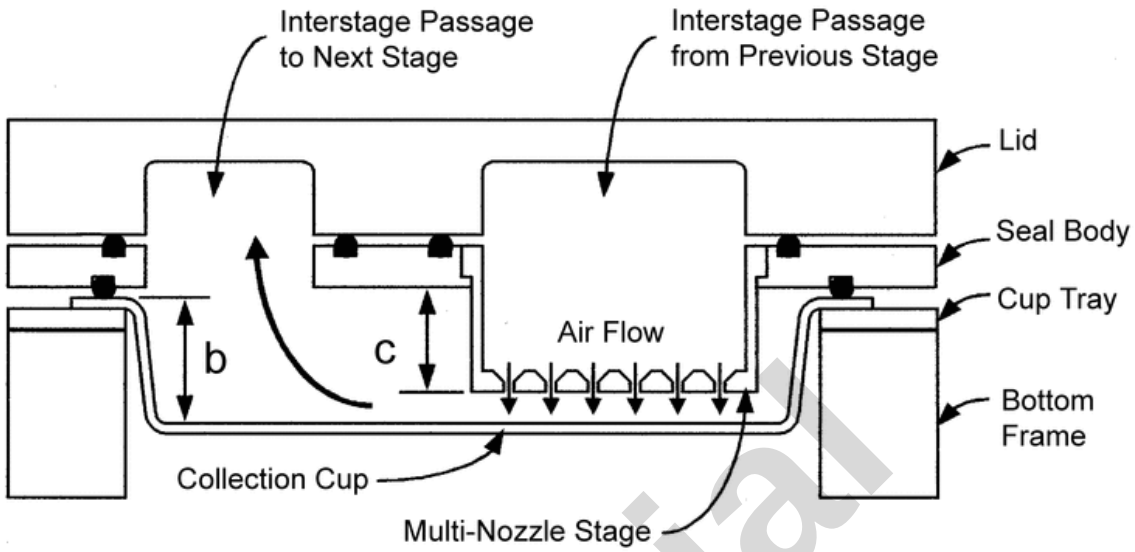

Figure 8b. A layout of interstage passageways of the Next Generation Impactor.

The Next Generation Impactor with pre-separator in place is presented in *Figure 9a*.

The impactor layout has removable impaction cups with all of the cups in one plane. There are three main sections to the impactor: the bottom frame that holds the impaction cups, the seal body that holds the nozzles, and the lid that contains the interstage passageways. Multiple nozzles are used at all but the first stage. The flow passes through the impactor in a saw-tooth pattern.

Stage mensuration is performed periodically (see *C.1.1 Stage Mensuration*) together with confirmation of other dimensions critical to the effective operation of the impactor. Critical dimensions are provided in *Table 6*.

**Table 6. Critical Dimensions for Next Generation Impactor**

| Description | Nominal Nozzle Diameter (mm) | Nominal Nozzle to Seal Body Distance (mm)[a, b] |
|---|---|---|
| Pre-separator[c] | 12.80 ± 0.05 | — |
| Stage 1[d] | 14.30 ± 0.05 | 1.18 |
| Stage 2[d] | 4.88 ± 0.04 | 5.236 ± 0.736 |
| Stage 3[d] | 2.185 ± 0.020 | 8.445 ± 0.410 |
| Stage 4[d] | 1.207 ± 0.010 | 11.379 ± 0.237 |
| Stage 5[d] | 0.608 ± 0.010 | 13.176 ± 0.341 |
| Stage 6[d] | 0.323 ± 0.010 | 13.999 ± 0.071 |
| Stage 7[d] | 0.206 ± 0.010 | 14.000 ± 0.071 |
| MOC[d] | ~0.070 | 14.429–14.571 |
| Optional cup depth (see *b* in *Figure 8b*) | 14.625 ± 0.100 | — |
| Collection cup surface roughness | 0.5–2 µm | — |

[a] See *Figure 8a*.
[b] Refer to manufacturer for specifications on tolerance/precision of the dimensions.
[c] See *Figure 9b*.
[d] See *Figure 8a*.

During routine operation, the seal body and lid are held together as a single assembly. The impaction cups are accessible when this assembly is opened at the end of a product test. The cups are held in a support tray so that all cups can be removed from the impactor simultaneously by lifting out the tray.

The USP induction port (*Figure 6b*) is connected to the impactor inlet. A suitable mouthpiece/nosepiece adapter is used to provide an airtight seal between the product's mouthpiece/nosepiece and the induction port.

Official

https://pharmacopeia.cn/

The apparatus contains a terminal MOC that for most formulations may eliminate the need for a final filter if this capability is demonstrated by method validation. The MOC is an impactor nozzle plate and collection cup. The nozzle plate contains, nominally, 4032 holes, each approximately 70 µm in diameter. Most particles not captured on Stage 7 of the impactor may be captured on the cup surface below the MOC. There is an optional filter holder that can replace the MOC for formulations with a significant fraction of particles not captured by the MOC. Alternatively, an after-filter (glass fiber is often suitable) can be placed in a filter holder external to the Next Generation Impactor with and without pre-separator, which is located downstream of the MOC.

### C.4.2 PROCEDURE—NEXT GENERATION IMPACTOR WITHOUT PRE-SEPARATOR

Assemble the apparatus without the pre-separator. Place cups into the apertures in the cup tray. To ensure efficient particle capture, coat the particle collection surface of each stage with glycerol, silicone oil, or other suitable liquid, unless this has been demonstrated to be unnecessary. Insert the cup tray into the bottom frame, and lower into place. Close the impactor lid with the seal body attached, and operate the handle to lock the impactor together so that the system is airtight. Connect the USP induction port (*Figure 6b*) to the impactor inlet. Attach a mouthpiece/nosepiece adapter to the end of the induction port to produce an airtight seal between the product's mouthpiece/nosepiece and the induction port as shown in *Figure 6a*. Use a mouthpiece/nosepiece adapter that ensures that the tip of the product's mouthpiece/nosepiece is flush with the open end of the induction port. Turn on the vacuum pump to draw air through the impactor, and calibrate the flow rate through the system with an appropriate flowmeter attached to the open end of the induction port.

Adjust the flow-control valve (see H in *Figure 7c*) on the vacuum pump to achieve steady flow through the system at 30 L/min (±5%). Prepare the product for use according to the label instructions for shaking, priming, and firing. With the vacuum pump running, insert the mouthpiece/nosepiece into the mouthpiece/nosepiece adapter and immediately fire into the cascade impactor the first of the minimum recommended number of actuations. Keep the valve depressed, as applicable, for a duration sufficient to ensure that the actuation has been completely discharged. If additional sprays are required for the sample, wait for 5 s before firing the next actuation. Repeat until the required number of actuations has been discharged. The number of actuations discharged must be sufficient to ensure an accurate and precise determination of aerodynamic size distribution. After the last actuation has been discharged, remove the product from the mouthpiece/nosepiece adapter. Rinse the mouthpiece/nosepiece adapter and induction port with a suitable solvent, and dilute quantitatively to an appropriate volume.

Dismantle the apparatus, and recover the drug for analysis as follows. Remove the induction port and mouthpiece/nosepiece adapter from the apparatus, and extract the drug from each component of the system into an aliquot of solvent and recover quantitatively the active ingredient from all inner surfaces. Open the impactor by releasing the handle and lifting the lid; remove the cup tray with the collection cups; and extract the active ingredient in each cup into an aliquot of solvent. Using a validated method of analysis, determine the mass of drug contained in each of the aliquots of solvent. Only data from analysis of deposition on the collection cups should be used for the determination of stage deposition.

## C.5 Next Generation Impactor with Pre-separator for Inhalation Powders and Nasal Powders

### C.5.1 DESIGN—NEXT GENERATION IMPACTOR WITH PRE-SEPARATOR

The Next Generation Impactor is identical to that described in *C.4.1 Design—Next Generation Impactor without Pre-separator* (*Figure 8a* and *Figure 8b*), except that the pre-separator (*Figure 9b*) is used. A pre-separator may not be required for certain engineered powders, notably those of low bulk density. Connect the cascade impactor into the control system specified in *Figure 7c*.

### C.5.2 PROCEDURE—NEXT GENERATION IMPACTOR WITH PRE-SEPARATOR

Assemble the apparatus with the pre-separator (*Figure 9a*).

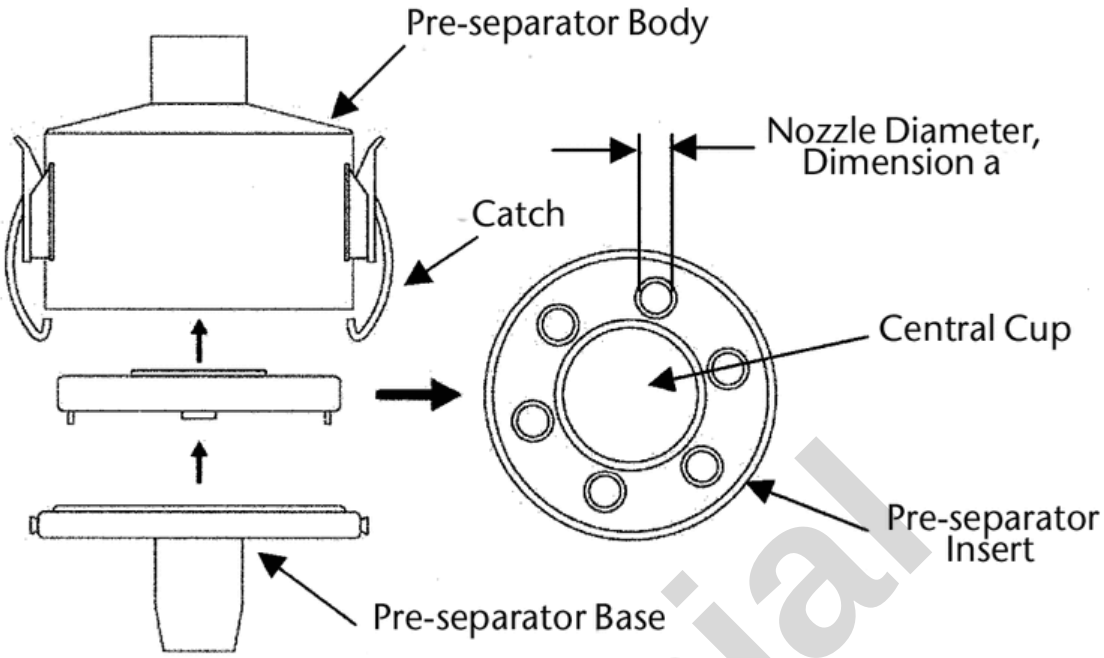

Figure 9b. Pre-separator layout for Next Generation Impactor.

The pre-separator can be assembled as follows. Assemble the pre-separator insert into the pre-separator base; fit the pre-separator base to the impactor inlet; add an appropriate predefined volume (up to 15 mL) of appropriate solvent used for sample recovery to the central cup of the pre-separator insert; place the pre-separator body on top of this assembly; and close the two catches. [**CAUTION**—Some solvents form flammable vapor–air mixtures that can be ignited during passage through a vacuum pump. Take appropriate precautions (e.g., alternative solvents, use of vapor traps, minimal pump operating times, etc.) to ensure operator safety during testing.]

Connect the USP induction port (*Figure 6b*) to the pre-separator inlet atop the cascade impactor (*Figure 9a*). Place a suitable mouthpiece/nosepiece adapter to the inlet of the induction port so that the mouthpiece/nosepiece end of the product, when inserted, lines up along the horizontal axis of the induction port. The front face of the product's mouthpiece/nosepiece is flush with the front face of the induction port, producing an airtight seal. When attached to the mouthpiece/nosepiece adapter, the product should be positioned in the same orientation as intended for use. Connect the apparatus to a flow system according to the scheme specified in *Figure 7c*.

Conduct the test at the flow rate used in the test for *Delivered Dose Uniformity*, drawing 4.0 L of air from the mouthpiece/nosepiece of the product and through the apparatus. Connect a flowmeter to the induction port. Use a flowmeter calibrated for the volumetric flow leaving the meter. Adjust the flow-control valve (see H in *Figure 7c*) to achieve steady flow through the system at the required rate, $Q_{out}$ (±5%). Ensure that critical flow occurs in the flow-control valve at the flow rate to be used during testing by using the following procedure. With the product in place, and the intended flow running, measure the absolute pressure on both sides of the flow-control valve (P2 and P3 in *Figure 7c*). A ratio of P3/P2 $\leq$0.5 indicates critical flow. If this ratio of P3/P2 is not achieved, switch to a more powerful pump, and remeasure the test flow rate.

Prepare the inhalation powder or nasal powder according to the labeled instructions. With the vacuum pump running and the two-way solenoid valve closed, insert the product's mouthpiece/nosepiece, held horizontally, into the mouthpiece/nosepiece adapter. Adjust the timer controlling the operation of the two-way solenoid valve so that it opens the valve for a duration of 2*T* s to sample 4.0 L of air, based on determined duration of *T* seconds for testing of *Delivered Dose Uniformity*. After total air volume of 4.0 L sampled per actuation, the two-way solenoid valve is closed and the product is removed. If additional actuations are required for a determination, reload the inhalation powder or nasal powder according to the labeled instructions while inserted into the mouthpiece/nosepiece adapter, and repeat the operation until the required number of actuations has been discharged. Certain types of oral or nasal DPIs, e.g., capsule-based premetered or other DPI designs, may need removal of the DPI from the mouthpiece/nosepiece adapter after each discharged dose for reloading of the device according to the labeled instructions. After each reload, reinsert the mouthpiece of the DPI into the mouthpiece/nosepiece adapter. Repeat the same operation until the required number of actuations has been discharged. After discharge of the last actuation, remove the product from the mouthpiece/nosepiece adapter, and switch off the vacuum pump.

Dismantle the apparatus, and recover drug for analysis as follows. Remove the induction port and mouthpiece/nosepiece adapter from the pre-separator, and extract the drug from each component of the system into an aliquot of appropriate solvent; remove the pre-separator from the impactor without spilling the solvent into the impactor; and recover quantitatively the active ingredient from all inner surfaces. Open the impactor by releasing the handle and lifting the lid. Remove the cup tray, with the collection cups, and recover the active ingredient from each cup into an aliquot of solvent. Using a validated method of analysis, determine the mass of drug contained in each of the aliquots of solvent.▲ (USP 1-May-2021)

# ⟨602⟩ PROPELLANTS

[**Caution**—Hydrocarbon propellants are highly flammable and explosive. Observe precautions, and perform sampling and analytical operations in a well-ventilated fume hood.]

## GENERAL SAMPLING PROCEDURE

This procedure is used to obtain test specimens for those propellants that occur as gases at about 25° and that are stored in pressurized cylinders. Use a stainless steel sample cylinder equipped with a stainless steel valve with a capacity of NLT 200 mL and a pressure rating of 240 psi or more. Dry the cylinder with the valve open at 110° for 2 h, and evacuate the hot cylinder to less than 1 mm of mercury. Close the valve, cool, and weigh. Connect one end of a charging line tightly to the propellant container and the other end loosely to the sample cylinder. Carefully open the propellant container, and allow the propellant to flush out the charging line through the loose connection. Avoid excessive flushing, which causes moisture to freeze in the charging line and connections. Tighten the fitting on the sample cylinder, and open the sample cylinder valve, allowing the propellant to flow into the evacuated cylinder. Continue sampling until the desired amount of specimen is obtained, then close the propellant container valve, and finally close the sample cylinder valve.

[**Caution**—Do not overload the sample cylinder. Hydraulic expansion due to temperature change can cause overloaded cylinders to explode.]

Again weigh the charged sample cylinder, and calculate the weight of the specimen.

## APPROXIMATE BOILING TEMPERATURE

Transfer a 100-mL specimen to a tared, pear-shaped, 100-mL centrifuge tube containing a few boiling stones, and weigh. Suspend a thermometer in the liquid, and place the tube in a medium maintained at a temperature of 32° above the expected boiling temperature. When the thermometer reading becomes constant, record as the boiling temperature the thermometer reading after at least 5% of the specimen has distilled. Retain the remainder of the specimen for the determination of high-boiling residues.

## HIGH-BOILING RESIDUES, METHOD I

Allow 85 mL of the specimen to distill as directed in the test for *Approximate Boiling Temperature*, and transfer the centrifuge tube containing the remaining 15 mL of specimen to a medium maintained at a temperature 10° above the boiling temperature. After 30 min, remove the tube from the water bath, blot dry, and weigh. Calculate the weight of the residue.

## HIGH-BOILING RESIDUES, METHOD II

Prepare a cooling coil from copper tubing (about 6 mm outside diameter × about 6.1 m long) to fit into a vacuum-jacketed flask. Immerse the cooling coil in a mixture of dry ice and acetone in a vacuum-jacketed flask, and connect one end of the tubing to the propellant sample cylinder. Carefully open the sample cylinder valve, flush the cooling coil with about 50 mL of the propellant, and discard this portion of liquefied propellant. Continue delivering liquefied propellant from the cooling coil, and collect it in a previously chilled 1000-mL sedimentation cone until the cone is filled to the 1000-mL mark. Allow the propellant to evaporate, using a warm water bath maintained at about 40° to reduce evaporating time. When all of the liquid has evaporated, rinse the sedimentation cone with two 50-mL portions of pentane, and combine the rinsings in a tared 150-mL evaporating dish. Transfer 100 mL of the pentane solvent to a second tared 150-mL evaporating dish, place both evaporating dishes on a water bath, evaporate to dryness, and heat the dishes in an oven at 100° for 60 min. Cool the dishes in a desiccator, and weigh. Repeat the heating for 15-min periods until successive weighings are within 0.1 mg, and calculate the weight of the residue obtained from the propellant as the difference between the weights of the residues in the two evaporating dishes.

## WATER CONTENT

Proceed as directed in *Water Determination* ⟨921⟩, with the following modifications: (a) Provide the closed-system titrating vessel with an opening through which passes a coarse-porosity gas dispersion tube connected to a sampling cylinder. (b) Dilute the *Reagent* with anhydrous methanol to give a water equivalence factor of between 0.2 and 1.0 mg/mL, and age this diluted solution for NLT 16 h before standardization. (c) Obtain a 100-g specimen as directed under *General Sampling Procedure*, and introduce the specimen into the titration vessel through the gas dispersion tube at a rate of about 100 mL of gas per min. If necessary, heat the sample cylinder gently to maintain this flow rate.

## OTHER DETERMINATIONS

For those aerosols that use propellants, perform the tests specified in the individual *NF* propellant monographs.

Official

https://pharmacopeia.com/

# ⟨603⟩ TOPICAL AEROSOLS

## INTRODUCTION

Topical aerosol products contain the drug in solution or in suspension, packaged under pressure, and released upon activation of an appropriate valve system. The topical aerosol products should follow the product quality test requirements described in general test chapters *Inhalation and Nasal Drug Products—General Information and Product Quality Tests* ⟨5⟩, *Microbial Enumeration Tests* ⟨61⟩, *Tests for Specified Organisms* ⟨62⟩, *Minimum Fill* ⟨755⟩, and *Leak Rate* ⟨604⟩. The topical aerosols include dermatological foams and sprays. Topical aerosol foams should include a physical appearance of both the foam and also of the collapsed foam.

## DELIVERY RATE AND DELIVERED AMOUNT

Perform these tests only on containers fitted with continuous valves.

**Delivery Rate:** Select NLT four aerosol containers; shake, if the label includes this directive; remove the caps and covers; and actuate each valve for 2–3 s. Weigh each container accurately, and immerse in a constant-temperature bath until the internal pressure is equilibrated at a temperature of 25° as determined by constancy of internal pressure, as directed under the *Pressure Test* below. Remove the containers from the bath; remove excess moisture by blotting with a paper towel; shake, if the label includes this directive; actuate each valve for 5.0 s (accurately timed by use of a stopwatch); and weigh each container again. Return the containers to the constant-temperature bath, and repeat the foregoing procedure three times for each container. Calculate the average *Delivery Rate*, in g/s, for each container.

**Delivered Amount:** Return the containers to the constant-temperature bath, continuing to deliver 5 s actuations to waste, until each container is exhausted. [NOTE—Ensure that sufficient time is allowed between each actuation to avoid significant canister cooling.] Calculate the total weight loss from each container. This is the *Delivered Amount*.

## PRESSURE TEST

Perform this test only on topical aerosols fitted with continuous valves.

Select NLT four aerosol containers, remove the caps and covers, and immerse in a constant-temperature bath until the internal pressure is constant at a temperature of 25°. Remove the containers from the bath, shake, and remove the actuator and water, if any, from the valve stem. Place each container in an upright position, and determine the pressure in each container by placing a calibrated pressure gauge on the valve stem, holding firmly, and actuating the valve so that it is fully open. The gauge is of a calibration approximating the expected pressure and is fitted with an adapter appropriate for the particular valve stem dimensions. Read the pressure directly from the gauge.

## MINIMUM FILL

Topical aerosols meet the requirements for aerosols in *Minimum Fill* ⟨755⟩.

## LEAKAGE TEST

Proceed as directed in *Leak Rate* ⟨604⟩.

## NUMBER OF DISCHARGES PER CONTAINER

Perform this test only on topical aerosols fitted with dose-metering valves, at the same time as, and on the same containers used for, the test for *Delivered-Dose Uniformity*. Determine the number of discharges or deliveries by counting the number of priming discharges plus those used in determining the spray contents, and continue to fire until the label claim number of discharges. The requirements are met if all the containers or inhalers tested contain NLT the number of discharges stated on the label.

***Change to read:***

## DELIVERED-DOSE UNIFORMITY

The test for *Delivered-Dose Uniformity* is required for topical aerosols fitted with dose-metering valves. For collection of the minimum dose, proceed as directed in ▲*Inhalation and Nasal Drug Products: Aerosols, Sprays, and Powders—Performance Quality Tests* ⟨601⟩*, A. Delivered-Dose Uniformity/A.1 Inhalation Aerosols and Inhalation Sprays*▲ (CN 1-May-2021), and ▲*A.3 Inhalation Powders*▲ (CN 1-May-2021), as described in ⟨601⟩, except modify the dose sampling apparatus so that it is capable of quantitatively capturing the delivered dose from the preparation being tested.

https://pharmacopeia.com/

# ⟨604⟩ LEAK RATE

Select 12 aerosol containers, and record the date and time to the nearest half hour. Weigh each container to the nearest mg, and record the weight, in mg, of each as $W_1$. Allow the containers to stand in an upright position at a temperature of 25.0 ± 2.0° for not less than 3 days, and again weigh each container, recording the weight, in mg, of each as $W_2$ and recording the date and time to the nearest half hour. Determine the time, $T$, in hours, during which the containers were under test. Calculate the leakage rate, in mg per year, of each container taken by the formula:

$$(365)(24/T)(W_1 - W_2).$$

Where plastic-coated glass aerosol containers are tested, dry the containers in a desiccator for 12–18 h, and allow them to stand in a constant-humidity environment for 24 h prior to determining the initial weight as indicated above. Conduct the test under the same constant-humidity conditions. Empty the contents of each container tested by employing any safe technique (e.g., chill to reduce the internal pressure, remove the valve, and pour). Remove any residual contents by rinsing with suitable solvents, then rinse with a few portions of methanol. Retain as a unit the container, the valve, and all associated parts, and heat them at 100° for 5 min. Cool, weigh, record the weight as $W_3$, and determine the net fill weight ($W_1 - W_3$) for each container tested. [NOTE—If the average net fill weight has been determined previously, that value may be used in place of the value ($W_1 - W_3$) above.] The requirements are met if the average leakage rate per year for the 12 containers is not more than 3.5% of the net fill weight, and none of the containers leaks more than 5.0% of the net fill weight per year. If 1 container leaks more than 5.0% per year, and if none of the containers leaks more than 7.0% per year, determine the leakage rate of an additional 24 containers as directed herein. Not more than 2 of the 36 containers leak more than 5.0% of the net fill weight per year, and none of the 36 containers leaks more than 7.0% of the net fill weight per year. Where the net fill weight is less than 15 g and the label bears an expiration date, the requirements are met if the average leakage rate of the 12 containers is not more than 525 mg per year and none of the containers leaks more than 750 mg per year. If 1 container leaks more than 750 mg per year but not more than 1.1 g per year, determine the leakage rate of an additional 24 containers as directed herein. Not more than 2 of the 36 containers leak more than 750 mg per year, and none of the 36 containers leaks more than 1.1 g per year. This test is in addition to the customary in-line leak testing of each container.

# ▲⟨607⟩ PHARMACEUTICAL FOAMS—PRODUCT QUALITY TESTS

## INTRODUCTION

Foams are a dispersion of gas in a liquid or a semisolid continuous phase wherein the liquid or semisolid contains the drug substance and suitable excipients. Typical foam dosage forms include aqueous or nonaqueous carriers, foam structuring agents, surfactants, and propellants (for pressurized systems). Foams are produced by mechanical means or via interaction of propellant (vapor or gas) and the formulation under pressure. Foams dispensed from nonpressurized containers use mechanical forces allowing the mixing of the formulation and air, resulting in foam generation. Foams dispensed from pressurized containers use propellant present in gas phase to increase pressure inside the container. When the nozzle of the actuator is opened, the liquid phase containing a dispersed vapor or gas is emitted through an actuator. As a result, a foam is generated.

Foams are primarily used to apply drug substances to topically accessible sites. The most significant of these sites is the skin where direct application is frequently used to alleviate symptoms (e.g., inflammation, infection). An extension of this approach is to apply foams to accessible but not superficial sites such as the ear canal, or to mucosal sites such as the rectum, vagina, or oropharynx. Invasive approaches such as application at surgical sites or insertion in blood vessels extend the application of foams and their purpose.

This chapter provides a list of product quality tests that may be applied to pharmaceutical foam products. In part or in its entirety, this chapter applies when referenced in a drug product monograph (see *General Notices, 3.10 Applicability of Standards*). Manufacturers may use quality tests listed in this chapter, as appropriate, when considering the content of new drug product monographs for submission to USP.

## PRODUCT QUALITY TESTS FOR PHARMACEUTICAL FOAMS

Drug product quality tests fall into two categories: 1) universal tests that are applicable to all drug products and should be included in the monograph, and 2) specific tests that should be considered for inclusion for specific types of products. Universal tests include identification, assay, and impurities and are discussed in the following *USP* chapters, based on route of administration: *Injections and Implanted Drug Products* ⟨1⟩, *Oral Drug Products—Product Quality Tests* ⟨2⟩, *Topical and Transdermal Drug Products—Product Quality Tests* ⟨3⟩, *Mucosal Drug Products—Product Quality Tests* ⟨4⟩, and *Inhalation and Nasal Drug Products—General Information and Product Quality Tests* ⟨5⟩. Pharmaceutical foams are delivered by the injection, topical, and mucosal routes. For more information on specific tests by those routes of administration, see ⟨1⟩, ⟨3⟩, and ⟨4⟩, respectively.

## QUALITY TESTS FOR FOAM PRODUCTS BY ALL ROUTES OF ADMINISTRATION

- **Dispersed Content Uniformity Throughout Canister Life**

  **Non-metered products:** Select one container and determine its weight. Dispense quantities according to the labeled instructions separately collecting an appropriate amount, individually weighed. The sample size should be sufficient for at least one quantitative determination of the active ingredients(s) and should not exceed the maximum dose recommended by the product labeling for a single application. [Note—Refer to the labeled use instructions to determine whether or not the can is shaken prior to expelling foam and to determine the orientation (upright or inverted) when dispensing. Use the labeled content and the weights of samples collected and material discarded for the following sampling procedure.] Retain the portions of foam corresponding to: 1) an initial portion from the filled canister, 2) a portion from the middle of the canister (in the range of 40%–60% of labeled canister content), and 3) the portion corresponding to the canister contents with 85% of the labeled contents delivered. [Note—The canister should be dispensed at room temperature. If the canister cools as a result of dispensing, the canister should be warmed to room temperature before subsequent delivery. Properly discard the material removed from the canister by valve actuations required to collect specified samples. Using an appropriate sample preparation (such as outgassing) and analytical method, determine the drug substance concentration in each of the three portions.]

  **Acceptance criteria:** None of the three results are outside of the product assay range. The maximum difference in the amount of active ingredient(s) determined within the canister is NMT 10.0%. For example, if the three measurements within the canister are 97.0%, 95.2%, and 99.7%, the maximum difference would be 4.5% (i.e., 99.7%–95.2% = 4.5%).

  **Metered-dose products:** Delivered dose uniformity measures the drug substance content as dispensed over the entire unit life. Select one container. Refer to the labeled use instructions to determine whether or not the can is shaken prior to expelling foam. Using separate collection vessels, quantitatively collect delivered doses representing actuations for the initial dose, a middle dose, and the final dose from the container. [Note—Between actuations, warm the canister in a water bath at 25° for 3 min.] Discard the material removed from the canister by valve actuations required to collect specified samples. Determine the drug substance content of each of the three collected samples.

  **Acceptance criteria:** None of the three results are more than 10% outside of the labeled amount per dose, and the maximum difference between any of the results is NMT 10% of the claim for delivered dose.

- **Minimum Fill:** Proceed as directed for *Minimum Fill* ⟨755⟩, *Procedure for Aerosols and Sprays*. This procedure also can be applied to foams.

  **Acceptance criteria:** Meets the requirements

## OTHER TESTS

- **Leak Rate (Aerosol Products):** Proceed as directed in *Leak Rate* ⟨604⟩.

  **Acceptance criteria:** Meets the requirements

- **Propellant (Aerosol Products):** Proceed as directed in *Propellants* ⟨602⟩.

  **Acceptance criteria:** Meets the requirements as specified in the monograph

@2024 USPC

- **Pressure in Canister (Aerosol Products):** See *Topical Aerosols* ⟨603⟩, *Pressure Test*. Pressure in the canister is only measured for products with continuous valves using a mechanism that attaches to a pressure gauge while sealing against the valve in a manner that contains the expelled gas and foam.
  **Acceptance criteria:** Meets the requirements for the pressure test as specified in the monograph
- **pH:** Apply *pH* ⟨791⟩ for the collapsed foam, as appropriate. In order to measure this attribute, the collapsed foam may require dilution.
- **Sterility:** If applicable, see *Sterility Tests* ⟨71⟩.
- **Microbial Limits:** Apply microbial limits tests (see *Microbial Enumeration Tests* ⟨61⟩ and *Tests for Specified Microorganisms* ⟨62⟩), as appropriate.
- **Antimicrobial Preservative Content:** If applicable, see *Antimicrobial Effectiveness Testing* ⟨51⟩ and *Antimicrobial Agents—Content* ⟨341⟩.
- **Antioxidant Content:** If applicable, see *Topical and Transdermal Drug Products—Product Quality Tests* ⟨3⟩, *Product Quality Tests for Topical and Transdermal Drug Products, Specific Tests, Antioxidant preservative content*.
- **Osmolarity and Osmolality** If applicable, see *Osmolality and Osmolarity* ⟨785⟩.

**ADDITIONAL QUALITY TESTS APPLICABLE FOR TOPICAL FOAM PRODUCTS**

- **Time to Break:** Rate of foam liquid drainage and collapse can be observed by dispensing a foam into a graduated cylinder maintained at an appropriate temperature. Record the foam volume as freshly dispensed and again after a period (e.g., complete collapse or as specified in the monograph). The ratio of the freshly dispensed volume to the volume of drained liquid on complete collapse of the foam or at the time specified in the monograph is as specified in the monograph.
- **Delivery Rate:** See *Topical Aerosols* ⟨603⟩, *Delivery Rate and Delivered Amount, Delivery Rate*.
  **Acceptance criteria:** Meets the requirements as specified in the monograph
- **Delivered Amount:** See *Topical Aerosols* ⟨603⟩, *Delivery Rate and Delivered Amount, Delivered Amount*.
  **Acceptance criteria:** Meets the requirements as specified in the monograph
- **Relative Density of Uncollapsed Foam:** If applicable, determine the relative foam density by weighing a mass of uncollapsed foam ($m$) and a mass of the same volume of water ($e$) in a suitable container:

$$\text{Relative density of uncollapsed foam} = m/e$$

$m$ = mass of uncollapsed foam (g/mL)
$e$ = volume of water (g/mL)

- **Water Content:** If applicable (where stability may be affected, primarily for nonaqueous formulations), see *Water Determination* ⟨921⟩.
- **Particle Size:** When the finished product contains a suspended drug substance or is an emulsion, the product should be examined for particle size (in case of suspended solid drug substance) or globule size (in case of an emulsion). These tests are generally formulation dependent. Therefore, such tests are not included in compendial monographs but are part of the manufacturer's approved regulatory specification for the product.▲ (USP 1-Dec-2020)

# ⟨610⟩ ALTERNATIVE MICROBIOLOGICAL SAMPLING METHODS FOR NONSTERILE INHALED AND NASAL PRODUCTS

## INTRODUCTION

Proper microbiological sampling of microbiologically susceptible nonsterile products can be difficult because these products are often filled into unique primary containers that are designed to protect the product from inadvertent contamination during storage and use. These unique designs may increase the difficulty of taking an aseptic sample of sufficient size or volume for microbiological testing. Unless special approaches are used, products such as inhaled, nasal liquid, or powder dosage forms can be difficult to sample without potential exposure to extraneous microbial contamination. This general test chapter provides these special approaches for sampling either low- or high-content inhaled or nasal dosage forms. Alternative sampling approaches may provide better ways to sample containers in an aseptic manner. Any alternative methodology should employ aseptic techniques and should be conducted under environmental and other conditions that are appropriate for aseptic sampling.

## INHALED OR NASAL DOSAGE FORMS

Low-content inhaled and nasal drug products (low-content INDP) are products that have a target fill of less than 100 mg of powder or 1 mL of liquid formulation per unit (primary container). Examples are pre-metered inhalation powders, more commonly known as dry powder inhalers (DPIs), and single-dose nasal sprays.

High-content INDP are multidose drug products that have a target fill of more than 100 mg of powder or more than 1 mL of liquid formulation per unit. Examples are aerosols for inhalation and nasal delivery, known as metered-dose inhalers (MDIs); device-metered inhalation powders; and multidose nasal sprays.

The appropriate sample quantity or volume should be based on the test methodology, including any relevant general test chapters, such as ⟨61⟩ *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* and ⟨62⟩ *Microbiological Examination of Nonsterile Products: Tests for Specified Microorganisms*. Testing may be performed on the unpackaged bulk dry powder or liquid formulation or the finished product. If testing is performed on the bulk material alone, then the process leading from the bulk to the finished product should be validated for its ability to prevent microbial contamination. Testing should be performed on the finished product if this process is not validated.

Official

## SAMPLE SIZE DETERMINATION

For each microbiological test, sample 10 drug product containers or units or a number of units that can provide a minimum of 1 gram of product that are representative of the batch. For batch sizes smaller than 200 units (e.g., batches used in clinical trials), sample size may be reduced to 1% of the units or 1 unit, whichever is greater. The contents of individual containers may be pooled for testing.

### Bulk Testing for Low-Content INDP

Bulk lot testing may be preferable for low-content INDP in lieu of finished product testing to allow larger sample sizes that are representative of the batch, without unduly increasing the risk of inadvertent microbial contamination. Bulk testing can be performed on the bulk powder or liquid formulation just before filling. If bulk testing is performed in lieu of finished product testing, then manufacturing processes following bulk sampling (e.g., filling and packaging) must be validated in accordance with current good manufacturing practice (CGMP) for their ability to prevent microbial contamination. For microbial enumeration tests, at least 10 g or 10 mL of bulk material, or, for specified microorganisms tests, 1 g or 1 mL of bulk material may be sampled. For small batch sizes (i.e., less than 1000 g or 1000 mL), the recommended sample size is 1% of the batch for both microbial enumeration and specified microorganisms tests.

## SAMPLING METHODS FOR HIGH-CONTENT INDP

### Dry Powder Inhalers

DPIs have an internal reservoir that contains a sufficient quantity of formulation for multiple doses that are metered by the device itself during activation by the patient. For DPIs, appropriate validated procedures should be used to sample a nonsterile drug product container.

### Inhalation Aerosols

Consider safety issues related to both inhalation of the drug substance and the potential of a flammability hazard. Avoid contamination of samples by employing aseptic techniques whenever necessary.

@2024 USPC

### AUTOMATIC ACTUATION METHOD

The contents of the inhalation aerosol containers may be collected by automatically actuating each aerosol container and collecting the delivered formulation on a suitable sterile filter.

### ROOM TEMPERATURE METHOD

Disinfect the outside of the test containers with an appropriate disinfectant, and allow the containers to dry in a controlled environment. Empty the contents of the aerosol container into a sterile vessel using a needle apparatus or similar device (e.g., icemaker water line tap). If it has been demonstrated that the propellant does not inhibit the growth of microorganisms, the contents of the sterile vessel may be added directly to the liquid media or buffer for the test. Otherwise, allow the propellant to evaporate from the vessel by leaving the vessel at room temperature for several minutes. Remove any residual gaseous propellant by tilting the vessel slightly or by allowing a slow stream of microbiologically inert sterile gas to pass over the surface. For some less volatile propellants such as chlorofluorocarbon (CFC) 11/12 combinations, the vessel may be heated slightly (to temperatures $\leq$ 45°) to assist with evaporation. After the propellant has evaporated, add the liquid media or buffer, and mix the contents to prepare for testing.

Direct expulsion into the broth media or buffer may be feasible if a needle apparatus that is thin and strong enough to puncture the container and to allow slow removal of the contents is available. In this case, the contents may be expelled into and mixed with the aqueous medium. Layering of the propellant and aqueous medium may occur, in which case a longer time period and slight heating (not to exceed 45°) may be required for propellant evaporation.

### CHILLING METHOD

Place the disinfected aerosol containers in dry ice, or a dry ice slurry (ensure the microbial quality of the dry ice and slurry-forming liquid), or a cryofreezer for the period required to liquefy the contents. Disinfect the outside of the test containers with an appropriate disinfectant, and allow the containers to dry in an aseptic environment. Aseptically open the aerosol containers using an appropriate tool. Be aware that freezing can affect the viability of microorganisms. For CFC-based products, pour the contents of the containers into sterile vessels. Allow the propellant to escape, and combine residues with a diluent appropriate for the drug product. Other drug-specific procedures may also be employed. For hydrofluoroalkane-based products, pour the contents of the containers into sterile vessels partially immersed in larger vessels containing dry ice. Drive off the propellant, for example by allowing a slow stream of sterile, filtered, oil-free compressed air to evaporate the material to dryness. Combine residues with a diluent appropriate for the drug product. An alternative procedure when testing the entire contents of a previously chilled container is to pour the contents of the opened container onto a sterile membrane filtration unit, allow the propellant to escape, and then rinse with an appropriate amount of sterile diluent.

## Multidose Nasal Sprays

Multidose nasal spray containers usually have a cap that is screwed on, crimped on, or forms a snap-fit. The container can be opened by unscrewing the cap, cutting the seal, or using a decrimping tool, taking care to avoid microbial contamination during the process. Following cap removal, traditional sampling methods as described in general test chapters such as ⟨61⟩ *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* and ⟨62⟩ *Microbiological Examination of Nonsterile Products: Tests for Specified Microorganisms* are typically appropriate for use.

# ⟨611⟩ ALCOHOL DETERMINATION

## PROCEDURES

### Method I—Distillation Method

Method I is to be used for the determination of alcohol, unless otherwise specified in the individual monograph. It is suitable for examining most fluidextracts and tinctures, provided the capacity of the distilling flask is sufficient (commonly two to four times the volume of the liquid to be heated) and the rate of distillation is such that clear distillates are produced. Cloudy distillates may be clarified by agitation with talc, or with calcium carbonate, and filtered, after which the temperature of the filtrate is adjusted and the alcohol content determined from the specific gravity. During all manipulations, take precautions to minimize the loss of alcohol by evaporation.

Treat liquids that froth to a troublesome extent during distillation by rendering them strongly acidic with phosphoric, sulfuric, or tannic acid, or treat with a slight excess of calcium chloride solution or with a small amount of paraffin or silicone oil before starting the distillation.

Prevent bumping during distillation by adding porous chips of insoluble material such as silicon carbide, or beads.

**For liquids presumed to contain 30% of alcohol or less:** By means of a pipet, transfer to a suitable distilling apparatus not less than 25 mL of the liquid in which the alcohol is to be determined, and note the temperature at which the volume was measured. Add an equal volume of water, distill, and collect a volume of distillate about 2 mL less than the volume taken of the original test liquid, adjust to the temperature at which the original test liquid was measured, add sufficient water to measure exactly the original volume of the test liquid, and mix. The distillate is clear or not more than slightly cloudy, and does not contain more than traces of volatile substances other than alcohol and water. Determine the specific gravity of the liquid at 25°, as directed under *Specific Gravity* ⟨841⟩, using this result to ascertain the percentage, by volume, of $C_2H_5OH$ contained in the liquid examined by reference to the *Alcoholometric Table* in the section *Reference Tables.*

**For liquids presumed to contain more than 30% of alcohol:** Proceed as directed in the foregoing paragraph, except to do the following: dilute the specimen with about twice its volume of water, collect a volume of distillate about 2 mL less than twice the volume of the original test liquid, bring to the temperature at which the original liquid was measured, add sufficient water to measure exactly twice the original volume of the test liquid, mix, and determine its specific gravity. The proportion of $C_2H_5OH$, by volume, in this distillate, as ascertained from its specific gravity, equals one-half that in the liquid examined.

#### Special Treatment

**Volatile acids and bases:** Render preparations containing volatile bases slightly acidic with diluted sulfuric acid before distilling. If volatile acids are present, render the preparation slightly alkaline with sodium hydroxide TS.

**Glycerin:** To liquids that contain glycerin add sufficient water so that the residue, after distillation, contains not less than 50% of water.

**Iodine:** Treat all solutions containing free iodine with powdered zinc before the distillation, or decolorize with just sufficient sodium thiosulfate solution (1 in 10), followed by a few drops of sodium hydroxide TS.

**Other volatile substances:** Spirits, elixirs, tinctures, and similar preparations that contain appreciable proportions of volatile materials other than alcohol and water, such as volatile oils, chloroform, ether, camphor, etc., require special treatment, as follows:

**For liquids presumed to contain 50% of alcohol or less:** Mix 25 mL of the specimen under examination, accurately measured, with about an equal volume of water in a separator. Saturate this mixture with sodium chloride, then add 25 mL of solvent hexane, and shake the mixture to extract the interfering volatile ingredients. Draw off the separated, lower layer into a second separator, and repeat the extraction twice with two further 25-mL portions of solvent hexane. Extract the combined solvent hexane solutions with three 10-mL portions of a saturated solution of sodium chloride. Combine the saline solutions, and distill in the usual manner, collecting a volume of distillate having a simple ratio to the volume of the original specimen.

**For liquids presumed to contain more than 50% of alcohol:** Adjust the specimen under examination to a concentration of approximately 25% of alcohol by diluting it with water, then proceed as directed in *For liquids presumed to contain 50% of alcohol or less,* beginning with "Saturate this mixture with sodium chloride."

In preparing *Collodion* or *Flexible Collodion* for distillation, use water in place of the saturated solution of sodium chloride directed above.

If volatile oils are present in small proportions only, and a cloudy distillate is obtained, the solvent hexane treatment not having been employed, the distillate may be clarified and rendered suitable for the specific gravity determination by shaking it with about one-fifth its volume of solvent hexane, or by filtering it through a thin layer of talc.

### Method II—Gas Chromatographic Method

Use *Method IIa* when *Method II* is specified in the individual monograph. For a discussion of the principles upon which it is based, see *Gas Chromatography* under *Chromatography* ⟨621⟩.

• **METHOD IIA**

**Apparatus:** Under typical conditions, use a gas chromatograph equipped with a flame-ionization detector and a 4-mm × 1.8-m glass column packed with 100- to 120-mesh chromatographic column packing support S3, using nitrogen or helium as the carrier. Prior to use, condition the column overnight at 235° with a slow flow of carrier gas. The column temperature is maintained at 120°, and the injection port and detector temperatures are maintained at 210°. Adjust the carrier flow and temperature so that acetonitrile, the internal standard, elutes in 5 to 10 minutes.

#### Solutions

**Test stock preparation:** Dilute the specimen under examination stepwise with water to obtain a solution containing approximately 2% (v/v) of alcohol.

Official

https://pharmacopeia.cn/v29240/

**Test preparation:** Pipet 5 mL each of the *Test stock preparation* and the USP Alcohol Determination—Acetonitrile RS [NOTE—Alternatively, a 2% aqueous solution of acetonitrile of suitable quality may be used as the internal standard solution] into a 50-mL volumetric flask, dilute with water to volume, and mix.

**Standard preparation:** Pipet 5 mL each of the USP Alcohol Determination—Alcohol RS and the USP Alcohol Determination—Acetonitrile RS. [NOTE—Alternatively, a 2% aqueous solution of acetonitrile of suitable quality may be used as the internal standard solution] into a 50-mL volumetric flask, dilute with water to volume, and mix.

**Procedure:** Inject about 5 µL each of the *Test preparation* and the *Standard preparation,* in duplicate, into the gas chromatograph, record the chromatograms, and determine the peak response ratios. Calculate the percentage of alcohol (v/v) in the specimen under test according to the formula:

$$\text{Result} = CD(R_U/R_S)$$

$C$ = labeled concentration of USP Alcohol Determination—Alcohol RS
$D$ = dilution factor (the ratio of the volume of the *Test stock preparation* to the volume of the specimen taken)
$R_U$ = peak response ratio obtained from the *Test preparation*
$R_S$ = peak response ratio obtained from the *Standard preparation*

**System suitability test:** In a suitable chromatogram, the resolution factor, R, is not less than 2; the tailing factor of the alcohol peak is not greater than 2.0; and six replicate injections of the *Standard preparation* show a relative standard deviation of not more than 2.0% in the ratio of the peak of alcohol to the peak of the internal standard.

- **METHOD IIB**

**Apparatus:** The gas chromatograph is equipped with a split injection port with a split ratio of 5:1, a flame-ionization detector, and a 0.53-mm × 30-m capillary column coated with a 3.0-µm film of phase G43. Helium is used as the carrier gas at a linear velocity of 34.0 cm per second. The chromatograph is programmed to maintain the column temperature at 50° for 5 minutes, then to increase the temperature at a rate of 10° per minute to 200°, and maintain at this temperature for 4 minutes. The injection port temperature is maintained at 210° and the detector temperature at 280°.

**Solutions**

**Test stock preparation:** Dilute the specimen under examination stepwise with water to obtain a solution containing approximately 2% (v/v) of alcohol.

**Test preparation:** Pipet 5 mL each of the *Test stock preparation* and the USP Alcohol Determination—Acetonitrile RS [NOTE—Alternatively, a 2% aqueous solution of acetonitrile of suitable quality may be used as the internal standard solution] into a 25-mL volumetric flask, dilute with water to volume, and mix.

**Standard preparation:** Pipet 5 mL each of the USP Alcohol Determination—Alcohol RS and the USP Alcohol Determination—Acetonitrile RS. [NOTE—Alternatively, a 2% aqueous solution of acetonitrile of suitable quality may be used as the internal standard solution] into a 25-mL volumetric flask, dilute with water to volume, and mix.

**Procedure:** Inject about 0.2 to 0.5 µL each of the *Test preparation* and the *Standard preparation,* in duplicate, into the gas chromatograph, record the chromatograms, and determine the peak response ratios. Calculate the percentage of alcohol (v/v) in the specimen under test according to the formula:

$$\text{Result} = CD(R_U/R_S)$$

$C$ = labeled concentration of USP Alcohol Determination—Alcohol RS
$D$ = dilution factor (the ratio of the volume of the *Test stock preparation* to the volume of the specimen taken)
$R_U$ = peak response ratio obtained from the *Test preparation*
$R_S$ = peak response ratio obtained from the *Standard preparation*

**System suitability test:** In a suitable chromatogram, the resolution factor, R, between alcohol and the internal standard is not less than 4; the tailing factor of the alcohol peak is not greater than 2.0; and six replicate injections of the *Standard preparation* show a relative standard deviation of not more than 4.0% in the ratio of the peak of alcohol to the peak of the internal standard.

# ⟨616⟩ BULK DENSITY AND TAPPED DENSITY OF POWDERS

## BULK DENSITY

This general chapter has been harmonized with the corresponding texts of the *European Pharmacopoeia* and/or the *Japanese Pharmacopoeia*. ♦The portion that is not harmonized is marked with symbols (♦,♦) to specify this fact.♦

The bulk density of a powder is the ratio of the mass of an untapped powder sample and its volume including the contribution of the interparticulate void volume. Hence, the bulk density depends on both the density of powder particles and the spatial arrangement of particles in the powder bed. The bulk density is expressed in grams per mL (g/mL) although the international unit is kilograms per cubic meter (1 g/mL = 1000 kg/m$^3$) because the measurements are made using cylinders. It may also be expressed in grams per cubic centimeter (g/cm$^3$). The bulking properties of a powder are dependent upon the preparation, treatment, and storage of the sample, i.e., how it was handled. The particles can be packed to have a range of bulk densities; however, the slightest disturbance of the powder bed may result in a changed bulk density. Thus, the bulk density of a powder is often very difficult to measure with good reproducibility and, in reporting the results, it is essential to specify how the determination was made. The bulk density of a powder is determined by measuring the volume of a known weight of powder sample, that may have been passed through a sieve, into a graduated cylinder (*Method I*), or by measuring the mass of a known volume of powder that has been passed through a volumeter into a cup (*Method II*) or a measuring vessel (*Method III*).

*Method I* and *Method III* are favored.

### Method I—Measurement in a Graduated Cylinder

#### PROCEDURE

Pass a quantity of material sufficient to complete the test through a sieve with apertures greater than or equal to 1.0 mm, if necessary, to break up agglomerates that may have formed during storage; this must be done gently to avoid changing the nature of the material. Into a dry graduated 250-mL cylinder (readable to 2 mL) introduce, without compacting, approximately 100 g of test sample, *M*, weighed with 0.1% accuracy. Carefully level the powder without compacting, if necessary, and read the unsettled apparent volume ($V_0$) to the nearest graduated unit. Calculate the bulk density in g/mL by the formula $m/V_0$. Generally, replicate determinations are desirable for the determination of this property. If the powder density is too low or too high, such that the test sample has an untapped apparent volume of either more than 250 mL or less than 150 mL, it is not possible to use 100 g of powder sample. Therefore, a different amount of powder has to be selected as the test sample, such that its untapped apparent volume is 150–250 mL (apparent volume greater than or equal to 60% of the total volume of the cylinder); the weight of the test sample is specified in the expression of results. For test samples having an apparent volume between 50 mL and 100 mL, a 100-mL cylinder readable to 1 mL can be used; the volume of the cylinder is specified in the expression of results.

### Method II—Measurement in a Volumeter

#### APPARATUS

The apparatus (*Figure 1*) consists of a top funnel fitted with a 1.0-mm sieve.[1] The funnel is mounted over a baffle box containing four glass baffle plates over which the powder slides and bounces as it passes. At the bottom of the baffle box is a funnel that collects the powder and allows it to pour into a cup of specified capacity mounted directly below it. The cup may be cylindrical (25.00 ± 0.05 mL volume with an inside diameter of 30.00 ± 2.00 mm) or cubical (16.39 ± 0.20 mL volume with inside dimensions of 25.400 ± 0.076 mm).

[1] The apparatus (the Scott Volumeter) conforms to the dimensions in ASTMB329–06(2012).

@2024 USPC

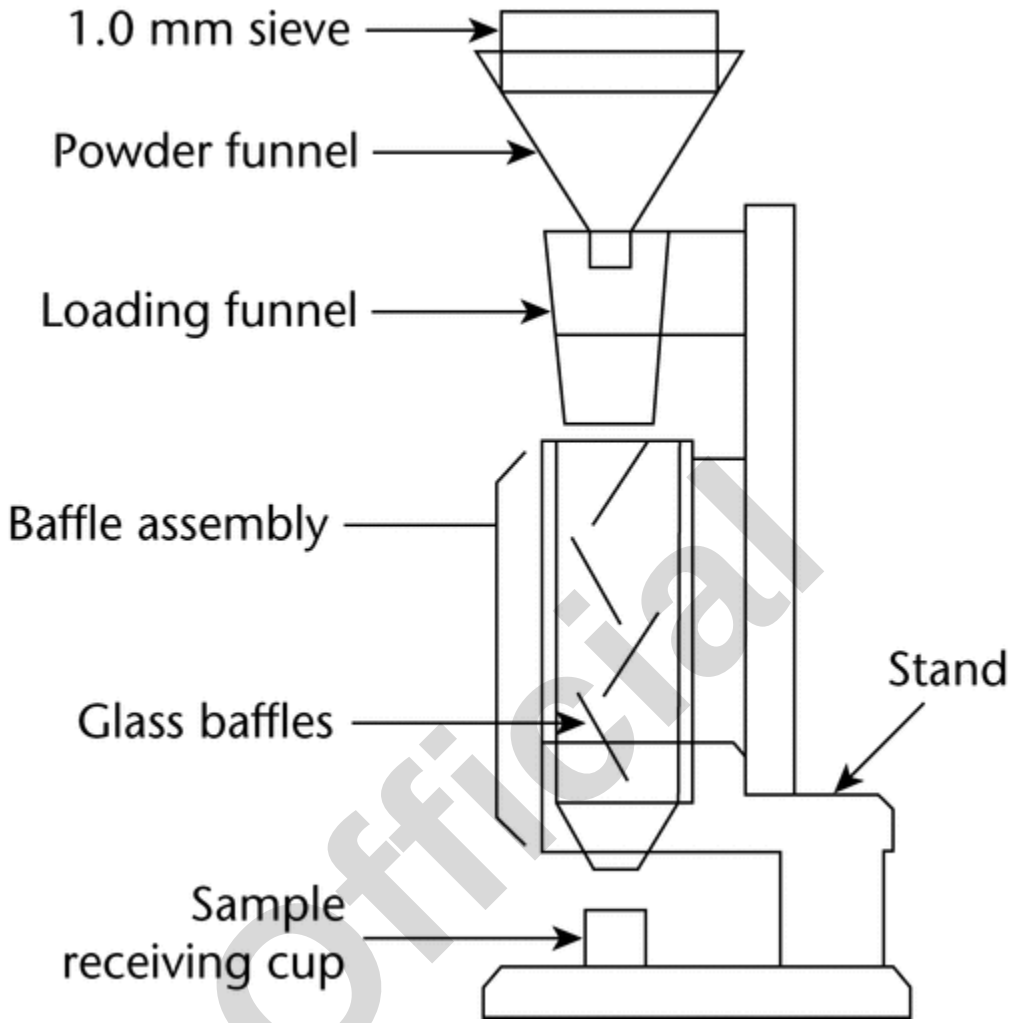

Figure 1.

PROCEDURE—Allow an excess of powder to flow through the apparatus into the sample receiving cup until it overflows, using a minimum of 25 $cm^3$ of powder with the square cup and 35 $cm^3$ of powder with the cylindrical cup. Carefully scrape excess powder from the top of the cup by smoothly moving the edge of the blade of a spatula perpendicular to and in contact with the top surface of the cup, taking care to keep the spatula perpendicular to prevent packing or removal of powder from the cup. Remove any material from the sides of the cup, and determine the weight, *M*, of the powder to the nearest 0.1%. Calculate the bulk density, in g/mL, by the formula:

$$(M)/(V_0)$$

in which $V_0$ is the volume, in mL, of the cup. Record the average of three determinations using three different powder samples.

## Method III—Measurement in a Vessel

APPARATUS

The apparatus consists of a 100-mL cylindrical vessel of stainless steel with dimensions as specified in *Figure 2*.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99375_01_01
@2024 USPC

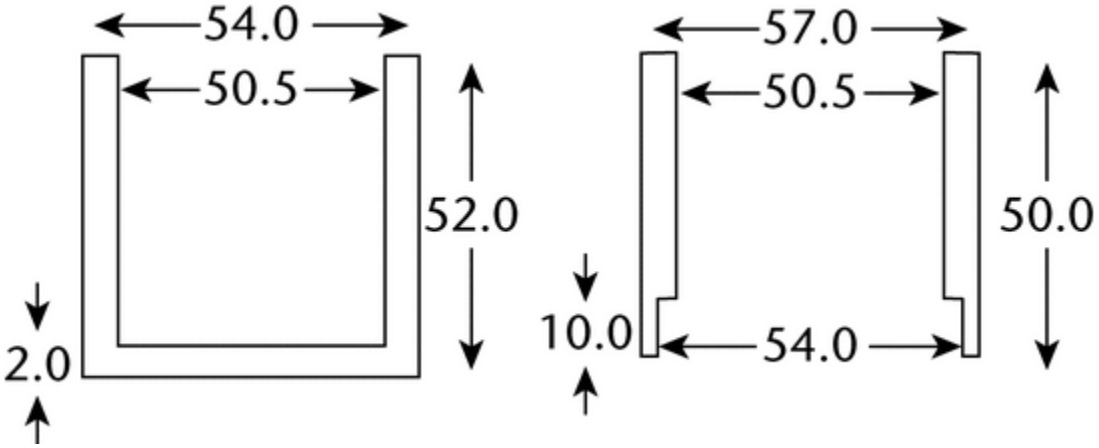

Figure 2.

PROCEDURE

Pass a quantity of powder sufficient to complete the test through a 1.0-mm sieve, if necessary, to break up agglomerates that may have formed during storage, and allow the obtained sample to flow freely into the measuring vessel until it overflows. Carefully scrape the excess powder from the top of the vessel as described for *Method II*. Determine the weight ($M_0$) of the powder to the nearest 0.1% by subtraction of the previously determined mass of the empty measuring vessel. Calculate the bulk density (g/mL) by the formula $M_0/100$, and record the average of three determinations using three different powder samples.

## TAPPED DENSITY

The tapped density is an increased bulk density attained after mechanically tapping a container containing the powder sample. Tapped density is obtained by mechanically tapping a graduated measuring cylinder or vessel containing a powder sample. After observing the initial powder volume or weight, the measuring cylinder or vessel is mechanically tapped, and volume or weight readings are taken until little further volume or weight change is observed. The mechanical tapping is achieved by raising the cylinder or vessel and allowing it to drop under its own weight a specified distance by either of three methods as described below. Devices that rotate the cylinder or vessel during tapping may be preferred to minimize any possible separation of the mass during tapping down.

### Method I

APPARATUS

The apparatus (*Figure 3*) consists of the following:

- A 250-mL graduated cylinder (readable to 2 mL with a mass of 220 ± 44 g)
- A settling apparatus capable of producing, in 1 min, either nominally 250 ± 15 taps from a height of 3 ± 0.2 mm, or nominally 300 ± 15 taps from a height of 14 ± 2 mm. The support for the graduated cylinder, with its holder, has a mass of 450 ± 10 g.

DOI: https://doi.org/10.31003/USPNF_M99375_01_01
@2024 USPC

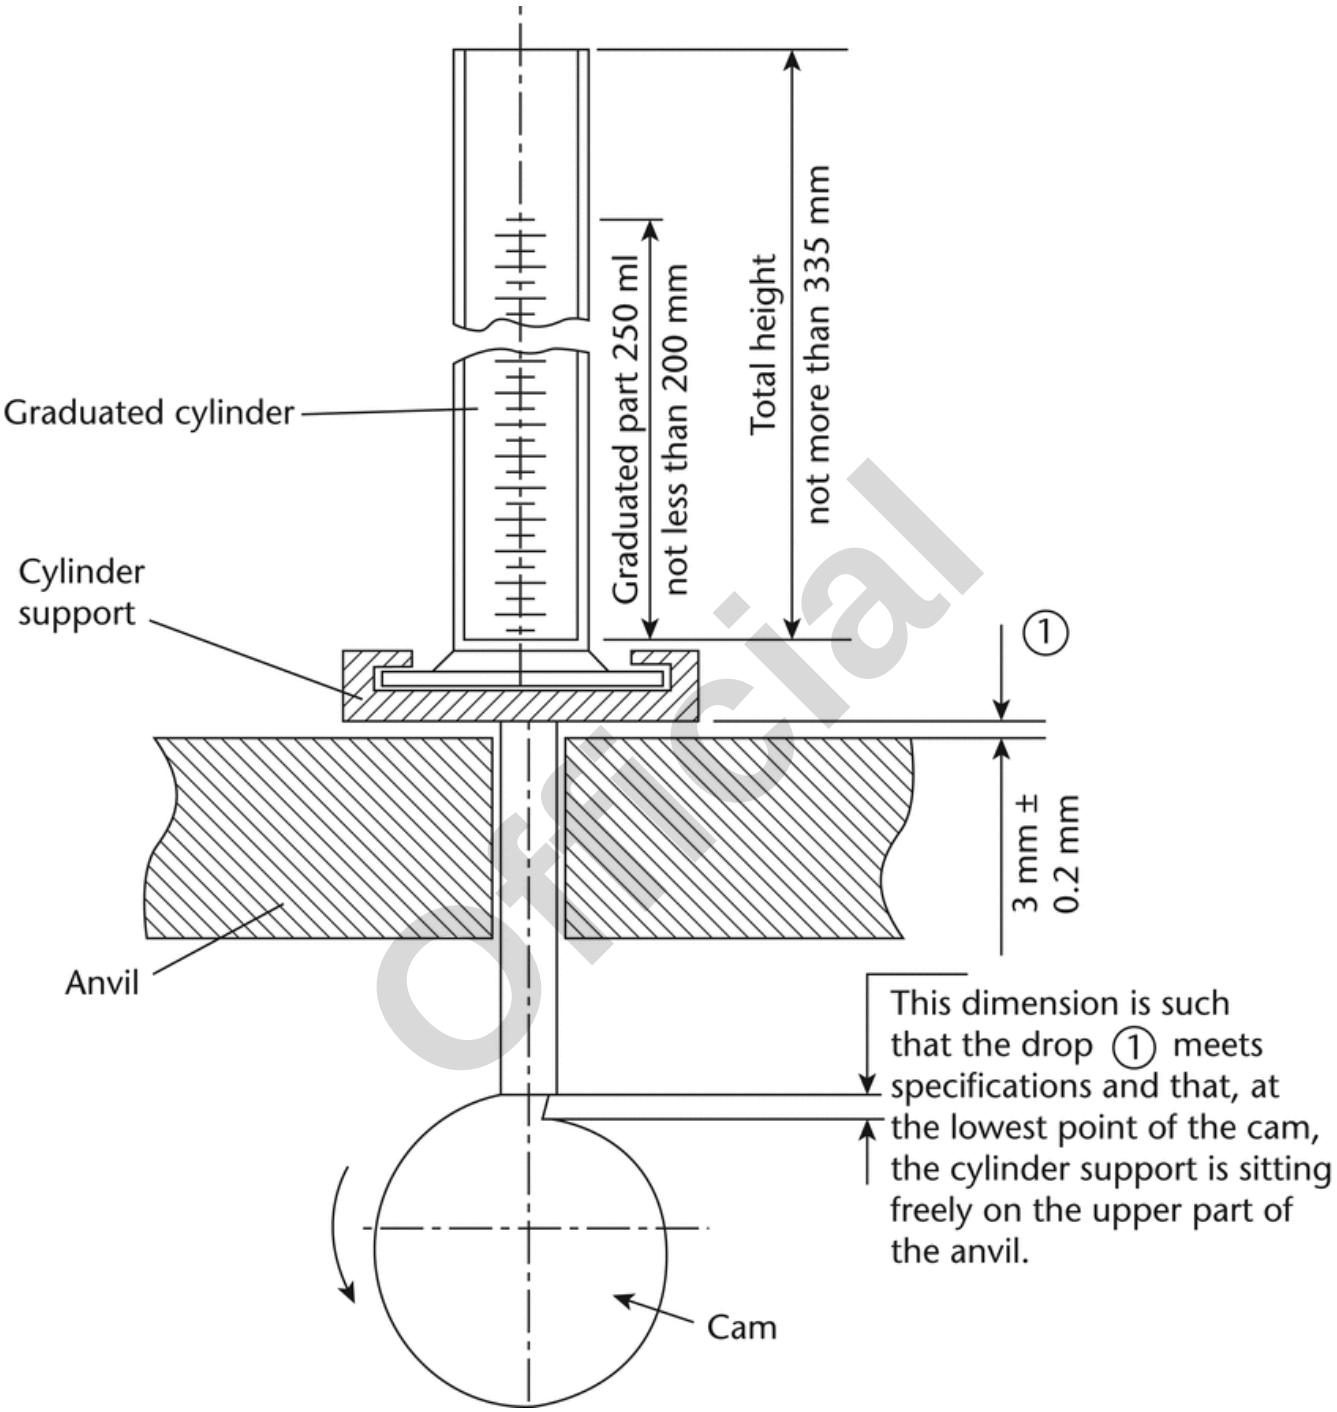

Figure 3.

PROCEDURE

Proceed as described above for the determination of the bulk volume ($V_0$). Secure the cylinder in the holder. Carry out 10, 500, and 1250 taps on the same powder sample and read the corresponding volumes $V_{10}$, $V_{500}$, and $V_{1250}$ to the nearest graduated unit. If the difference between $V_{500}$ and $V_{1250}$ is less than or equal to 2 mL, $V_{1250}$ is the tapped volume. If the difference between $V_{500}$ and $V_{1250}$ exceeds 2 mL, repeat in increments such as 1250 taps, until the difference between succeeding measurements is less than or equal to 2 mL. Fewer taps may be appropriate for some powders, when validated. Calculate the tapped density (g/mL) using the formula $m/V_F$, in which $V_F$ is the final tapped volume. Generally, replicate determinations are desirable for the determination of this property. Specify the drop height with the results. If it is not possible to use a 100-g test sample, use a reduced amount and a suitable 100-mL graduated cylinder (readable to 1 mL) weighing 130 ± 16 g and mounted on a holder weighing 240 ± 12 g. If the difference between $V_{500}$ and $V_{1250}$ is less than or equal to 1 mL, $V_{1250}$ is the tapped

volume. If the difference between $V_{500}$ and $V_{1250}$ exceeds 1 mL, repeat in increments such as 1250 taps, until the difference between succeeding measurements is less than or equal to 1 mL. The modified test conditions are specified in the expression of the results.

### Method II

APPARATUS and PROCEDURE

Proceed as directed under *Method I* except that the mechanical tester provides a fixed drop of 3 ± 0.2 mm at a nominal rate of 250 taps per min.

### Method III

APPARATUS and PROCEDURE

Proceed as directed in *Method III—Measurement in a Vessel* for measuring bulk density using the measuring vessel equipped with the cap shown in *Figure 2*. The measuring vessel with the cap is lifted 50–60 times per min by the use of a suitable tapped density tester. Carry out 200 taps, remove the cap, and carefully scrape excess powder from the top of the measuring vessel as described in *Method III—Measurement in a Vessel* for measuring the bulk density. Repeat the procedure using 400 taps. If the difference between the two masses obtained after 200 and 400 taps exceeds 2%, carry out a test using 200 additional taps until the difference between succeeding measurements is less than 2%. Calculate the tapped density (g/mL) using the formula $M_F/100$, where $M_F$ is the mass of powder in the measuring vessel. Record the average of three determinations using three different powder samples. The test conditions including tapping height are specified in the expression of the results.

## MEASURES OF POWDER COMPRESSIBILITY

Because the interparticulate interactions influencing the bulking properties of a powder are also the interactions that interfere with powder flow, a comparison of the bulk and tapped densities can give a measure of the relative importance of these interactions in a given powder. Such a comparison is often used as an index of the ability of the powder to flow, for example the *Compressibility Index* or the *Hausner Ratio* as described below.

The *Compressibility Index* and *Hausner Ratio* are measures of the propensity of a powder to be compressed as described above. As such, they are measures of the powder's ability to settle, and they permit an assessment of the relative importance of interparticulate interactions. In a free-flowing powder, such interactions are less significant, and the bulk and tapped densities will be closer in value. For poorer flowing materials, there are frequently greater interparticle interactions, and a greater difference between the bulk and tapped densities will be observed. These differences are reflected in the *Compressibility Index* and the *Hausner Ratio*.

### Compressibility Index

Calculate by the formula:

$$100(V_0 - V_F)/V_0$$

$V_0$ = unsettled apparent volume
$V_F$ = final tapped volume

### Hausner Ratio

$$V_0/V_F$$

Depending on the material, the compressibility index can be determined using $V_{10}$ instead of $V_0$. [NOTE—If $V_{10}$ is used, it will be clearly stated in the results.]

# ⟨621⟩ CHROMATOGRAPHY

***Change to read:***

**(The sections *System Sensitivity* and *Peak Symmetry* will become official on ▲May 1, 2025▲** (RB 1-Oct-2023) **as indicated.)**

To view the Notice from the Expert Committee that posted in conjunction with this accelerated revision, please click https://www.uspnf.com/rb-gc-621-20230929.

## INTRODUCTION

Chromatographic separation techniques are multistage separation procedures in which the components of a sample are distributed between two phases, one of which is stationary while the other is mobile. The stationary phase may be a solid or a liquid supported on a solid or a gel. The stationary phase may be packed in a column, spread as a layer, or distributed as a film, etc. The mobile phase may be gaseous or liquid or supercritical fluid. The separation may be based on adsorption, mass distribution (partition), ion exchange, etc., or may be based on differences in the physicochemical properties of the molecules such as size, mass, volume, etc.

Portions of the present general chapter text that are national *USP–NF* text, and therefore not part of the harmonized text, are marked with symbols (♦♦) to specify this fact.

♦This chapter describes general procedures, definitions, and calculations of common parameters and generally applicable requirements for system suitability.

The types of chromatography useful in qualitative and quantitative analysis employed in USP procedures are column, gas, paper, thin-layer (including high-performance thin-layer chromatography), and pressurized liquid chromatography (commonly called high-pressure or high-performance liquid chromatography).

## GENERAL PROCEDURES

This section describes the basic procedures used when a chromatographic method is described in a monograph. The following procedures are followed unless otherwise indicated in the individual monograph.

### Paper Chromatography

#### STATIONARY PHASE

The stationary phase is a sheet of paper of suitable texture and thickness. Development may be ascending, in which the solvent is carried up the paper by capillary forces, or descending, in which the solvent flow is also assisted by gravitational force. The orientation of paper grain with respect to solvent flow is to be kept constant in a series of chromatograms. (The machine direction is usually designated by the manufacturer.)

#### APPARATUS

The essential equipment for paper chromatography consists of a vapor-tight chamber with inlets for addition of solvent and a rack of corrosion-resistant material about 5 cm shorter than the inside height of the chamber. The rack serves as a support for solvent troughs and for antisiphon rods that, in turn, hold up the chromatographic sheets. The bottom of the chamber is covered with the prescribed solvent system or mobile phase. Saturation of the chamber with solvent vapor is facilitated by lining the inside walls with paper wetted with the prescribed solvent system.

#### SPOTTING

The substance or substances analyzed are dissolved in a suitable solvent. Convenient volumes delivered from suitable micropipets of the resulting solution, normally containing 1–20 µg of the compound, are placed in 6- to 10-mm spots not less than 3 cm apart.

#### DESCENDING PAPER CHROMATOGRAPHY PROCEDURE

1. A spotted chromatographic sheet is suspended in the apparatus, using the antisiphon rod to hold the upper end of the sheet in the solvent trough. [NOTE—Ensure that the portion of the sheet hanging below the rods is freely suspended in the chamber without touching the rack, the chamber walls, or the fluid in the chamber.]
2. The chamber is sealed to allow equilibration (saturation) of the chamber and the paper with the solvent vapor. Any excess pressure is released as necessary.
3. After equilibration of the chamber, the prepared mobile phase is introduced into the trough through the inlet.
4. The inlet is closed, and the mobile solvent phase is allowed to travel the desired distance down the paper.
5. The sheet is removed from the chamber.
6. The location of the solvent front is quickly marked, and the sheet is dried.
7. The chromatogram is observed and measured directly or after suitable development to reveal the location of the spots of the isolated drug or drugs.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99380_08_01
@2024 USPC

### ASCENDING PAPER CHROMATOGRAPHY PROCEDURE

1. The mobile phase is added to the bottom of the chamber.
2. The chamber is sealed to allow equilibration (saturation) of the chamber and the paper with the solvent vapor. Any excess pressure is released as necessary.
3. The lower edge of the stationary phase is dipped into the mobile phase to permit the mobile phase to rise on the chromatographic sheet by capillary action.
4. When the solvent front has reached the desired height, the chamber is opened, the sheet is removed, the location of the solvent front is quickly marked, and the sheet is dried.
5. The chromatogram is observed and measured directly or after suitable development to reveal the location of the spots of the isolated drug or drugs.

## Thin-Layer Chromatography

### STATIONARY PHASE

The stationary phase is a relatively thin, uniform layer of dry, finely powdered material applied to a glass, plastic, or metal sheet or plate (typically called the plate). The stationary phase of thin-layer chromatography (TLC) plates has an average particle size of 10–15 µm, and that of high-performance TLC (HPTLC) plates has an average particle size of 5 µm. Commercial plates with a preadsorbent zone can be used if they are specified in a monograph. Sample applied to the preadsorbent region develops into sharp, narrow bands at the preadsorbent–sorbent interface. The separations achieved may be based on adsorption, partition, or a combination of both effects, depending on the particular type of stationary phase.

### APPARATUS

A chromatographic chamber made of inert, transparent material and having the following specifications is used: a flat-bottom or twin trough, a tightly fitted lid, and a size suitable for the plates. The chamber is lined on at least one wall with filter paper. Sufficient mobile phase or developing solvent is added to the chamber so that, after impregnation of the filter paper, a depth appropriate to the dimensions of the plate used is available. The chromatographic chamber is closed and allowed to equilibrate. [NOTE—Unless otherwise indicated, the chromatographic separations are performed in a saturated chamber.]

### DETECTION/VISUALIZATION

An ultraviolet (UV) light source suitable for observations under short- (254 nm) and long- (365 nm) wavelength UV light and a variety of spray reagents to make spots visible are often used.

### SPOTTING

Solutions are spotted on the surface of the stationary phase (plate) at the prescribed volume in sufficiently small portions to obtain circular spots of 2–5 mm in diameter (1–2 mm on HPTLC plates) or bands of 10–20 mm × 1–2 mm (5–10 mm × 0.5–1 mm on HPTLC plates) at an appropriate distance from the lower edge and sides of the plate. [NOTE—During development, the application position must be at least 5 mm (TLC) or 3 mm (HPTLC) above the level of the mobile phase.] The solutions are applied on a line parallel to the lower edge of the plate with an interval of at least 10 mm (5 mm on HPTLC plates) between the centers of spots, or 4 mm (2 mm on HPTLC plates) between the edges of bands, then allowed to dry.

### PROCEDURE

1. Place the plate in the chamber, ensuring that the spots or bands are above the surface of the mobile phase.
2. Close the chamber.
3. Allow the mobile phase to ascend the plate until the solvent front has traveled three-quarters of the length of the plate, or the distance prescribed in the monograph.
4. Remove the plate, mark the solvent front with a pencil, and allow to dry.
5. Visualize the chromatograms as prescribed.
6. Determine the chromatographic *retardation factor* ($R_F$) values for the principal spots or zones.
7. Presumptive identification can be made by observation of spots or zones of identical $R_F$ value and about equal magnitude obtained, respectively, with an unknown and a standard chromatographed on the same plate. A visual comparison of the size or intensity of the spots or zones may serve for semiquantitative estimation. Quantitative measurements are possible by means of densitometry (absorbance or fluorescence measurements).

## Column Chromatography

### SOLID SUPPORT

Purified siliceous earth is used for normal-phase separation. Silanized chromatographic siliceous earth is used for reverse-phase partition chromatography.

Official

https://pharmacopeia.com/

### STATIONARY PHASE

The solid support is modified by the addition of a stationary phase specified in the individual monograph. If a mixture of liquids is used as the stationary phase, mix the liquids before the introduction of the solid support.

### MOBILE PHASE

The mobile phase is specified in the individual monograph. If the stationary phase is an aqueous solution, equilibrate with water. If the stationary phase is a polar organic fluid, equilibrate with that fluid.

### APPARATUS

Unless otherwise specified in the individual monograph, the chromatographic tube is about 22 mm in inside diameter and 200–300 mm in length. Attached to it is a delivery tube, without stopcock, about 4 mm in inside diameter and about 50 mm in length.

**Apparatus preparation:** Pack a pledget of fine glass wool in the base of the tube. Combine the specified volume of stationary phase and the specified amount of solid support to produce a homogeneous, fluffy mixture. Transfer this mixture to the chromatographic tube, and tamp using gentle pressure to obtain a uniform mass. If the specified amount of solid support is more than 3 g, transfer the mixture to the column in portions of approximately 2 g, and tamp each portion. If the assay or test requires a multisegment column with a different stationary phase specified for each segment, tamp after the addition of each segment, and add each succeeding segment directly to the previous one. Pack a pledget of fine glass wool above the completed column packing. [NOTE—The mobile phase should flow through a properly packed column as a moderate stream or, if reverse-phase chromatography is applied, as a slow trickle.]

If a solution of the analyte is incorporated into the stationary phase, complete the quantitative transfer to the chromatographic tube by scrubbing the beaker used for the preparation of the test mixture with a mixture of about 1 g of solid support and several drops of the solvent used to prepare the sample solution before adding the final portion of glass wool.

### PROCEDURE

1. Transfer the mobile phase to the column space above the column packing, and allow it to flow through the column under the influence of gravity.
2. Rinse the tip of the chromatographic column with about 1 mL of mobile phase before each change in composition of mobile phase and after completion of the elution.
3. If the analyte is introduced into the column as a solution in the mobile phase, allow it to pass completely into the column packing, then add mobile phase in several small portions, allowing each to drain completely, before adding the bulk of the mobile phase.
4. Where the procedure indicates the use of multiple chromatographic columns mounted in series and the addition of mobile phase in divided portions is specified, allow each portion to drain completely through each column, and rinse the tip of each with mobile phase before the addition of each succeeding portion.

## Gas Chromatography (GC)

### LIQUID STATIONARY PHASE

This type of phase is available in packed or capillary columns.

### PACKED COLUMN GC

The liquid stationary phase is deposited on a finely divided, inert solid support, such as diatomaceous earth, porous polymer, or graphitized carbon, which is packed into a column that is typically 2–4 mm in internal diameter and 1–3 m in length.

### CAPILLARY COLUMN GC

In capillary columns, which contain no packed solid support, the liquid stationary phase is deposited on the inner surface of the column and may be chemically bonded to it.

### SOLID STATIONARY PHASE

This type of phase is available only in packed columns. In these columns the solid phase is an active adsorbent, such as alumina, silica, or carbon, packed into a column. Polyaromatic porous resins, which are sometimes used in packed columns, are not coated with a liquid phase. [NOTE—Packed and capillary columns must be conditioned before use until the baseline and other characteristics are stable. The column or packing material supplier provides instructions for the recommended conditioning procedure.]

### APPARATUS

A gas chromatograph consists of a carrier gas source, injection port, column, detector, and recording device. The injection port, column, and detector are temperature controlled and may be varied as part of the analysis. The typical carrier gas is helium, nitrogen, or hydrogen, depending on the column and detector in use. The type of detector used depends on the nature of the

compounds analyzed and is specified in the individual monograph. Detector output is recorded as a function of time, and the instrument response, measured as peak area or peak height, is a function of the amount present.

### TEMPERATURE PROGRAM

The length and quality of a GC separation can be controlled by altering the temperature of the chromatographic column. When a temperature program is necessary, the individual monograph indicates the conditions in table format. The table indicates the initial temperature, rate of temperature change (ramp), final temperature, and hold time at the final temperature.

### PROCEDURE

1. Equilibrate the column, injector, and detector with flowing carrier gas until a constant signal is received.
2. Inject a sample through the injector septum, or use an autosampler.
3. Begin the temperature program.
4. Record the chromatogram.
5. Analyze as indicated in the monograph.

## Liquid Chromatography

The term "liquid chromatography" (LC), as used in the compendia, is synonymous with high-pressure liquid chromatography and high-performance liquid chromatography. LC is a separation technique based on a solid stationary phase and a liquid mobile phase.

### STATIONARY PHASE

Separations are achieved by partition, adsorption, or ion-exchange processes, depending on the type of stationary phase used. The most commonly used stationary phases are modified silica or polymeric beads. The beads are modified by the addition of long-chain hydrocarbons. The specific type of packing needed to complete an analysis is indicated by the “L” designation in the individual monograph (see also the section *Chromatographic Columns*). The size of the beads is often described in the monograph as well. Changes in the packing type and size are covered in the *System Suitability* section of this chapter.

### CHROMATOGRAPHIC COLUMN

The term "column" includes stainless steel, lined stainless steel, and polymeric columns, packed with a stationary phase. The length and inner diameter of the column affects the separation, and therefore typical column dimensions are included in the individual monograph. Changes to column dimensions are discussed in the *System Suitability* section of this chapter. Compendial monographs do not include the name of appropriate columns; this omission avoids the appearance of endorsement of a vendor’s product and natural changes in the marketplace. See the section *Chromatographic Columns* for more information.

In LC procedures, a guard column may be used with the following requirements, unless otherwise is indicated in the individual monograph: (a) the length of the guard column must be NMT 15% of the length of the analytical column, (b) the inner diameter must be the same or smaller than that of the analytical column, and (c) the packing material should be the same as the analytical column (e.g., silica) and contain the same bonded phase (e.g., C18). In any case, all system suitability requirements specified in the official procedure must be met with the guard column installed.

### MOBILE PHASE

The mobile phase is a solvent or a mixture of solvents, as defined in the individual monograph.

### APPARATUS

A liquid chromatograph consists of a reservoir containing the mobile phase, a pump to force the mobile phase through the system at high pressure, an injector to introduce the sample into the mobile phase, a chromatographic column, a detector, and a data collection device.

### GRADIENT ELUTION

The technique of continuously changing the solvent composition during the chromatographic run is called gradient elution or solvent programming. The gradient elution profile is presented in the individual monograph as a gradient table, which lists the time and proportional composition of the mobile phase at the stated time.

### PROCEDURE

1. Equilibrate the column and detector with mobile phase at the specified flow rate until a constant signal is received.
2. Inject a sample through the injector, or use an autosampler.
3. Begin the gradient program.
4. Record the chromatogram.
5. Analyze as directed in the monograph.

## CHROMATOGRAPHIC COLUMNS

A complete list of packings (L), phases (G), and supports (S) used in *USP–NF* tests and assays is located in *USP–NF*, Reagents, Indicators, and Solutions—Chromatographic Columns. This list is intended to be a convenient reference for the chromatographer in identifying the pertinent chromatographic column specified in the individual monograph.♦

## DEFINITIONS

The system suitability and acceptance criteria in monographs have been set using parameters as defined below. With some equipment, certain parameters, such as the signal-to-noise ratio and resolution, can be calculated using software provided by the manufacturer. It is the responsibility of the user to ensure that the calculation methods used in the software are equivalent to the requirements of the *US Pharmacopeia* and to make any necessary corrections if this is not the case.

**Chromatogram:** A graphical or other representation of detector response, effluent concentration, or other quantity used as a measure of effluent concentration versus time or volume. Idealized chromatograms are represented as a sequence of Gaussian peaks on a baseline (*Figure 1*).

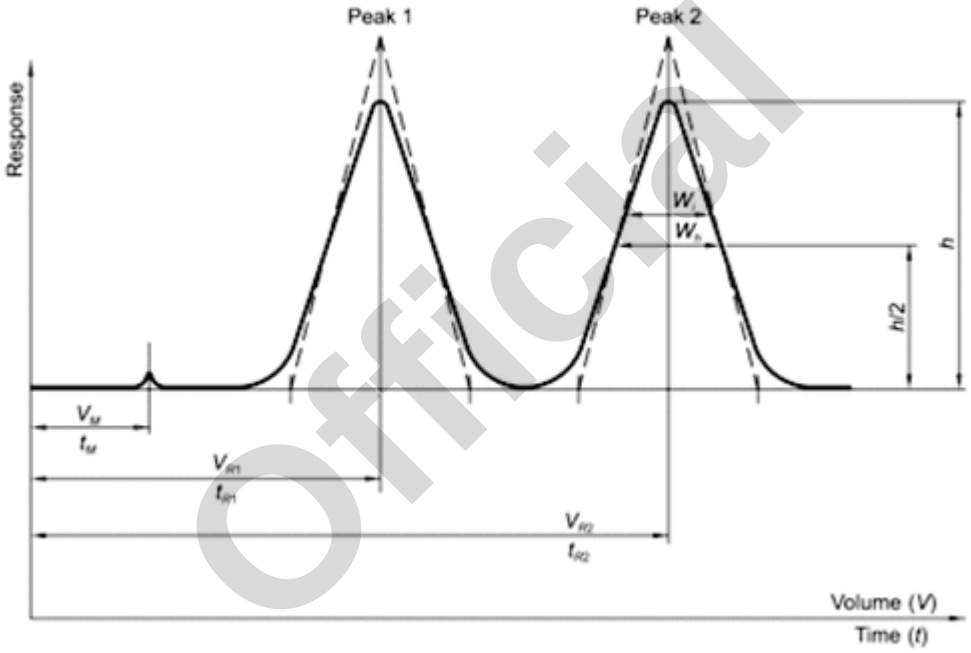

Figure 1.

$V_M$ = hold-up volume
$t_M$ = hold-up time
$V_{R1}$ = retention volume of peak 1
$t_{R1}$ = retention time of peak 1
$V_{R2}$ = retention volume of peak 2
$t_{R2}$ = retention time of peak 2
$W_h$ = peak width at half-height
$W_i$ = peak width at the inflection point
$h$ = height of the peak
$h/2$ = half-height of peak

**Distribution constant ($K_0$):** In size-exclusion chromatography, the elution characteristics of a component in a particular column may be given by the distribution constant (also referred to as distribution coefficient), which is calculated using the following equation:

$$K_0 = \frac{t_R - t_0}{t_t - t_0}$$

$t_R$ = retention time
$t_0$ = retention time of an unretained compound
$t_t$ = total mobile phase time

DOI: https://doi.org/10.31003/USPNF_M99380_08_01
@2024 USPC

**Dwell volume (*D*) (also referred to as $V_D$):** The dwell volume (also known as gradient delay volume) is the volume between the point at which the eluents meet and the inlet of the column. It can be determined using the following procedure.

COLUMN: Replace the chromatographic column by an appropriate capillary tubing (e.g., 1 m × 0.12 mm).

MOBILE PHASE: See *Table 1*.

MOBILE PHASE A: Water

MOBILE PHASE B: 0.1% v/v solution of acetone in water

**Table 1**

| Time (min) | Mobile phase A (% v/v) | Mobile phase B (% v/v) |
|---|---|---|
| 0–20 | 100→0 | 0→100 |
| 20–30 | 0 | 100 |

FLOW RATE: Set to obtain sufficient back-pressure (e.g., 2 mL/min).

DETECTION: Spectrophotometer at 265 nm

Determine the time ($t_{0.5}$), in minutes, when the absorbance has increased by 50% (*Figure 2*).

$$D = t_D \times F$$

$t_D$ = $t0.5 — 0.5tG$ (min)
$t_G$ = pre-defined gradient time, 20 min
$F$ = flow rate (mL/min)

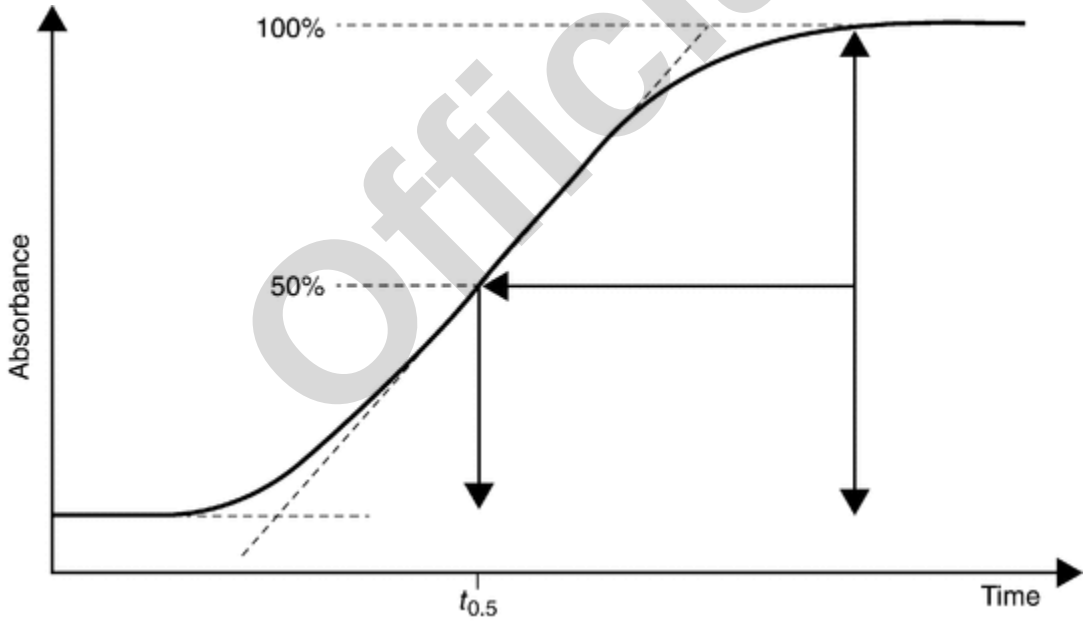

Figure 2.

[NOTE—where applicable, this measurement is performed with the autosampler in the "inject" position so as to include the injection loop volume in the dwell volume.]

**Hold-up time ($t_M$):** Time required for elution of an unretained component (see *Figure 1*, baseline scale being in minutes or seconds).

In size-exclusion chromatography, the term retention time of an unretained compound ($t_0$) is used.

**Hold-up volume ($V_M$):** Volume of the mobile phase required for elution of an unretained component. It may be calculated from the hold-up time and the flow rate ($F$) in milliliters per minute using the following equation:

$$V_M = t_M \times F$$

In size-exclusion chromatography, the term "retention volume" of an unretained compound $V_0$ is used.

**Peak:** Portion of a chromatogram recording the detector response when a single component (or two or more unresolved components) is eluted from the column.

The peak response may be represented by the peak area or the peak height ($h$).

DOI: https://doi.org/10.31003/USPNF_M99380_08_01
@2024 USPC

**Peak-to-Valley Ratio (*p*/*v*):** The peak-to-valley ratio may be employed as a system suitability criterion when baseline separation between two peaks is not achieved (see *Figure 3*).

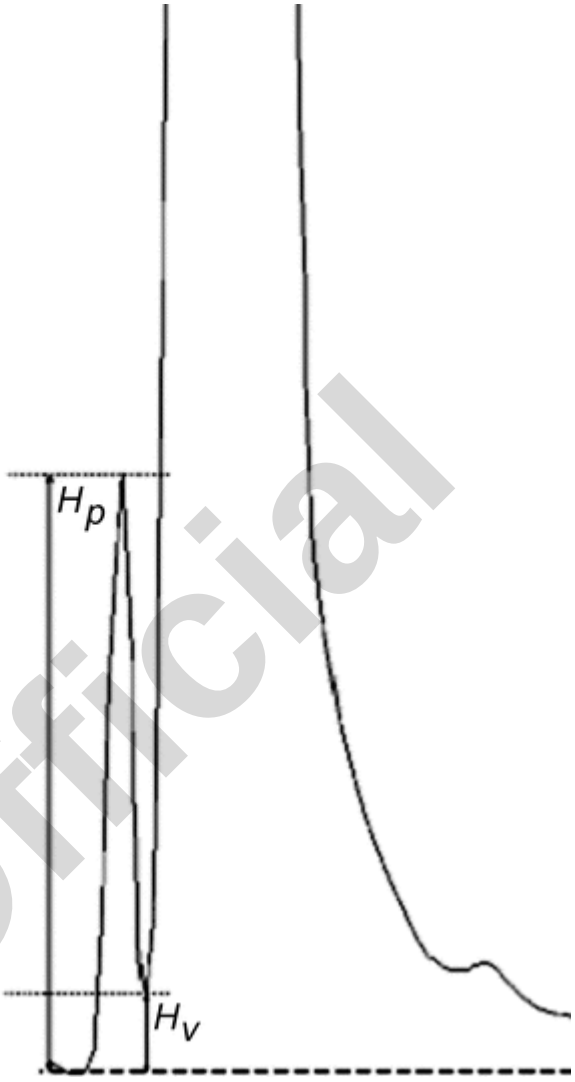

Figure 3.

$$p/v = \frac{H_p}{H_v}$$

$H_p$ = height above the extrapolated baseline of the minor peak
$H_v$ = height above the extrapolated baseline at the lowest point of the curve separating the minor and major peaks

**Plate height (*H*) (height equivalent to one theoretical plate [HETP]):** Ratio of the column length (*L*), in micrometers, to the plate number (*N*):

$$H = \frac{L}{N}$$

**Plate number (*N*) (number of theoretical plates):** A number indicative of column performance (column efficiency) can only be calculated from data obtained under either isothermal, isocratic, or isodense conditions, depending on the technique, as the plate number, using the following equation, the values of $t_R$ and $W_h$ being expressed in the same units:

$$N = 5.54 \left(\frac{t_R}{W_h}\right)^2$$

$t_R$ = retention time of the peak corresponding to the component
$W_h$ = peak width at half-height ($h$/2)

Official

https://pharmacopeia.cn/v29240/

The plate number varies with the component as well as with the column, the column temperature, the mobile phase, and the retention time.

**Reduced plate height (*h*):** Ratio of the plate height (*H*), in micrometers, to the particle diameter ($d_p$) in micrometers:

$$h = \frac{H}{d_p}$$

**Relative retardation ($R_{rel}$):** The relative retardation, used in thin-layer chromatography, is calculated as the ratio of the distances travelled by the spot of the compound of interest and a reference compound (*Figure 4*).

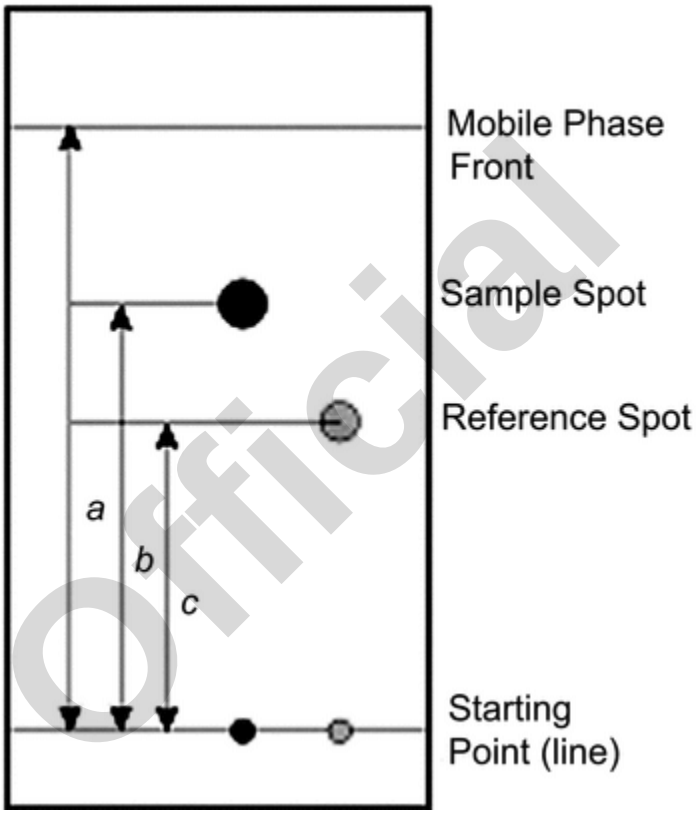

Figure 4.

$$R_{rel} = b/c$$

*a* = migration distance of the mobile phase
*b* = migration distance of the compound of interest
*c* = migration distance of the reference compound

**Relative retention (*r*):** Relative retention is calculated as an estimate using the following equation:

$$r = \frac{t_{Ri} - t_M}{t_{Rst} - t_M}$$

$t_{Ri}$ = retention time of the peak of interest
$t_{Rst}$ = retention time of the reference peak (usually the peak corresponding to the substance to be examined)
$t_M$ = hold-up time

### Relative retention, unadjusted ($r_G$)♦or (RRT)♦

The unadjusted relative retention is calculated using the following equation:

$$r_G = \frac{t_{Ri}}{t_{Rst}}$$

Official

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99380_08_01
@2024 USPC

Unless otherwise indicated, values for relative retention stated in monographs correspond to unadjusted relative retention.

♦**Relative retention time (RRT):** See *Relative retention, unadjusted*♦

**Resolution ($R_s$):** The resolution between peaks of two components (*Figure 1*) may be calculated using the following equation:

$$R_S = \frac{1.18(t_{R2} - t_{R1})}{W_{h1} + W_{h2}}$$
$$t_{R2} > t_{R1}$$

$t_{R1}$, $t_{R2}$ = retention times of the peaks
$W_{h1}$, $W_{h2}$ = peak widths at half-height

In quantitative thin-layer chromatography, using densitometry, the migration distances are used instead of retention times and the resolution between peaks of two components may be calculated using the following equation:

$$R_S = \frac{1.18a(R_{F2} - R_{F1})}{W_{h1} + W_{h2}}$$
$$R_{F2} > R_{F1}$$

$R_{F1}$, $R_{F2}$ = retardation factors of the peaks
$W_{h1}$, $W_{h2}$ = peak widths at half-height
$a$ = migration distance of the solvent front

**Retardation factor ($R_F$):** The retardation factor, used in thin-layer chromatography, is the ratio of the distance from the point of application to the center of the spot and the distance simultaneously travelled by the solvent front from the point of application (*Figure 4*).

$$R_F = \frac{b}{a}$$

$b$ = migration distance of the component
$a$ = migration distance of the solvent front

**Retention factor ($k$):** The retention factor (also known as mass distribution ratio ($D_m$) or capacity factor ($k'$)) is defined as:

$$k = \frac{amount\ of\ component\ in\ stationary\ phase}{amount\ of\ component\ in\ mobile\ phase} = K_C \frac{V_S}{V_M}$$

$K_C$ = distribution constant (also known as equilibrium distribution coefficient)
$V_S$ = volume of the stationary phase
$V_M$ = volume of the mobile phase

The retention factor of a component may be determined from the chromatogram using the following equation:

$$k = \frac{t_R - t_M}{t_M}$$

$t_R$ = retention time
$t_M$ = hold-up time

**Retention time ($t_R$):** Time elapsed between the injection of the sample and the appearance of the maximum peak response of the eluted sample zone (*Figure 1*, baseline scale being in minutes or seconds).

**Retention volume ($V_R$):**

Volume of the mobile phase required for elution of a component. It may be calculated from the retention time and the flow rate ($F$), in milliliters per minute, using the following equation:

$$V_R = t_R \times F$$

**Retention time of an unretained compound ($t_0$):** In size-exclusion chromatography, retention time of a component whose molecules are larger than the largest gel pores (*Figure 5*).

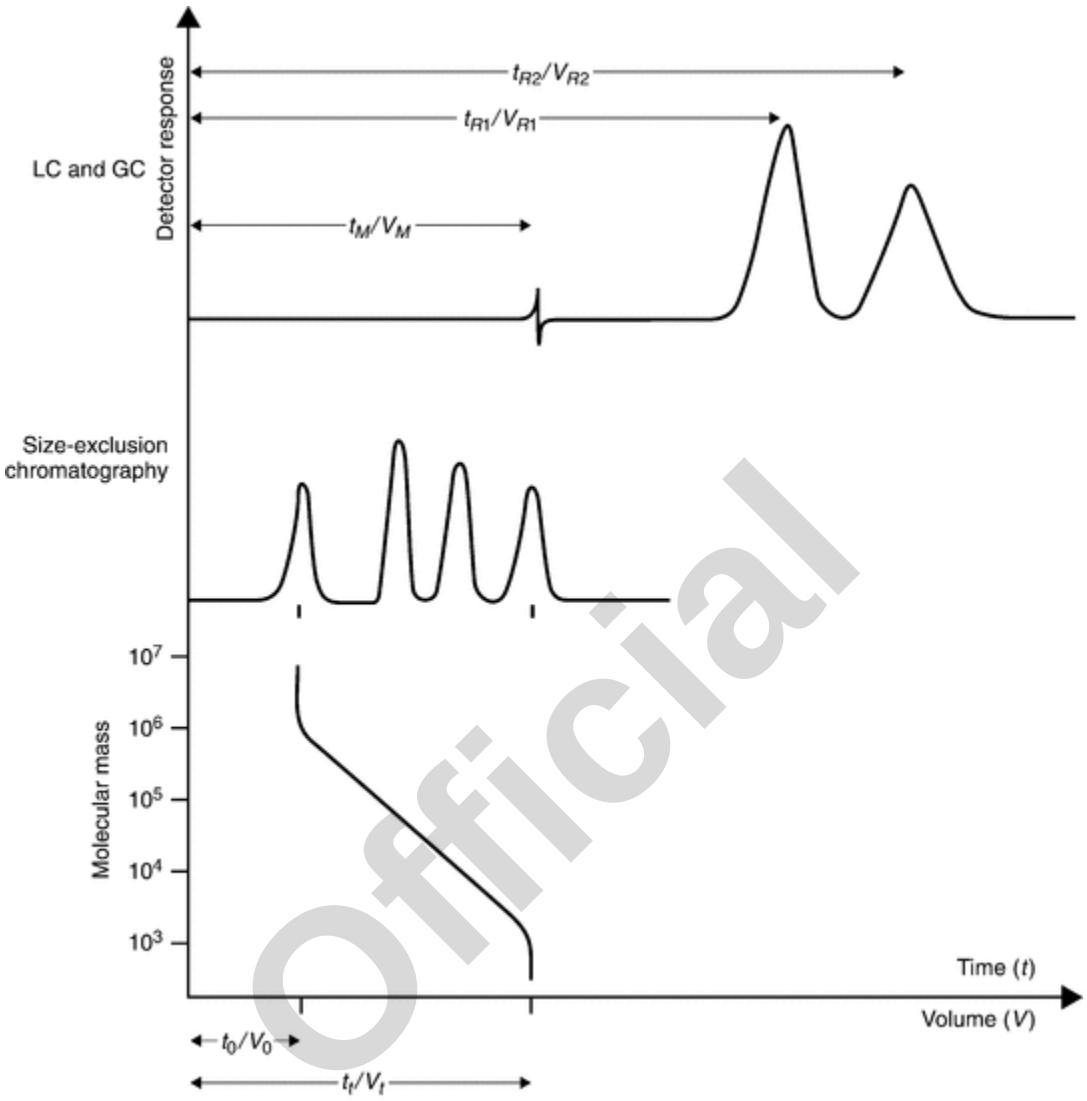

Figure 5.

**Retention volume of an unretained compound ($V_0$):** In size-exclusion chromatography, retention volume of a component whose molecules are larger than the largest gel pores. It may be calculated from the retention time of an unretained compound and the flow rate ($F$), in milliliters per minute, using the following equation:

$$V_0 = t_0 \times F$$

**Separation factor ($\alpha$):** Relative retention calculated for two adjacent peaks (by convention, the value of the separation factor is always >1):

$$\alpha = k_2/k_1$$

$k_1$ = retention factor of the first peak
$k_2$ = retention factor of the second peak

**Signal-to-noise ratio ($S/N$):** The short-term noise influences the precision and accuracy of quantitation. The signal-to-noise ratio is calculated using the following equation:

$$S/N = \frac{2H}{h}$$

$H$ = height of the peak (*Figure 6*) corresponding to the component concerned, in the chromatogram obtained with the prescribed reference solution, measured from the maximum of the peak to the extrapolated baseline of the signal observed over a distance of at least 5 times the width at half-height

*h* = range of the noise in a chromatogram obtained after injection of a blank (*Figure 7*), observed over a distance of at least 5 times the width at half-height of the peak in the chromatogram obtained with the prescribed reference solution and, if possible, situated equally around the place where this peak would be found

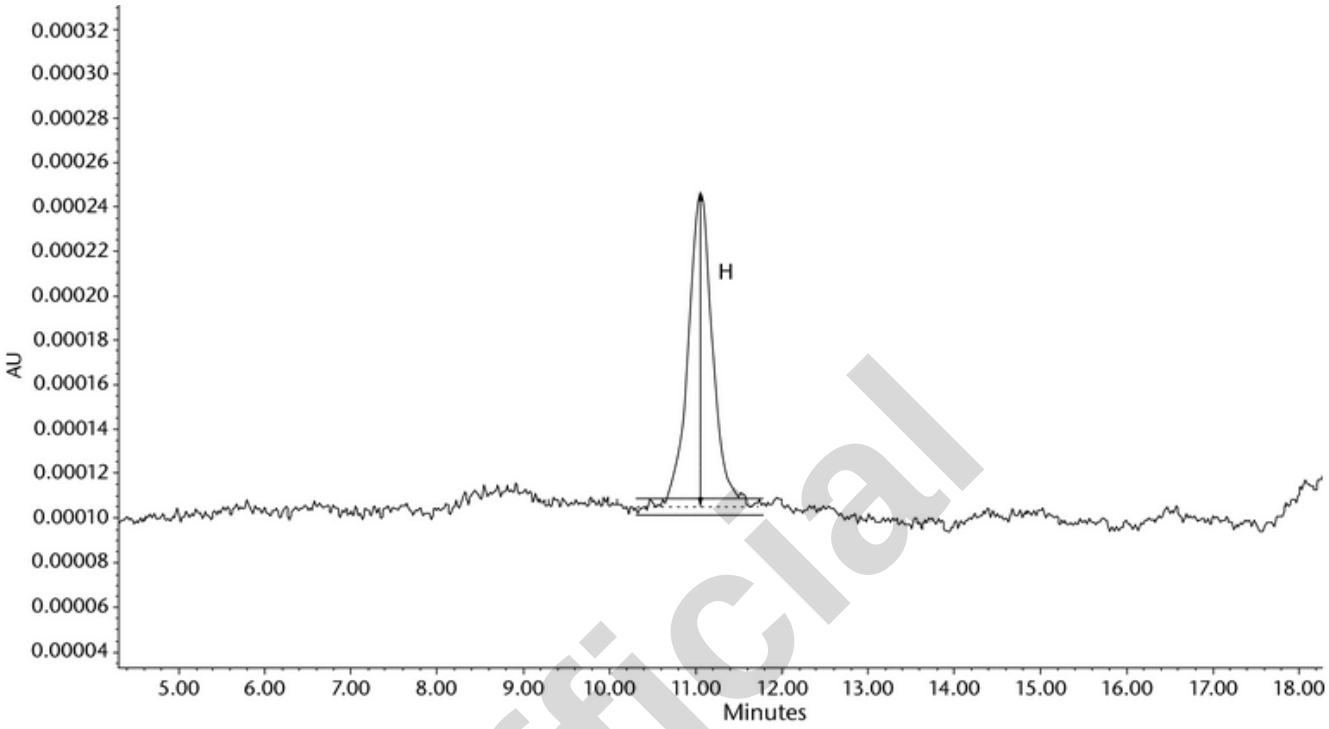

Figure 6. Chromatogram of the reference solution

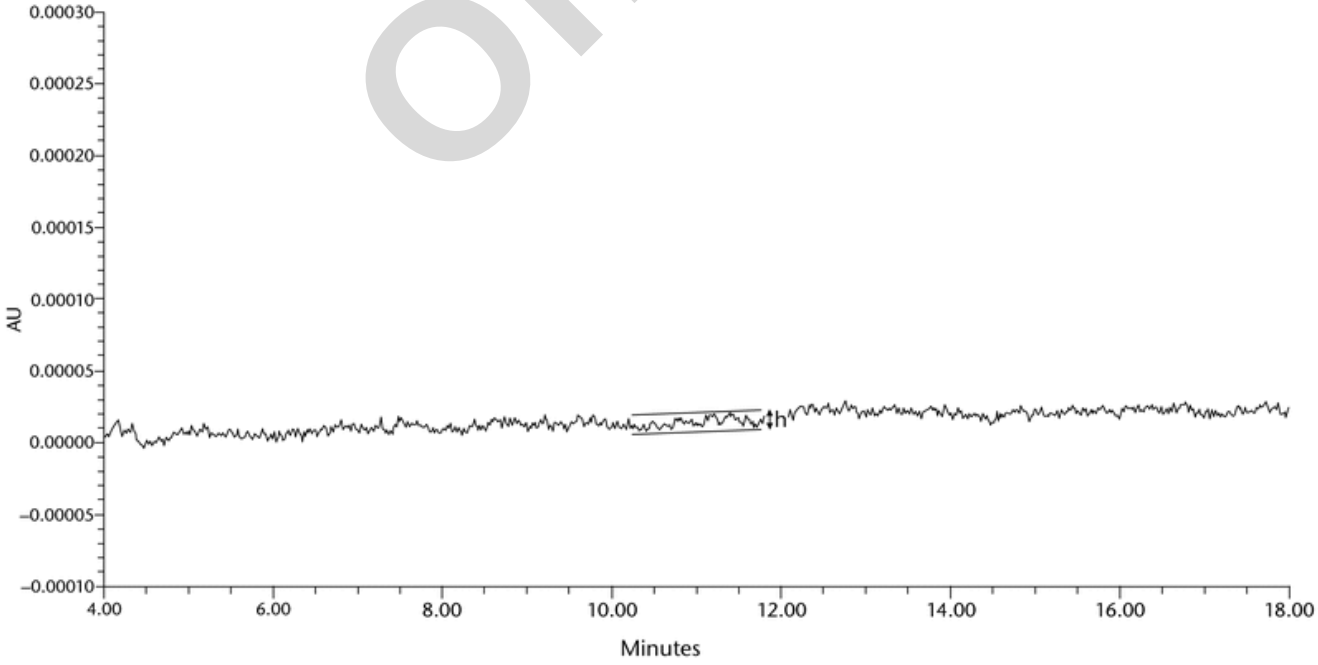

Figure 7.

**Symmetry factor ($A_S$):** The symmetry factor of a peak (also known as the asymmetry factor or tailing factor) (*Figure 8*) is calculated using the following equation:

@2024 USPC

$$A_s = \frac{W_{0.05}}{2d}$$

$W_{0.05}$ = width of the peak at one-twentieth of the peak height
$d$ = distance between the perpendicular dropped from the peak maximum and the leading edge of the peak at one-twentieth of the peak height

An $A_s$ value of 1.0 signifies symmetry. When $A_s > 1.0$, the peak is tailing. When $A_s < 1.0$, the peak is fronting.

Figure 8.

**System repeatability:** The repeatability of response is expressed as an estimated percentage relative standard deviation (%RSD) of a consecutive series of measurements for not fewer than three injections or applications of a reference solution, and is calculated using the following equation.

$$\%\,RSD = \frac{100}{\overline{y}}\sqrt{\frac{\Sigma(y_i - \overline{y})^2}{n-1}}$$

$y_i$ = individual values expressed as peak area, peak height, or ratio of areas by the internal standardization method
$\overline{y}$ = mean of individual values
$n$ = number of individual values

**Total mobile phase time ($t_t$):** In size-exclusion chromatography, retention time of a component whose molecules are smaller than the smallest gel pores (*Figure 5*).

**Total mobile phase volume ($V_t$):** In size-exclusion chromatography, retention volume of a component whose molecules are smaller than the smallest gel pores. It may be calculated from the total mobile phase time and the flow rate ($F$), in milliliters/minute, using the following equation:

$$V_t = t_t \times F$$

***Change to read:***

## SYSTEM SUITABILITY

[NOTE—This section only covers liquid chromatography and gas chromatography]

The various components of the equipment employed must be qualified and be capable of achieving the performance required to conduct the test or assay. The system suitability tests represent an integral part of the analytical procedure and are used to ensure adequate performance of the chromatographic system. Column plate number, retention factor (mass distribution ratio), system repeatability, signal-to-noise, symmetry factor, and resolution/peak-to-valley ratio are the parameters that may be employed in assessing the performance of the chromatographic system. When it is indicated in the individual monograph, in case of complex chromatographic profiles (e.g., for biotechnological and biological products) visual comparison of the profiles can be used as a system suitability test. Factors that may affect the chromatographic behavior include:

- Composition and temperature of the mobile phase
- Ionic strength and pH of the aqueous component, of the mobile phase
- Flow rate, column dimensions, column temperature, and pressure
- Stationary phase characteristics including, type of chromatographic support (particle-based or monolithic), particle or pore size, and porosity, and specific surface area
- Reverse phase and other surface modification of the stationary phases, the extent of chemical modification (as expressed by end-capping, carbon loading, etc.)

Retention times and relative retentions may be provided in monographs for information purposes only, unless otherwise stated in the monograph. There are no acceptance criteria applied to relative retentions.

Compliance with the system suitability criteria is required throughout the chromatographic procedure. No sample analysis is acceptable unless the suitability of the system has been demonstrated.

The following requirements are to be fulfilled, in addition to any other system suitability criteria stated in the monograph. When specific requirements are stated in the monograph, they supersede the requirements mentioned in this chapter.

## System Repeatability

♦When a relative standard deviation requirement is specified in an individual monograph, if the requirement is 2.0 or less the calculation is based on data from five replicate injections of the analyte, if the requirement is more than 2.0% data from six replicate injections are used.♦

In an assay of an active substance or an excipient, where the target value is 100% for a pure substance, and a system repeatability requirement is not specified, the maximum permitted relative standard deviation (%$RSD_{max}$) for the defined limits is calculated for a series ($n$ = 3 to 6) of injections of the reference solution. The maximum permitted relative standard deviation of the peak response does not exceed the appropriate value given in *Table 2*.

$$\%\,RSD_{\max} = \frac{KB\sqrt{n}}{t_{90\,\%,\,n-1}}$$

$K$ = constant (0.349), obtained from the expression $K = \frac{0.6}{\sqrt{2}} \times \frac{t_{90\,\%,\,n-1}}{\sqrt{6}}$ in which $\frac{0.6}{\sqrt{2}}$ represents the required percentage relative standard deviation determined on 6 injections for $B$ = 1.0
$B$ = upper limit given in the definition of the individual monograph minus 100%
$n$ = number of replicate injections of the reference solution ($3 \le n \le 6$)
$t_{90\%,n-1}$ = Student's $t$ at the 90% probability level (double sided) with $n$–1 degrees of freedom

**Table 2. Maximum Permitted Relative Standard Deviation of Peak Response (Assay)**

| | Number of Individual Injections ($n$) | | | |
|---|---|---|---|---|
| | 3 | 4 | 5 | 6 |
| $B$ (%) | Maximum Permitted Relative Standard Deviation (%) | | | |
| 2.0 | 0.41 | 0.59 | 0.73 | 0.85 |
| 2.5 | 0.52 | 0.74 | 0.92 | 1.06 |
| 3.0 | 0.62 | 0.89 | 1.10 | 1.27 |

$B$ = upper limit of content given in the individual monograph minus 100%

## ▲System Sensitivity

The signal-to-noise ratio is used to define the system sensitivity. The limit of quantitation (corresponding to a signal-to-noise ratio of 10) is equal to or less than the reporting threshold.

## Peak Symmetry

Unless otherwise stated, in a test or assay, the symmetry factor (tailing factor) of the peak used for quantification is 0.8–1.8.▲ (Official 1-May-2025)

# ADJUSTMENT OF CHROMATOGRAPHIC CONDITIONS

The chromatographic conditions described have been validated during the elaboration of the monograph.

The extent to which the various parameters of a chromatographic test may be adjusted without fundamentally modifying the pharmacopeial analytical procedures are listed below. Changes other than those indicated require revalidation of the procedure.

Multiple adjustments can have a cumulative effect on the performance of the system and are to be properly evaluated by the users. This is particularly important in cases where the separation pattern is described as a profile. In those cases, a risk assessment has to be carried out.

Any adjustments must be made on the basis of the pharmacopeial procedure.

If adjustments are made to a pharmacopeial procedure, additional verification tests may be required. To verify the suitability of the adjusted pharmacopeial procedure, assess the relevant analytical performance characteristics potentially affected by the change.

When a pharmacopeial procedure has been adjusted according to the requirements stated below, no further adjustments are allowed without appropriate revalidation.

Compliance with the system suitability criteria is required to verify that conditions for satisfactory performance of the test or assay are achieved.

Adjustment of conditions with gradient elution (HPLC) or temperature programming (GC) is more critical than with isocratic (HPLC) or isothermal (GC) elution, since it may shift some peaks to a different step of the gradient or to different elution temperatures, potentially causing partial or complete coelution of adjacent peaks or peak inversion, and, thus leading to the incorrect assignment of peaks and to the masking of peaks or a shift such that elution occurs beyond the prescribed elution time.

For some parameters the adjustments are explicitly defined in the monograph to ensure the system suitability.

## Thin-Layer Chromatography

*Composition of the mobile phase*: the amount of the minor solvent components may be adjusted by ±30% relative or ±2% absolute, whichever is the larger; no other component is altered by more than 10% absolute. A minor component comprises less than or equal to (100/*n*)%, *n* being the total number of components of the mobile phase. For a minor component at 10% of the mobile phase, a 30% relative adjustment allows a range of 7%–13% whereas a 2% absolute adjustment allows a range of 8%–12%, the relative value therefore being the larger; for a minor component at 5% of the mobile phase, a 30% relative adjustment allows a range of 3.5%–6.5% whereas a 2% absolute adjustment allows a range of 3%–7%, the absolute value being the larger in this case.

*pH of the aqueous component of the mobile phase*: ±0.2 pH units, unless otherwise prescribed

*Concentration of salts in the buffer component of a mobile phase*: ± 10%

*Application volume*: 10%–20% of the prescribed volume if using fine particle size plates (2–10 µm)

## Liquid Chromatography: Isocratic Elution

### COLUMN PARAMETERS AND FLOW RATE

*Stationary phase*: No change of the identity of the substituent (e.g., no replacement of C18 by C8); the other physicochemical characteristics of the stationary phase, i.e., chromatographic support, surface modification and extent of chemical modification must be similar; a change from totally porous particle (TPP) columns to superficially porous particle (SPP) columns is allowed provided the above-mentioned requirements are met.

*Column dimensions (particle size, length)*: The particle size and/or length of the column may be modified, provided that the ratio of the column length (*L*) to the particle size (*dp*) remains constant or in the range between –25% to +50% of the prescribed *L*/*dp* ratio.

*Adjustments from totally porous to superficially porous particles*: For the application of particle-size adjustment from totally porous to superficially porous particles, other combinations of *L* and *dp* can be used, provided that the plate number (*N*) is within –25% to +50%, relative to the prescribed column. These changes are acceptable, provided that system suitability criteria are fulfilled, and selectivity and elution order of the specified impurities to be controlled are demonstrated to be equivalent.

*Internal diameter*: In absence of a change in particle size and/or length, the internal diameter of the column may be adjusted.

Caution is necessary when the adjustment results in smaller peak volumes due to a smaller particle size or smaller internal column diameter, a situation that may require adjustments to minimize extra-column band broadening by factors such as instrument connections, detector cell volume and sampling rate, and injection volume.

When the particle size is changed, the flow rate requires adjustment, because smaller-particle columns will require higher linear velocities for the same performance (as measured by reduced plate height). The flow rate is adjusted for both the change in column diameter and particle size using the following equation:

$$F_2 = F_1 \times \left[\left(dc_2^2 \times dp_1\right) / \left(dc_1^2 \times dp_2\right)\right]$$

$F_1$ = flow rate indicated in the monograph (mL/min)
$F_2$ = adjusted flow rate (mL/min)
$dc_1$ = internal diameter of the column indicated in the monograph
$dc_2$ = internal diameter of the column used (mm)
$dp_1$ = particle size indicated in the monograph (µm)
$dp_2$ = particle size of the column used (µm)

When a change is made from ≥3-µm to <3-µm particles in isocratic separations, an additional increase in linear velocity (by adjusting the flow rate) may be justified, provided that the column performance does not drop by more than 20%. Similarly, when a change is made from <3-µm to ≥3-µm particles, an additional reduction of linear velocity (flow rate) may be justified to avoid reduction in column performance by more than 20%.

After an adjustment due to a change in column dimensions, an additional change in flow rate of ±50% is permitted.

*Column temperature*: ± 10°C, where the operating temperature is specified, unless otherwise prescribed

Further adjustments in analytical procedure conditions (mobile phase, temperature, pH, etc.) may be required, within the permitted ranges described under *System Suitability* and *Adjustment of Chromatographic Conditions* in this chapter.

### MOBILE PHASE

*Composition*: The amount of the minor components of the mobile phase can be adjusted by ±30% relative. However, the change in any component cannot exceed ±10% absolute. A minor component comprises less or equal than (100/n) %, *n* being the total number of components of the mobile phase:

♦Examples of adjustments for binary and ternary mixtures are given below.

### BINARY MIXTURES

*Specified ratio of 50:50:* 30% of 50 is 15% absolute, but this exceeds the maximum permitted change of ±10% absolute in either component. Therefore, the mobile phase ratio may be adjusted only within the range of 40:60–60:40.

*Specified ratio of 2:98:* 30% of 2 is 0.6% absolute. Therefore, the maximum allowed adjustment is within the range of 1.4: 98.6–2.6: 97.4.

@2024 USPC

TERNARY MIXTURES

*Specified ratio of 70:25:5*: For the second component, 30% of 25 is 7.5% absolute. Therefore, the second component may be adjusted within the range of 32.5%–17.5% absolute. For the third component, 30% of 5 is 1.5% absolute. In all cases, a sufficient quantity of the first component is used to give a total of 100%. Therefore, mixture ranges of 62.5: 32.5: 5 to 77.5: 17.5: 5 or 68.5: 25: 6.5 to 71.5: 25: 3.5 would meet the requirement.♦

- *pH of the aqueous component of the mobile phase*: ±0.2 pH units, unless otherwise prescribed
- *Concentration of salts in the buffer component of a mobile phase*: ±10%
- *Flow rate*: In absence of a change in column dimensions, an adjustment of the flow rate by ±50% is permitted

DETECTOR WAVELENGTH

No adjustment permitted.

INJECTION VOLUME

When the column dimensions are changed, the following equation may be used for adjusting the injection volume:

$$V_{inj2} = V_{inj1}\left(L_2\ {d_{c2}}^2\right)/\left(L_1\ {d_{c1}}^2\right)$$

$V_{inj1}$ = injection volume indicated in the monograph (µL)
$V_{inj2}$ = adjusted injection volume (µL)
$L_1$ = column length indicated in the monograph (mm)
$L_2$ = new column length (mm)
$dc_1$ = column internal diameter indicated in the monograph (mm)
$dc_2$ = new column internal diameter (mm)

This equation may not be applicable to changes from TPP columns to SPP columns.

Even in the absence of any column dimension change, the injection volume may be varied provided System Suitability criteria remain within their established acceptability limits. When the injection volume is decreased, special attention is given to (limit of) detection and repeatability of the peak response(s) to be determined. An increase is permitted provided, in particular, linearity and resolution of the peak(s) to be determined remain satisfactory.

## Liquid Chromatography: Gradient Elution

Adjustment of chromatographic conditions for gradient systems requires greater caution than for isocratic systems.

COLUMN PARAMETERS AND FLOW RATE

*Stationary phase*: No change of the identity of the substituent (e.g., no replacement of C18 by C8); the other physicochemical characteristics of the stationary phase i.e., chromatographic support, surface modification, and extent of chemical modification must be similar; a change from totally porous particle (TPP) columns to superficially porous particle (SPP) columns is allowed provided the above-mentioned requirements are met.

*Column dimensions (particle size, length)*: The particle size and/or length of the column may be modified provided that the ratio of the column length (*L*) to the particle size (*dp*) remains constant or in the range between –25% to +50% of the prescribed *L/dp* ratio.

*Adjustments from totally porous to superficially porous particles*: For the application of particle-size adjustment from totally porous to superficially porous particles, other combinations of *L* and *dp* can be used provided that the ratio $(t_R/W_h)^2$ is within –25% to +50%, relative to the prescribed column ♦for all the peaks used to determine the system suitability parameters♦. These changes are acceptable provided system suitability criteria are fulfilled, and selectivity and elution order of the specified impurities to be controlled are demonstrated to be equivalent.

*Internal diameter*: In absence of a change in particle size and/or length, the internal diameter of the column may be adjusted.

Caution is necessary when the adjustment results in smaller peak volume resulting from smaller particle size or smaller internal column diameter, a situation which may require adjustments to minimize extra-column band broadening by factors such as instrument connections, detector cell volume and sampling rate, and injection volume.

When the particle size is changed, the flow rate requires adjustment, because smaller-particle columns will require higher linear velocities for the same performance (as measured by reduced plate height). Flow rate is adjusted for both the change in column diameter and particle size using the following equation:

$$F_2 = F_1 \times \left[\left({dc_2}^2 \times dp_1\right)/\left({dc_1}^2 \times dp_2\right)\right]$$

$F_1$ = flow rate indicated in the monograph (mL/min)
$F_2$ = adjusted flow rate (mL/min)
$dc_1$ = internal diameter of the column indicated in the monograph (mm)
$dc_2$ = internal diameter of the column used (mm)
$dp_1$ = particle size indicated in the monograph (µm)
$dp_2$ = particle size of the column used (µm)

Official

https://mathuedu.gcad.in.net/

A change in column dimensions, and thus in column volume, impacts the gradient volume which controls selectivity. Gradients are adjusted to the column volume by changing the gradient volume in proportion to the column volume. This applies to every gradient segment volume. Since the gradient volume is the gradient time, $t_G$, multiplied by the flow rate, $F$, the gradient time for each gradient segment needs to be adjusted to maintain a constant ratio of the gradient volume to the column volume (expressed as $L \times dc^2$). Thus, the new gradient time, $t_{G2}$ can be calculated from the original gradient time, $t_{G1}$, the flow rate(s), and the column dimensions as follows:

$$t_{G2} = t_{G1} \times (F_1/F_2) \left[\left(L_2 \times {dc_2}^2\right)/\left(L_1 \times {dc_1}^2\right)\right]$$

Thus, the change in conditions for gradient elution requires three steps:

1. Adjust the column length and particle size according to *L/dp*.
2. Adjust the flow rate for changes in particle size and column diameter.
3. Adjust the gradient time of each segment for changes in column length, diameter, and flow rate. The example below illustrates this process.

**Table 3**

| Variable | Original Conditions | Adjusted Conditions | Comment |
|---|---|---|---|
| Column length (*L*), in mm | 150 | 100 | User's choice |
| Column diameter (*dc*), in mm | 4.6 | 2.1 | User's choice |
| Particle size (*dp*), in µm | 5 | 3 | User's choice |
| *L/dp* | 30.0 | 33.3 | (1) |
| Flow rate, in mL/min | 2.0 | 0.7 | (2) |
| Gradient adjustment factor ($t_{G2}/t_{G1}$) | — | 0.4 | (3) |
| Gradient conditions | — | — | — |
| B (%) | Time (min) | Time (min) | |
| 30 | 0 | 0 | — |
| 30 | 3 | (3 × 0.4) = 1.2 | — |
| 70 | 13 | [1.2 + (10 × 0.4)] = 5.2 | — |
| 30 | 16 | [5.2 + (3 × 0.4)] = 6.4 | — |

1. An 11% increase within allowed *L/dp* change of –25% to +50%
2. Calculated using $F_2 = F_1\ [(dc_2^2 \times dp_1)/(dc_1^2 \times dp_2)]$
3. Calculated using $t_{G2} = t_{G1} \times (F_1/F_2)\ [(L_2 \times dc_2^2)/(L_1 \times dc_1^2)]$

*Column temperature*: ±5° C, where the operating temperature is specified, unless otherwise prescribed

Further adjustments in procedure conditions (mobile phase, temperature, pH, etc.) may be required, within the permitted ranges described under *System Suitability* and *Adjustment of Chromatographic Conditions* in this chapter.

## MOBILE PHASE

*Composition/gradient*: Adjustments of the composition of the mobile phase and the gradient are acceptable provided that:

- The system suitability criteria are fulfilled.
- The principal peak(s) elute(s) within ±15% of the retention time(s) obtained with the original conditions; this requirement does not apply when the column dimensions are changed.
- The composition of the mobile phase and the gradient are such that the first peaks are sufficiently retained and the last peaks are eluted.

*pH of the aqueous component of the mobile phase*: ±0.2 pH units, unless otherwise prescribed

*Concentration of salts in the buffer component of a mobile phase*: ±10%

Where compliance with the system suitability criteria cannot be achieved, it is often preferable to consider the dwell volume or to change the column.

## DWELL VOLUME

The configuration of the equipment employed may significantly alter the resolution, retention time, and relative retentions described. Should this occur, it may be due to a change in dwell volume. Monographs preferably include an isocratic step before the start of the gradient program so that an adaptation can be made to the gradient time points to take account of differences in dwell volume between the system used for analytical procedure development and that actually used. It is the user's responsibility to adapt the length of the isocratic step to the analytical equipment used. If the dwell volume used during the elaboration of the monograph is given in the monograph, the time points ($t$ min) stated in the gradient table may be replaced by adapted time points ($t_c$ min), calculated using the following equation:

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99380_08_01
@2024 USPC

$$t_c = t - \frac{(D - D_0)}{F}$$

$D$ = dwell volume (mL)
$D_0$ = dwell volume used for development of the method (mL)
$F$ = flow rate (mL/min)

The isocratic step introduced for this purpose may be omitted if validation data for application of the analytical procedure without this step is available.

Detector wavelength: No adjustment permitted

Injection volume: When the column dimensions are changed, the following equation may be used for adjusting the injection volume:

$$V_{inj2} = V_{inj1}\left(L_2 dc_2^2\right)/\left(L_1 dc_1^2\right)$$

$V_{inj1}$ = injection volume indicated in the monograph (µL)
$V_{inj2}$ = adjusted injection volume (µL)
$L_1$ = column length indicated in the monograph (cm)
$L_2$ = new column length (cm)
$d_{c1}$ = column internal diameter indicated in the monograph (mm)
$d_{c2}$ = new column internal diameter (mm)

This equation may not be applicable to changes from TPP columns to SPP columns.

Even in the absence of any column dimension change, the injection volume may be varied provided system suitability criteria remain within their established acceptability limits. When the injection volume is decreased, special attention is given to (limit of) detection and repeatability of the peak response(s) to be determined. An increase is permitted provided, in particular, linearity and resolution of the peak(s) to be determined remain satisfactory.

## Gas Chromatography

COLUMN PARAMETERS

**Stationary phase**
*Particle size*: Maximum reduction of 50%; no increase permitted (packed columns)
*Film thickness*: –50% to +100% (capillary columns)
**Column dimensions**
*Length*: –70% to +100%
*Internal diameter*: ±50%
**Column temperature:** ±10%
**Temperature program:** Adjustment of temperatures is permitted as stated above; adjustment of ramp rates and hold times of up to ±20% is permitted.
**Flow rate:** ±50%

The above changes are acceptable provided system suitability criteria are fulfilled and selectivity and elution order of the specified impurities to be controlled are demonstrated to be equivalent.
**Injection volume and split ratio:** May be varied provided system suitability criteria remain within their established acceptability limits. When the injection volume is decreased, or the split ratio is increased special attention is given to (limit of) detection and repeatability of the peak response(s) to be determined. An increase in injection volume or decrease in split ratio is permitted provided, in particular, linearity and resolution of the peak(s) to be determined remain satisfactory.
**Injection port temperature and transfer-line temperature in static headspace conditions:** ±10° C, provided no decomposition or condensation occurs

# QUANTITATION

The following quantitation approaches may be used in general texts or monographs.

## External Standard Method

Using a calibration function: Standard solutions with several graded amounts of a reference standard of the compound to be analyzed are prepared in a range that has been demonstrated to give a linear response, and a fixed volume of these standard solutions is injected. With the chromatograms obtained, a calibration function is prepared by plotting the peak areas or peak heights on the ordinate against the amount of reference standard on the abscissa. The calibration function is generally obtained by linear regression. Then, a sample solution is prepared according to the procedure specified in the individual monograph. The chromatography is performed under the same operating conditions as for the preparation of the calibration function, the peak area or peak height of the compound to be analyzed is measured, and the amount of the compound is read out or calculated from the calibration function.

Using one-point calibration: In an individual monograph, generally one of the standard solutions with a concentration within the linear range of the calibration function and a sample solution with a concentration close to that of the standard solution

Official

https://pharmacopeia.com/

are prepared, and the chromatography is performed under fixed conditions to obtain the amount of the component by comparing the responses obtained. In this method, all procedures, such as the injection procedure, must be carried out under constant conditions.

### Internal Standard Method

Using a calibration function: In the internal standard method, a stable compound is chosen as an internal standard which shows a retention time close to that of the compound to be analyzed, and whose peak is well separated from all other peaks in the chromatogram. Several standard solutions containing a fixed amount of the internal standard and graded amounts of a reference standard of the compound to be analyzed are prepared. Based on the chromatograms obtained by injection of a fixed volume of individual standard solutions, the ratio of peak area or peak height of the reference standard to that of the internal standard is calculated. A calibration function by plotting these ratios on the ordinate against the amount of the reference standard or the ratio of the amount of reference standard to that of the internal standard on the abscissa is prepared. The calibration function is generally obtained by linear regression. Then, a sample solution containing the internal standard in the same amount as in the standard solutions used for the preparation of the calibration function is prepared according to the procedure specified in the individual monograph. The chromatography is performed under the same operating conditions as for the preparation of the calibration function. The ratio of the peak area or peak height of the compound to be analyzed to that of the internal standard is calculated, and the amount of the compound is read out or calculated from the calibration function.

Using one-point calibration: In an individual monograph, generally one of the standard solutions with a concentration within the linear range of the calibration function and a sample solution with a concentration close to that of the standard solution, both containing a fixed amount of the internal standard, are prepared, and the chromatography is performed under fixed conditions to determine the amount of the compound to be analyzed by comparing the ratios obtained.

*Normalization procedure*: Provided linearity of the peaks has been demonstrated, individual monographs may prescribe that the percentage content of a component of the substance to be examined is calculated by determining the area of the corresponding peak as a percentage of the total area of all the peaks, excluding those due to solvents or reagents or arising from the mobile phase or the sample matrix, and those at or below the disregard limit or reporting threshold.

## OTHER CONSIDERATIONS

Detector response: ♦The detector sensitivity is the signal output per unit concentration or unit mass of a substance (also known as response factor) in the mobile phase entering the detector. The relative detector response factor, commonly referred to as relative response factor, expresses the sensitivity of a detector for a given substance relative to a standard substance.

In tests for related substances, any correction factors indicated in the monograph are applied.♦

Interfering peaks: Peaks due to solvents and reagents or arising from the mobile phase or the sample matrix are disregarded.

Measurement of peaks: Integration of the peak area of any impurity that is not completely separated from the principal peak is preferably performed by tangential skim (*Figure 9*).

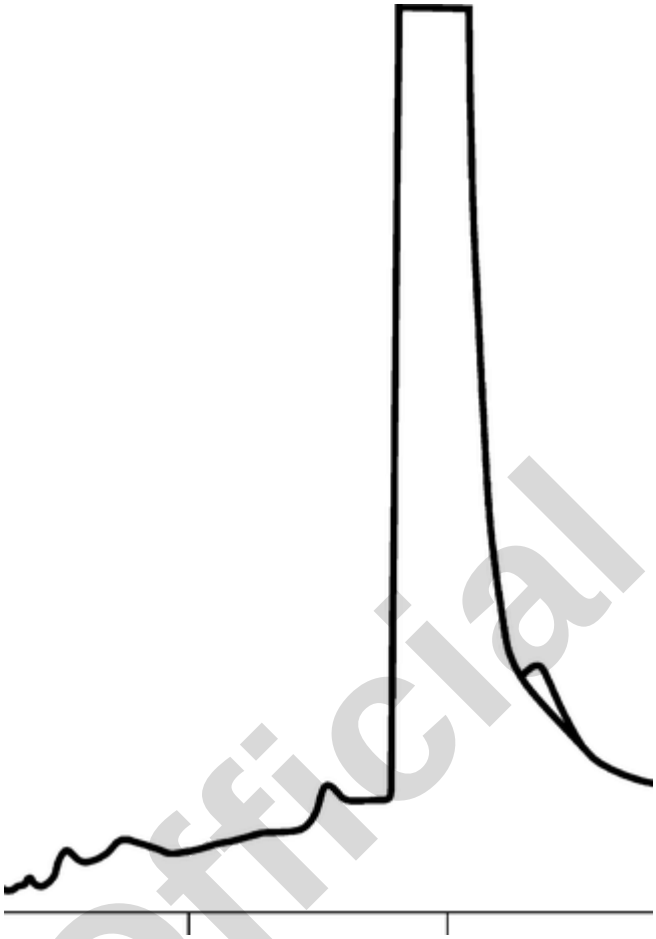

Figure 9.

**reporting threshold**

When the related substances test prescribes a limit for the total of impurities or a quantitative determination of an impurity, it is important to choose an appropriate reporting threshold and appropriate conditions for the integration of the peak areas.

In such tests the reporting threshold, i.e., the limit above which a peak is reported, is defined generally 0.05%.

***Add the following:***

# ▲⟨630⟩ VISUAL COMPARISON

The purpose of this test is to provide the details for the visual comparison of the color and/or turbidance of sample solutions of certain concentration to a standard solution or a series of standard solutions of known concentration. Where a color or turbidity comparison is directed, follow the procedures and conditions outlined below for performing these tests.

**Comparison vessels:** Color-comparison tubes matched as closely as possible in internal diameter, in depth of sample solution, and in all other respects should be used.

**Viewing conditions for turbidity comparison:** Tubes should be viewed horizontally against a dark background with the aid of a light source directed from the sides of the tubes.

**Viewing conditions for color comparison:** Tubes should be viewed downward against a white background. Most of the time, common room lighting is sufficient to perform the assessment. A light source directed from beneath the bottoms of the tubes may be used if needed and if the practice is consistent between the materials under comparison.▲ (USP 1-May-2019)

# ⟨631⟩ COLOR AND ACHROMICITY

## INTRODUCTION

The purpose of this chapter is to provide well-controlled methods for the assessment of color and achromicity of uniform liquid samples. The methods described in this chapter may be applied to the liquid phase of dispersed systems in cases where the dispersed phase can be removed prior to color measurements. Color is an organoleptic characteristic, which means that the value is based on the human response to stimuli. To reliably evaluate color, it is important to control both the illumination and observation parameters. By using a characteristic response for a standard observer, it is possible to perform precise instrumental evaluations of color. This chapter provides guidance for both an organoleptic assessment (*Method I*) and an instrumental assessment (*Method II*) of color and achromicity in liquid samples.

Color may be defined as an observer's perception of or subjective response to a stimulus of radiant energy in the visible spectrum extending over the wavelength range of 400–700 nm. Perceived color is a function of three variables: spectral properties of the object, spectral power distribution of the source of illumination, and visual perception of the observer.

Two objects are said to have a color match for a particular source of illumination when an observer cannot detect a color difference. Where a pair of objects exhibit a color match for one source of illumination and not another, they constitute a metameric pair. Color matches of two objects occur for all sources of illumination if the absorption and reflectance spectra of the two objects are identical.

Achromicity or colorlessness is one extreme of any color scale for transmission of light. It implies the complete absence of color; therefore, the visible spectrum of the sample lacks absorbances. For practical purposes, the observer in this case perceives little if any absorption taking place in the visible spectrum and is unable to discern the difference between an almost colorless sample and a colorless reference.

## COLOR ATTRIBUTES AND COLOR SPACE COORDINATES

Because the sensation of color has both a subjective and an objective part, color cannot be described solely in spectrophotometric terms. The common attributes of color therefore cannot be given a one-to-one correspondence with spectral terminology.

Three attributes are commonly used to identify a color: 1) hue (angle), or the color dimension dominant in its purest form, such as red, yellow, blue, green, and intermediate terms; 2) lightness, or the quality that distinguishes a light color from a dark one; and 3) chroma, or the quality that distinguishes an intense color from a weak one, such as the extent to which a color differs from a gray of the same lightness.

The three attributes of color may be used to define a three-dimensional color space in which any color is located by its coordinates. The color space chosen is visually uniform if the geometric distance between two colors in the color space is correlated with the perceived difference between the two colors. Cylindrical coordinates are often chosen for convenience. Points along the vertical axis represent the lightness from dark to light (or black to white) and have indeterminate hue (angle) and no chroma. Focusing on a cross-section perpendicular to the lightness axis, hue is determined by the angle about the long axis and chroma is determined by the geometric distance from the vertical axis. Red, yellow, green, blue, and intermediate hues are differentiated by various hue angles. Colors of the same hue angle become more intense (i.e., chromatic) as they move further from the vertical axis (larger chroma). For example, colorless or achromic water has an indeterminate hue angle, high lightness, and little to no chroma. If a colored solute is added, the water takes on a particular hue (angle). As more is added, the color becomes darker, more intense, or deeper; that is, the chroma increases and lightness decreases. However, if the solute is a neutral color, such as gray, the lightness decreases, no increase in chroma occurs, and the hue (angle) remains indeterminate.

Laboratory spectroscopic measurements can be converted to measurements of the color attributes by using the response factors for a standardized observer. Spectroscopic results are weighted by three distribution functions to yield the tristimulus values X, Y, and Z (for additional information, see *Color—Instrumental Measurement* ⟨1061⟩).

The tristimulus values are not coordinates in a visually uniform color space; however, they can be transformed into a more uniform chroma–hue color space known as the CIELAB color space, defined by the International Commission on Illumination (CIE) in 1976. Also known as CIE L*a*b* or sometimes abbreviated as simply "Lab" color space, CIELAB was designed so that the same amount of numerical change in these values corresponds to roughly the same amount of visually perceived change. The resulting $L^*$, $a^*$, $b^*$, $C^*_{ab}$, and $h^*_{ab}$ values indicate the following:

- $L^*$ is the lightness coordinate. $L$ is always positive and ranges from 0 to 100; 100 is the colorless (white) standard and 0 is the zero (black) standard.
- $a^*$ is the red/green coordinate. $+a^*$ is red, and $-a^*$ is green.
- $b^*$ is the yellow/blue coordinate. $+b^*$ is yellow, and $-b^*$ is blue.
- $C^*_{ab}$ is the chroma in the ($a^*$, $b^*$) plane. $C^*_{ab} = [(a^*)^2 + (b^*)^2\ ]^{1/2}$.
- $h^*_{ab}$ is the hue angle in the ($a^*$, $b^*$) plane, measured from the $a^*$ axis increasing counterclockwise, and is reported as a value from 0 to 360 degrees. The hue angles for the elementary colors are approximately 25 (red), 92 (yellow), 162 (green), 220 (cyan), 271 (blue), and 337 (magenta) degrees.

Additionally, the difference between two points in the CIELAB color space ($\Delta E^*$) can be calculated as follows:

$$\Delta E^* = \sqrt{\Delta L^{*2} + \Delta a^{*2} + \Delta b^{*2}}$$

Slight differences in colors are not perceptible in visual comparisons. Although it is possible for the human eye to differentiate between colors with a $\Delta E^*$ of about 1, it is frequently difficult for an observer with normal color vision to reliably differentiate

@2024 USPC

between colors with a $\Delta E^*$ of less than 3. Therefore, it is preferable to rely on quantitative assessment of color and color differences when precise, reliable comparisons are required.

## COLOR DETERMINATION AND STANDARDS

The perception of color and color matches is dependent on conditions of viewing and illumination. Determinations should be made using diffuse, uniform illumination under conditions that reduce shadows and minimize non-spectral reflectance. Liquids should be compared in matched color-comparison containers that are transparent to the illumination light. Either organoleptic (qualitative) or instrumental (quantitative) assessment of color may be used.

### Containers for Liquid Samples and Matching Fluids

For liquid samples, the containers used to hold the samples during the color measurements should be non-absorbing in the 400–700 nm range and must be identical for the sample and matching fluids. The containers may be round or square, and the diameter or depth of the container may be adjusted to provide a shorter path length for darker samples or a longer path length for lighter samples. The use of cuvettes or glass tubes with a path length of about 10 mm is recommended.

### Turbid and Opaque Samples

When using transparent color-matching fluids, the color evaluation of the sample should be based on evaluation of the clarified sample. If the sample is turbid or opaque, the dispersed phase should be removed by centrifugation or filtration before evaluating the color. If the sample or matching fluid contains air bubbles or foam, these should be removed by centrifugation before evaluation of the color.

### Matching Fluids

The colors of standards should be as close as possible to those of test specimens for quantifying color differences. Any well-defined and well-characterized matching fluid is permitted (*1*). For example, matching fluids may be prepared according to *Table 1* or may be prepared as described in the *European Pharmacopoeia* (*2*) (*2.2.2. Degree of Coloration of Liquids*) or *Chinese Pharmacopoeia* (*3*) (*Appendix IX, Colour of Solution*). To prepare the matching fluids in *Table 1*, pipet the prescribed volumes of the colorimetric test solutions (see *Reagents, Indicators, and Solutions—Colorimetric Solutions*) and water into one of the matching containers and mix the solution in the container.

**Table 1. Matching Fluids**

| Matching Fluid | Parts[1] of Cobaltous Chloride CS | Parts of Ferric Chloride CS | Parts of Cupric Sulfate CS | Parts of Water |
|---|---|---|---|---|
| A | 0.1 | 0.4 | 0.1 | 4.4 |
| B | 0.3 | 0.9 | 0.3 | 3.5 |
| C | 0.1 | 0.6 | 0.1 | 4.2 |
| D | 0.3 | 0.6 | 0.4 | 3.7 |
| E | 0.4 | 1.2 | 0.3 | 3.1 |
| F | 0.3 | 1.2 | 0.0 | 3.5 |
| G | 0.5 | 1.2 | 0.2 | 3.1 |
| H | 0.2 | 1.5 | 0.0 | 3.3 |
| I | 0.4 | 2.2 | 0.1 | 2.3 |
| J | 0.4 | 3.5 | 0.1 | 1.0 |
| K | 0.5 | 4.5 | 0.0 | 0.0 |
| L | 0.8 | 3.8 | 0.1 | 0.3 |

[1] The composition in Table 1 is described on a v/v basis and indicates the relative volume of each ingredient required to make the reference solution.

If a matching fluid is prepared, it must be freshly prepared on the day of use unless suitable data demonstrating the stability of the color in the matching fluid are available to support the use for longer time periods. For purchased color standards or matching fluids, follow the appropriate use instructions and expiry dates.

## METHOD I: ORGANOLEPTIC (QUALITATIVE) ASSESSMENT OF COLOR AND COLOR MATCHES

### Illuminant

A standard illuminant is a theoretical source of visible light with a profile (its spectral power distribution) that is published. Standard illuminants are designated by a letter or by a letter-number combination. Illuminants A, B, and C were introduced in 1931, with the intention of representing average incandescent light, direct sunlight, and average daylight, respectively. The illumination of the sample(s) and matching fluid(s) should be solely due to the controlled illuminant source. Any additional illumination from room lighting or windows should be minimized (for example, by use of a light box or light booth). A daylight illuminant capable of providing a correlated color temperature (CCT) of 6000–7000 K should be used. Filtered tungsten halogen lamps are recommended, but daylight fluorescent lamps with comparable spectral and illuminance characteristics also can be used. The spectral power distribution should conform to ISO 23603/CIE S 012 (*4*) for the D65 illuminant with a grade of B/C or better. The illumination of the sample and matching fluid should be diffuse and not at an angle that will provide specular reflections to the observer. Recommended geometries include 0:45 and 45:0 illuminant viewer, in degrees.

### Observer

The observer angle may be normal (vertical) or at 90 degrees (horizontal) if the illumination angle is controlled to avoid specular reflection and provides diffuse illumination relative to the observer angle. The sample and one or more matching fluids should subtend a viewing angle of 2–10 degrees and be in the field of view simultaneously. Using identical tubes of colorless, transparent, and neutral glass of 12-mm external diameter, compare 2.0 mL of the liquid to be examined with 2.0 mL of water or matching fluid. A small, discernible gap should exist between the sample and matching fluid. The surrounding field should be white, black, or neutral gray.

### Procedures

Evaluate the sample and at least one other matching fluid simultaneously. Evaluate the brightness, saturation, and hue (angle). Hue (angle) differences between the sample and the reference should be interpreted as a failure of the comparative test unless there are explicit instructions in the monograph to ignore hue (angle) differences.

When analyzing samples that are expected to have color, there are three approaches:

1. Establish a minimum level of color. If the sample matches the reference sample or has more color, it passes the test.
2. Establish a maximum level of color. If the sample matches the reference sample or has less color, it passes.
3. Select a matching (or reference) solution to determine an indiscernible difference between the test sample and the reference. In this case, the sample must match the matching solution. It is preferred, in this case, to establish a standard of the same compound as the analyte of interest to avoid situations of metamerism.

*Table 2* illustrates how the results of these color evaluations should be interpreted and reported.

**Table 2. Interpretation of Color Comparisons for Qualitative Color Evaluations**

| Color Evaluation Test | Test Requirement | Sample Has More Color | Reference Has More Color | Sample Matches Reference |
|---|---|---|---|---|
| Almost Colorless | Compare sample to Purified Water. | Fails the test | Passes the test | Passes the test |
| Maximum Level of Color | Compare to a matching fluid that should exhibit discernibly more color than sample. | Fails the test | Passes the test | If used for achromicity, fails the test. Otherwise, passes the test |
| Minimum Level of Color | Identify a matching fluid that represents minimum acceptable color. | Passes the test | Fails the test | Passes the test |
| Indiscernible from Color Standard | Prepare color standard; compare test sample to color standard. | Fails the test | Fails the test | Passes the test |

Achromicity is a special case of an evaluation of the maximum level of color. For achromicity evaluations, one must either perform an *Indiscernible from Color Standard* test using Purified Water as the standard or perform a *Maximum Level of Color* test with a color standard with a low level of color that is discernibly different from Purified Water (i.e., a $\Delta E^*$ relative to Purified Water of 3–6). Matching fluids that are almost colorless are generally not useful for qualitative color evaluations and should be avoided. *Table 3* lists the matching fluids that should be avoided and those that are recommended for achromicity evaluations using the *Maximum Level of Color* test.

# METHOD II: INSTRUMENTAL (QUANTITATIVE) ASSESSMENT OF COLOR AND COLOR MATCHES

## Instrumentation

For evaluating the color of solutions, it is acceptable to use any spectrometer or colorimeter (in transmission mode) that has been qualified for use, according to *Ultraviolet–Visible Spectroscopy* ⟨857⟩, in the operating range of 400–700 nm and has a bandwidth of 10 nm or less.

## Calibration

For verification of the calibration in transmission mode, a black tile (or block of the light path) is used to determine the zero end of the lightness scale; Purified Water (or relevant solvent) is used for 100% transmission (for more information, see *Analytical Instrument Qualification* ⟨1058⟩).

## Recording of Spectroscopic Data

The spectroscopic data should be recorded from 400–700 nm at 10-nm intervals. If results are acquired at more frequent intervals, only the results from the 10-nm intervals will be used to calculate the instrumental color values. If the samples are turbid, they should be clarified by centrifugation or filtration prior to loading into the cuvette. Samples also should be checked to ensure that the light transmission path is free from air bubbles or foam.

## Calculation of CIELAB Values

This instrumental method relies on calculation of the color values in the CIELAB color space using either illuminant C with the 2-degree observer or illuminant D65 with the 10-degree observer. *Table 4* and *Table 5* contain the weighting factors for illuminant C with the 2-degree observer (C/2) and for illuminant D65 with the 10-degree observer (D65/10), respectively. These weighting factors should be used to convert the spectroscopic data into CIELAB values (for additional information, see ⟨1061⟩). As an example, *Table 6* contains three sets of spectroscopic transmittance data for the ideal Lovibond 10R, 10Y, and 10B glasses (*6*). *Table 7* shows the CIELAB (C/2) and CIELAB (D65/10) values calculated from these data using the weighting factors in *Table 4* and *Table 5*.

## METHOD IIA: COMPARATIVE TEST OF COLORS USING CIELAB VALUES

The CIELAB values for a sample and a matching solution may be evaluated to determine the acceptability of the sample. *Table 8* lists the different metrics that may be used to compare the color values of a sample to the color values of a matching solution. In evaluating stability, the color values may be tracked over time to assess trends. The variability in the color values may be used to assess process control and variability due to raw materials or processing.

**Table 8. Interpretation of Color Comparisons[a, b]**

| Color Evaluation Test | Test | Requirement |
|---|---|---|
| Almost Colorless | Compare the sample to Purified Water. | Measure the sample and Purified Water. Calculate $\Delta E^*$ relative to Purified Water. Requirement is that $\Delta E^* < 1$. |
| Maximum Level of Color | Identify a matching fluid of similar hue angle ($\Delta h^*_{ab} < 15$) that is discernibly more colored than the sample. | Measure the matching fluid and calculate the $\Delta E0^*$ relative to Purified Water. Measure the sample and calculate the $\Delta E^*$ relative to Purified Water. Requirement is $\Delta E^* < \Delta E0^*$. |
| Minimum Level of Color | Identify a matching fluid of similar hue angle ($\Delta h^*_{ab} < 15$) that is discernibly less colored than the sample. | Measure the matching fluid and calculate the $\Delta E0^*$ relative to Purified Water. Measure the sample and calculate the $\Delta E^*$ relative to Purified Water. Requirement is $\Delta E^* > \Delta E0^*$. |
| Indiscernible from Color Standard | Prepare color standard; compare the test sample to the color standard. | Calculate $\Delta E^*$ relative to selected color standard. Requirement is that $\Delta E^* < 3$. |

[a] Comparisons rely on the numerical values of $L^*$, $a^*$, and $b^*$, and the comparison of these values to those of the matching solution or standard.
[b] *CIELAB values must be calculated with the same illuminant and observer for evaluating differences between the sample and matching fluid.*

## METHOD IIB: INSTRUMENTAL COLOR ASSESSMENT

The CIELAB values (calculated as described in *Method IIa: Comparative Testing of Colors Using CIELAB Values*) may be used directly as a quantitative measure of the color attributes of a sample. Acceptable specifications for the color attributes can be established in the CIELAB color space and applied to color values obtained for a sample.

For new monographs under development, which do not already have a visual color determination method, the following approach harnesses the advantages of instrumental colorimetry to its fullest and removes drawbacks associated with limiting the control space to what is encompassed by existing visual standards. Also, for new monographs under development, acceptable numerical limits within color space should be determined based on process capability, stability, and analytical variability. A specification would then take the form of one of the following:

- A solution with $L^*$ NLT XX, NMT XX; $a^*$ NMT XX, NLT XX; and $b^*$ NMT XX, NLT XX (XX being a numerical value).
- $\Delta E^*$ versus a single point in 3-dimensional space. Ideally this point would represent the average based on multiple batches or based on representative material, such as a well-characterized reference standard. Other points may be justified.

Limits may be set with individual color parameters (e.g., $L^*$, $a^*$, and $b^*$ or another suitably validated color space) or as a $\Delta E^*$ versus a single point in color space when considering batch release or stability studies.

Official

https://pharmacopeia.cn/v-pharmacopeia/

## Reporting of Results

The calculated CIELAB color values are dependent on the illuminant and observer used and, therefore, should be reported. The CIELAB values for the coordinates *L**, *a**, and *b** should be reported. The values for chroma ($C^*_{ab}$) and hue angle ($h^*_{ab}$) are derived from *a** and *b** and do not need to be reported. A recommended method for reporting the CIELAB results is to report the color values as shown in the following examples:

CIELAB ([illuminant]/[observer]) = (*L**, *a**, *b**)
CIELAB (C/2) = (50.70, −11.30, −33.30)
CIELAB (D65/10) = (52.69, −19.43, 29.61)

# ⟨641⟩ COMPLETENESS OF SOLUTION

***Add the following:***

▲The purpose of these methods is to verify that one or more materials are completely dissolved in a solution. These methods may be used to verify the descriptive solubility of a material according to the solubility table in *General Notices, 5.30 Description and Solubility*.

To verify the descriptive solubility, use the maximum amount of solvent specified for the descriptive solubility in the solubility table (see *General Notices, 5.30 Description and Solubility*). For example, for "soluble" use 30 parts of solvent. Into this amount of solvent, add 1 part of solute weighed accurately to 0.5%. Unless otherwise specified in the monograph, completeness of solution should be evaluated at 25°.

Evaluation of the completeness of solution, as described in this chapter, does not provide a precise measure of compound solubility. The descriptive solubility terms above should also not be confused with the terms "high solubility" and "low solubility" as applied to drug substances in the *Biopharmaceutical Classification System*.[1,2] For more information on precise solubility measurements and biorelevant solubility determinations, see *Solubility Measurements* ⟨1236⟩.

Unless otherwise directed in the individual monograph, use *Method I*.▲ (USP 1-Aug-2020)

***Change to read:***

## ▲METHOD I▲ (USP 1-AUG-2020)

Place the quantity of the substance specified in the individual monograph in a meticulously cleansed, glass-stoppered, 10-mL ▲color-comparison tube.▲ (USP 1-Aug-2020) Using the solvent that is specified in the monograph or on the label of the product, fill the ▲color-comparison tube to the 10-mL mark.▲ (USP 1-Aug-2020) Shake gently to dissolve: the solution is not less clear than an equal volume of the same solvent contained in a ▲matched color-comparison tube▲ (USP 1-Aug-2020) and examined similarly ▲(see *Visual Comparison* ⟨630⟩*, Viewing conditions for turbidity comparison*).▲ (USP 1-Aug-2020)

***Add the following:***

## ▲METHOD II

Place the quantity of the substance specified in the individual monograph into a meticulously cleansed 10-mL flask. Add 10 mL of the solvent that is specified in the monograph or on the label of the product. Shake gently to dissolve. Transfer the solution to a suitable measurement tube and measure the turbidity of the prepared solution per *Nephelometry and Turbidimetry* ⟨855⟩. The acceptance criterion is that the turbidity of the sample preparation is NMT that of *Reference suspension II* in ⟨855⟩, *Table 1* [NMT 6 nephelometric turbidity units (NTU)].▲ (USP 1-Aug-2020)

# ⟨643⟩ TOTAL ORGANIC CARBON

## INTRODUCTION

Total organic carbon (TOC) is an indirect measure of organic molecules present in pharmaceutical waters measured as carbon. Organic molecules are introduced into the water from the source water, from purification and distribution system materials, from biofilm growing in the system, and from the packaging of sterile and nonsterile waters. TOC also can be used as a process control attribute to monitor the performance of unit operations comprising the purification and distribution system. A TOC measurement is not a replacement test for endotoxin or microbiological control. Although there can be a qualitative relationship between a food source (TOC) and microbiological activity, there is no direct numerical correlation.

A number of acceptable methods exist for analyzing TOC. This chapter does not endorse, limit, or prevent any technologies from being used, but this chapter provides guidance on how to qualify these analytical technologies as well as how to interpret instrument results for use as a limit test.

Apparatuses commonly used to determine TOC in water for pharmaceutical use have in common the objective of oxidizing the organic molecules in the water to produce carbon dioxide followed by the measurement of the amount of carbon dioxide produced. Then the amount of carbon dioxide produced is determined and used to calculate the organic carbon concentration in the water.

All technologies must discriminate between the inorganic carbon, which may be present in the water from sources such as dissolved carbon dioxide and bicarbonate, and the carbon dioxide generated from the oxidation of organic molecules in the sample. The discrimination may be accomplished either by determining the inorganic carbon and subtracting it from the total carbon (the sum of organic carbon and inorganic carbon), or by purging inorganic carbon from the sample before oxidation. Although purging may entrain volatile organic molecules, such purgeable organic carbon is present in negligible quantities in water for pharmaceutical use.

***Change to read:***

## PROCEDURES

**1. Bulk Water**

The following sections apply to tests for bulk *Purified Water*, *Water for Injection*, *Water for Hemodialysis*, and the condensate of *Pure Steam*.

**1.1 Instrumentation requirements:** This test method is performed either as an on-line test or as an off-line laboratory test using a calibrated instrument. The suitability of the instrument must be periodically demonstrated as described below. In addition, it must have a manufacturer's specified limit of detection of 0.05 mg/L (0.05 ppm) or lower of carbon.

When testing water for quality control purposes, ensure that the instrument and its data are under appropriate control and that the sampling approaches and locations of both on-line and off-line measurements are representative of the quality of the water used. The water purification process, distribution, and use should be considered when selecting either on-line or off-line measurement.

**1.2 Reagent water:** Use water with a TOC level of NMT 0.10 mg/L. [NOTE—A conductivity requirement may be necessary to ensure method reliability.]

**1.3 Container preparation:** Organic contamination of labware and sample containers results in higher TOC values. Therefore, use labware and containers that have been scrupulously cleaned of organic residues. Any method that is effective in removing organic matter can be used (see *Cleaning Glass Apparatus* ⟨1051⟩). Use *Reagent water* (section 1.2) for the final rinse.

**1.4 System suitability solution:** Dissolve an accurately weighed quantity of USP 1,4-Benzoquinone RS in *Reagent water* (section 1.2) to obtain a solution with a concentration of 0.75 mg/L (0.50 mg/L of carbon).

**1.5 Standard solution:** Unless otherwise directed in the individual monograph, dissolve an accurately weighed quantity of USP Sucrose RS in the *Reagent water* (section 1.2) to obtain a solution with a concentration of 1.19 mg/L of sucrose (0.50 mg/L of carbon).

**1.6 Reagent water control:** Use a suitable quantity of *Reagent water* (section 1.2) obtained at the same time as those used in the preparations of the *Standard solution* (section 1.5) and the *System suitability solution* (section 1.4).

**1.7 Water sample:** Obtain an on-line or off-line sample that suitably reflects the quality of water used.

**1.8 Other control solutions:** Prepare appropriate reagent blank solutions or other specified solutions needed for establishing the apparatus baseline or for calibration adjustments following the manufacturer's instructions, and run the appropriate blanks to zero the instrument, if necessary.

**1.9 Limit response:** Measure the TOC of the *Reagent water control* (section 1.6) in the instrument, and record the response ($r_w$). Also measure the TOC of the *Standard solution* (section 1.5) in the instrument, and record the response ($r_S$). Calculate the corrected *Standard solution* response, which is also the *Limit response* ($r_L$), for the contribution from the *Reagent water* (section 1.2), by subtracting the *Reagent water control* response from the *Standard solution* response:

$$r_L = r_S - r_W$$

$r_S$ = instrument response to the *Standard solution* (section 1.5)
$r_W$ = instrument response to the *Reagent water control* (section 1.6)

The *Limit response* ($r_L$) of 0.50 mg/L of carbon will be equal to this corrected *Standard solution* response.

**1.10 System suitability:** Measure the TOC of the *System suitability solution* (section 1.4) in the instrument, and record the response ($r_{SS}$). Calculate the corrected *System suitability solution* response ($r_C$) by subtracting the *Reagent water control* response from the *System suitability solution* response:

Official

https://mhathaway@gmail.com/

$$r_C = r_{SS} - r_W$$

$r_{SS}$ = instrument response to the *System suitability solution* (section 1.4)
$r_W$ = instrument response to the *Reagent water control* (section 1.6)

Calculate the percent response efficiency ($r_E$):

$$r_E = 100 \times \blacktriangle\blacktriangle_{\text{(ERR 1-Sep-2021)}}(r_C / r_L)$$

$r_C$ = corrected instrument response to the *System suitability solution* (section 1.4)
$r_L$ = corrected instrument response to the *Standard solution* (section 1.5) (also known as the *Limit response*)

The TOC measuring system is suitable if the percent response efficiency ($r_E$) is NLT 85% and NMT 115%. The suitability of the instrument must be periodically demonstrated.

**1.11 Procedure:** Measure the TOC of the *Water sample* (section 1.7) and record the response ($r_U$). The *Water sample* meets the requirements if $r_U$ is NMT $r_L$. This method can be performed using on-line or off-line instrumentation that meets the *Instrumentation requirements* (section 1.1).

**2. Sterile Water**

The following sections apply to tests for *Sterile Water for Injection*, *Sterile Purified Water*, *Sterile Water for Irrigation*, *Sterile Water for Inhalation*, and any other monographs that specify this section. The sterile waters are derived from *Purified Water* or *Water for Injection*, and therefore have been determined to be compliant with the *Bulk Water* (section 1) requirements before being stored and sterilized in the container.

Follow the requirements for *Container preparation* (section 1.3) and *Other control solutions* (section 1.8). Prepare the *Standard solution* (section 2.4) and the *System suitability solution* (section 2.3) that correspond to the *Limit response* (section 2.7) for the volume of the container being tested as specified in *Table 1* and as described in steps 2 and 4 in *Procedure* (section 2.9).

**Table 1. TOC Limit Based on Container Volume**

| Nominal Container Volume (mL) | Limit 1 (*L1*) (mg/L of carbon) | Limit 2 (*L2*)[a] (mg/L of carbon) |
|---|---|---|
| ≤5 | 32.00 | 48.00 |
| >5 and ≤100 | 24.00 | 36.00 |
| >100 | 8.00 | 12.00 |

[a] *Limit 2* concentrations are utilized to determine the system suitability requirements for the container volume being tested.

**2.1 Instrument requirements:** The suitability of the instrument must be periodically demonstrated as described below. In addition, it must have a manufacturer's specified limit of detection of 0.10 mg/L (0.10 ppm) or lower of carbon.

**2.2 Reagent water:** Use water with a TOC level of NMT 0.50 mg/L. [NOTE—See *General Notices, 8.230.30 Water in a Compendial Procedure*. A conductivity requirement may be necessary in order to ensure method reliability.]

**2.3 System suitability solution:** /Dissolve an accurately weighed quantity of USP 1,4-Benzoquinone RS in *Reagent water* (section 2.2) to obtain a solution with a concentration that corresponds to the container volume being tested, as specified in *Table 2*:

**Table 2. System Suitability Solution Based on Container Volume**

| Nominal Container Volume (mL) | 1,4-Benzoquinone (mg/L) | Equivalent Carbon Concentration (mg/L of carbon) |
|---|---|---|
| ≤5 | 72.00 | 48.00 |
| >5 and ≤100 | 54.00 | 36.00 |
| >100 | 18.00 | 12.00 |

**2.4 Standard solution:** Unless otherwise directed in the individual monograph, dissolve an accurately weighed quantity of USP Sucrose RS in the *Reagent water* (section 2.2) to obtain a solution with a concentration that corresponds to the *Standard solution* (section 2.4), measured for the container volume being tested, as specified in *Table 3*:

**Table 3. Standard Solution Based on Container Volume**

| Nominal Container Volume (mL) | Limit 1 (*L1*) | | Limit 2 (*L2*) | |
|---|---|---|---|---|
| | Sucrose Concentration (mg/L) | Equivalent Carbon Concentration (mg/L of carbon) | Sucrose Concentration (mg/L) | Equivalent Carbon Concentration (mg/L of carbon) |
| ≤5 | 76.00 | 32.00 | 114.00 | 48.00 |
| >5 and ≤100 | 57.00 | 24.00 | 85.50 | 36.00 |

**Table 3. Standard Solution Based on Container Volume** *(continued)*

| Nominal Container Volume (mL) | Limit 1 (*L1*) | | Limit 2 (*L2*) | |
|---|---|---|---|---|
| | Sucrose Concentration (mg/L) | Equivalent Carbon Concentration (mg/L of carbon) | Sucrose Concentration (mg/L) | Equivalent Carbon Concentration (mg/L of carbon) |
| >100 | 19.00 | 8.00 | 28.50 | 12.00 |

**2.5 Reagent water control:** Use a suitable quantity of *Reagent water* (section 2.2) obtained at the same time as those used in the preparations of the *Standard solution* and the *System suitability solution* (section 2.3).

**2.6 Water sample:** Obtain water samples that suitably reflect the quality of the sterile water batch being tested. [NOTE—See *Container preparation* (section 1.3).] Before opening the water packages to remove water samples for analysis, vigorously agitate the packages to homogenize any TOC residues that may be present in packages. For small packages, several packages may be required in order to collect a sufficient water volume for analysis. Otherwise test water samples individually.

**2.7 Limit response:** Measure the TOC of the *Reagent water control* (section 2.5) and record the response ($r_W$). Also measure the TOC of the *Standard solution* (section 2.4) prepared at concentrations corresponding to the appropriate *Limit 1*, and, if required for step 4 in *Procedure* (section 2.9), *Limit 2* values from *Table 1* for the container volume being tested. The values in this table are the TOC limits based on container volume. Finally, record the instrument response to each of the *Standard solutions* (section 2.4) for *Limit 1* ($r_{S1}$) and, if required, *Limit 2* ($r_{S2}$) from *Table 1*.

Calculate the corrected instrument response to the *Standard solutions* prepared at the *Limit 1* ($r_{L1}$) or *Limit 2* ($r_{L2}$) concentrations, as appropriate, by subtracting the *Reagent water control* response ($r_W$) from the *Limit 1 Standard solution* response ($r_{S1}$) and, if required, the *Limit 2 Standard solution* response ($r_{S2}$):

$$r_{L1} = r_{S1} - r_W$$

and if required:

$$r_{L2} = r_{S2} - r_W$$

$r_{S1}$ = instrument response to the *Limit 1 Standard solution*
$r_{S2}$ = instrument response to the *Limit 2 Standard solution*
$r_W$ = instrument response to the *Reagent water control*

**2.8 System suitability:** Prepare the *Standard solution* (section 2.4) at the TOC concentrations corresponding to the *Limit 2* in *Table 3* for the container volume being tested. Prepare the *System suitability solution* (section 2.3) according to *Table 2* for the container volume being tested. Measure the TOC of the *Reagent water control* (section 2.5) in the instrument, and record the response ($r_W$). Measure the TOC of the *Standard solution* (section 2.4), and record the response ($r_S$). Calculate the corrected *Standard solution* response ($r_S - r_W$), by subtracting the *Reagent water control* response ($r_W$) from the *Standard solution* response ($r_S$). Measure the TOC of the *System suitability solution* (section 2.3) in the instrument, and record the response ($r_{SS}$). Calculate the corrected *System suitability solution* response ($r_{SS} - r_W$) by subtracting the *Reagent water control* response ($r_W$) from the *System suitability solution* response ($r_{SS}$) (section 2.3). Calculate the percent response efficiency ($r_E$):

$$r_E = 100 \times [(r_{SS} - r_W)/(r_S - r_W)]$$

$r_{SS}$ = instrument response to the *System suitability solution*
$r_W$ = instrument response to the *Reagent water control*
$r_S$ = instrument response to the *Standard solution*

The system is suitable if the percent response efficiency is NLT 85% and NMT 115%. The suitability of the instrument must be periodically demonstrated.

**2.9 Procedure**

1. Measure the TOC of the *Water sample* (section 2.6) and record the response ($r_U$).
2. Compare the $r_U$ to the corrected instrument response ($r_{L1}$) for *Limit 1* [see *Limit Response* (section 2.7)] for the appropriate nominal container volume.
3. If $r_U$ is NMT $r_{L1}$, then the *Water sample* (section 2.6) meets the requirements and the test is completed.
4. If $r_U$ is greater than $r_{L1}$, then compare $r_U$ from step 1 to $r_{L2}$ for the appropriate nominal container volume.
5. If $r_U$ is greater than $r_{L2}$, then the *Water sample* does not meet the requirements and the test is completed.
6. If $r_U$ is greater than $r_{L1}$ but NMT $r_{L2}$, then use suitable analytical procedures appropriate for the intended use to identify and quantify each individual organic impurity exceeding a concentration of 0.20 mg/L of carbon.
7. If there are no individual impurities that exceed 0.20 mg/L of carbon, then the *Water sample* (section 2.6) meets requirements and the test is completed.
8. If there are individual impurities that exceed 0.20 mg/L of carbon, then evaluate them for safety at the concentrations found in this testing.

Official

https://pharmacopeia.com/

9. If the evaluation of the organic impurities is deemed safe, then the *Water sample* (section 2.6) meets the requirements and the test is completed.
10. If the evaluation of the organic impurities is deemed to impact patient safety, then the *Water sample* (section 2.6) does not meet the requirements and the test is completed.

# ⟨644⟩ CONDUCTIVITY OF SOLUTIONS

Portions of the chapter text that are national *USP* text and are not part of the harmonized text, are marked with symbols (••) to specify this fact.

## INTRODUCTION

This chapter provides information on how to apply electrical conductivity measurements (hereafter referred to as "conductivity") of fluid solutions, including pure fluids. •This chapter does not replace the official *Water Conductivity* ⟨645⟩ procedure, which is used to ensure the ionic purity of compendial waters such as *Water for Injection*, *Purified Water*, *Pure Steam* condensate, and *Sterile Water for Injection*, among others.• This chapter is intended for •other• fluid applications when conductivity is used to measure, monitor, or control chemical dispensing, chemical purity, ionic concentration, and other applications where the ionic character of the fluid needs to be known or controlled.

Applications include, but are not limited to, solutions that may be used in clean-in-place, chromatography detection, ionic solution preparations, endpoint detection, dosing, fermentation, and buffer production. In some cases, conductivity measurements can be extended to pure organic fluids such as alcohols and glycols where a weak conductivity signal exists, and the signal can be significantly increased if the organics become contaminated with water or salts. • [NOTE—For additional background information, see *Theory and Practice of Electrical Conductivity Measurements of Solutions* ⟨1644⟩.] •

Conductivity is the measurement of the ability of a fluid to conduct electricity via its chemical ions. The ability of any ion to electrically conduct is directly related to its ion mobility. Conductivity is directly proportional to the concentrations of ions in the fluid, according to *Equation 1*:

$$\kappa = 1000 \sum_{i}^{all\ ions} C_i \lambda_i$$

$\kappa$ = conductivity (S/cm)
$C_i$ = concentration of chemical ion *i* (mol/L)
$\lambda_i$ = specific molar conductance of ion *i* ($S \cdot cm^2/mol$)

Although the SI unit S/m is the appropriate SI unit for conductivity, historically the unit S/cm has been selected by industry as the accepted unit.

On the basis of *Equation 1*, conductivity is not ion selective because it responds to all ions. Furthermore, the specific molar conductance of each ion is different. As a result, unless the percentage composition of ions of the solution is limited and known, the precise concentrations of ionic species cannot be determined from conductivity measurements. However, for examples such as a solution of a single salt or acid or base, such as a caustic solution used in cleaning, the precise concentration can be directly determined. Despite the lack of ionic specificity, conductivity is a valuable laboratory and process tool for measurement and control of total ionic content because it is proportional to the sum of the concentrations of all ionic species (anions and cations) for diluted solutions as described in *Equation 1*. At higher concentrations, conductivity measurements are not perfectly linear with concentration. Conductivity measurements cannot be applied to solids or gases, but they can be applied to the condensate of gases.

Another variable that influences conductivity measurements is the fluid temperature. As the fluid temperature increases, the ion conductance increases, making this physicochemical phenomenon the predominant reason for the temperature-compensation requirement when testing conductive fluids.

The conductivity, $\kappa$, is proportional to the conductance, *G* (S), of a fluid between two electrodes (*Equation 2*):

$$\kappa = G \times \left(\frac{d}{A}\right) = G \times K$$

$\kappa$ = conductivity (S/cm)
*G* = conductance (S)
*d* = distance between the electrodes (cm)
*A* = area of the conducting electrodes ($cm^2$)
*K* = cell constant ($cm^{-1}$), which also equals the ratio of *d*/*A*

The resistivity *p* (Ω-cm) of the fluid is, by definition, the reciprocal of the conductivity (*Equation 3*):

$$\rho = 1/\kappa = 1/(G \times K) = R/K$$

$\rho$ = resistivity (Ω-cm)
$\kappa$ = conductivity (S/cm)
*G* = conductance (S)
*K* = cell constant ($cm^{-1}$)
*R* = resistance (Ω), which is the reciprocal of the conductance, *G*

## APPARATUS

An electrical conductivity measurement consists of the determination of resistance of the fluid between and around the electrodes of the conductivity sensor. To achieve this measurement, the primary instrumentation is the resistance-measuring circuit and the conductivity sensor, and they are usually connected by a cable when the sensor and the user interface are separated.

The resistance measurement is made by applying an alternating current (AC, meaning the flow of electric charge periodically reverses direction) voltage (or current) to the electrodes, measuring the current (or voltage), and calculating the resistance according to Ohm's law. The alternating source is used to prevent the polarization (collection of ions) at the electrodes. Depending on the instrument, the measuring frequency of the measuring system adjusts automatically according to the measuring conditions of the instrument, and there may be multiple resistance-measuring circuits embedded in the measuring system. The resistance-measurement circuit may be embedded in the transmitter or in the sensor.

The conductivity sensor consists of at least two electrical conductors of a fixed size and geometry, separated by an electrical insulator. The electrodes, insulator, and any other wetted materials should be constructed of materials that are unreactive to fluids with which they may come into contact. Also, the sensor construction should withstand the environmental conditions (process or ambient temperature, pressure, cleaning applications) that it would be subjected to.

Most conductivity sensors have temperature devices such as a platinum resistance temperature device (RTD) or negative temperature coefficient (NTC) thermistor embedded inside the sensor, although external temperature measurement is possible. The purpose of the temperature measurement is for temperature compensation of the conductivity measurement.

## CELL CONSTANT DETERMINATION

The purpose of the sensor's cell constant is to normalize the conductance (or resistance) measurement for the geometrical construction of the two electrodes.

The cell constant is determined by immersing the conductivity sensor in a solution of known conductivity. Solutions of known conductivity can be obtained by preparation of specific mixtures according to national authoritative sources or procurement of commercially available certified and traceable standard solutions. These recipes or certified solutions can range from 5 to 200,000 µS/cm, depending on the level of accuracy desired. Alternatively the cell constant is determined by comparison to other reference conductivity measuring systems (also available as an accredited calibration service). [NOTE—Conductivity measurements are not perfectly linear with concentration.]

The measured cell constant of the conductivity sensor must be within 5% of the nominal value indicated by the sensor certificate, unless otherwise prescribed.

Modern conductivity sensors normally do not change their cell constant over their lifetime. If a change of the cell constant is detected during calibration, a cleaning of the sensor is appropriate according to the manufacturer's recommendations. Following that, the calibration procedure should be repeated. Sometimes "memory effects" appear, particularly when changing from high to low concentrations if the sensor is not well flushed.

## CALIBRATION OF TEMPERATURE

In addition to verifying the sensor's cell constant, the embedded temperature device (or external temperature device) should be appropriately calibrated for the application to apply the temperature compensation algorithm accurately. The temperature accuracy that is required depends on the criticality of the temperature to the application. An accuracy of ±1° typically suffices.

## CALIBRATION OF MEASUREMENT ELECTRONICS

The measurement circuit of the system is fundamentally an AC resistance measuring device. Appropriate verification and/or calibration of the measuring circuit is required for measurement systems with signal transfer via analog cable. This is accomplished by disconnecting the measuring circuit from the sensor's electrodes, attaching traceable resistors of known value with the cable of the measurement system to the measuring circuit, and verifying that the measured resistance agrees with the resistor value to an acceptable level. A typical acceptance criterion for the resistance accuracy is <2% of the reading at resistances >100 Ω, and increasing to 5% at lower resistances. However, the application criticality should ultimately determine the desired accuracy.

For conductivity systems that cannot have the resistance-measuring circuit disconnected from the electrodes (e.g., measurement circuit and electrodes in one mutual housing), it may be difficult to directly adjust or verify the circuit accuracy, depending on the sensor design. An alternative method of verifying the measurement system integrity is a system calibration according to the procedures for the cell constant determination for each measuring circuit that is intended to be used.

If verification/calibration of the sensor's cell constant, temperature device, and measuring circuit are done at the same service interval, the measuring circuit should be verified first, the temperature device next, and the cell constant last. Because all of these parameters are typically very stable due to modern electronics and stable sensor construction, frequent calibration (such as daily) is not usually required. Comparison to qualified reference systems is also a proper means of calibration. Calibration is performed at appropriate intervals as defined in the quality management system.

## TEMPERATURE COMPENSATION

Because the conductivity of a fluid is temperature dependent, temperature compensation of the conductivity measurement is necessary unless otherwise prescribed (e.g., purified water, water for injection). An appropriate temperature compensation algorithm will ensure that changes in the conductivity measurement can be ascribed to concentration changes and not temperature changes. Conductivity measurements are normally referenced to 25°. A common form of linear temperature compensation uses *Equation 4*:

$$\kappa_{25} = \frac{\kappa_T}{[1 + \alpha(T - 25)]}$$

$\kappa_{25}$ = conductivity compensated to 25°
$\kappa_T$ = conductivity at $T$
$\alpha$ = temperature coefficient of the conductivity
$T$ = measured temperature

A temperature coefficient of 2.1% per 1° is commonly used for many salt solutions. Most salt-based solutions have linear compensation factors ranging from 1.9% to 2.2% per 1°. Depending on the fluid samples, other forms of temperature compensation may be appropriate. Non-linear temperature compensation data for a variety of solutions is widely available (e.g., as described in ISO 7888 *Water quality—Determination of electrical conductivity*). In cases of very low conductivity (<10 µS/cm), such as purified ▲water for cleaning/rinsing purposes,▲ (USP 1-May-2021) two compensations need to be made. One is for the intrinsic conductivity of water, and the other is for the other ionic species in water. These compensations are normally combined and embedded in the microprocessor-controlled conductivity measurement systems. This is not supplied in all conductivity measurement technologies.

***Change to read:***

## CONDUCTIVITY MEASUREMENT OF FLUIDS

For off-line ▲or at-line▲ (USP 1-May-2021) batch measurements, rinse the cleaned sensor with the fluid to be measured. Then immerse the sensor in the fluid to be measured, and record the temperature and the temperature-compensated conductivity as required. Be sure that the position of the sensor in the container does not affect the conductivity measurement, because the container walls can affect the measurement for some electrode designs.

For continuous on-line or ▲in▲ (USP 1-May-2021)-line measurements, install the cleaned sensor into the pipe, tank, or other containment vessel, and flush, if necessary. Make sure proper installation procedures are applied to prevent bubbles or particles from collecting between the electrodes. Be sure that the position of the sensor in the pipe or tank does not affect the conductivity measurement, because the nearby surfaces can affect the measurement for some electrode designs.

Record the temperature and the temperature-compensated conductivity as required.

For all batch or continuous measurements, ensure that the wetted components of the sensor are compatible with the fluid and the temperature to be measured.

# ⟨645⟩ WATER CONDUCTIVITY

## INTRODUCTION

Electrical conductivity in water is a measure of the ion-facilitated electron flow through it. Water molecules dissociate into ions as a function of pH and temperature and result in a very predictable conductivity. Some gases, most notably carbon dioxide, readily dissolve in water and interact to form ions, which predictably affect conductivity also. For the purpose of this discussion, these ions and their resulting conductivity can be considered intrinsic to the water.

Water conductivity is also affected by the presence of extraneous ions. The extraneous ions used in modeling the conductivity specifications described below are the chloride and ammonia ions. The conductivity of the ubiquitous chloride ion (at the theoretical endpoint concentration of 0.47 ppm when chloride was a required attribute test in *USP 22* and earlier revisions) and the ammonium ion (at the limit of 0.3 ppm) represents a major portion of the allowed water ionic impurity level. A balancing quantity of anions (such as chloride, to counter the ammonium ion) and cations (such as sodium, to counter the chloride ion) is included in this allowed impurity level to maintain electroneutrality. Extraneous ions such as these may have a significant effect on the water's chemical purity and suitability for use in pharmaceutical applications.

The procedure in the section *Bulk Water* is specified for measuring the conductivity of waters such as *Purified Water*, *Water for Injection*, *Water for Hemodialysis*, and the condensate of *Pure Steam*. The procedure in the section *Sterile Water* is specified for measuring the conductivity of waters such as *Sterile Purified Water*, *Sterile Water for Injection*, *Sterile Water for Inhalation*, and *Sterile Water for Irrigation*.

The procedures below shall be performed using instrumentation that has been calibrated, has conductivity sensor cell constants that have been accurately determined, and has a temperature compensation function that has been disabled for *Bulk Water* Stage 1 testing. For both online and offline measurements, the suitability of instrumentation for quality control testing is also dependent on the sampling location(s) in the water system. The selected sampling instrument location(s) must reflect the quality of the water used.

## INSTRUMENT SPECIFICATIONS AND OPERATING PARAMETERS

Water conductivity must be measured accurately with calibrated instrumentation. An electrical conductivity measurement consists of the determination of the conductance, $G$ (or its inverse, resistance, $R$), of the fluid between and around the electrodes. The conductance ($1/R$) is directly affected by the geometrical properties of the electrodes; i.e., the conductance is inversely proportional to the distance ($d$) between the electrodes and proportional to the area ($A$) of the electrodes. This geometrical ratio ($d/A$) is known as the cell constant, $\Theta$. Thus the measured conductance is normalized for the cell constant to determine the conductivity, $\kappa$, according to the following equation:

$$\text{conductivity, } \kappa \text{ (S/cm)} = \Theta \text{ (cm}^{-1}\text{)}/R \text{ } (\Omega)$$

It is the cell constant and the resistance measurement that must be verified and adjusted, if necessary.

### Cell Constant

The cell constant must be known within ±2%. The cell constant can be verified directly by using a solution of known or traceable conductivity, or indirectly by comparing the instrument reading taken with the conductivity sensor in question to readings from a conductivity sensor of known or traceable cell constant. If necessary, adjust the cell constant following the manufacturer's instrument protocol. The frequency of verification/calibration is a function of the sensor design.

### Resistance Measurement

Calibration (or verification) of the resistance measurement is accomplished by replacing the conductivity sensor electrodes with precision resistors having standards traceable to NIST or equivalent national authorities in other countries (accurate to ±0.1% of the stated value) to give a predicted instrument conductivity response. The accuracy of the resistance measurement is acceptable if the measured conductivity with the traceable resistor is within ±0.1 µS/cm of the calculated value according to the equation above. For example, the traceable resistor is 50 kΩ, and the cell constant, Θ, is 0.10 $cm^{-1}$. The calculated value is $2.0 \times 10^{-6}$ S/cm or 2.0 µS/cm. The measured value should be 2.0 ± 0.1 µS/cm. The instrument must have a minimum resolution of 0.1 µS/cm on the lowest range.

The target conductivity value(s) should be based on the type of water to be analyzed, and it should be equal to or less than the water conductivity limit for that type of water. Multiple measuring circuits may be embedded in the meter or the sensor, and each circuit may require separate verification or calibration before use. The frequency of recalibration is a function of instrument system design.

### System Verification

The cell constant of the user's sensor can be determined with the user's resistance measurement system, or the cell constant can be determined with an independent resistance measurement system. If the cell constant is determined with an independent resistance measurement system, it is recommended that the user verify that the sensor has been properly connected to the resistance measurement system to ensure proper performance. Verification can be made by comparing the conductivity (or

@2024 USPC

resistivity) values displayed by the measuring equipment with those of an external calibrated conductivity-measuring device. The two non–temperature-compensated conductivity (or resistivity) values should be equivalent to or within ±5% of each other, or should have a difference that is acceptable on the basis of product water criticality and/or the water conductivity ranges in which the measurements are taken. The two conductivity sensors should be positioned close enough together to measure the same water sample at the same temperature and water quality.

### Temperature Compensation and Temperature Measurements

Because temperature has a substantial effect on conductivity readings of specimens at high and low temperatures, many instruments automatically correct the actual reading to display the value that theoretically would be observed at the nominal temperature of 25°. This is typically done using a temperature sensor embedded in the conductivity sensor and a software algorithm embedded in the instrument. This temperature compensation algorithm may not be accurate for the various water types and impurities. For this reason, conductivity values used in the *Stage 1* test for *Bulk Water* are non–temperature-compensated measurements. Other conductivity tests that are specified for measurement at 25° can use either temperature-compensated or non–temperature-compensated measurements.

A temperature measurement is required for the *Stage 1* test or for the other tests at 25°. It may be made using the temperature sensor embedded in the conductivity cell sensor. An external temperature sensor positioned near the conductivity sensor is also acceptable. Accuracy of the temperature measurement must be ±2°.

## BULK WATER

The procedure and test limits in this section are intended for *Purified Water*, *Water for Injection*, *Water for Hemodialysis*, the condensate of *Pure Steam*, and any other monographs that specify this section.

This is a three-stage test method to accommodate online or offline testing. Online conductivity testing provides real-time measurements and opportunities for real-time process control, decision, and intervention. Precautions should be taken while collecting water samples for offline conductivity measurements. The sample may be affected by the sampling method, the sampling container, and environmental factors such as ambient carbon dioxide concentration and organic vapors. This procedure can be started at *Stage 2* if offline testing is preferred.

### Procedure

#### STAGE 1

*Stage 1* is intended for online measurement or may be performed offline in a suitable container.

1. Determine the temperature of the water and the conductivity of the water with a non–temperature-compensated conductivity reading.
2. Using *Table 1*, find the temperature value that is NMT the measured temperature, i.e., the next lower temperature. The corresponding conductivity value on this table is the limit.

[NOTE—Do not interpolate.]

3. If the measured conductivity is NMT the table value determined in step 2, the water meets the requirements of the test for conductivity. If the conductivity is higher than the table value, proceed with *Stage 2*.

**Table 1. Stage 1—Temperature and Conductivity Requirements** (for non–temperature-compensated conductivity measurements only)

| Temperature | Conductivity Requirement (µS/cm) |
|---|---|
| 0 | 0.6 |
| 5 | 0.8 |
| 10 | 0.9 |
| 15 | 1.0 |
| 20 | 1.1 |
| 25 | 1.3 |
| 30 | 1.4 |
| 35 | 1.5 |
| 40 | 1.7 |
| 45 | 1.8 |
| 50 | 1.9 |
| 55 | 2.1 |
| 60 | 2.2 |
| 65 | 2.4 |
| 70 | 2.5 |

DOI: https://doi.org/10.31003/USPNF_M99405_01_01

**Table 1. Stage 1—Temperature and Conductivity Requirements** (for non–temperature-compensated conductivity measurements only) *(continued)*

| Temperature | Conductivity Requirement (µS/cm) |
|---|---|
| 75 | 2.7 |
| 80 | 2.7 |
| 85 | 2.7 |
| 90 | 2.7 |
| 95 | 2.9 |
| 100 | 3.1 |

STAGE 2

4. Transfer a sufficient amount of water to a suitable container, and stir the test specimen. Adjust the temperature, if necessary, and, while maintaining it at 25 ± 1°, begin vigorously agitating the test specimen while periodically observing the conductivity. When the change in conductivity (due to uptake of atmospheric carbon dioxide) is less than a net of 0.1 µS/cm per 5 min, note the conductivity.

[NOTE—Conductivity measurements at this stage may be temperature-compensated to 25° or non–temperature-compensated.]

5. If the conductivity is not greater than 2.1 µS/cm, the water meets the requirements of the test for conductivity. If the conductivity is greater than 2.1 µS/cm, proceed with *Stage 3*.

STAGE 3

6. Perform this test within approximately 5 min of the conductivity determination in step 5, while maintaining the sample temperature at 25 ± 1°. Add a saturated potassium chloride solution to the same water sample (0.3 mL per 100 mL of the test specimen), and determine the pH to the nearest 0.1 pH unit, as directed in *pH* ⟨791⟩.

7. Referring to *Table 2*, determine the conductivity limit at the measured pH value. If the measured conductivity in step 4 is NMT the table value determined in step 6, the water meets the requirements of the test for conductivity. If either the measured conductivity is greater than this value or the pH is outside the range of 5.0–7.0, the water does not meet the requirements of the test for conductivity.

**Table 2. Stage 3—pH and Conductivity Requirements** (for atmosphere- and temperature-equilibrated samples only)

| pH | Conductivity Requirement (µS/cm) |
|---|---|
| 5.0 | 4.7 |
| 5.1 | 4.1 |
| 5.2 | 3.6 |
| 5.3 | 3.3 |
| 5.4 | 3.0 |
| 5.5 | 2.8 |
| 5.6 | 2.6 |
| 5.7 | 2.5 |
| 5.8 | 2.4 |
| 5.9 | 2.4 |
| 6.0 | 2.4 |
| 6.1 | 2.4 |
| 6.2 | 2.5 |
| 6.3 | 2.4 |
| 6.4 | 2.3 |
| 6.5 | 2.2 |
| 6.6 | 2.1 |
| 6.7 | 2.6 |
| 6.8 | 3.1 |
| 6.9 | 3.8 |
| 7.0 | 4.6 |

# STERILE WATER

The procedure and test limits are intended for *Sterile Purified Water*, *Sterile Water for Injection*, *Sterile Water for Inhalation*, and *Sterile Water for Irrigation*, and any other monographs that specify this section. The sterile waters are derived from *Purified Water* or *Water for Injection*, and therefore have been determined to be compliant with the *Bulk Water* requirements before being stored in the container. The specification provided represents the maximum allowable conductivity value, taking into consideration the limitation of the measurement method and reasonable container leaching. Such specification and the sampling volume choices should be defined and validated on the basis of the intended purpose of the water.

## Procedure

Obtain a sample that suitably reflects the quality of water used. Before opening, vigorously agitate the package to homogenize the water sample. Several packages may be required to collect sufficient water for analysis.

Transfer a sufficient amount of water to a suitable container, and stir the test specimen. Adjust the temperature, if necessary, and, while maintaining it at 25 ± 1°, begin vigorously agitating the test specimen while periodically observing the conductivity. When the change in conductivity (due to uptake of ambient carbon dioxide) is less than a net of 0.1 µS/cm per 5 min, note the conductivity.

For containers with a nominal volume of 10 mL or less, if the conductivity is NMT 25 µS/cm, the water meets the requirements. For containers with a nominal volume greater than 10 mL, if the conductivity is NMT 5 µS/cm, the water meets the requirements.

# ⟨651⟩ CONGEALING TEMPERATURE

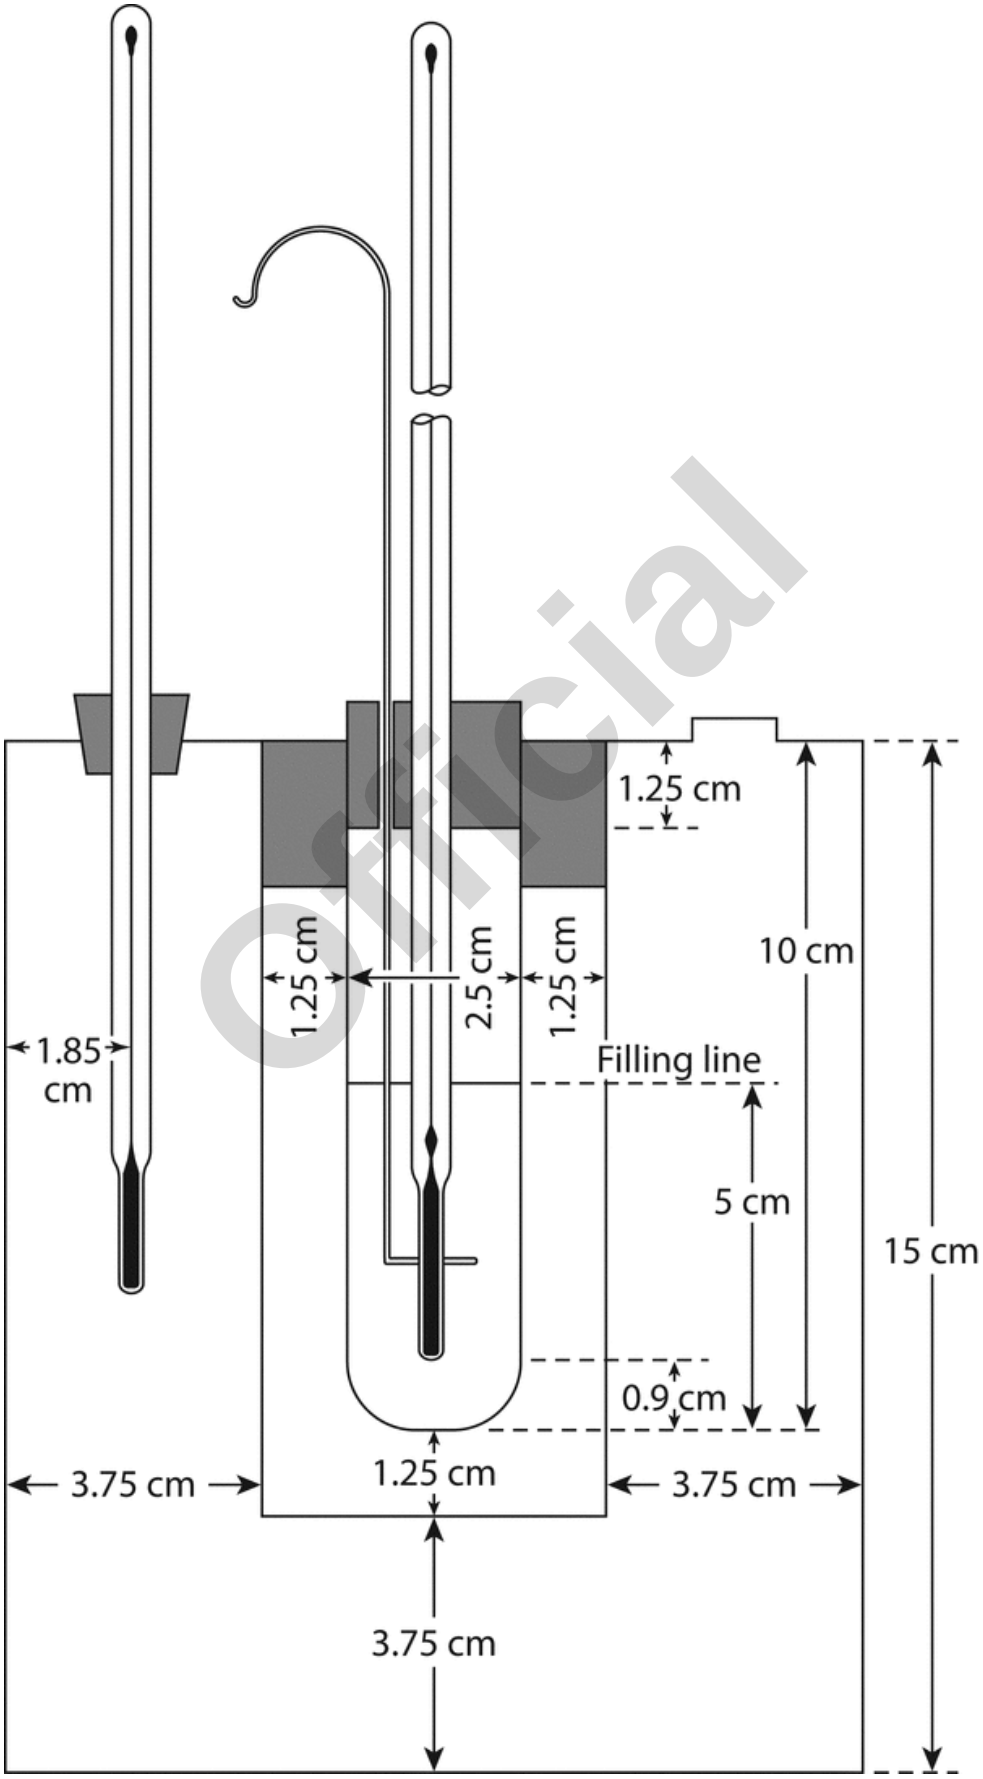
The temperature at which a substance passes from the liquid to the solid state upon cooling is a useful index to purity if heat is liberated when the solidification takes place, provided that any impurities present dissolve in the liquid only, and not in the solid. Pure substances have a well-defined freezing point, but mixtures generally freeze over a range of temperatures. For many mixtures, the congealing temperature, as determined by strict adherence to the following empirical methods, is a useful index of purity. The method for determining congealing temperatures set forth here is applicable to substances that melt between –20° and 150°, the range of the thermometer used in the bath. The congealing temperature is the maximum point (or lacking a maximum, the point of inflection) in the temperature-time curve.

## APPARATUS

Assemble an apparatus similar to that *illustrated,*

Official

https://pharmacopeia.cn/v-gbook-en/



Congealing Temperature Apparatus

Official

https://pharmacopeia.com/

in which the container for the substance is a 25- × 100-mm test tube. This is provided with a suitable, short-range thermometer suspended in the center, and a wire stirrer, about 30 cm long, bent at its lower end into a horizontal loop around the thermometer. Use a thermometer having a range not exceeding 30°, graduated in 0.1° divisions, and calibrated for, but not used at, 76-mm immersion. A suitable series of thermometers, covering a range from −20° to +150°, is available as the ASTM E1 series 89C through 96C. Other temperature-measuring devices may be used if they are validated for this procedure (see *General Notices, 6.80.30. Temperature Reading Devices*). Dimensions should be within ±20% of those given in the illustration.

The specimen container is supported, by means of a cork, in a suitable water-tight cylinder about 50 mm in internal diameter and 11 cm in length. The cylinder, in turn, is supported in a suitable bath sufficient to provide not less than a 37-mm layer surrounding the sides and bottom of the cylinder. The outside bath is provided with a suitable thermometer.

## PROCEDURE

Melt the substance, if a solid, at a temperature not exceeding 20° above its expected congealing point, and pour it into the test tube to a height of 50 to 57 mm. Assemble the apparatus with the bulb of the test tube thermometer immersed halfway between the top and bottom of the specimen in the test tube. Fill the bath to about 12 mm from the top of the tube with suitable fluid at a temperature 4° to 5° below the expected congealing point.

In case the substance is a liquid at room temperature, carry out the determination using a bath temperature about 15° below the expected congealing point.

When the test specimen has cooled to about 5° above its expected congealing point, adjust the bath to a temperature 7° to 8° below the expected congealing point. Stir the specimen continuously during the remainder of the test by moving the loop up and down between the top and bottom of the specimen, at a regular rate of 20 complete cycles per minute.

Congelation frequently may be induced by rubbing the inner walls of the test tube with the thermometer, or by introducing a small fragment of the previously congealed substance. Pronounced supercooling may cause deviation from the normal pattern of temperature changes. If the latter occurs, repeat the test, introducing small particles of the material under test in solid form at 1° intervals as the temperature approaches the expected congealing point.

Record the reading of the test tube thermometer every 30 seconds. Continue stirring only so long as the temperature is gradually falling, stopping when the temperature becomes constant or starts to rise slightly. Continue recording the temperature in the test tube every 30 seconds for at least 3 minutes after the temperature again begins to fall after remaining constant.

The average of not less than four consecutive readings that lie within a range of 0.2° constitutes the congealing temperature. These readings lie about a point of inflection or a maximum, in the temperature-time curve, that occurs after the temperature becomes constant or starts to rise and before it again begins to fall. The average to the nearest 0.1° is the congealing temperature.

# ⟨659⟩ PACKAGING AND STORAGE REQUIREMENTS

**(A portion of the *Packaging* section of this chapter will become official on December 1, 2025 as indicated. Early adoption of the requirements in this chapter and *Plastic Materials of Construction* ⟨661.1⟩ and *Plastic Packaging Systems for Pharmaceutical Use* ⟨661.2⟩ is permitted by USP.)**

## INTRODUCTION

The purpose of this chapter is to provide packaging definitions, auxiliary packaging information, and storage condition definitions relevant to the storage and distribution of active ingredients, excipients, and medical products, such as pharmaceuticals, combination products, and,when labeled as being USP compliant, dietary supplements.

***Change to read:***

## PACKAGING

Packaging materials must not interact physically or chemically with a packaged article in a manner that causes its safety, identity, strength, quality, or purity to fail to conform to established requirements. ▲Any plastic material used to construct a *Packaging system* must meet the applicable requirements of *Plastic Materials of Construction* ⟨661.1⟩.▲ (Official 1-Dec-2025) All *Packaging systems* must meet the applicable requirements specified in *Containers—Glass* ⟨660⟩, *Plastic Packaging Systems and Their Materials of Construction* ⟨661⟩, ▲*Plastic Packaging Systems for Pharmaceutical Use* ⟨661.2⟩,▲ (Official 1-Dec-2025) and *Auxiliary Packaging Components* ⟨670⟩. All elastomeric closures must meet the applicable requirements in *Elastomeric Components in Injectable Pharmaceutical Product Packaging/Delivery Systems* ⟨381⟩.

Every monograph in *USP–NF* must have packaging and storage requirements. For the packaging portion of the statement, the choice of containers is provided in this chapter. For active pharmaceutical ingredients (APIs), the choice would be a tight or well-closed container (as specified in the monograph), and, where needed, a light-resistant container. For excipients, given their typical presentation as large-volume commodity items (*Packaging systems* ranging from drums to tank cars), a well-closed container is an appropriate default requirement. Articles must be protected from moisture, freezing, and excessive heat (see *General Definitions*) when no specific directions or limitations are provided.

The compendial requirements for the use of specified containers apply also to articles packaged by *Dispensers*, *Repackagers*, or other individuals, unless otherwise indicated in the individual drug product monograph.

## POISON PREVENTION PACKAGING ACT

This act, which is administered by the US Consumer Product Safety Commission (CPSC), requires special packaging for most human oral prescription drugs, oral controlled drugs, certain non-oral prescription drugs, certain dietary supplements, and many over-the-counter (OTC) drug preparations, to protect the public from personal injury or illness from misuse of these preparations [16 Code of Federal Regulations (CFR) §1700].

The primary packaging of substances regulated under the Poison Prevention Packaging Act (PPPA) must comply with the special packaging standards. These apply to all packaging types, including reclosable, non-reclosable, and unit-dose types.

Special packaging is not required for drugs dispensed within a hospital setting for inpatient administration. Also, special packaging does not need to be used by manufacturers and packagers of bulk-packaged prescription drugs that will be repackaged by the pharmacist. PPPA-regulated prescription drugs may be dispensed in non-*Child-resistant packaging* upon the request of the purchaser or when directed in a legitimate prescription.

Manufacturers or packagers of PPPA-regulated OTC preparations are allowed to package one size in non-*Child-resistant packaging* as long as popular-size, special packages are also supplied. The non-*Child-resistant packaging* requires special labeling.

## TEMPERATURE AND STORAGE

Specific directions are stated in some monographs with respect to storage conditions (e.g., the temperature or humidity) at which an article must be stored and shipped. Storage and shipping directions apply except where the label on the article or its prescribing information has different storage conditions that are based on stability studies. Where no specific directions or limitations are provided in the article's labeling or prescribing information, articles must be protected from moisture, freezing, and excessive heat, and, where necessary, from light during shipping and distribution; drug substances are exempt from this requirement.

Official

# GENERAL DEFINITIONS

## Packaging Definitions

**Packaging system** (also referred to as a Container–closure system)**:** The sum of *Packaging components* and materials that together contain and protect the article. This includes *Primary packaging components* as well as *Secondary packaging components* when such components are required to provide additional protection.

**Container:** A receptacle that holds an intermediate compound, API, excipient, or dosage form, and is in direct contact with the article (e.g., ampules, vials, bottles, syringes, and pen injectors).

**Closure:** A material that seals an otherwise open space of a *Container* and provides protection for the contents. It also provides access to the contents of the *Container* (e.g., screw caps and stoppers).

**Packaging component:** Any single part of the *Package* or *Container–closure system,* including: the *Container*; *Closures*; ferrules and overseals; *Closure* liners; *Container* liners (e.g., tube cartridge liners); inner seals; administration ports; overwraps; administration accessories; labels; cardboard boxes; and shrink wrap.

**Primary packaging component:** A *Packaging component* that is in direct contact with or may come into direct contact with the article.

**Secondary packaging component:** A *Packaging component* that is in direct contact with a *Primary packaging component* and may provide additional protection for the article.

**Tertiary packaging component:** A *Packaging component* that is in direct contact with a *Secondary packaging component* and may provide additional protection for the article during transportation and/or storage.

**Ancillary component:** A component or entity that may come into contact with a *Tertiary packaging component* during the distribution, storage, and/or transportation of the packaged article (e.g., pallets, skids, and shrink wrap).

**Associated component:** A *Packaging component* that is typically intended to deliver the drug article to the patient but is not stored in contact with the article for its entire shelf life (e.g., spoons, *Dosing cups*, and dosing syringes).

**Materials of construction:** The materials (e.g., glass, plastic, elastomers, and metal) of which a *Packaging component* consists.

**Small-volume injection** (also referred to as Small-volume parenteral)**:** An injectable dosage form that is packaged in *Containers* labeled as containing 100 mL or less.

**Large-volume injection** (also referred to as Large-volume parenteral)**:** An injectable dosage form that is packaged in *Containers* labeled as containing more than 100 mL.

**Child-resistant packaging:** A *Packaging system* designed or constructed to meet CPSC standards pertaining to opening by children (16 CFR §1700.20 et seq. and 16 CFR §1700.15).

**Senior-friendly packaging:** A *Packaging system* designed or constructed to meet CPSC standards pertaining to opening by senior adults (16 CFR §1700.15 and 16 CFR §1700.20).

**Restricted delivery system:** A *Packaging system* designed or constructed to restrict (control) the amount of the drug product that may be delivered in order to limit unintended access by children and other similarly vulnerable populations. *Restricted delivery systems* should meet and may exceed CPSC standards for special packaging [*Child-resistant* and *Senior-friendly packaging* (16 CFR §1700.15 et seq.)]. For oral medicinal liquids, surface and flow characteristics vary. It is the responsibility of the manufacturer to ensure that all components of the *Restricted delivery system* provide the intended safety protection. One component of the *Restricted delivery system* is the flow restrictor, which is a *Packaging component* that restricts the flow of liquid. The flow restrictor may be used as part of a *Restricted delivery system* or as an adapter to facilitate use of a measuring device for oral medicinal liquids. A flow restrictor should not compromise CPSC standards for special packaging [*Child-resistant* and *Senior-friendly packaging* (16 CFR §1700.15 et seq.)].

**Tamper-evident packaging:** A *Packaging system* that may not be accessed without obvious destruction of the seal or some portion of the *Packaging system*. *Tamper-evident packaging* must be used for sterile drug products intended for ophthalmic or otic use, except where extemporaneously compounded for immediate dispensing on prescription. Drug products intended for sale without prescription are also required to comply with the *Tamper-evident packaging* and labeling requirements of the FDA where applicable (21 CFR §211.132). Preferably, the immediate *Container* and/or the outer *Container* or protective packaging used by a manufacturer or distributor for all dosage forms that are not specifically exempt is designed to show evidence of any tampering with the contents.

**Reclosable packaging:** A package that after it has been initially opened is capable of being reclosed with a similar degree of security and is capable of being used a sufficient number of times to dispense the total contents without loss of security. *Reclosable packaging* may incorporate child-resistance capabilities.

**Non-reclosable packaging:** A package or part of a package that cannot be closed again after all or part of the contents have been removed. Examples of *Non-reclosable packaging* are blisters, sachets, strips, and other *Single-unit containers*. *Non-reclosable packaging* may include cold-formed foil blisters, foil strip packs, and polyvinyl chloride (PVC)/Aclar combining multilayer materials that are thermo-formed or cold-formed foil blisters. *Non-reclosable packaging* may be child resistant depending on the intended use and place of use. Household non-reclosables are subject to the PPPA as defined in 16 CFR §1700.14.

**Hermetic container:** A *Container–closure system* that is impervious to air or any other gas under the ordinary or customary conditions of handling, shipment, storage, and distribution.

**Tight container:** A *Container–closure system* that protects the contents from contamination by extraneous liquids, solids, or vapors; from loss of the article; and from efflorescence, deliquescence, or evaporation under the ordinary or customary conditions of handling, shipment, storage, and distribution, and is capable of tight reclosure. Where a tight container is specified, it may be replaced by a hermetic container for a single dose of an article. [NOTE—Where packaging and storage in a tight container or well-closed container is specified in the individual monograph, the container used for an article when dispensed on prescription meets the requirements in *Containers—Performance Testing* ⟨671⟩.]

**Well-closed container:** A *Container–closure system* that protects the contents from contamination by extraneous solids and from loss of the article under the ordinary or customary conditions of handling, shipment, storage, and distribution. See ⟨671⟩.

**Light-resistant container:** A *Container–closure system* that protects the contents from the effects of light by virtue of the specific properties of the material of which it is composed, including any coating applied to it. A clear and colorless or a translucent container may be made light-resistant by means of an opaque covering or by use of secondary packaging, in which case the label of the container bears a statement that the opaque covering or secondary packaging is needed until the articles are to be used or administered. Where it is directed to "protect from light" in an individual monograph, preservation in a light-resistant container is intended. See ⟨671⟩, *Spectral Transmission* ▲*for Light-Resistant Packaging Components or Systems*▲ (ERR 1-Apr-2021) or ⟨661.2⟩, *Functionality* ▲*Test Method,*▲ (ERR 1-Dec-2025) *Spectral Transmission Requirements for Light-Resistant Components and Systems*.

**Equivalent container–closure system:** A *Container–closure system* that is as protective as or more protective than the original manufacturer's *Packaging system* in terms of moisture vapor transmission rate, oxygen transmission, light transmission, and compatibility. System equivalency extends to any special protective materials, such as those for seals or desiccants associated with the original *Packaging system*.

**Table 1. Packaging Systems Definitions: Injection versus Noninjection**

| Injection | Noninjection |
|---|---|
| Multiple-dose | Multiple-unit |
| Single-dose | Single-unit |
| — | Unit-dose |
| — | Unit-of-use |
| Pharmacy bulk package | — |
| Imaging bulk package | — |

## Injection Packaging Systems

**Multiple-dose container** (also referred to as Multi-dose)**:** A *Container–closure system* that holds a sterile medication for parenteral administration (injection or infusion) that has met antimicrobial effectiveness testing requirements, or is excluded from such testing requirements by FDA regulation. A *Multiple-dose container* is intended to contain more than one dose of a drug product. When space permits, a *Multiple-dose container* is labeled as such. *Multiple-dose containers* are generally expected to contain 30 mL or less of medications. The beyond-use date for an opened or entered (e.g., needle-punctured) *Multiple-dose container* is 28 days unless otherwise specified by the manufacturer on the label. An example of a *Multiple-dose container* is a vial.

**Single-dose container:** A *Container–closure system* that holds a sterile medication for parenteral administration (injection or infusion) that is not required to meet the antimicrobial effectiveness testing requirements. A *Single-dose container* is designed for use with a single patient as a single injection/infusion.[1] When space permits, a *Single-dose container* is labeled as such and should include on the label appropriate discard statements. Examples of *Single-dose containers* are vials, ampules, and prefilled syringes.

**Pharmacy bulk package:** A *Container–closure system* of a sterile preparation for parenteral use that contains many single doses. The contents are intended for use in a pharmacy admixture program and are restricted to the preparation of admixtures for infusion or, through a sterile transfer device, for the filling of empty sterile syringes. The *Closure* must be penetrated only one time after constitution, if necessary, with a suitable sterile transfer device or dispensing set that allows measured dispensing of the contents. The *Pharmacy bulk package* is to be used only in a suitable work area such as a laminar flow hood (or an equivalent clean-air compounding area). Designation as a *Pharmacy bulk package* is limited to injection, for injection, or injectable emulsion dosage forms as defined in *Nomenclature* ⟨1121⟩, *General Nomenclature Forms*.

*Pharmacy bulk packages*, although containing more than one single dose, are exempt from the *Multiple-dose container* volume limit of 30 mL and the requirement that they contain a substance or suitable mixture of substances to prevent the growth of microorganisms. See *Labeling* ⟨7⟩ for labeling requirements.

**Imaging bulk package:** A container of a sterile preparation for parenteral use that contains many single doses of a contrast agent (medical imaging drug product) for use with a medical imaging device. The contents are restricted to use in direct conjunction with a device with features to mitigate the risk of cross-contamination (i.e., an automated contrast injection system, contrast management system, or contrast media transfer set approved or cleared for use with an *Imaging bulk package*). The sterility assurance of the *Imaging bulk package* contents in part is dependent upon the automated contrast injection system, the contrast management system, or the contrast media transfer set.

The *Imaging bulk package* is to be used only in a room designated for radiological procedures that involve intravascular administration of a contrast agent. Using aseptic technique, the *Imaging bulk package* closure must be penetrated only one time with a suitable sterile component of the automated contrast injection system, the contrast management system,or the contrast media transfer set. If the integrity of the *Imaging bulk package* and the delivery system cannot be assured through direct continuous supervision, the *Imaging bulk package* and all associated disposables for the automated contrast injection system, the contrast management system, or the contrast media transfer set should be discarded.

Designation as an *Imaging bulk package* is limited to injection, for injection, or injectable emulsion dosage forms as defined in ⟨1121⟩, *General Nomenclature Forms*. *Imaging bulk packages*, although containing more than one single dose, are exempt from the multiple-dose container volume limit of 30 mL. The contents of the *Imaging bulk package* must have demonstrated the ability to limit the growth of microorganisms over the labeled period of use.

[1] Exceptions may be considered only under conditions described in *Pharmaceutical Compounding—Sterile Preparations* ⟨797⟩.

Official

https://pharmacopeia.com/

Where a container is offered as an *Imaging bulk package*, the label must: 1) state prominently "Imaging Bulk Package" and, in juxtaposition with this statement, include the following use statement: "For use only with an automated contrast injection system, contrast management system, or contrast media transfer set approved or cleared for use with this contrast agent in this Imaging Bulk Package"; 2) bear a statement limiting the time frame in which the container may be used once it has been entered, provided it is held under the labeled storage conditions; and 3) bear the statement, "See drug and device labeling for information on devices indicated for use with this Imaging Bulk Package and techniques to help assure safe use".

## Noninjection Packaging Systems

**Multiple-unit container:** A *Container–closure system* that permits withdrawal of successive portions of a noninjection article without changing the safety, strength, quality, or purity of the remaining portion (e.g., bottle of capsules, tablets, oral or topical liquids, and semisolids).

**Single-unit container:** A *Container–closure system* that holds a quantity of a noninjection article intended for administration as a single dose or a single finished device intended for use promptly after the *Packaging system* is opened.

**Unit-dose container:** A single-unit *Container–closure system* for an article intended for administration by other than the parenteral route as a single dose.

**Unit-of-use container:** A *Container–closure system* that contains a specific quantity of an article that is intended to be dispensed as such without further modification except for the addition of appropriate labeling (see ⟨7⟩). It is not permitted to repackage *Unit-of-use containers* for sale.

## Miscellaneous

**Repackaging:** The act of removing a drug product from the original manufacturer's *Packaging system* and placing it into another *Packaging system*, usually one of smaller size.

**Repackager:** A firm that repackages drug products for distribution (e.g., for resale to distributors, hospitals, or pharmacies). For drug products, this applies to a function that is beyond the regular practice of a pharmacy. The distribution is not patient-specific, in that there are no prescriptions.

**Contract packager/contract repackager:** A firm that is contracted by another organization, such as a manufacturer, to package bulk into a marketed *Container* of a drug product. A *Contract packager* does not take ownership from the manufacturer and generally receives the assigned expiration date from the manufacturer.

**Dispenser:** A licensed or registered practitioner who is legally responsible for providing the patient with a preparation that is in compliance with a prescription or a medication order and contains a specific patient label. In addition, dispensers may prepare limited quantities in anticipation of a prescription or medication order from a physician. *Dispensers* are governed by the board of pharmacy of the individual state. The terms "dispenser" and "pharmacy" are used interchangeably.

**Beyond-use date:** See ⟨7⟩.

**Expiration date:** See ⟨7⟩.

**Black closure system or black bands:** The use of a *Black closure system* on a vial (e.g., a black cap overseal and a black ferrule to hold the elastomeric closure) or the use of a *Black band* or series of bands above the constriction on an ampule is prohibited, except for ⟨7⟩, *Labels and Labeling for Injectable Products, Potassium Chloride for Injection Concentrate*.

Official

# INJECTION PACKAGING

Packaging for sterile products intended for injection must be validated as meeting the containment, protection, and compatibility requirements that are essential for maintaining the article's strength, quality, and purity. Refer to *Package Integrity Evaluation—Sterile Products* ⟨1207⟩, *Package Integrity Testing in the Product Life Cycle—Test Method Selection and Validation* ⟨1207.1⟩, *Package Integrity Leak Test Technologies* ⟨1207.2⟩, and *Package Seal Quality Test Technologies* ⟨1207.3⟩ for further information regarding sterile product container–closure integrity testing and validation. *Closures* for *Multiple-dose containers* permit the withdrawal of the contents without removal or destruction of the *Closure*. The *Closure* permits penetration by a needle and, upon withdrawal of the needle, closes at once, protecting the contents against contamination. Refer to ⟨381⟩ for *Closure* reseal tests that are useful for screening multiple-dose *Closures* for their reseal properties. Additional testing may be needed to ensure that the specific *Closure* selected for a product package is able to prevent loss of product contents and microbial contamination under anticipated conditions of multiple entry and use. Piggyback *Packaging systems* are usually intravenous infusion *Container–closure systems* that are used to administer a second infusion through a connector of some type or an injection port on the administration set of the first fluid, thereby avoiding the need for another injection site on the patient's body. Piggyback *Packaging systems* also are known as secondary infusion containers.

The volume of injection in a *Single-dose container* provides the amount specified for one-time parenteral administration, and in no case is more than sufficient to permit the withdrawal and administration of 1 L. Preparations intended for intraspinal, intracisternal, or peridural administration are packaged in *Single-dose containers* only. Unless otherwise specified in the individual monograph, a *Multiple-dose container* contains a volume of injection sufficient to permit the withdrawal of NMT 30 mL.

The following injections are exempt from the 1-L restriction of the foregoing requirements relating to packaging:

- Injections packaged for extravascular use as irrigation solutions or peritoneal dialysis solutions
- Injections packaged for intravascular use as parenteral nutrition or as replacement or substitution fluid to be administered continuously during hemofiltration

Injections packaged for intravascular use that may be used for intermittent, continuous, or bolus replacement fluid administration during hemodialysis or other procedures, unless excepted above, must conform to the 1-L restriction. Injections labeled for veterinary use are exempt from the packaging and storage requirements concerning the limitation to single-dose *Packaging systems* and the limitation on the volume of *Multiple-dose containers*.

## Packaging for Constitution

*Containers*, including the *Closures*, for dry solids intended for injection must not interact physically or chemically with the preparation in any manner that alters the strength, quality, or purity beyond the official requirements under the ordinary or customary conditions of handling, shipment, storage, sale, and use. A *Packaging system* for a sterile solid permits the addition of a suitable solvent and withdrawal of portions of the resulting solution or suspension in such manner that the sterility of the product is maintained. Where the assay in a monograph provides a procedure for the sample solution, in which the total withdrawable contents are to be withdrawn from a *Single-dose container* with a hypodermic needle and syringe, the contents are to be withdrawn as completely as possible into a dry hypodermic syringe of a rated capacity not exceeding 3 times the volume to be withdrawn and fitted with a 21-gauge needle NLT 2.5 cm (1 inch) in length. Care must be taken to expel any air bubbles, and the contents are then discharged into a *Container* for dilution and assay.

## MEDICAL GAS PACKAGING

**Gas cylinder:** A metallic *Packaging system* constructed of steel or aluminum and designed to hold medical gases under pressure; these gases may include: *Carbon Dioxide USP*, *Helium USP*, *Medical Air USP*, *Nitrogen NF*, and *Oxygen USP*. As a safety measure, for carbon dioxide, helium, medical air, nitrous oxide, and oxygen, the Pin Index Safety System of matched fittings is recommended for cylinders of Size E or smaller.

## ASSOCIATED COMPONENTS

Many *Associated Components* are graduated for measurement and dose administration. *Associated Components* can be packaged with the drug product or sold and purchased separately. It is the responsibility of the manufacturer to ensure that the appropriate measurement and dosing component is provided or that a general purpose component, such as those described in this section, is specified for delivering the appropriate amount/dose with the intended accuracy. Liquid preparations have unique surface and flow characteristics. Consequently, the volume delivered from a measurement/dosing component may vary for each preparation.

The graduated *Associated Components* described in this section are for general use and should be composed of safe materials. Graduated markings should be legible and indelible, and on an extraoral surface that does not contact the product.

The markings on associated components must be in metric units only and limited to a single measurement scale that corresponds with the dosing instructions on the OTC or prescription container label (see *Prescription Container Labeling* ⟨17⟩). Under expected conditions of use, the volume error incurred in measuring an individual dose by means of such graduated components should be NMT 10% of the indicated amount of the preparation with which the graduated component will be used.

**Dosing cup:** A measuring device consisting of a small cup that may be packaged with oral liquid articles.

**Dosing spoon:** A measuring device consisting of a bowl and handle that may be packaged with oral liquid articles. The handle may be a graduated tube.

**Medicine dropper:** A measuring device consisting of a transparent or translucent barrel or tube that is generally fitted with a collapsible bulb. It may be packaged with liquid articles.

**Oral syringe:** A measuring device consisting of a plunger and barrel made of transparent or translucent plastic material and a seal on the end. It may be packaged with oral liquid articles. The syringe should deliver a measured amount of a liquid drug product.

## TEMPERATURE AND STORAGE DEFINITIONS

**Freezer:** A place in which the temperature is controlled between –25° and –10° (–13° and 14° F). It is noted that, in some instances, articles may have a recommended storage condition below –20° (–4° F). In such cases, the temperature of the storage location should be controlled to ±10° of the recommended storage condition.

**Refrigerator:** A cold place in which the temperature is controlled between 2° and 8° (36° and 46° F).

**Cold:** Any temperature not exceeding 8° (46° F).

**Cool:** Any temperature between 8° and 15° (46° and 59° F). [NOTE—An article for which storage in a cool place is directed may, alternatively, be stored and shipped as refrigerated, unless otherwise specified by the individual monograph.]

**Room temperature** (also referred to as Ambient temperature)**:** The temperature prevailing in a working environment.

**Controlled cold temperature:** The temperature maintained thermostatically between 2° and 8° (36° and 46° F), which allows for temperature excursions between 2° and 15° (36° and 59° F) that may be experienced during storage, shipping, and distribution, but not to exceed 24 h, such that the allowable calculated mean kinetic temperature (MKT) is NMT 8° (46° F) with no excursions below 2° (36° F) or above 15° (59° F). These limits (time and temperature) and the calculated MKT must be documented (see *Mean Kinetic Temperature in the Evaluation of Temperature Excursions During Storage and Transportation of Drug Products* ⟨1079.2⟩). Additionally, controlled cold excursions may only occur one time during the possession of the product within the supply chain unless directed otherwise by the manufacturer. The length of time the product is held at 2° and 15° (36° and 59° F) should be supported by stability data. Other limits may be permitted if the manufacturer so instructs as supported by the manufacturer's stability data and/or thermal cycling studies.

**Controlled room temperature:** The temperature maintained thermostatically that encompasses the usual and customary working environment of 20°–25° (68°–77° F).

MKT may be used during an excursion provided: 1) MKT does not exceed 25° (77° F); 2) excursion between 15° and 30° (59° and 86° F); 3) transient excursions are NMT 40° (104° F); and 4) excursion time is NMT 24 h.[2] These limits (time and temperature) and the calculated MKT must be documented.

[2] Anderson C, Seevers R, Hunt D. The use of mean kinetic temperature to aid evaluation of temperature excursions: proper and improper application. *Pharm Forum.* 2018;44(4). www.usppf.com/pf/pub/index.html.

https://pharmacopeia.com/

Articles may be labeled for storage at "controlled room temperature" or at "20°–25°", or other wording based on the same MKT. (See ⟨1079.2⟩.)

An article for which storage at *Controlled room temperature* is directed may, alternatively, be stored and shipped in a cool place or refrigerated, unless otherwise specified in the individual monograph or on the label. Storage time in controlled cold or cool place cannot be used to calculate excursion temperature outside of controlled room temperature ranges.

**Warm:** Any temperature between 30° and 40° (86° and 104° F).

**Excessive heat:** Any temperature above 40° (104° F).

**Dry place:** A place that does not exceed 40% average relative humidity at 20° (68° F) or the equivalent water vapor pressure at other temperatures. The determination may be made by direct measurement at the place. Determination is based on NLT 12 equally spaced measurements that encompass either a season, a year, or, where recorded data demonstrate, the storage period of the article. There may be values of up to 45% relative humidity provided that the average value does not exceed 40% relative humidity. Storage in a *Container* validated to protect the article from moisture vapor, including storage in bulk, is considered a *Dry place*.

**Do not refrigerate:** The *Container* label will bear an appropriate instruction to protect the article from refrigeration in cases where refrigeration exposes the article to loss of strength or potency or destructive alteration of its characteristics (e.g., precipitation, cloudiness). These risks are increased when a drug product with the storage temperature of 20°–25° (68°–77° F) is formulated at near-maximum solubility.

**Protect from freezing:** The *Container* label will bear an appropriate instruction to protect the article from freezing in cases where freezing exposes an article to loss of strength or potency or to destructive alteration of its characteristics. These risks are present in addition to the risk that the *Container* may break if exposed to freezing temperatures.

**Protect from light:** Where light subjects an article to loss of strength or potency or to destructive alteration of its characteristics, the *Container* label bears an appropriate instruction to protect the article from light. The article must be packaged in a light-resistant *Container*.

# ⟨660⟩ CONTAINERS—GLASS

***Change to read:***

## DESCRIPTION

▲Glass containers for pharmaceutical use are intended to come into direct contact with pharmaceutical products.▲ (IRA 1-Oct-2023) The following recommendations can be made as to the suitability of ▲a▲ (IRA 1-Oct-2023) glass ▲container▲ (IRA 1-Oct-2023) for pharmaceutical products, based on the tests for hydrolytic resistance. ▲Glass▲ (IRA 1-Oct-2023) containers ▲meeting Type I performance▲ (IRA 1-Oct-2023) are suitable for most products for parenteral and nonparenteral uses ▲(e.g., borosilicate). Glass▲ (IRA 1-Oct-2023) containers ▲meeting Type II performance▲ (IRA 1-Oct-2023) are suitable for most acidic and neutral aqueous products for parenteral and nonparenteral uses ▲(e.g., treated soda-lime silica). Glass▲ (IRA 1-Oct-2023) containers ▲meeting Type II performance▲ (IRA 1-Oct-2023) may be used for alkaline parenteral products where stability data demonstrate their suitability. ▲Glass▲ (IRA 1-Oct-2023) containers ▲meeting Type III performance (e.g., soda-lime silica)▲ (IRA 1-Oct-2023) usually are not used for parenteral products or for powders for parenteral use, except where suitable stability test data indicate that ▲containers meeting Type III performance are▲ (IRA 1-Oct-2023) satisfactory.

The inner surface of glass containers may be treated to improve hydrolytic resistance. The outer surface of glass containers may be treated to reduce friction or for protection against abrasion or breakage. The outer surface treatment is such that it does not contaminate the inner surface of the container.

Information on chemical composition of glass types, the formation of glass containers, and factors that influence inner surface durability of glass containers is provided in *Evaluation of the Inner Surface Durability of Glass Containers* ⟨1660⟩. This chapter also contains recommended approaches to evaluate the potential of a drug product to cause the formation of glass particles and delamination.

Glass may be colored to provide protection from light by the addition of small amounts of metal oxides and is tested as described in *Spectral Transmission for Colored Glass Containers*. A clear and colorless container that is made light resistant by means of an opaque enclosure (see *Packaging and Storage Requirements* ⟨659⟩*, General Definitions, Packaging Definitions, Light-resistant container*) is exempt from the requirements for spectral transmission.

***Change to read:***

## SPECIFIC TESTS

The *Glass Grains Test* combined with the *Surface Glass Test* for hydrolytic resistance determines glass ▲performance.▲ (IRA 1-Oct-2023) The hydrolytic resistance is determined by the quantity of alkali released from the glass under the conditions specified. This quantity of alkali is extremely small in the case of the more resistant glasses, thus calling for particular attention to all details of the tests and the use of apparatus of high quality and precision. Conducting these tests in conjunction with a glass standard reference material (SRM) on a routine basis will help to ensure the accuracy of the method. Reference materials are available for both borosilicate glass (SRM 623) and soda-lime-silica glass (SRM 622) from the National Institute of Standards and Technology. The tests should be conducted in an area relatively free from fumes and excessive dust. Test selection is shown in *Table 1* and *Table 2*.

**Table 1. Determination of Glass ▲Performance▲ (IRA 1-Oct-2023)**

| ▲Performance▲ (IRA 1-Oct-2023) Type | Test | Reason |
|---|---|---|
| I, II, III | *Glass Grains Test* | Distinguishes Type I ▲▲ (IRA 1-Oct-2023) from Type II and III ▲▲ (IRA 1-Oct-2023) |

The inner surface of glass containers is the contact surface for pharmaceutical preparations, and the quality of this surface is determined by the *Surface Glass Test* for hydrolytic resistance. The *Surface Etching Test* may be used to determine whether high hydrolytic resistance is due to chemical composition or to surface treatment. Alternatively, the comparison of data from the *Glass Grains Test* and the *Surface Glass Test* may be used in *Table 2*.

**Table 2. Determination of Inner Surface Hydrolytic Resistance**

| ▲Performance▲ (IRA 1-Oct-2023) Type | Test | Reason |
|---|---|---|
| I, II, III | *Surface Glass Test* | Determines hydrolytic resistance of inner surface; distinguishes between *Type I* and *Type II* containers with high hydrolytic resistance and *Type III* containers with moderate hydrolytic resistance |
| I, II | *Surface Etching Test* or comparison of *Glass Grains Test* and *Surface Glass Test* data | Where it is necessary, determines whether high hydrolytic resistance is due to inner surface treatment or to the chemical composition of the glass containers |

Glass containers must comply with their respective specifications for ▲▲ (IRA 1-Oct-2023) surface hydrolytic resistance ▲as noted in *Table 1* and *Table 2*.▲ (IRA 1-Oct-2023) Type I or Type II containers for aqueous parenteral products are tested for extractable arsenic.

## Hydrolytic Resistance

APPARATUS

**Autoclave:** For these tests, use an autoclave capable of maintaining a temperature of 121 ± 1°, equipped with a thermometer, or a calibrated thermocouple device, allowing a temperature measurement independent of the autoclave system; a suitable recorder; a pressure gauge; a vent cock; and a tray of sufficient capacity to accommodate the number of containers needed to carry out the test above the water level. Clean the autoclave and other apparatus thoroughly with purified water before use.
**Mortar and pestle:** Use a hardened-steel mortar and pestle, made according to the specifications in *Figure 1*.

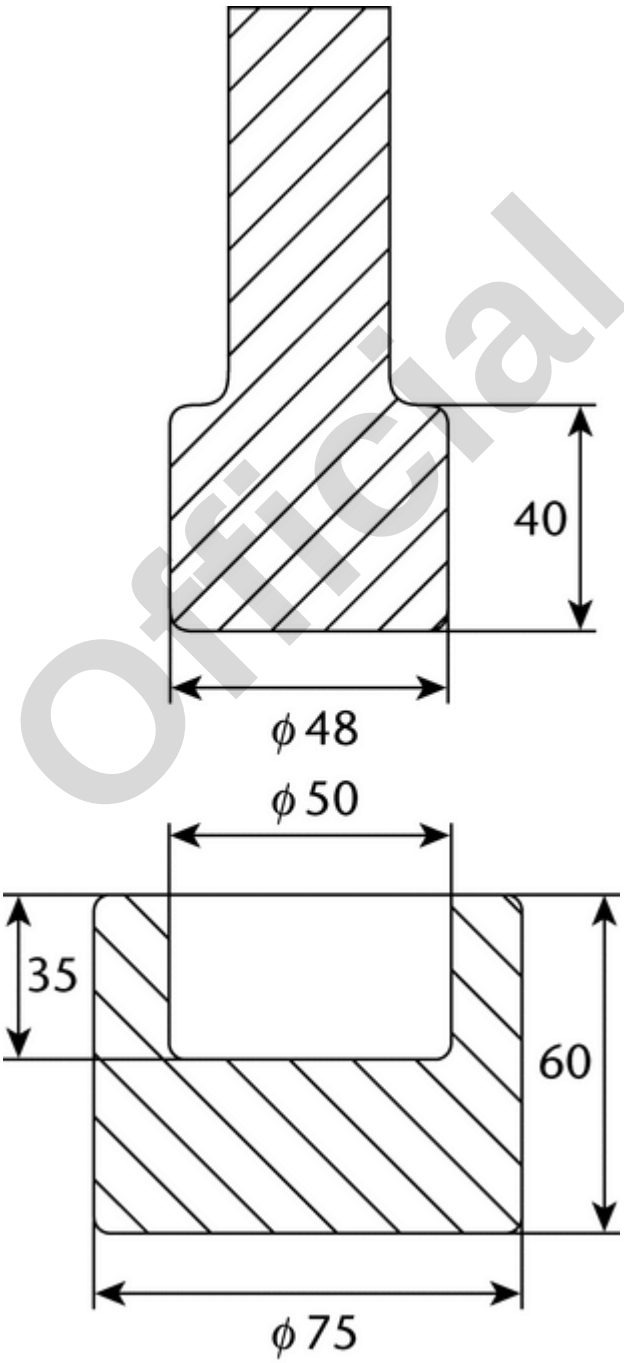

Figure 1. Mortar and pestle for pulverizing glass.

**Other apparatus:** Also required are a set of three square-mesh stainless steel sieves mounted on frames consisting of US Sieve Nos. 25, 40, and 50 (see *Particle Size Distribution Estimation by Analytical Sieving* ⟨786⟩, *Table 1. Sizes of Standard Sieve Series in Range of Interest*); a mechanical sieve-shaker or a sieving machine that may be used to sieve the grains; a tempered, magnetic

steel hammer; a permanent magnet; weighing bottles; stoppers; metal foil (e.g., aluminum, stainless steel); a hot air oven, capable of maintaining 140 ± 5°; a balance, capable of weighing up to 500 g with an accuracy of 0.005 g; a desiccator; and an ultrasonic bath.

### REAGENTS

**Carbon dioxide-free water:** This is purified water that has been boiled vigorously for 5 min or more and allowed to cool while protected from absorption of carbon dioxide from the atmosphere, or purified water that has a resistivity of not less than 18 Mohm-cm.

**Methyl red solution:** Dissolve 50 mg of methyl red in 1.86 mL of 0.1 M sodium hydroxide and 50 mL of ethanol (96%), and dilute with purified water to 100 mL. To test for sensitivity, add 100 mL of carbon dioxide-free water and 0.05 mL of 0.02 M hydrochloric acid to 0.1 mL of the methyl red solution. The resulting solution should be red. NMT 0.1 mL of 0.02 M sodium hydroxide is required to change the color to yellow. A color change from red to yellow corresponds to a change in pH from pH 4.4 (red) to pH 6.0 (yellow).

## Glass Grains Test

The *Glass Grains Test* may be performed either on the canes used for the manufacture of tubing glass containers or on the containers.

### SAMPLE PREPARATION

Rinse the containers to be tested with purified water, and dry in the oven. Wrap at least three of the glass articles in clean paper, and crush to produce two samples of about 100 g each in pieces NMT 30 mm across. Place in the mortar 30–40 g of the pieces between 10 and 30 mm across taken from one of the samples, insert the pestle, and strike it heavily with the hammer once only. Alternatively, transfer samples into a ball mill-breaker, add the balls, and crush the glass. Transfer the contents of the mortar or ball mill to the coarsest sieve (No. 25) of the set. Repeat the operation until all fragments have been transferred to the sieve. Shake the set of sieves for a short time by hand, and remove the glass that remains on sieves No. 25 and No. 40. Submit these portions to further fracture, repeating the operation until about 10 g of glass remains on sieve No. 25. Reject this portion and the portion that passes through sieve No. 50. Reassemble the set of sieves, and shake for 5 min. Transfer to a weighing bottle the glass grains that passed through sieve No. 40 and are retained on sieve No. 50. Repeat the crushing and sieving procedure with the second glass sample until two samples of grains are obtained, each of which weighs more than 10 g.

Spread each sample on a piece of clean glazed paper, and remove any iron particles by passing the magnet over them. Transfer each sample into a beaker for cleaning. Add 30 mL of acetone to the grains in each beaker, and scour the grains, using suitable means such as a rubber-tipped or plastic-coated glass rod. After scouring the grains, allow to settle, and decant as much acetone as possible. Add another 30 mL of acetone, swirl, decant, and add a new portion of acetone. Fill the bath of the ultrasonic vessel with water at room temperature, then place the beaker in the rack, and immerse it until the level of the acetone is at the level of the water; apply the ultrasound for 1 min. Swirl the beaker, allow to settle, and decant the acetone as completely as possible; then repeat the ultrasonic cleaning operation. If a fine turbidity persists, repeat the ultrasonic cleaning and acetone washing until the solution remains clear. Swirl, and decant the acetone. Dry the grains, first by putting the beaker on a warm plate, then by heating at 140° for 20 min in a drying oven. Transfer the dried grains from each beaker into separate weighing bottles, insert the stoppers, and cool in a desiccator.

### METHOD

**Filling and heating:** Weigh 10.00 g of the cleaned and dried grains into two separate conical flasks. Pipet 50 mL of carbon dioxide-free purified water into each of the conical flasks (test solutions). Pipet 50 mL of carbon dioxide-free purified water into a third conical flask that will serve as a blank. Distribute the grains evenly over the flat bases of the flasks by shaking gently. Close the flasks with neutral glass dishes or aluminum foil rinsed with purified water or with inverted beakers so that the inner surfaces of the beakers fit snugly down onto the top rims of the flasks. Place all three flasks in the autoclave containing the water at ambient temperature, and ensure that they are held above the level of the water in the vessel. Carry out the following operations:

1. Insert the end of a calibrated thermometric device in a filled container through a hole of approximately the diameter of the thermocouple and connect it to an external measuring device. If the container is too small to insert a thermocouple, apply a thermocouple in a suitable, similar container. Alternatively, use the internal thermometer of the autoclave.
2. Close the autoclave door or lid securely but leave the vent-cock open.
3. Start automatic recording of the temperature versus time, and heat the autoclave at a regular rate such that steam issues vigorously from the vent-cock after 20–30 min, and maintain a vigorous evolution of steam for a further 10 min. For autoclaves using a steam generator, it is not necessary to maintain the temperature for 10 min at 100°.
4. Close the vent-cock, and raise the temperature from 100° to 121° at a rate of 1°/min within 20–22 min.
5. Maintain the temperature at 121 ± 1° for 30 ± 1 min from the time when the holding temperature is reached.
6. Cool down to 100° at a rate of 0.5°/min, venting to prevent formation of a vacuum, within 40–44 min.
7. Do not open the autoclave until it has cooled to 95°.
8. Remove the hot samples from the autoclave using appropriate safety precautions, and cool the samples cautiously down to room temperature within 30 min, avoiding thermal shock.

**Titration:** To each of the three flasks add 0.05 mL of *Methyl red solution*. Titrate the blank solution immediately with 0.02 M hydrochloric acid, then titrate the test solutions until the color matches that obtained with the blank solution. Subtract the titration volume for the blank solution from that for the test solutions. Calculate the mean value of the results in mL of 0.02 M

hydrochloric acid per g of the sample. Repeat the test if the highest and lowest observed values differ by more than the permissible range given in *Table 3*.

**Table 3. Permissible Range for Values Obtained**

| Mean of the Values Obtained for the Consumption of Hydrochloric Acid Solution per g of Glass Grains (mL/g) | Permissible Range of the Values Obtained |
|---|---|
| NMT 0.10 | 25% of the mean |
| 0.10–0.20 | 20% of the mean |
| NLT 0.20 | 10% of the mean |

[NOTE—Where necessary to obtain a sharp endpoint, decant the clear solution into a separate 250-mL flask. Rinse the grains by swirling with three 15-mL portions of carbon dioxide-free water, and add the washings to the main solution. Add 0.05 mL of the *Methyl red solution*. Titrate, and calculate as before. In this case also add 45 mL of carbon dioxide-free purified water and 0.05 mL of *Methyl red solution* to the blank solution.]

LIMITS

The volume does not exceed the values indicated in *Table 4*.

**Table 4. Test Limits for Glass Grains Test**

| Filling Volume (mL) | Maximum Volume of 0.02 M HCl per g of Test Glass (mL) | |
|---|---|---|
| | Type I | Types II and III |
| All | 0.1 | 0.85 |

## Surface Glass Test

DETERMINATION OF THE FILLING VOLUME

The filling volume is the volume of purified water to be added to the container for the purpose of the test. For vials, bottles, cartridges, and syringes, the filling volume is 90% of the brimful capacity. For ampules, it is the volume up to the height of the shoulder.

**Vials and bottles:** Select six dry vials or bottles from the sample lot, or three if their capacity exceeds 100 mL, and remove any dirt or debris. Weigh the empty containers with an accuracy of 0.1 g. Place the containers on a horizontal surface, and fill them with purified water to about the rim edge, avoiding overflow and the introduction of air bubbles. Adjust the liquid levels to the brimful line. Weigh the filled containers to obtain the mass of the water expressed to two decimal places, for containers having a nominal volume less than or equal to 30 mL, and expressed to one decimal place, for containers having a nominal volume greater than 30 mL. Calculate the mean value of the brimful capacity in mL, and multiply it by 0.9. This volume, expressed to one decimal place, is the filling volume for the particular container lot.

**Cartridges and syringes:** Select six dry syringes or cartridges, and seal the small opening (mouth of cartridges, Luer cone, or staked needle of syringes), using an inert material. Determine the mean brimful capacity and filling volume according to *Vials and Bottles*.

**Ampules:** Place at least six dry ampules on a flat, horizontal surface, and fill them with purified water from a buret until the water reaches point A, where the body of the ampule starts to decrease to the shoulder of the ampule (see *Figure 2*). Read the capacities, expressed to two decimal places, and calculate the mean value. This volume, expressed to one decimal place, is the filling volume for the particular ampule lot. The filling volume may also be determined by weighing.

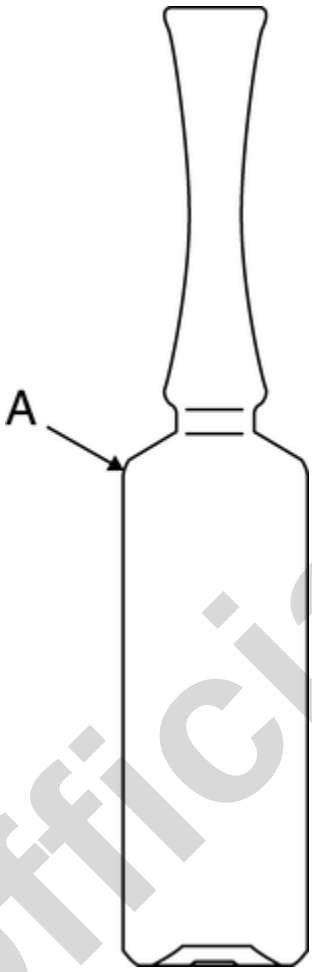

Figure 2. Filling volumes of ampules up to point A.

Official

TEST

The determination is carried out on unused containers. The volumes of the test solution necessary for the final determination are shown in *Table 5*.

**Table 5. Volume of Test Solution and Number of Titrations**

| Filling Volume (mL) | Volume of Test Liquid for One Titration (mL) | Number of Titrations |
|---|---|---|
| NMT 3 | 25.0 | 1 |
| 3–30 | 50.0 | 2 |
| 30–100 | 100.0 | 2 |
| NLT 100 | 100.0 | 3 |

METHOD

**Cleaning:** Remove any debris or dust. Shortly before the test, rinse each container carefully at least twice with purified water, refilled, and allow to stand. Immediately before testing, empty the containers; rinse once with purified water, then with carbon dioxide-free water; and allow to drain. Complete the cleaning procedure from the first rinsing within 20–30 min. Closed ampules may be warmed in a water bath or in an air oven at about 40° for approximately 2 min before opening to avoid container pressure when opening. Do not rinse before testing.

**Filling and heating:** The containers are filled with carbon dioxide-free water up to the filling volume. Containers in the form of cartridges or prefillable syringes are closed in a suitable manner with material that does not interfere with the test. Each container, including ampules, shall be loosely capped with an inert material such as a dish of neutral glass or aluminum foil previously rinsed with purified water. Place the containers on the tray of the autoclave. Place the tray in an autoclave containing a quantity of water such that the tray remains clear of the water. Close the autoclave, and carry out autoclaving procedure steps 1–8 as described in the *Glass Grains Test*, except that the temperature is maintained at 121 ± 1° for 60 ± 1 min. If a water bath

@2024 USPC

is used for cooling samples, take care that the water does not make contact with the loose foil caps to avoid contamination of the extraction solution. The extraction solutions are analyzed by titration according to the method described below.
**Titration:** Carry out the titration within 1 h of the removal of the containers from the autoclave. Combine the liquids obtained from the containers, and mix. Introduce the prescribed volume (see *Table 5*) into a conical flask. Transfer the same volume of carbon dioxide-free water, to be used as a blank, into a second similar flask. Add to each flask 0.05 mL of *Methyl red solution* for each 25 mL of liquid. Titrate the blank with 0.01 M hydrochloric acid. Titrate the test solution with the same acid until the color of the resulting solution is the same as that obtained for the blank. Subtract the value found for the blank titration from that found for the test solution, and express the results in mL of 0.01 M hydrochloric acid per 100 mL of test solution. Express titration values of less than 1.0 mL to two decimal places; express titration values of greater than or equal to 1.0 mL to one decimal place.

### LIMITS

The results, or the average of the results if more than one titration is performed, are not greater than the values stated in *Table 6*.

**Table 6. Limit Values for the Surface Glass Test**

| Filling Volume (mL) | Maximum Volume of 0.01 M HCl per 100 mL of Test Solution (mL) | |
|---|---|---|
| | Types I and II | Type III |
| NMT 1 | 2.0 | 20.0 |
| 1–2 | 1.8 | 17.6 |
| 2–3 | 1.6 | 16.1 |
| 3–5 | 1.3 | 13.2 |
| 5–10 | 1.0 | 10.2 |
| 10–20 | 0.80 | 8.1 |
| 20–50 | 0.60 | 6.1 |
| 50–100 | 0.50 | 4.8 |
| 100–200 | 0.40 | 3.8 |
| 200–500 | 0.30 | 2.9 |
| NLT 500 | 0.20 | 2.2 |

## Surface Etching Test

The *Surface Etching Test* is used in addition to the *Surface Glass Test* when it is necessary to determine whether a container has been surface treated and/or to distinguish between Type I and Type II glass containers. Alternatively, the *Glass Grains Test* and *Surface Glass Test* may be used. The *Surface Etching Test* may be carried out either on unused samples or on samples used in the *Surface Glass Test*.

### METHOD

**Vials and bottles:** The volumes of test solution required are shown in *Table 5*. Rinse the containers twice with purified water, fill to the brimful point with a mixture of one volume of hydrofluoric acid and nine volumes of hydrochloric acid, and allow to stand for 10 min. Empty the containers, and rinse carefully five times with purified water. Immediately before the test, rinse once again with purified water. Submit these containers to the same autoclaving and determination procedure as described in the *Surface Glass Test*. If the results are considerably higher than those obtained from the original surfaces (by a factor of about 5–10), the samples have been surface treated.
[**CAUTION**—Hydrofluoric acid is extremely aggressive. Even small quantities can cause life threatening injuries.]
**Ampules, cartridges, and syringes:** Apply the test method as described in *Vials and Bottles*. If the ampules, cartridges, and syringes are not surface treated, the values obtained are slightly lower than those obtained in the previous tests.
[NOTE—Ampules, cartridges, and syringes made from Type I glass tubing are not normally subjected to internal surface treatment.]

### DISTINCTION BETWEEN TYPE I AND TYPE II GLASS CONTAINERS

The results obtained from the *Surface Etching Test* are compared to those obtained from the *Surface Glass Test*. For Type I glass containers, the values obtained are close to those found in the *Surface Glass Test*. For Type II glass containers, the values obtained greatly exceed those found in the *Surface Glass Test*; and they are similar to, but not greater than, those obtained for Type III glass containers of the same filling volume.

# IMPURITIES

## Arsenic ⟨211⟩

Use as the *Test Preparation* 35 mL of the water from one Type I or Type II glass container, or, in the case of smaller containers, 35 mL of the combined contents of several Type I or Type II glass containers, prepared as directed in the *Surface Glass Test*. The limit does not exceed 0.1 µg/g.

# FUNCTIONALITY

## Spectral Transmission for Colored Glass Containers

### APPARATUS

A UV-Vis spectrophotometer, equipped with either a photodiode detector or a photomultiplier tube coupled with an integrating sphere

### SAMPLE PREPARATION

Break the glass container or cut it with a circular saw fitted with a wet abrasive wheel, such as a carborundum or a bonded diamond wheel. Select sections representative of the wall thickness, and trim them as suitable for mounting in a spectrophotometer. After cutting, wash and dry each specimen, taking care to avoid scratching the surfaces. If the specimen is too small to cover the opening in the specimen holder, mask the uncovered portion of the opening with opaque paper or tape, provided that the length of the specimen is greater than that of the slit. Before placing in the holder, wash, dry, and wipe the specimen with lens tissue. Mount the specimen with the aid of wax, or by other convenient means, taking care to avoid leaving fingerprints or other marks.

### METHOD

Place the specimen in the spectrophotometer with its cylindrical axis parallel to the slit and in such a way that the light beam is perpendicular to the surface of the section and the losses due to reflection are at a minimum. Measure the transmission of the specimen with reference to air in the spectral region of 290–450 nm, continuously or at intervals of 20 nm.

### LIMITS

The observed spectral transmission for colored glass containers for products for nonparenteral use does not exceed 10% at any wavelength in the range of 290–450 nm, irrespective of the type and capacity of the glass container. The observed spectral transmission in colored glass containers for parenteral products does not exceed the limits given in *Table 7*.

**Table 7. Limits of Spectral Transmission for Colored Glass Containers for Parenteral Products**

| Nominal Volume (mL) | Maximum Percentage of Spectral Transmission at Any Wavelength between 290 and 450 nm | |
|---|---|---|
| | Flame-Sealed Containers | Containers with Closures |
| NMT 1 | 50 | 25 |
| 1–2 | 45 | 20 |
| 2–5 | 40 | 15 |
| 5–10 | 35 | 13 |

# ⟨661⟩ PLASTIC PACKAGING SYSTEMS AND THEIR MATERIALS OF CONSTRUCTION

**(If the option of early adoption of** *Plastic Materials of Construction* ⟨661.1⟩ **and** *Plastic Packaging Systems for Pharmaceutical Use* ⟨661.2⟩ **is not used prior to December 1, 2025, the requirements under this chapter will apply.)**

## INTRODUCTION

The purpose of this chapter is to provide standards for plastic articles (materials, components, and systems) used to package medical articles (pharmaceuticals, biologics, and dietary supplements). Definitions that apply to this chapter are provided in *Packaging and Storage Requirements* ⟨659⟩. Standards and tests for the functional properties of containers and their components are provided in *Containers—Performance Testing* ⟨671⟩.

Plastics are composed of a mixture of homologous polymers, having a range of molecular weights. Plastics may contain other substances such as residues from the polymerization process and additives such as plasticizers, stabilizers, antioxidants, pigments, and lubricants.

Plastic articles are identified and characterized by infrared (IR) spectroscopy and differential scanning calorimetry (DSC). Standards are provided in this chapter for the identification and characterization of the different types of plastic, and the test procedures are provided at the end of the chapter. Furthermore, plastics are characterized to establish that they are suited for their intended use. Plastics and their additives, regardless of their risk and application, must meet the requirements for food contact as provided in Title 21 of the *Code of Federal Regulations* (CFR). Ingredients added to these items, must conform to the requirements in the applicable sections of 21 CFR, Indirect Food Additives, or have been evaluated by the FDA and determined to be acceptable substances for the intended use.

Physicochemical tests are performed on plastics used in high risk applications (inhalation, parenteral preparation, and ophthalmics) to characterize the extracted components and identify possible migrants. To this end, resin-specific extraction tests are provided in this chapter for polyethylene, polypropylene, polyethylene terephthalate, and polyethylene terephthalate G used in such high risk applications. Test all other plastics as directed for *Physicochemical Tests*. Conduct the *Buffering Capacity* test only when the containers are intended to hold a liquid product. *Physicochemical Tests* are not required for articles used in low risk applications (those intended for oral or topical administration). The degree or extent of biological testing is also dependent on the intended use of the plastic article and the degree of risk that extracted substances could adversely impact the efficacy of the compendial article (drug, biologic, dietary supplement, or device).

Plastic articles used for high risk products, such as those intended for inhalation, parenteral preparation, and ophthalmics, are tested using *Biological Tests*. Plastic articles used for low risk products, such as those intended for oral or topical administration, do not require *Biological Tests*. Standards are also provided for polyethylene containers used to package dry oral dosage forms that are not meant for constitution into solutions.

## POLYETHYLENE CONTAINERS

### Scope

The standards and tests provided in this section characterize containers and components, produced from either low-density polyethylene or high-density polyethylene of either homopolymer or copolymer resins that are interchangeably suitable for packaging dry oral dosage forms not meant for constitution into solution. All polyethylene components are subject to testing by IR spectroscopy and DSC. Where stability studies have been performed to establish the expiration date of a particular dosage form in the appropriate polyethylene container, then any other polyethylene container meeting these requirements may be similarly used to package such a dosage form, provided that the appropriate stability programs are expanded to include the alternative container, in order to ensure that the identity, strength, quality, and purity of the dosage form are maintained throughout the expiration period.

### Background

High-density and low-density polyethylene are long-chain polymers synthesized under controlled conditions of heat and pressure, with the aid of catalysts from NLT 85.0% ethylene and NLT 95.0% total olefins. Other olefin ingredients that are most frequently used are butene, hexene, and propylene. High-density polyethylene and low-density polyethylene both have an IR absorption spectrum that is distinctive for polyethylene, and each possesses characteristic thermal properties. High-density polyethylene has a density between 0.941 and 0.965 g/cm$^3$. Low-density polyethylene has a density between 0.850 and 0.940 g/cm$^3$. Other properties that may affect the suitability of polyethylene include modulus of elasticity, melt index, environmental stress crack resistance, and degree of crystallinity after molding.

### High-Density Polyethylene

#### INFRARED SPECTROSCOPY

Proceed as directed for *Multiple Internal Reflectance*. The corrected spectrum of the specimen exhibits major absorption bands only at the same wavelengths as the spectrum of USP High-Density Polyethylene RS.

Official

https://pharmacopeia.com/

DIFFERENTIAL SCANNING CALORIMETRY

Proceed as directed for *Thermal Analysis*. The thermal analysis curve of the specimen is similar to the thermal analysis curve of USP High-Density Polyethylene RS, and the melting peak temperature obtained from the thermal analysis curve of the specimen does not differ from that of the Reference Standard by more than 6.0°.

HEAVY METALS AND NONVOLATILE RESIDUE

Prepare extracts of specimens for these tests as directed for *Physicochemical Tests*, except that for each 20.0 mL of *Extracting medium* under the *Physicochemical Tests*, the portion shall be 60 $cm^2$, regardless of thickness.
**Heavy metals:** Containers meet the requirements for *Physicochemical Tests, Heavy Metals*.
**Nonvolatile residue:** Proceed as directed for *Physicochemical Tests, Nonvolatile Residue*, except that the *Blank* shall be the same solvent used in each of the following test conditions: the difference between the amounts obtained from the *Sample preparation* and the *Blank* is NMT 12.0 mg when water maintained at a temperature of 70° is used as the *Extracting medium*; is NMT 75.0 mg when alcohol maintained at a temperature of 70° is used as the *Extracting medium*; and is NMT 100.0 mg when hexanes maintained at a temperature of 50° is used as the *Extracting medium*.

COMPONENTS USED IN CONTACT WITH ORAL LIQUIDS

Proceed as directed for *Physicochemical Tests, Buffering Capacity*.

### Low-Density Polyethylene

INFRARED SPECTROSCOPY

Proceed as directed for *Multiple Internal Reflectance*. The corrected spectrum of the specimen exhibits major absorption bands only at the same wavelengths as the spectrum of USP Low-Density Polyethylene RS.

DIFFERENTIAL SCANNING CALORIMETRY

Proceed as directed for *Thermal Analysis*. The thermal analysis curve of the specimen is similar to the thermal analysis curve of USP Low-Density Polyethylene RS, and the melting peak temperature obtained from the thermal analysis curve of the specimen does not differ from that of the Reference Standard by more than 8.0°.

HEAVY METALS AND NONVOLATILE RESIDUE

Prepare extracts of specimens for these tests as directed for *Physicochemical Tests, Testing Parameters, Sample preparation*, except that for each 20.0 mL of *Extracting medium* the portion shall be 60 $cm^2$, regardless of thickness.
**Heavy metals:** Containers meet the requirements for *Physicochemical Tests, Heavy Metals*.
**Nonvolatile residue:** Proceed as directed for *Physicochemical Tests, Nonvolatile Residue*, except that the *Blank* shall be the same solvent used in each of the following test conditions: the difference between the amounts obtained from the *Sample preparation* and the *Blank* is NMT 12.0 mg when water maintained at a temperature of 70° is used as the *Extracting medium*; is NMT 75.0 mg when alcohol maintained at a temperature of 70° is used as the *Extracting medium*; and is NMT 350.0 mg when hexanes maintained at a temperature of 50° is used as the *Extracting medium*.

COMPONENTS USED IN CONTACT WITH ORAL LIQUIDS

Proceed as directed for *Physicochemical Tests, Buffering Capacity*.

## POLYPROPYLENE CONTAINERS

### Scope

The standards and tests provided in this section characterize polypropylene containers, produced from either homopolymers or copolymers, that are interchangeably suitable for packaging dry solid and liquid oral dosage forms. Where suitable stability studies have been performed to establish the expiration date of a particular dosage form in the appropriate polypropylene container, then any other polypropylene container meeting these requirements may be similarly used to package such a dosage form, provided that the appropriate stability programs are expanded to include the alternative container, in order to ensure that the identity, strength, quality, and purity of the dosage form are maintained throughout the expiration period.

### Background

Propylene polymers are long-chain polymers synthesized from propylene or propylene and other olefins under controlled conditions of heat and pressure, with the aid of catalysts. Examples of other olefins most commonly used include ethylene and butene. The propylene polymers, the ingredients used to manufacture the propylene polymers, and the ingredients used in the fabrication of the containers conform to the applicable sections of 21 CFR.

Official

https://mhatheo.org.com/

Factors such as plastic composition, processing and cleaning procedures, contacting media, inks, adhesives, absorption, adsorption and permeability of preservatives, and conditions of storage may also affect the suitability of a plastic for a specific use. The suitability of a specific polypropylene must be established by appropriate testing.

Polypropylene has a distinctive IR spectrum and possesses characteristic thermal properties. It has a density between 0.880 and 0.913 g/cm$^3$. The permeation properties of molded polypropylene containers may be altered when reground polymer is incorporated, depending on the proportion of reground material in the final product. Other properties that may affect the suitability of polypropylene used in containers for packaging drugs are the following: oxygen and moisture permeability, modulus of elasticity, melt flow index, environmental stress crack resistance, and degree of crystallinity after molding. The requirements in this section are to be met when dry solid and liquid oral dosage forms are to be packaged in a container defined by this section.

### Infrared Spectroscopy

Proceed as directed for *Multiple Internal Reflectance*. The corrected spectrum of the specimen exhibits major absorption bands only at the same wavelengths as the spectrum of the respective USP Homopolymer Polypropylene RS or copolymer polypropylene standard, similarly determined.

### Differential Scanning Calorimetry

Proceed as directed for *Thermal Analysis*. The melting peak temperature in the thermal analysis curve does not differ from that of USP Homopolymer Polypropylene RS by more than 12.0°.

### Heavy Metals and Nonvolatile Residue

Prepare extracts of specimens for these tests as directed for *Physicochemical Tests, Testing Parameters, Sample preparation*, except that for each 20 mL of *Extracting medium* the portion shall be 60 cm$^2$, regardless of thickness.

HEAVY METALS

Containers meet the requirements for *Physicochemical Tests, Heavy Metals*.

NONVOLATILE RESIDUE

Proceed as directed for *Physicochemical Tests, Nonvolatile Residue*, except that the *Blank* shall be the same solvent used in each of the following test conditions: the difference between the amounts obtained from the *Sample preparation* and the *Blank* is NMT 10.0 mg when water maintained at a temperature of 70° is used as the *Extracting medium*; is NMT 60.0 mg when alcohol maintained at a temperature of 70° is used as the *Extracting medium*; and is NMT 225.0 mg when hexanes maintained at a temperature of 50° is used as the *Extracting medium*. Containers meet these requirements for *Nonvolatile Residue* for all of the above extracting media.

[NOTE—Hexanes and alcohol are flammable. When evaporating these solvents, use a current of air with the water bath; when drying the residue, use an explosion-proof oven.]

### Components Used in Contact with Oral Liquids

Proceed as directed for *Physicochemical Tests, Buffering Capacity*.

***Change to read:***

## POLYETHYLENE TEREPHTHALATE BOTTLES AND POLYETHYLENE TEREPHTHALATE G CONTAINERS

### Scope

The standards and tests provided in this section characterize polyethylene terephthalate (PET) and polyethylene terephthalate G (PETG) bottles that are interchangeably suitable for packaging liquid oral dosage forms. Where stability studies have been performed to establish the expiration date of a particular liquid oral dosage form in a bottle meeting the requirements set forth herein for either PET or PETG bottles, any other PET or PETG bottle meeting these requirements may be similarly used to package such a dosage form, provided that the appropriate stability programs are expanded to include the alternative bottle in order to ensure that the identity, strength, quality, and purity of the dosage form are maintained throughout the expiration period. The suitability of a specific PET or PETG bottle for use in the dispensing of a particular pharmaceutical liquid oral dosage form must be established by appropriate testing.

### Background

PET resins are long-chain crystalline polymers prepared by the condensation of ethylene glycol with dimethyl terephthalate or terephthalic acid. PET copolymer resins are prepared in a similar way, except that they may also contain a small amount of

Official

https://mathuseonly.com/

either isophthalic acid (NMT 3 mole percent) or 1,4-cyclohexanedimethanol (NMT 5 mole percent). Polymerization is conducted under controlled conditions of heat and vacuum, with the aid of catalysts and stabilizers.

PET copolymer resins have physical and spectral properties similar to PET and for practical purposes are treated as PET. The tests and specifications provided in this section to characterize PET resins and bottles apply also to PET copolymer resins and to bottles fabricated from them.

PET and PET copolymer resins generally exhibit a large degree of order in their molecular structure. As a result, they exhibit characteristic composition-dependent thermal behavior, including a glass transition temperature of about 76° and a melting temperature of about 250°. These resins have a distinctive IR absorption spectrum that allows them to be distinguished from other plastic materials (e.g., polycarbonate, polystyrene, polyethylene, and PETG resins). PET and PET copolymer resins have a density between 1.3 and 1.4 g/cm$^3$ and a minimum intrinsic viscosity of 0.7 dL/g, which corresponds to a number average molecular weight of about 23,000 Da.

PETG resins are high molecular weight polymers prepared by the condensation of ethylene glycol with dimethyl terephthalate or terephthalic acid and 15–34 mole percent of 1,4-cyclohexanedimethanol. PETG resins are clear, amorphous polymers, having a glass transition temperature of about 81° and no crystalline melting point, as determined by DSC. PETG resins have a distinctive IR absorption spectrum that allows them to be distinguished from other plastic materials, including PET. PETG resins have a density of approximately 1.27 g/cm$^3$ and a minimum intrinsic viscosity of 0.65 dL/g, which corresponds to a number average molecular weight of about 16,000 Da.

PET and PETG resins, and other ingredients used in the fabrication of these bottles, conform to the requirements in the applicable sections of 21 CFR regarding use in contact with food and alcoholic beverages. PET and PETG resins do not contain any plasticizers, processing aids, or antioxidants. Colorants, if used in the manufacture of PET and PETG bottles, do not migrate into the contained liquid.

## Infrared Spectroscopy

Proceed as directed for *Multiple Internal Reflectance*. The corrected spectrum of the specimen exhibits major absorption bands only at the same wavelengths as the spectrum of USP Polyethylene Terephthalate RS, or USP Polyethylene Terephthalate G RS, similarly determined.

## Differential Scanning Calorimetry

Proceed as directed for *Thermal Analysis*. For polyethylene terephthalate, the thermal analysis curve of the specimen is similar to the thermal analysis curve of USP Polyethylene Terephthalate RS and the melting peak temperature obtained from the thermal analysis curve of the specimen does not differ by more than 4.0°. For polyethylene terephthalate G, the thermal analysis curve of the specimen is similar to the thermal analysis curve of USP Polyethylene Terephthalate G RS. The melting peak temperature obtained from the thermal analysis curve of the specimen does not differ by more than 6.0°.

## Colorant Extraction

Select 3 test bottles. Cut a relatively flat portion from the side wall of 1 bottle, and trim it as necessary to fit the sample holder of the spectrophotometer. Obtain the visible spectrum of the side wall by scanning the portion of the visible spectrum from 350 to 700 nm. Determine, to the nearest 2 nm, the wavelength of maximum absorbance. Fill the remaining 2 test bottles, using 50% alcohol for PET bottles and 25% alcohol for PETG bottles. Fit the bottles with impervious seals, such as aluminum foil, and apply closures. Fill a glass bottle having the same capacity as that of the test bottles with the corresponding solvent, fit the bottle with an impervious seal, such as aluminum foil, and apply a closure. Incubate the test bottles and the glass bottle at 49° for 10 days. Remove the bottles, and allow them to equilibrate to room temperature. Concomitantly determine the absorbances of the test solutions in 5-cm cells at the wavelength of maximum absorbance (see *Ultraviolet-Visible Spectroscopy* ⟨857⟩), using the corresponding solvent from the glass bottle as the blank. The absorbance values so obtained are less than 0.01 for both test solutions.

**25 percent alcohol:** Dilute 125 mL of *50 percent alcohol* with water to 250 mL, and mix.
▲***n*-Heptane**▲ (ERR 1-Nov-2020)
**General procedure:** [NOTE—Use an *Extracting medium* of *50 percent alcohol* for PET bottles and *25 percent alcohol* for PETG bottles.] For each *Extracting medium*, fill a sufficient number of test bottles to 90% of their nominal capacity to obtain NLT 30 mL. Fill a corresponding number of glass bottles with *Purified Water*, a corresponding number of glass bottles with *50 percent alcohol* or *25 percent alcohol*, and a corresponding number of glass bottles with *n*-heptane for use as *Extracting media* blanks. Fit the bottles with impervious seals, such as aluminum foil, and apply closures. Incubate the test bottles and the glass bottles at 49° for 10 days. Remove the test bottles with the *Extracting media* samples and the glass bottles with the *Extracting media* blanks, and store them at room temperature. Do not transfer the *Extracting media* samples to alternative storage vessels.

Official

https://pharmacopeia.cn/v-29cn/

HEAVY METALS

Pipet 20 mL of the ▲*Purified Water Extracting medium*▲ (ERR 1-Nov-2020) extract of the test bottles, filtered if necessary, into one of two matched 50-mL color-comparison tubes, and retain the remaining ▲*Purified Water Extracting medium*▲ (ERR 1-Nov-2020) extract in the test bottles for use in the test for *Ethylene Glycol*. Adjust the extract with 1 N acetic acid or 6 N ammonium hydroxide to a pH between 3.0 and 4.0, using short-range pH paper as an external indicator. Dilute with water to about 35 mL, and mix.

Into the second color-comparison tube, pipet 2 mL of freshly prepared (on day of use) *Standard lead solution* (see *Physicochemical Tests, Heavy Metals*), and add 20 mL of ▲*Purified Water Extracting medium*▲ (ERR 1-Nov-2020). Adjust with 1 N acetic acid or 6 N ammonium hydroxide to a pH between 3.0 and 4.0, using short-range pH paper as an external indicator. Dilute with water to about 35 mL, and mix.

To each tube add 1.2 mL of thioacetamide–glycerin base TS and 2 mL of *pH 3.5 acetate buffer* (see *Physicochemical Tests, Heavy Metals*), dilute with water to 50 mL, and mix: any color produced within 10 min in the tube containing the ▲*Purified Water Extracting medium*▲ (ERR 1-Nov-2020) extract of the test bottles is NMT that in the tube containing the *Standard lead solution*, both tubes being viewed downward over a white surface (1 ppm in extract).

TOTAL TEREPHTHALOYL MOIETIES

Determine the absorbance of the *50 percent alcohol* or *25 percent alcohol* extract in a 1-cm cell at the wavelength of maximum absorbance at about 244 nm (see ⟨857⟩), using the corresponding *Extracting medium* as the blank: the absorbance of the extract NMT 0.150, corresponding to NMT 1 ppm of total terephthaloyl moieties.

Determine the absorbance of the *n-heptane* extract in a 1-cm cell at the wavelength of maximum absorbance at about 240 nm (see ⟨857⟩), using *n-heptane* as the blank: the absorbance of the extract is NMT 0.150, corresponding to NMT 1 ppm of total terephthaloyl moieties.

ETHYLENE GLYCOL

**Periodic acid solution:** Dissolve 125 mg of periodic acid in 10 mL of water.
**Dilute sulfuric acid:** To 50 mL of water add slowly and with constant stirring 50 mL of sulfuric acid, and allow to cool to room temperature.
**Sodium bisulfite solution:** Dissolve 0.1 g of sodium bisulfite in 10 mL of water. Use this solution within 7 days.
**Disodium chromotropate solution:** Dissolve 100 mg of disodium chromotropate in 100 mL of sulfuric acid. Protect this solution from light, and use within 7 days.
**Standard solution:** Dissolve an accurately weighed quantity of ethylene glycol in water, and dilute quantitatively, and stepwise if necessary, to obtain a solution having a known concentration of about 1 µg/mL.
**Test solution:** Use the ▲*Purified Water Extracting medium*▲ (ERR 1-Nov-2020) extract.
**Procedure:** Transfer 1.0 mL of the *Standard solution* to a 10-mL volumetric flask. Transfer 1.0 mL of the *Test solution* to a second 10-mL volumetric flask. Transfer 1.0 mL of the ▲*Purified Water Extracting medium*▲ (ERR 1-Nov-2020) to a third 10-mL volumetric flask. To each of the 3 flasks, add 100 µL of *Periodic acid solution*, swirl to mix, and allow to stand for 60 min. Add 1.0 mL of *Sodium bisulfite solution* to each flask, and mix. Add 100 µL of *Disodium chromotropate solution* to each flask, and mix.

[NOTE—All solutions should be analyzed within 1 h after addition of the *Disodium chromotropate solution*.]

Cautiously add 6 mL of sulfuric acid to each flask, mix, and allow the solutions to cool to room temperature. [**CAUTION**—Dilution of sulfuric acid produces substantial heat and can cause the solution to boil. Perform this addition carefully. Sulfur dioxide gas will be evolved. Use of a fume hood is recommended.] Dilute each solution with *Dilute sulfuric acid* to volume, and mix. Concomitantly determine the absorbances of the solutions from the *Standard solution* and the *Test solution* in 1-cm cells at the wavelength of maximum absorbance at about 575 nm (see ⟨857⟩), using ▲*Purified Water Extracting medium* as the blank▲ (ERR 1-Nov-2020): the absorbance of the solution from the *Test solution* is NMT that of the solution from the *Standard solution*, corresponding to NMT 1 ppm of ethylene glycol.

# TEST METHODS

## Multiple Internal Reflectance

APPARATUS

Use an IR spectrophotometer capable of correcting for the blank spectrum and equipped with a multiple internal reflectance accessory.

SPECIMEN PREPARATION

Cut 2 flat sections representative of the average wall thickness of the container, and trim them as necessary to obtain segments that are convenient for mounting in the multiple internal reflectance accessory. Taking care to avoid scratching the surfaces, wipe the specimens with dry paper or, if necessary, clean them with a soft cloth dampened with methanol, and permit them to dry. Securely mount the specimens ensuring adequate surface contact. Prior to mounting the specimens on the plate, they may be compressed to thin uniform films by exposing them to temperatures of about 177° under high pressures (15,000 psi or more).

@2024 USPC

GENERAL PROCEDURE

Place the mounted specimen sections within the multiple internal reflectance accessory, and place the assembly in the specimen beam of the IR spectrophotometer. Adjust the specimen position and mirrors within the accessory to permit maximum light transmission of the unattenuated reference beam. (For a double-beam instrument, upon completing the adjustments in the accessory, attenuate the reference beam to permit full-scale deflection during the scanning of the specimen.) Determine the IR spectrum from 3500 to 600 $cm^{-1}$ for polyethylene and polypropylene and from 4000 to 400 $cm^{-1}$ for PET and PETG.

## Thermal Analysis

GENERAL PROCEDURE

Cut a section weighing about 12 mg, and place it in the test specimen pan. [NOTE—Intimate contact between the pan and the thermocouple is essential for reproducible results.] Determine thermal analysis curve under nitrogen, using the heating and cooling conditions as specified for the resin type and using equipment capable of performing the determinations as specified under *Thermal Analysis* ⟨891⟩.

FOR POLYETHYLENE

Determine the thermal analysis curve under nitrogen at temperatures between 40° and 200° at a heating rate between 2° and 10°/min followed by cooling at a rate between 2° and 10°/min to 40°.

FOR POLYPROPYLENE

Determine the thermal analysis curve under nitrogen at temperatures ranging from ambient to 30° above the melting point. Maintain the temperature for 10 min, then cool to 50° below the peak crystallization temperature at a rate of 10° to 20°/min.

FOR POLYETHYLENE TEREPHTHALATE

Heat the specimen from room temperature to 280° at a heating rate of about 20°/ min. Hold the specimen at 280° for 1 min. Quickly cool the specimen to room temperature, and reheat it to 280° at a heating rate of about 5°/min.

FOR POLYETHYLENE TEREPHTHALATE G

Heat the specimen from room temperature to 120° at a heating rate of about 20°/min. Hold the specimen at 120° for 1 min. Quickly cool the specimen to room temperature, and reheat it to 120° at a heating rate of about 10°/min.

## Biological Tests

The in vitro biological tests are performed according to the procedures set forth under *Biological Reactivity Test, In Vitro* ⟨87⟩[1] Materials that do not meet the requirements of the in vitro tests are not suitable for containers for drug products.

## Physicochemical Tests

The following tests, designed to determine physical and chemical properties of plastics and their extracts, are based on the extraction of the plastic material, and it is essential that the designated amount of the plastic be used. Also, the specified surface area must be available for extraction at the designated temperature.

TESTING PARAMETERS

**Extracting medium:** Unless otherwise directed in a specific test below, use *Purified Water* as the *Extracting medium*, maintained at a temperature of 70° during the extraction of the *Sample preparation*.
**Blank:** Use *Purified Water* where a blank is specified in the tests that follow.
**Apparatus:** Use a water bath and the *Extraction Containers* as described in *Biological Reactivity Tests, In Vivo* ⟨88⟩, *Classification of Plastics, Apparatus*. Proceed as directed in the first paragraph of *Classification of Plastics, Preparation of Apparatus*. [NOTE—The containers and equipment need not be sterile.]
**Sample preparation:** From a homogeneous plastic specimen, use a portion, for each 20.0 mL of *Extracting medium*, equivalent to 120 $cm^2$ total surface area (both sides combined), and subdivide into strips approximately 3 mm in width and as near to 5 cm in length as is practical. Transfer the subdivided sample to a glass-stoppered, 250-mL graduated cylinder of Type I glass, and add about 150 mL of *Purified Water*. Agitate for about 30 s, drain off and discard the liquid, and repeat with a second washing.
**Sample preparation extract:** Transfer the prepared *Sample preparation* to a suitable extraction flask, and add the required amount of *Extracting medium*. Extract by heating in a water bath at the temperature specified for the *Extracting medium* for

[1] Biological reactivity testing in support of plastic packaging materials, components, and systems used for final pharmaceutical product packaging/delivery systems (drugs and drug/device combination products) provides baseline information and will often not be sufficient to assess the final suitability for use expectations of regulatory authorities. Thus, it is important to work with the appropriate regulatory authority for guidance regarding a product specific application.

@2024 USPC

24 h. Cool, but not below 20°. Pipet 20 mL of the prepared extract into a suitable container. [NOTE—Use this portion in the test for *Buffering Capacity*.] Immediately decant the remaining extract into a suitably cleansed container, and seal.

### NONVOLATILE RESIDUE

Transfer, in suitable portions, 50.0 mL of the *Sample preparation extract* to a suitable, tared crucible (preferably a fused-silica crucible that has been acid-cleaned), and evaporate the volatile matter on a steam bath. Similarly evaporate 50.0 mL of the *Blank* in a second crucible. [NOTE—If an oily residue is expected, inspect the crucible repeatedly during the evaporation and drying period, and reduce the amount of heat if the oil tends to creep along the walls of the crucible.] Dry at 105° for 1 h: the difference between the amounts obtained from the *Sample preparation extract* and the *Blank* is NMT 15 mg.

### RESIDUE ON IGNITION ⟨281⟩

[NOTE—It is not necessary to perform this test when the *Nonvolatile Residue* test result is NMT 5 mg.] Proceed with the residues obtained from the *Sample preparation extract* and from the *Blank* in the test for *Nonvolatile Residue* above, using, if necessary, additional sulfuric acid but adding the same amount of sulfuric acid to each crucible: the difference between the amounts of residue on ignition obtained from the *Sample preparation extract* and the *Blank* is NMT 5 mg.

### HEAVY METALS

**Lead nitrate stock solution:** Dissolve 159.8 mg of lead nitrate in 100 mL of water to which has been added 1 mL of nitric acid, then dilute with water to 1000 mL. Prepare and store this solution in glass containers free from soluble lead salts.
**Standard lead solution:** On the day of use, dilute 10.0 mL of *Lead nitrate stock solution* with water to 100.0 mL. Each milliliter of *Standard lead solution* contains the equivalent of 10 µg of lead. A comparison solution prepared on the basis of 100 µL of *Standard lead solution* per gram of substance being tested contains the equivalent of 1 part of lead per million parts of substance being tested.
**pH 3.5 acetate buffer:** Dissolve 25.0 g of ammonium acetate in 25 mL of water, and add 38.0 mL of 6 N hydrochloric acid. Adjust, if necessary, with 6 N ammonium hydroxide or 6 N hydrochloric acid to a pH of 3.5, dilute with water to 100 mL, and mix.

Pipet 20 mL of the *Sample preparation extract*, filtered if necessary, into one of two matched 50-mL color-comparison tubes. Adjust with 1 N acetic acid or 6 N ammonium hydroxide to a pH between 3.0 and 4.0, using short-range pH paper as an external indicator, dilute with water to about 35 mL, and mix.

Into the second color-comparison tube pipet 2 mL of *Standard lead solution*, and add 20 mL of the *Blank*. Adjust with 1 N acetic acid or 6 N ammonium hydroxide to a pH between 3.0 and 4.0, using short-range pH paper as an external indicator, dilute with water to about 35 mL, and mix. To each tube add 1.2 mL of thioacetamide–glycerin base TS and 2 mL of *pH 3.5 acetate buffer*, dilute with water to 50 mL, and mix: any brown color produced within 10 min in the tube containing the *Sample preparation extract* is NMT that in the tube containing the *Standard lead solution*, both tubes being viewed downward over a white surface (1 ppm in extract).

### BUFFERING CAPACITY

Titrate the previously collected 20-mL portion of the *Sample preparation extract* potentiometrically to a pH of 7.0, using either 0.010 N hydrochloric acid or 0.010 N sodium hydroxide, as required. Treat a 20.0-mL portion of the *Blank* similarly: if the same titrant was required for both the *Sample preparation extract* and the *Blank*, the difference between the two volumes is NMT 10.0 mL; and if acid was required for either the *Sample preparation extract* or the *Blank* and alkali for the other, the total of the two volumes required is 10.0 mL.

**(The text above is official until November 30, 2025. The text beginning below becomes official on December 1, 2025.)**

## ▲INTRODUCTION

Packaging systems used for drug products (pharmaceuticals, biologics) are defined in *Packaging and Storage Requirements* ⟨659⟩ and such systems may be constructed from plastic materials and components. Plastics are made of polymers, which can have a range of molecular weights and may contain other substances such as residues from the polymerization process, plasticizers, stabilizers, antioxidants, pigments, and lubricants. The nature and amount of additives in the plastics used for packaging systems are dictated by the type of polymer, the polymer's use, and the process used to convert the polymer into components, containers, or packaging systems.

Drug products will be in direct contact with the primary packaging system and may result in an interaction between the product and the packaging system. Such an interaction should not adversely affect the dosage form, and this will be facilitated by the use of well-characterized plastic materials of construction in components and packaging systems and by the appropriate testing of packaging systems.

## SCOPE

Establishing the suitability of plastic packaging systems for drug products involves multiple tests and testing procedures, as briefly outlined below:

Official

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:38:01 AM(EST)
Printed by: USP NF
Do Not Distribute

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Nov-2020
DOI Ref: ru4rn

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99420_04_01
@2024 USPC

- Material screening: Characterization of a packaging system's materials of construction to evaluate ingredients as probable extractables and potential leachables. Such a characterization facilitates the identification of materials that are suitable for use in packaging systems.
- Controlled extraction (simulation) study: Worst-case controlled extraction (simulation) study to determine the extent to which extractables may become probable leachables (for additional information, see *Assessment of Extractables Associated with Pharmaceutical Packaging/Delivery Systems* ⟨1663⟩).
- Product assessment: Actual-case measurement of confirmed leachables in the therapeutic product in the pharmaceutical packaging/delivery system intended for the commercial market (for additional information, see *Assessment of Drug Product Leachables Associated with Pharmaceutical Packaging/Delivery Systems* ⟨1664⟩).

Additionally, information provided by the vendor(s) of plastic packaging systems and their associated materials or components of construction can facilitate suitability for use assessments, as such information may be appropriate additions to or surrogates for the results obtained by performing the tests noted previously.

Testing of these plastic materials of construction to establish that they are well characterized and suitable for use in packaging components or systems is addressed in *Plastic Materials of Construction* ⟨661.1⟩.

Testing of packaging systems and components to establish that they are suited for their intended uses is addressed in *Plastic Packaging Systems for Pharmaceutical Use* ⟨661.2⟩. The requirements of ⟨661⟩ are met by performing applicable tests in ⟨661.1⟩ or by meeting the requirements of ⟨661.2⟩.

For more information on the scope of, applicability of, and other topics related to the ⟨661⟩ suite of general chapters, see *Evaluation of Plastic Packaging Systems and Their Materials of Construction with Respect to Their User Safety Impact* ⟨1661⟩.▲ (Official 1-Dec-2025)

# ⟨670⟩ AUXILIARY PACKAGING COMPONENTS

***Change to read:***

Auxiliary packaging components are articles that are used to support or enhance container–closure systems. These articles include, but are not limited to, pharmaceutical coil, desiccants, and ▲odor adsorbents▲ (USP 1-Dec-2023) for containers. The components covered in this chapter must meet the applicable requirements provided and the additional applicable requirements provided in other specified chapters.

***Change to read:***

## PHARMACEUTICAL COIL

Pharmaceutical coil is used as a filling material in multiple-unit containers for solid oral dosage forms to prevent breakage of tablets or capsules during shipment. The filling material should be discarded once the bottle is opened.

- **Solutions**

**Iodinated zinc chloride solution:** Dissolve 20 g of zinc chloride and 6.5 g of potassium iodide in 10.5 mL of *Purified Water*. Add 0.5 g of iodine, and shake for 15 min. Filter if necessary. Protect from light.

**Zinc chloride–formic acid solution:** Dissolve 20 g of zinc chloride in 80 g of an 850-g/L solution of anhydrous formic acid.

**1% DuPont Fiber Identification Stain No. 4[1] solution:** Dissolve 3.8 g of powdered stain in 378.5 mL of deionized water.

- **Cotton Pharmaceutical Coil**

Purified cotton is the hair of the seed of cultivated varieties of *Gossypium hirsutum* Linné, or of other species of *Gossypium* (Fam. Malvaceae). It is deprived of fatty matter and bleached and does not contain more than traces of leaf residue, pericarp, seed coat, or other impurities. Cotton pharmaceutical coil is used in bottles of solid oral dosage forms to prevent breakage.

**Identification**

**A.** When examined under a microscope, each fiber is seen to consist of a single cell, up to about 4 cm long and 40 µm wide, in the form of a flattened tube with thick and rounded walls that are often twisted.

**B.** When treated with *Iodinated zinc chloride solution*, the fibers become violet.

**C.** To 0.1 g of fibers add 10 mL of *Zinc chloride–formic acid solution*, heat to 40°, and allow to stand for 2 h, shaking occasionally: the fibers do not dissolve.

**D.** Weigh about 5 g of fibers, wet with water, and squeeze out the excess. Add fibers to 100 mL of a boiling solution of a *1% DuPont Fiber Identification Stain No. 4 solution*, and gently boil for at least 1 min. Remove the fibers, rinse well in cold water, and squeeze out the excess moisture: the fibers become green.

**Acidity or alkalinity:** Immerse about 10 g of fibers in 100 mL of recently boiled and cooled *Purified Water*, and allow to macerate for 2 h. Decant 25-mL portions of the water, with the aid of a glass rod, into each of two dishes. To one portion add 3 drops of phenolphthalein TS, and to the other portion add 1 drop of methyl orange TS. Neither portion appears pink when viewed against a white background.

**Fluorescence:** Examine a layer of about 5 mm in thickness under UV light at 365 nm. It displays only a slight brownish-violet fluorescence and a few yellow particles. It shows no intense blue fluorescence, apart from that which may be shown by a few isolated fibers.

**Residual hydrogen peroxide concentration:** Place 1 g of fibers in a beaker containing 30 mL of *Purified Water*, and stir for 3 min with a stirring rod. Pour contents into another clean container (do not squeeze sample), or alternatively, remove the fibers from the solution with clean tweezers. Remove a peroxide analytical test strip[2] from its container, and immerse the test end into the sample liquid for 2 s. Shake to remove the excess liquid, immediately insert the test strip into a suitable reflectometry instrument, and record the reading in mg/kg (ppm), and calculate residual hydrogen peroxide concentration in ppm.

For an alternate method, place 20 g in a beaker, add 400 mL of *Purified Water*, stir, add 20 mL of 20% sulfuric acid, and stir the contents. Titrate with 0.100 N potassium permanganate solution to a faint pink color that remains for 30 s. Record the amount of titer, and calculate the concentration in ppm.

**▲Calculation**

$$\%\ \text{Hydrogen peroxide} = \frac{(\text{mL of Titrant})(0.0017)}{20} \times 100$$

To calculate ppm of hydrogen peroxide, multiply % hydrogen peroxide (w/w) by 10,000.▲ (USP 1-Dec-2023)
Not more than 50 ppm is found using either method.

**Loss on Drying** ⟨731⟩

**Analysis:** Dry 5 g of fibers in an oven at 105° to constant weight.

**Acceptance criteria:** NMT 8.0%

**Residue on Ignition** ⟨281⟩

**Analysis:** Place 5 g of fibers in a porcelain or platinum dish, and moisten with 2 N sulfuric acid. Gently heat the cotton until it is charred, then ignite more strongly until the carbon is completely consumed.

**Acceptance criteria:** NMT 0.20%

**Water-soluble substances:** Place 10 g of fibers in a beaker containing 1000 mL of *Purified Water*, and boil gently for 30 min, adding water as required to maintain the volume. Pour the water through a funnel into another vessel, and press out the excess water from the cotton with a glass rod. Wash the cotton in the funnel with two 250-mL portions of boiling water,

@2024 USPC

pressing the cotton after each washing. Filter the combined extract and washings, and wash the filter thoroughly with hot water. Evaporate the combined extract and washings to a small volume, transfer to a tared porcelain or platinum dish, evaporate to dryness, and dry the residue at 105° to constant weight. The residue weighs NMT 0.35%.

**Fatty matter:** Pack 10 g of fibers in a Soxhlet extractor provided with a tared receiver, and extract with ethyl ether for 4 h at a rate such that the ether siphons over not less than 4 times per hour. The ethyl ether solution in the flask shows no trace of blue, green, or brownish color. Evaporate the extract to dryness, and dry at 105° for 1 h. The weight of the residue does not exceed 0.7%.

**Dyes:** Pack about 10 g of fibers in a narrow percolator ▲or a porcelain Büchner funnel,▲ (USP 1-Dec-2023) and extract slowly with alcohol until the percolate measures 50 mL. When observed downward through a column 20 cm in depth, the percolate may show a yellowish color, but not a blue or a green tint.

**Other foreign matter:** Pinches contain no oil stains or metallic particles by visual inspection.

• **RAYON PHARMACEUTICAL COIL**

Rayon pharmaceutical coil is a fibrous form of bleached, regenerated cellulose, to be used as a filler in bottles of solid oral dosage forms to prevent breakage. It consists exclusively of rayon fibers except for a few isolated foreign fibers that may be present. [NOTE—Rayon pharmaceutical coil has been found to be a potential source of dissolution problems for gelatin capsules or gelatin-coated tablets resulting from gelatin cross-linking.]

**Identification**

**A.** When treated with *Iodinated zinc chloride solution*, the fibers become violet.

**B.** Add 10 mL of *Zinc chloride–formic acid solution* to 0.1 g of fibers, heat to 40°, and allow to stand for 2 h, shaking occasionally: the fibers dissolve completely, except for mat rayon fibers where titanium particles remain.

**C.** Weigh about 5 g of fibers, wet with water, and squeeze out the excess. Add fibers to 100 mL of a boiling solution of a *1% DuPont Fiber Identification Stain No. 4 solution*, and gently boil for at least 1 min. Remove the fibers, rinse well in cold water, and squeeze out the excess moisture: the fibers become blue–green.

**Acidity or alkalinity, Fluorescence, Fatty matter, Dyes,** and **Other foreign matter:** Proceed as directed under *Cotton Pharmaceutical Coil*, except use rayon pharmaceutical coil. The sample weight for fatty matter is 5 g and weight of the residue does not exceed 0.5%.

**Loss on Drying** ⟨731⟩

**Analysis:** Dry 5 g of fibers in an oven at 105° to constant weight.

**Acceptance criteria:** NMT 11.0%

**Residue on Ignition** ⟨281⟩**:** NMT 1.50%, determined on a 5-g test specimen

**Acid-insoluble ash:** To the residue obtained in the test for *Residue on Ignition*, add 25 mL of 3 N hydrochloric acid, and boil for 5 min. Collect the insoluble matter on a tared filtering crucible, wash with hot water, ignite, and weigh: the residue weighs not more than 1.25%.

**Water-soluble substances:** Proceed as directed under *Cotton Pharmaceutical Coil*, except to use rayon pharmaceutical coil. The residue weighs not more than 1.0%.

• **POLYESTER PHARMACEUTICAL COIL**

Polyester pharmaceutical coil is a white odorless material, to be used as a filler in bottles of solid oral dosage forms to prevent breakage.

**Identification**

**A.** Proceed as directed under *Infrared spectroscopy* in the *Test Methods* section. Determine the IR spectrum from 4000 to 650 $cm^{-1}$ (2.5 to 15 µm). The spectrum obtained from the specimen exhibits major absorption bands only at the same wavelengths as the spectrum of USP Polyethylene Terephthalate RS.

**B.** Weigh about 5 g of fibers, wet with water, and squeeze out excess. Add fibers to 100 mL of a boiling solution of a *1% DuPont Fiber Identification Stain No. 4 solution*, and gently boil for at least 1 min. Remove the fibers, rinse well in cold water, and squeeze out the excess moisture: the fibers become pale orange.

**Acidity or alkalinity:** Proceed as directed under *Cotton Pharmaceutical Coil*, except to use polyester pharmaceutical coil.

**Loss on Drying** ⟨731⟩

**Analysis:** Dry 5 g of fibers in an oven at 105° to constant weight.

**Acceptance criteria:** NMT 1.0%

**Residue on Ignition** ⟨281⟩**:** NMT 0.5%, determined on a 5-g test specimen

**Finish on fibers:** The finish on fibers used for processing should comply with FDA food contact regulations.

• **TEST METHODS**

**Infrared spectroscopy**[3]

**Apparatus:** FTIR or a double-beam spectrophotometer capable of scanning from 4000 to 650 $cm^{-1}$ (2.5–15 µm).

**Specimen preparation:** The ATR *Spectroscopic Identification Tests* ⟨197⟩, *Infrared Spectroscopy* 197A technique can be used as alternative methods where the Reference Standard spectra is similarly obtained.

**Method 1** (potassium bromide disc)**:** Use scissors to cut polyester fibers (1–3 mg) into short lengths (less than 1 mm long), mix with 200 mg of powdered potassium bromide, and grind in a ball mill for 1–2 min. Transfer to potassium bromide-disc die, and form a disc.

**Method 2** (melt film)**:** Produce film by pressing polyester fibers between tetrafluoroethylene-fluorocarbon sheets and place between heated plates.

**DESICCANT▲** ▲ (USP 1-Dec-2023)

Desiccants are used to remove moisture from air in containers in order to protect drug products, particularly solid oral dosage forms. They are supplied in a number of different packaging materials including cotton, Kraft paper, rayon and polyester

[3] Additional information on fiber identification methods may be found in "Standard Test Methods for Identification of Fibers in Textiles". Current version of ASTM Method D276, published by ASTM International, 100 Barr Harbor Drive, P.O. Box C700, West Conshohocken, PA 19428-2959; www.astm.org.

cloth bags, perforated plastic, polymer films, or polymer housings▲▲ (USP 1-Dec-2023). The most common types of commercial desiccants are bentonite; calcium chloride; calcium oxide; ▲carbon, activated;▲ (USP 1-Dec-2023) molecular sieves; and silica gel. Other desiccants are subject to appropriate testing to ensure suitability for the intended application.

Where desiccants are incorporated directly into the wall or cap of packaging containers or bound by a carrier material, use unincorporated desiccant in the test methods. For desiccants that are loaded with a predetermined moisture content, perform the testing before the moisture has been loaded or after the desiccant has been regenerated.

- **BENTONITE**

Bentonite clay (also referred to as montmorillonite clay) is a native, colloidal, hydrated aluminum silicate.

**Appearance:** Grayish-white powder or pellets with a yellowish or pinkish tint

**Identification—X-Ray Powder Diffraction** ⟨941⟩**:** For *Sample preparation A*, the largest peak corresponds to a *d* value between 15.0 and 17.2 Å. The major peak in the region between 1.48 and 1.54 Å from the pattern of *Sample preparation B* is between 1.492 and 1.504 Å.

**Identification—precipitation:** Formation of a gelatinous white precipitate

**Inorganic impurities**

**Arsenic:** NMT 10 mg/kg

**Lead:** NMT 15 mg/kg

**Specific tests**

**pH** ⟨791⟩**:** 4.5–10.5. Disperse 4.0 g in 200 mL of water, mix vigorously to facilitate wetting.

**Loss on Drying** ⟨731⟩

**Sample:** 5–10-g sample

**Analysis:** Dry the *Sample* at 110° to a constant weight.

**Acceptance criteria:** It loses NMT 3.0%.

[NOTE—Conduct the assay immediately after opening the original container.]

**Moisture adsorption capacity**

NLT 13% at 40% ± 5% relative humidity (RH) and 25 ± 2°

NLT 23% at 80% ± 5% RH and 25 ± 2°

**Test methods**

**Identification—X-ray diffraction**

**Sample preparation A:** Add 2 g in small portions to 100 mL of water with intense agitation. Allow to stand for 12 h to ensure complete hydration. Place 2 mL of the mixture so obtained on a suitable glass slide, and allow to air-dry at room temperature to produce an oriented film. Place the slide in a vacuum desiccator over a free surface of ethylene glycol. Evacuate the desiccator, and close the stopcock so that ethylene glycol saturates the desiccator chamber. Allow the slide to stand for 12 h.

**Sample preparation B:** Prepare a random powder specimen of the sample.

**Analysis:** *Sample preparation A* and *Sample preparation B*. Record the X-ray diffraction pattern of the samples, and determine the *d* values.

**Identification—precipitation**

**Sample:** 5 g

**Analysis:** Add 1 g of potassium nitrate and 3 g of anhydrous sodium carbonate to the *Sample* contained in a metal crucible, heat until the mixture has melted, and allow it to cool. Add 20 mL of boiling water to the residue, mix, filter, and wash the residue with 50 mL of water. Add 1 mL of hydrochloric acid and 5 mL of water to the residue, and filter. Add 1 mL of 10 N sodium hydroxide to the filtrate, filter, and add 3 mL of 2 M ammonium chloride.

**Arsenic**

**Sample solution:** Transfer 8.0 g of dried sample into a 250-mL beaker containing 100 mL of dilute hydrochloric acid (1 in 25), mix, and cover with a watch glass. Boil gently, with occasional stirring, for 15 min without allowing excessive foaming. Pass the hot supernatant liquid through a rapid-flow filter paper into a 200-mL volumetric flask, and wash the filter with four 25-mL portions of hot dilute hydrochloric acid (1 in 25), collecting the washings in the volumetric flask. Cool the combined filtrates to room temperature, add dilute hydrochloric acid (1 in 25) to volume and mix.

**Arsenic trioxide stock solution:** Accurately weigh 132.0 mg of arsenic trioxide, previously dried at 105° for 1 h, and dissolve in 5 mL of sodium hydroxide solution (1 in 5) in a 1000-mL volumetric flask. Neutralize the solution with 2 N sulfuric acid, add an additional 10 mL of 2 N sulfuric acid, and bring to volume with recently boiled and cooled water and mix.

**Standard arsenic solution:** Dilute the *Arsenic trioxide stock solution* to obtain solutions of suitable concentrations, adaptable to the linear or working range of the instrument. Keep in an all-glass container, and use within 3 days.

**Analysis:** Proceed according to *Elemental Impurities—Procedures* ⟨233⟩.

**Lead**

**Sample solution:** Transfer 3.75 g of sample into a 250-mL beaker containing 100 mL of dilute hydrochloric acid (1 in 25), stir, and cover with a watch glass. Boil for 15 min, then cool to room temperature, and pass through a rapid-flow filter paper into a 400-mL beaker. Wash the filter with four 25-mL portions of hot water, collecting the washings in the 400-mL beaker. Concentrate the combined extracts by gentle boiling to approximately 20 mL. If a precipitate forms, add 2–3 drops of nitric acid, heat to boiling, and cool to room temperature. Pass the concentrated extracts through a rapid-flow filter paper into a 50-mL volumetric flask. Transfer the remaining contents of the 400-mL beaker through the filter paper and into the flask with water. Dilute with water to volume.

**Lead nitrate stock solution:** Dissolve 159.8 mg of lead nitrate in 100 mL of water to which has been added 1 mL of nitric acid, then dilute with water to 1000 mL. Prepare and store this solution in glass containers free from soluble lead salts.

**Standard lead solution:** On the day of use, dilute the *Lead nitrate stock solution* to obtain solutions of suitable concentrations, adaptable to the linear or working range of the instrument.

**Analysis:** Proceed according to ⟨233⟩.

**Moisture adsorption capacity**

**Equipment:** Temperature-humidity chambers capable of controlled humidity at 40% ± 5% RH and 80% ± 5% RH at 25 ± 2° or a desiccator containing water-saturated salts that provide %RH at the required level plus an oven capable of maintaining 25 ± 2°.

**Method:** 5–10 g. Remove the sample from the packaging material. Where absorbents are incorporated directly into the wall or cap of packaging containers, use unincorporated desiccant. Add the sample to the humidity chamber or desiccator and measure the weight gain over time until this reaches equilibrium when two successive consecutive weighings do not differ by more than 3 mg/g of substance taken, the second weighing following an additional 3 ± 1 h of storage at the required temperature and humidity conditions. Calculate the adsorption capacity as percentage weight gained over the initial sample weight. Where two absorbents are packaged in combination, the moisture adsorption capacity specification must be calculated in proportion of the mix. For example, for a mixture of 60% molecular sieve and 40% silica gel, the moisture adsorption capacity would be not less than 16.6% (9.0% + 7.6%) when the test condition is 40% ± 5% RH and 25 ± 2° and the moisture adsorption capacities taken at their minimum specification.

**Calculation**

**Molecular sieve:** 60% by weight × 15% moisture adsorption capacity = NLT 9.0% moisture adsorption capacity

**Silica gel:** 40% by weight × 19% moisture adsorption capacity = NLT 7.6% moisture adsorption capacity

- **CALCIUM CHLORIDE, ANHYDROUS**

**Identification—calcium:** Passes tests

**Identification—chloride:** Passes tests ▲(USP 1-Dec-2023)

**Assay:** NLT 93.0% and NMT 100.5% of calcium chloride ($CaCl_2$)

**Inorganic impurities**

**Arsenic:** NMT 3 ppm

**Fluoride:** NMT 0.004%

**Lead:** NMT 5 ppm

**Magnesium and alkali salts:** NMT 25 mg of residue (NMT 5.0%)

**Specific tests**

**pH** ⟨791⟩**:** 4.5–11.0 (1:20 aqueous solution)

**Moisture adsorption capacity:** NLT 28% at 80% ± 5% RH and 25 ± 2°

**Test methods**

**Identification—calcium**

**Sample solution—100 mg/mL:** Insoluble oxalate salts are formed when solutions of calcium salts are treated in the following manner. Using 2 drops of methyl red TS as the indicator, neutralize a 1:20 solution of a calcium salt with 6 N ammonia, then add 2.7 N hydrochloric acid, dropwise, until the solution is acid. A white precipitate of calcium oxalate forms upon the addition of ammonium oxalate TS. This precipitate is insoluble in acetic acid but dissolves in hydrochloric acid.

**Identification—chloride**

**Sample solution—100 mg/mL:** Solutions of chlorides yield with silver nitrate TS a white, curdy precipitate that is insoluble in nitric acid but soluble in a slight excess of 6 N ammonia.

**Assay**

**Sample:** 1.5 g

**Analysis:** Transfer the *Sample* into a 250-mL volumetric flask, dissolve it in a mixture of 100 mL of water and 5 mL of 2.7 N hydrochloric acid, dilute with water to volume, and mix. Transfer 50 mL of this solution into a suitable container and add 50 mL of water. While stirring, preferably with a magnetic stirrer, add about 30 mL of 0.05 M disodium ethylenediaminetetraacetic acid (EDTA) from a 50-mL buret. Then, add 15 mL of 1 N sodium hydroxide and 300 mg of hydroxy naphthol blue indicator. Continue the titration to a blue endpoint. Each milliliter of 0.05 M disodium EDTA is equivalent to 5.55 mg of calcium chloride ($CaCl_2$).

**Arsenic**

**Sample solution:** 1 g in 10 mL

**Arsenic trioxide stock solution** and **Standard arsenic solution:** Prepare as directed under *Bentonite*.

**Analysis:** Proceed as directed under *Bentonite*.

**Fluoride**

**Sodium fluoride solution—5 µg/mL:** Transfer 2.210 g of sodium fluoride, previously dried at 200° for 4 h and accurately weighed, into a 400-mL plastic beaker, add 200 mL of water, and stir until dissolved. Quantitatively transfer this solution into a 1000-mL volumetric flask with the aid of water, dilute with water to volume, and mix. Store this stock solution in a plastic bottle. On the day of use, transfer 5.0 mL of the stock solution into a 1000-mL volumetric flask, dilute with water to volume, and mix.

**Calibration curve:** Transfer 1.0, 2.0, 3.0, 5.0, 10.0, and 15.0 mL of the *Sodium fluoride solution* into separate 250-mL plastic beakers. Add 50 mL of water, 5 mL of 1 N hydrochloric acid, 10 mL of 1 M sodium citrate, and 10 mL of 0.2 M disodium EDTA to each beaker and mix. Transfer each solution into separate 100-mL volumetric flasks, dilute with water to volume, and mix. Transfer a 50-mL portion of each solution into separate 125-mL plastic beakers, and measure the potential of each solution with a suitable ion-selective electrode apparatus,[4] using a suitable reference electrode.[5] Plot the calibration curve on two-cycle semi-logarithmic paper[6] or with the use of a suitable graphing calculator or spreadsheet program. ▲▲(USP 1-Dec-2023)

[4] A suitable apparatus such as the Orion Model No. 94–09, with solid-state membrane may be used.
[5] A suitable electrode such as the Orion Model No. 90–01, with single junction may be used.
[6] A suitable semi-logarithmic paper such as K & E No. 465130 may be used.

DOI: https://doi.org/10.31003/USPNF_M2316_04_01

**Analysis:** Transfer 1.00 g of the sample into a 150-mL glass beaker, add 10 mL of water, and, while stirring continuously, slowly add 20 mL of 1 N hydrochloric acid to dissolve the sample. Boil rapidly for 1 min, then transfer into a 250-mL plastic beaker, and cool rapidly in ice water. Add 15 mL of 1 M sodium citrate and 10 mL of 0.2 M disodium EDTA, and mix. Adjust the pH to 5.5 ± 0.1 with 1 N hydrochloric acid or 1 N sodium hydroxide, if necessary. Transfer into a 100-mL volumetric flask, dilute with water to volume, and mix. Transfer a 50-mL portion of this solution into a 125-mL plastic beaker, and measure the potential of the solution with the apparatus described under *Calibration curve*. Determine the fluoride content, in µg, of the sample from the *Calibration curve*. Determine the percentage of fluoride in the sample taken:

$$\text{Result} = (C/W_S) \times F \times 100$$

$C$ = content of fluoride (µg)
$W_S$ = sample weight (g)
$F$ = factor converting µg to g, 0.000001

**Lead**
**Sample solution:** 1 g in 20 mL
**Lead nitrate stock solution** and **Standard lead solution:** Prepare as directed under *Bentonite*.
**Analysis:** Proceed as directed under *Bentonite*.
**Magnesium and alkali salts**
**Sample:** 1 g
**Analysis:** Dissolve the *Sample* in 50 mL of water, add 500 mg of ammonium chloride, mix, and boil for 1 min. Rapidly add 40 mL of oxalic acid TS and stir vigorously until precipitation is well established. Immediately add 2 drops of methyl red TS. Then add 6 N ammonium hydroxide, dropwise, until the mixture is just alkaline, and cool. Transfer the mixture to a 100-mL cylinder, dilute with water to 100 mL, and let it stand for 4 h or overnight. Decant the clear, supernatant liquid through a dry filter paper, and transfer 50 mL of the clear filtrate to a platinum dish. Add 0.5 mL of sulfuric acid to the dish and evaporate the mixture on a steam bath to a small volume. Carefully evaporate the remaining liquid to dryness over a free flame and continue heating until the ammonium salts have been completely decomposed and volatilized. Finally, ignite the residue to constant weight.
**Moisture adsorption capacity:** Proceed as directed under *Bentonite*.

• **CALCIUM OXIDE**
**Identification—calcium:** Passes tests
**Assay:** NLT 95.0% and NMT 100.5% of calcium oxide (CaO), on the ignited basis
**Inorganic impurities**

**Arsenic:** NMT 3 ppm
**Fluoride:** NMT 0.015%
**Lead:** NMT 2 mg/kg
**Magnesium and alkali salts:** NMT 3.6%
**Specific tests**
**Loss on ignition:** NMT 10.0%
**Moisture adsorption capacity:** NLT 28% at 80% ± 5% RH and 25 ± 2°
**Test methods**
**Identification—calcium**
**Sample solution:** Shake 1 g of sample with 20 mL of water and add glacial acetic acid until the sample is dissolved.
**Analysis:** Proceed as directed under *Calcium Chloride, Anhydrous*.
**Assay**
**Sample:** 1 g of sample ignited to a constant weight (see *Loss on ignition* below)
**Analysis:** Dissolve the *Sample* in 20 mL of 2.7 N hydrochloric acid. Cool the solution, dilute with water to 500.0 mL, and mix. Pipet 50.0 mL of this solution into a suitable container, and add 50 mL of water. While stirring, preferably with a magnetic stirrer, add about 30 mL of 0.05 M disodium EDTA from a 50-mL buret. Then, add 15 mL of 1 N sodium hydroxide and 300 mg of hydroxy naphthol blue indicator. Continue the titration with disodium EDTA to a blue endpoint. Each milliliter of 0.05 M disodium EDTA is equivalent to 2.804 mg of calcium oxide (CaO).
**Arsenic**
**Sample solution:** 1 g in 15 mL of 2.7 N hydrochloric acid
**Arsenic trioxide stock solution** and **Standard arsenic solution:** Prepare as directed under *Bentonite*.
**Analysis:** Proceed as directed under *Bentonite*.
**Fluoride**
**Sample:** 1.0 g
**Analysis:** Proceed as directed under *Calcium Chloride, Anhydrous*.
**Lead**
**Sample solution:** 1 g in 15 mL of 2.7 N hydrochloric acid
**Lead nitrate stock solution** and **Standard lead solution:** Prepare as directed under *Bentonite*.
**Analysis:** Proceed as directed under *Bentonite*.
**Acid-insoluble substances**
**Sample solution:** Shake 5 g of sample, and then mix it with 100 mL of water and sufficient hydrochloric acid, added dropwise, to dissolve it.

**Analysis:** Boil the *Sample solution*, cool, add hydrochloric acid, if necessary, to make the solution distinctly acid, and pass through a tared glass filter crucible. Wash the residue with water until free of chlorides, dry at 105° for 1 h, cool, and weigh.

**Magnesium and alkali salts**

**Sample:** 500 mg

**Analysis:** Dissolve the *Sample* in 30 mL of water and 15 mL of 2.7 N hydrochloric acid. Heat the solution, boil for 1 min, and rapidly add 40 mL of oxalic acid TS, and stir vigorously. Add 2 drops of methyl red TS, and neutralize the solution with 6 N ammonium hydroxide to precipitate the calcium completely. Heat the mixture on a steam bath for 1 h and allow it to cool. Dilute the mixture with water to 100 mL, mix well, and filter. Add 0.5 mL of sulfuric acid to 50 mL of the filtrate. Then evaporate to dryness and ignite to constant weight in a tared platinum crucible at 800 ± 25°.

**Loss on ignition**

**Sample:** 1 g

**Analysis:** Ignite the *Sample* to constant weight in a tared platinum crucible at 1100 ± 50°.

**Moisture adsorption capacity:** Proceed as directed under *Bentonite*.

▲• **CARBON, ACTIVATED**

Carbon, activated (also known as "active carbon") is a solid, porous material obtained from carbonaceous source materials (vegetable) matter by suitable carbonization processes, treated to increase its adsorptive power.

**Appearance:** Black-colored powder or granule, or a mixture of powder and granule

**Solubility:** Insoluble in water and in organic solvents

**Identification:** When heated to redness in atmosphere, it burns slowly without a flame.

**Inorganic impurities**

**Arsenic:** NMT 10 mg/kg (ppm)

**Lead:** NMT 15 mg/kg (ppm)

**Specific tests**

**Loss on Drying** ⟨731⟩

**Sample:** 5–10 g

**Analysis:** Dry the *Sample* at 105°–120° to a constant weight.

**Acceptance criteria:** It loses NMT 5% of its weight. [NOTE—Conduct assay immediately after opening the original container.]

**Residue on Ignition** ⟨281⟩

**Sample:** 1.0 g

**Acceptance criteria:** NMT 5.0%

**Moisture adsorption capacity:** NLT 21% weight at 80% ± 5% relative humidity (RH) and 25 ± 2°

**Higher aromatic hydrocarbons:** The sample shows no more color or fluorescence than the *Control solution* when observed under ultraviolet light at 365 nm.

**Water extractables:** NMT 5.0%

**Test methods**

**Inorganic impurities**

**Sample:** 2.0 g

**Analysis:** Combine the *Sample* and 50 mL of dilute hydrochloric acid in a conical flask with a ground glass neck. Boil gently under a reflux condenser for 1 h and wash the filter with dilute hydrochloric acid. Evaporate the combined filtrate and washings to dryness on a water bath. Dissolve the residue in 0.1 M hydrochloric acid and dilute with 0.1 M hydrochloric acid to 50 mL.

**Arsenic trioxide stock solution** and **Standard arsenic solution:** Prepare as directed under *Bentonite*.

**Lead nitrate stock solution** and **Standard lead solution:** Prepare as directed under *Bentonite*.

**Analysis:** Proceed as directed under *Bentonite*.

**Moisture adsorption capacity:** Proceed as directed under *Bentonite*.

**Higher aromatic hydrocarbons**

**Sample:** 1.0 g

**Analysis:** In a continuous-extraction apparatus, treat the *Sample* with 12 mL of cyclohexane for 2 h. Collect the liquid and dilute with cyclohexane to 12 mL. Place the *Sample* in a Nessler tube.

**Control solution:** Prepare a solution of 83 ng/mL of quinine in 0.1 N sulfuric acid and transfer into a matching Nessler tube.

**Water extractables**

**Sample:** 5.0 g

**Analysis:** Transfer about 5 g of the *Sample*, accurately weighed, into a 250-mL flask provided with a reflux condenser and a Bunsen valve. Add 100 mL of water and several glass beads, and reflux for 1 h. Cool slightly, and filter through filter paper,[7] discarding the first 10 mL of filtrate. Cool the filtrate to room temperature, and pipet 25.0 mL into a tared dish. Evaporate the filtrate in the dish to incipient dryness on a hot plate, never allowing the solution to boil. Dry for 1 h at 100° in a vacuum oven, cool, and weigh. Calculate the percentage of water extractables in the filtrate, based on the sample weight and volume of the sample taken for gravimetric measurement.▲ (USP 1-Dec-2023)

• **MOLECULAR SIEVES**

Molecular sieves are synthetic porous crystalline alkali-metal aluminosilicates in a beaded form with a tightly controlled pore size. The most commonly used molecular sieves for desiccants are described as types 3A, 4A, 5A, and 13X with a pore size range of approximately 3–10 Å.

**Identification A:** The drop of water becomes turbid.

**Identification B:** Passes tests

[7] A suitable filter paper such as Whatman No. 2 or equivalent may be used.

**Inorganic impurities**
**Lead:** NMT 5 ppm
**Specific tests**
**pH** ⟨791⟩: 6.5–12 (200 mg/mL in carbon dioxide-free water)
**Loss on Drying** ⟨731⟩
**Sample:** 5–10 g sample
**Analysis:** Dry the *Sample* at 575 ± 25° to a constant weight.
**Acceptance criteria:** It loses NMT 4.5%.
[NOTE—Conduct assay immediately after opening the original container.]
**Moisture adsorption capacity**
NLT 15.0% weight at 40% ± 5% RH and 25 ± 2°
NLT 16.5% weight at 80% ± 5% RH and 25 ± 2°
**Test methods**
**Identification A**
**Sample:** 500 mg
**Analysis:** Mix the *Sample* with 2.5 g of anhydrous potassium carbonate, and heat the mixture in a platinum or nickel crucible until it melts completely. Cool, add 5 mL of water, and allow to stand for 3 min. Heat the bottom of the crucible gently, detach the melt, and transfer it into a beaker with the aid of about 50 mL of water. Gradually add hydrochloric acid until no effervescence is observed, add 10 mL more of the acid, and evaporate to dryness on a steam bath. Cool, add 20 mL of water, boil, and pass through ash-free filter paper. An insoluble residue of silica remains. [NOTE—Retain the filtrate for *Identification B*.] Transfer the gelatinous residue to a platinum dish, and cautiously add 5 mL of hydrofluoric acid. [**CAUTION—**Handle hydrofluoric acid in a fume hood with appropriate precautions.] The precipitate dissolves. (If it does not dissolve, repeat the treatment with hydrofluoric acid.) Heat the solution and introduce a glass stirring rod with a drop of water on the tip into the resulting vapors.
**Identification B—aluminum**
**Sample:** Use 2 portions of the filtrate obtained in *Identification A*.
**Analysis:** The solution of a first portion of the filtrate obtained in *Identification A* yields a white, gelatinous precipitate with 6 N ammonia that is insoluble in an excess of this reagent. The solution of a second portion of the filtrate obtained in *Identification A* yields a white precipitate with a 1 N sodium hydroxide that is dissolved in an excess of this reagent.
**Lead**
**Sample solution:** Transfer 10.0 g of sample into a 250-mL beaker, add 50 mL of 0.5 N hydrochloric acid, cover with a watch glass, and heat slowly to boiling. Boil gently for 15 min, cool, and let the undissolved material settle. Decant the supernatant liquid through suitable filter paper[8] into a 100-mL volumetric flask, retaining as much as possible of the insoluble material in the beaker. Wash the slurry and beaker with three 10-mL portions of hot water, decanting each washing through the filter into the flask. Finally, wash the filter paper with 15 mL of hot water, cool the filtrate to room temperature, dilute with water to volume, and mix.
**Lead nitrate stock solution** and **Standard lead solution:** Prepare as directed under *Bentonite*.
**Analysis:** Proceed as directed under *Bentonite*.
**Moisture adsorption capacity:** Proceed as directed under *Bentonite*.

• **SILICA GEL**

Silica gel is silicon dioxide ($SiO_2 \cdot H_2O$) that has been manufactured by the addition of sodium silicate solution to a mineral acid to produce a gelatinous precipitate that is washed, then dehydrated to produce colorless silica gel in a bead, granular, or micronized form in a range of mesh sizes.
**Appearance:** A white or translucent bead or granule
**Identification**▲▲ (USP 1-Dec-2023)**:** A deep yellow color is produced.
▲▲ (USP 1-Dec-2023)
**Assay:** NLT 94.0% of silicon dioxide ($SiO_2$) on the ignited basis
**Inorganic impurities**
**Lead:** NMT 5 ppm
**Soluble ionizable salts** (as $Na_2SO_4$)**:** The conductance produced by the sample is not more than that produced by the control solution (equivalent to NMT 5.0%).
**Specific tests**
**pH** ⟨791⟩: 4–8 in a slurry (1 in 20)
**Loss on Drying** ⟨731⟩
**Sample:** 5–10 g
**Analysis:** Dry the *Sample* at 145° for 3 h.
**Acceptance criteria:** It loses NMT 3.0%.
[NOTE—Conduct assay immediately after opening the original container.]
**Moisture adsorption capacity**
NLT 19% weight at 40% ± 5% RH and 25 ± 2°

**Analysis:** Place into a platinum crucible, mix with 200 mg of anhydrous potassium carbonate, and ignite over a burner at a red heat for about 10 min. Cool, dissolve the melt in 2 mL of freshly distilled water, warming if necessary, and slowly add 2 mL of ammonium molybdate TS.

▲▲ (USP 1-Dec-2023)

**Assay**

**Sample:** 1 g, previously dried

**Analysis:** Transfer the *Sample* into a tared platinum crucible, ignite at 1000 ± 25° to constant weight, cool in a desiccator, and weigh to obtain the ignited sample weight ($W_1$). Moisten the residue with a few drops of alcohol, add 3 drops of sulfuric acid, then add enough hydrofluoric acid to cover the wetted sample.

[**CAUTION**—Handle hydrofluoric acid in a well-ventilated fume hood with appropriate precautions.]

Evaporate to dryness on a hot plate, using medium heat (95°–105°), then add a few milliliters of hydrofluoric acid enough to cover the *Sample*, swirl the dish carefully to wash down the sides, and again evaporate to dryness taking care that the *Sample* does not spatter as dryness is approached. Heat the crucible to a red heat using a Meker burner, a propane torch, or in a muffle furnace. Ignite the residue at 1000 ± 25° for 30 min, cool in a desiccator, and weigh to obtain the final weight ($W_2$). If a residue remains, repeat the *Analysis* beginning with the addition of hydrofluoric acid until a constant weight is obtained. The difference between the ignited sample weight and the final weight ($W_1 - W_2$) represents the weight, in g, of silicon dioxide ($SiO_2$) in the initially ignited sample. Express the result as a percentage of the initially ignited basis.

**Lead**

**Sample solution:** Transfer 5.0 g of sample into a 250-mL beaker, add 50 mL of 0.5 N hydrochloric acid, cover with a watch glass, and slowly heat to boiling. Boil gently for 15 min, cool, and let the undissolved material settle. Decant the supernatant liquid through a suitable filter paper[9] into a 100-mL volumetric flask, retaining as much as possible of the insoluble material in the beaker. Wash the slurry and beaker with three 10-mL portions of hot water, decanting each washing through the filter into the flask. Finally, wash the filter paper with 15 mL of hot water, cool the filtrate to room temperature, dilute with water to volume, and mix.

**Lead nitrate stock solution** and **Standard lead solution:** Prepare as directed under *Bentonite*.

**Analysis:** Proceed as directed under *Bentonite*.

**Soluble ionizable salts** (as $Na_2SO_4$)

**Sample:** 5 g, previously dried

**Control solution:** 1 mg/mL of anhydrous sodium sulfate, made to 250 mL

**Analysis:** Stir the *Sample* with 150 mL of water for at least 5 min in a high-speed mixer ▲or homogenizer capable of >1500 rpm.▲ (USP 1-Dec-2023) Filter with the aid of suction, and wash the mixer and filter with 100 mL of water in divided portions, adding the washings to the filtrate. Dilute the filtrate with water to 250 mL. Determine the conductances of the diluted filtrate and of the *Control solution* with a suitable conductance bridge assembly.

**Moisture adsorption capacity:** Proceed as directed under *Bentonite*.

**Reagents—test solutions**

**Ammonium molybdate TS:** Dissolve 6.5 g of finely powdered molybdic acid in a mixture of 14 mL of water and 14.5 mL of ammonium hydroxide. Cool the solution, and add it slowly, with stirring, to a well-cooled mixture of 32 mL of nitric acid and 40 mL of water. Allow to stand for 48 h, and filter through a fine-porosity, sintered-glass crucible. This solution deteriorates upon standing and is unsuitable for use if, upon the addition of 2 mL of dibasic sodium phosphate TS to 5 mL of the solution, an abundant yellow precipitate does not form at once or after slight warming. Store it in the dark. If a precipitate forms during storage, use only the clear supernatant.

**Oxalic acid TS:** Dissolve 6.3 g of oxalic acid in water to make 100 mL.

***Add the following:***

## ▲ODOR ADSORBENT

• **CARBON, ACTIVATED**[10]

Proceed as directed under *Carbon, Activated* as a desiccant plus the addition of the following test.

**Volatiles Organic Compounds (VOC) Adsorption Power**

**Butane activity**

This method determines the ability of carbon, activated to adsorb butane from dry air under controlled conditions and provides an indication of the pore size of carbon, activated for air/vapor applications. Butane activity is defined as the percent ratio of butane mass adsorbed by the mass of carbon, activated utilized when carbon, activated is saturated by butane under specified conditions.

**Method:** Dry the sample of charcoal, activated as per ⟨731⟩ and determine the bulk density (*Bulk Density and Tapped Density of Powders* ⟨616⟩). Assemble a perforated porcelain disk or an extra coarse fritted disk to a glass Schwartz drying tube to hold the sample. Accurately weigh the glass assembly together with the two glass stoppers to within 0.01 g. Transfer a sample of dried charcoal, activated equivalent to 16.70 ± 0.05 mL into the drying tube, add the two glass stoppers and weigh the assembly to within 0.01 g. Assemble a flow meter to a source of n-butane and connect the flow meter to a 1.9-m-long gas heat exchange coil. Attach the exchange coil to the inlet of the glass drying tube above the sample and an outlet tube to vent the butane. Securely clamp the drying tube in the vertical position in a water bath maintained at 25 ± 0.2° in a fume hood. Remove the right-angle stop cock and regulate the flow of butane through the carbon, activated bed at 250 ± 5 mL/min for at least 15 min.

[9] A suitable filter paper such as Whatman No. 3 or equivalent may be used.

[10] Additional information on the odor adsorption method may be found in "Standard Test Method for Determination of Butane Activity of Activated Charcoal". Current version of ASTM Method D5745, published by ASTM International, 100 Barr Harbor Drive, P.O. Box C700, West Conshohocken, PA 19428-2959; www.astm.org.

@2024 USPC

[**CAUTION**—n-Butane is highly flammable and can act as a narcotic and may cause asphyxiation and ventricular fibrillation.]

Turn off the butane flow, disconnect the tubing and immediately stopper the drying tube. Remove the drying tube from the water bath and thoroughly dry the outer surface. Inspect visually for any condensed water vapor within the tube. Repeat the test procedure if any condensed water is observed. Weigh the sample tube plus stoppers to the nearest 0.01 g.

Reconnect the sample tubing and repeat the procedure for consecutive 10-min intervals until the butane activity is constant within ±0.02 g.

**Calculation**

Calculate according to the following equation, where:

$$\%\ \text{Butane activity} = \frac{(D - C)}{(C - M)} \times 100$$

*D* = mass of butane-saturated carbon, sample tube, and stoppers
*C* = mass of carbon, sample tube, and stoppers
*M* = mass of sample tube and stoppers

**Acceptance criteria:** Butane activity is NLT 40%. ▲ (USP 1-Dec-2023)

## INTRODUCTION

It is the purpose of this chapter to provide standards for the functional properties of packaging systems used for solid oral dosage forms (SODFs) and liquid oral dosage forms (LODFs). The tests in this chapter may be applied to ▲packaging systems for▲ (USP 1-Dec-2020) other dosage forms with the appropriate justification. ▲These▲ (USP 1-Dec-2020) tests ▲▲ (USP 1-Dec-2020) determine the moisture vapor transmission rate (MVTR) i.e., water vapor permeation rate, for plastic packaging systems for manufacturers, packagers, and repackagers (*Table 1*). This chapter also includes a classification system that allows pharmacists and institutional repackagers to select appropriate containers to repackage SODFs and LODFs. Definitions that apply to this classification system are provided in *Packaging and Storage Requirements* ⟨659⟩.

▲Guidance on the application of these methods to determine the MVTR and the use of MVTR data to support the demonstration of the equivalence of plastic packaging systems when repackaging SODFs is contained in *The Application of Moisture Vapor Transmission Rates for Solid Oral Dosage Forms in Plastic Packaging Systems* ⟨1671⟩. Definitions of a blister, blister card, barrier blister types, moisture vapor transmission rate, and test specimen are contained in ⟨1671⟩, *Glossary*.

The chapter also contains a method for the determination of spectral transmission of plastic containers.▲ (USP 1-Dec-2020)

## MOISTURE VAPOR TRANSMISSION FOR ▲PLASTIC▲ (USP 1-DEC-2020) PACKAGING SYSTEMS

### Introduction

The purpose of the moisture vapor transmission test method, which is based upon American Society for Testing and Materials (ASTM) method D7709,[1] is to obtain reliable and specific MVTRs that can be used to distinguish barrier performance of

[1] ASTM D7709. *Standard Test Methods for Measuring Water Vapor Transmission Rate (WVTR) of Pharmaceutical Bottles and Blisters* published by ASTM International, 100 Barr Harbor Drive, P.O. Box C700, West Conshohocken, PA 19428-2959.

packaging systems used for regulated articles by manufacturers, packagers, and repackagers. This test method will establish a value that represents the MVTR of the container–closure system being evaluated. There may be additional packaging systems where the test methods in this section could be applied; however, any deviation should be described. If other methods are used to measure MVTR, these methods should be described in sufficient detail to justify their use.

## Desiccant Methods for Packaging Systems ▲▲ (USP 1-Dec-2020)

This section describes moisture vapor transmission test methods for multiple-unit containers (see *Method 1*), high-barrier ▲and ultra-high barrier▲ (USP 1-Dec-2020) single-unit and unit-dose containers (see *Method 2*), and low-barrier single-unit and unit-dose containers (see *Method 3*). ▲▲ (USP 1-Dec-2020)

These methods include the following:

- A specific moisture vapor transmission value for a container rather than a classification
- Sufficient sensitivity and precision to allow differentiation among moisture barrier performance for containers
- Conditions used for testing packaging systems that are the same as those used for accelerated stability testing of the primary packaging of regulated articles [typically 40°/75% relative humidity (RH)]

### EQUIPMENT

The following equipment should be used to complete the test method:

- A balance for weighing the test specimens that has sufficient capacity to weigh the test specimens throughout the period of the test. ▲▲ (USP 1-Dec-2020) The balance must have sensitivity adequate to measure small differences in weight from one time point to the next. The weighing uncertainty must be less than 5% of the weight gain from one time point to the next. The weighing uncertainty is typically three times the balance resolution/sensitivity. As an example, a balance with a resolution of 0.1 mg is acceptable for packaging systems whose weight gain per time interval is more than or equal to 6 mg [(0.1 × 3)/5%], which is 60 times the balance sensitivity.
- A chamber capable of maintaining 40 ± 2° and 75 ± 5% RH. Other chamber conditions can be used, ▲but should be noted in the report,▲ (USP 1-Dec-2020) as long as the balance sensitivity is adequate to measure small weight differences from one time point to the next time point.

### DESICCANT

**Method 1:** The desiccant is anhydrous calcium chloride in granular form. Other desiccants, such as a molecular sieve or silica gel, may be suitable. If anhydrous calcium chloride is used, pre-dry at 215 ± 5° for 7¼±¼ h to ensure that any hexahydrate present is fully converted to the anhydrate. Cool the desiccant in a desiccator for at least 2 h before use. [NOTE—It has been shown[2] that anhydrous calcium chloride may contain calcium hexahydrate, which loses water only when the temperature reaches 200°.]

**Methods 2 and 3:** ▲USP Desiccant, Small RS; USP Desiccant, Medium RS; and USP Desiccant, Large RS. The Reference Standards for desiccants are molecular sieves molded in a form to fit the size and shape of the blister cavity used. These desiccants should be at or near their original values when stored in their original and unopened containers, and thus drying should not be required. Prior to use, if the average weight of 10 tablets exceeds the weight specified on the USP certificate by more than 3%, drying shall be performed. Dry at 250 ± 5° for 1–2 h and cool in a desiccator for at least 2 h before use. Store desiccant in a tightly closed container in the driest conditions possible after being removed from original container.▲ (USP 1-Dec-2020)

### PROCEDURE

**Method 1:** Use 15 multiple-unit containers and 15 closures representative of the system to be tested. Prepare the test specimens by filling each multiple-unit container to two-thirds ▲of its nominal volume▲ (USP 1-Dec-2020) with desiccant and then, for screw-type closures, applying the closure using the torque that is within the range of tightness specified in *Table 2*. For other closure types, apply the closure according to the intended method. ▲If the intended use of the container shall have an impervious seal, then▲ (USP 1-Dec-2020) ensure that a proper seal has been made with the intended membrane to the land area of the bottle ▲opening.▲ (USP 1-Dec-2020) Identify each multiple-unit container with indelible ink. Do not use a label. If there is a need to increase the precision of the method, the user can test the system without the closure as long as an impervious seal remains on the container. If desired, weigh each multiple-unit container at ambient temperature and RH. Record this weight for time 0, but do not use it in the calculation of permeation. Place all containers in the test chamber (40°/75% RH) within 1 h of weighing. Weigh all multiple-unit containers at time intervals of 7 days ± 1 h. Weigh the multiple-unit containers at 7, 14, 21, 28, and 35 days to get ▲five▲ (USP 1-Dec-2020) steady-state data points. (The time interval from time 0 to day 7 is the period of equilibration.) Prior to weighing at each time interval, equilibrate the containers for about 30 min at the weighing temperature and RH. Limit the time out of the chamber to less than 2 h. Record the weights in an appropriate manner for later computation of the regression line.

| 110 | 45–70 | 5.09–7.91 |
| 120 | 55–95 | 6.22–10.74 |
| 132 | 60–95 | 6.78–10.74 |

[a] The torque designated for the next larger closure diameter is to be applied in testing containers having a closure diameter intermediate to the diameters listed.
[b] A suitable apparatus is available from SecurePak, www.secure-pak.com. An MRA model of a spring torque tester with indicators on both the removal and application sides is available in the following ranges: 1) 0–25 inch-pounds, read in 1-inch-pound increments; 2) 0–50 inch-pounds, read in 2-inch-pound increments; and 3) 0–100 inch-pounds, read in 5-inch-pound increments.

**Method 2:** Use 10 test units for this method. Provide a minimum of 10 blister cavities for each test unit. If the ▲blister▲ (USP 1-Dec-2020) card contains fewer than 10 cavities, bundle the cards to form a ▲▲ (USP 1-Dec-2020) test unit of at least 10 cavities. This is required to provide sufficient weight gain at each time interval. Fill with predried desiccant, and seal the blisters on equipment that is capable of correctly filling and sealing the blister. The desiccant should fill the cavity. The total weight of the desiccant must be sufficient to meet the quantity required to avoid partial saturation of the *Desiccant* before completion of the test. Fill the blisters in a low-humidity atmosphere (as low as possible, but not greater than 50% RH). Do not expose the desiccants to room humidity for more than 30 min before sealing. Identify each test specimen with indelible ink; do not use a label. ▲▲ (USP 1-Dec-2020) It should be noted that bundling of the blisters during storage can impact air flow and correspondingly increase data variability.

Weigh each test unit at ambient temperature and RH. Record this weight for time 0. Place all test units in the test chamber (40°/75% RH) within 1 h of weighing. Weigh all test units at time intervals of 7 days ± 1 h. Weigh the test units at 7, 14, 21, 28, and 35 days to get five steady-state data points. (The time interval from time 0 to day 7 is the period of equilibration.) Prior to weighing at each time interval, equilibrate the containers for 30 ± 5 min at the controlled weighing temperature and RH. Limit the time out of the chamber to less than 2 h. Record the weights in an appropriate manner for later computation of the regression line.

Ultra-high barrier blisters may not show the full measure of precision and sensitivity this method can provide. For ultra-high barrier blisters, test units should have more than 10 cavities, but NMT 30 cavities. Examples are foil–foil blisters or very small blisters formed from other materials. An alternative approach is to double or triple the length of weighing intervals to achieve at least a 6-mg weight gain per time interval by the test specimen.

**Method 3:** Prepare the test units as directed in *Method 2*. Place all test units in the test chamber (40°/75% RH) within 1 h of weighing. Weigh the test units at the end of 2 days (48 ± 1 h). At this time, the difference in weight (the weight gain) is divided

Official

https://pharmacopeia.cn/v29240/

by the number of blister ▲cavities▲ (USP 1-Dec-2020) and days (2) in each test unit and this is taken as the MVTR in mg/day/▲cavity.▲ (USP 1-Dec-2020) The number of blisters tested depends on the barrier characteristics of the material, the size of the blister, and the sensitivity of the balance used in the test. For this method, the requirement of five consecutive weighings is waived because the desiccant quickly becomes saturated when packed in a low-barrier package and stored at 40°/75% RH. [NOTE—For low-barrier single-unit and unit-dose containers, the weight gain after the second day displays a curvilinear profile typical of approaching saturation of the desiccant. To obtain five weighings within 2 days is not viable and is likely to increase variability. *Methods 2* and *3* may require that the blister cards be bundled in multiples to achieve periodic weight gains of sufficient magnitude to use the balance sensitivity; when bundled, these cards or test specimens are called test units. The weight gain in each weighing period must be 20 times the sensitivity of the balance, and the balance sensitivity is three times the balance precision. In other words, the minimal weight gain per time interval should be at least 60 times the balance precision.]

## CALCULATIONS

**Methods 1 and 2:** Perform the regression analysis for each test unit (see *Regression equation*). Typically, the initial data point (at day 0) is not included in fitting the regression line. The slope of the regression line is the MVTR of each test unit. For *Method 1*, the slope is the MVTR for the corresponding multiple-unit container. For *Method 2*, the MVTR of each blister cavity is calculated by dividing the slope by the number of cavities in each test unit.
**Method 3:** Calculate the weight gain in mg/day/▲cavity▲ (USP 1-Dec-2020) from day 0 to day 2 using the 10 test units (see *Calculations*). The MVTR of each blister ▲cavity▲ (USP 1-Dec-2020) is calculated by dividing the weight gain by 2 (for 2 days) and the number of ▲blister cavities▲ (USP 1-Dec-2020) in each test unit.
**Regression equation:**

$$W = I + MT$$

**Calculations:**

$$Slope\left(M\right) = \sum_{i=1}^{N}\left[\left(W_i - \overline{W}\right)\left(T_i - \overline{T}\right)\right] / \sum_{i=1}^{N}\left(T_i - \overline{T}\right)^2$$

$$\text{Intercept } (I) = \overline{W} - M\overline{T}$$

$W$ = measured weight (mg)
$I$ = regression line intercept (point where regression line intersects the vertical axis)
$M$ = regression line slope
$T$ = time point
$N$ = number of data points (each point consists of a weight and a time)
$\overline{W}$ = overall weight mean
$\overline{T}$ = overall time point mean

$$\sum_{i=1}^{N}\left[\left(W_i - \overline{W}\right)\left(T_i - \overline{T}\right)\right]$$

equals the sum of cross-products (for example, for each of the $N$ data points, subtract the overall weight mean from the measured weight and the overall time point mean from the time point and multiply the two differences to get a cross-product, then sum all $N$ cross-products).

$$\sum_{i-1}^{N}\left(T - \overline{T}\right)^2$$

equals the sum of squared deviations (for example, for each of the $N$ data points, subtract the overall time point mean from the time point and square the difference, then use the sum of all $N$ squared differences).

## RESULTS

**Method 1:** Report the MVTR as the average value, in mg/day/container, and the standard deviation of the 15 slopes. Properly describe the container–closure system tested ▲(e.g., material, size, shape, and color).▲ (USP 1-Dec-2020)
**Method 2:** Report the MVTR as the average value, in mg/day/cavity, and the standard deviation of the 10 test unit slopes. Properly describe the container–closure system tested ▲(e.g., material, size, shape, and color).▲ (USP 1-Dec-2020)
**Method 3:** Report the MVTR as the average value from day 0 to day 2, in mg/day/▲cavity,▲ (USP 1-Dec-2020) and the standard deviation of the 10 test unit slopes. Properly describe the container–closure system tested ▲(e.g., material, size, shape, and color).

# Water Method for Packaging Systems

This section describes moisture vapor transmission test methods (see *Method 4*) for low-barrier, high-barrier, and ultra-high barrier single-unit and unit-dose containers.

*Method 4* includes the following:

- A specific moisture vapor transmission value for a packaging system rather than a classification.

- Sufficient sensitivity and precision to allow differentiation among moisture barrier performance for plastic blister packaging systems.
- Inverse environmental conditions (40°/25% RH) from those that are used for the desiccant method and stability testing of the primary packaging of regulated articles (40°/75% RH). These inverse conditions achieve the same pressure difference when water is used in place of desiccant.
- MVTR determination is based upon weight loss instead of weight gain.

## EQUIPMENT

The following equipment should be used to complete the test method:

- A humidity-controlled glove box capable of maintaining relative humidity at 25% ± 5%.
- A balance for weighing the test specimens that has sufficient capacity to weigh the test specimens throughout the period of the test. The balance must have sensitivity adequate to measure small differences in weight from one time point to the next. The weighing uncertainty must be less than 5% of the weight gain from one time point to the next. The weighing uncertainty is typically three times the balance resolution/sensitivity. As an example, a balance with a resolution of 0.1 mg is acceptable for packaging systems whose weight gain per time interval is more than or equal to 6 mg [(0.1 × 3)/5%], which is 60 times the balance sensitivity.
- A chamber capable of maintaining 40 ± 2°/25% ± 5% RH.

## AMOUNT OF WATER FOR TEST CONTAINERS

For blisters, approximately 10–100 mg of water per blister cavity (about 1–10 drops), depending upon expected MVTR, is adequate for all blister types at 40°/25% RH. As an example, consider the preparation of a low-barrier MVTR package, e.g., a polyvinyl chloride (PVC) water-filled blister. The expected MVTR is about 1.5 mg water/(day × cavity) at 40° and a 75% RH vapor–pressure difference. The initial amount of water required to create 100% RH at 40° in this blister (approximately 0.5 cc volume) is 0.025 mg, on the basis of absolute humidity. For a typical MVTR study of a low-barrier blister, 7 days are allowed for equilibration, followed by a study period of 28 days for obtaining 3–5 weight determinations. This is a total exposure time, or permeation time, of 35 days. According to the *Water-based method equation*, a minimum of 52.5 mg of water is needed.
**Water-based method equation:** 1.5 mg water/(day × cavity) × 35 days + 0.025 mg = 52.5 mg water/cavity

The recommended amount of water for this blister system is about 100 mg per cavity. The water-based method equation can be used to determine the minimum amount of water for all blister types, and this amount should then be multiplied by a factor between 2 and 3 to achieve an excess.

## PROCEDURE

**Method 4:** Use 10 test units for this method. Provide a minimum of 10 blister cavities for each test unit. If the blister card contains fewer than 10 cavities, bundle the cards to form a test unit of at least 10 cavities. This is required to provide sufficient weight loss at each time interval.

Fill blister cavities with a sufficient quantity of water. Care should be taken to insure the cavities are not overfilled and that water does not end up on the seal area.

Identify each test specimen with indelible ink; do not use a label. High-barrier plastic blister cards may be bundled to increase weight loss between weight determinations. Low-barrier plastic blister cards do not need to be bundled, regardless of the number of cavities per card. For bundled test units, it should be noted that bundling of the blisters during testing can impact air flow and correspondingly increase data variability.

Place test units in the humidity-controlled glove box at 25% RH for 60 min. Remove test units from the glove box and record initial weight to nearest 0.1 mg and time. Place all test units in the test chamber (40°/25% RH) and weigh at time intervals of 7 days ± 1 h. Weigh the test units at 7, 14, 21, 28, and 35 days to get five steady-state data points. Additional time points can be added to provide for laboratory operations and higher barrier blisters. At each time point, place the test units in the humidity-controlled glove box and allow to equilibrate for 60 min, then weigh, and record the time. After weighing, samples are placed back into the test chamber. [NOTE—It is imperative that the weighing order of test units be consistent among all time point weight determinations.]

Ultra-high barrier blisters may not show the full measure of precision and sensitivity this method can provide. For ultra-high barrier blisters, test units should have more than 10 cavities, but NMT 30 cavities. Examples are foil–foil blisters or very small blisters formed from other materials. An alternative approach is to double or triple the length of weighing intervals to achieve at least a 6-mg weight gain per time interval by the test specimen.

All test units should be inspected for the presence of water at each time point. Opaque and cold-form foil blisters should be opened at the conclusion of the test to insure the presence of water in each cavity since visual inspection is not possible.

## CALCULATIONS

**Method 4:** Perform the linear regression analysis for each test unit by following the *Calculations* in *Methods 1 and 2* in *Desiccant Methods for Packaging Systems*, except the slope in *Water Method for Packaging Systems* is negative because of the moisture egresses and weight loss with time in the water method. The MVTR of each blister cavity is calculated by dividing the absolute value of the slope by the number of cavities in each test unit.

## RESULTS

**Method 4:** Report the MVTR as the average value, in mg/day/cavity, and the standard deviation of the 10 test unit slopes. Properly describe the container–closure system tested.▲ (USP 1-Dec-2020)

# CLASSIFICATION SYSTEM FOR PLASTIC PACKAGING SYSTEMS

## Introduction

A classification system is included to provide methods that allow pharmacists and institutional repackagers to select appropriate containers for repackaging. Repackaging is the act of taking a finished drug product from the container in which it was distributed by the original manufacturer and placing it into a different container without further manipulation of the drug. The classification system provided can also be used by the drug product manufacturer for testing packaging systems that have had the primary seal broached.

## Classification Based on Desiccant Method ▲for Solid Oral Dosage Forms▲ (USP 1-Dec-2020)

This section describes the methods for assigning the classification for multiple-unit containers (*Method ▲5*),▲ (USP 1-Dec-2020) multiple-unit containers with induction seals (*Method ▲6*),▲ (USP 1-Dec-2020) and single-unit and unit-dose containers (*Method ▲7*)▲ (USP 1-Dec-2020) used by pharmacists and institutional repackagers.

### DESICCANT

**Methods ▲5 and 6:**▲ (USP 1-Dec-2020) Place a quantity of 4- to 8-mesh, anhydrous calcium chloride[3] in a shallow container, taking care to exclude any fine powder, dry at 215 ± 5° for 7¼±¼ h, and cool in a desiccator ▲for at least 2 h before use.▲ (USP 1-Dec-2020) [NOTE—It has been shown[2] that anhydrous calcium chloride may contain calcium hexahydrate, which loses water only when the temperature reaches 200°.]

**Method ▲7:** Use USP Desiccant, Small RS; USP Desiccant, Medium RS; or USP Desiccant, Large RS. The USP Reference Standards for desiccants are molecular sieves molded in a form to fit the size and shape of the blister cavity used. These desiccants should be at or near their original values when stored in their original and unopened containers, and thus drying should not be required. Prior to use, if the average weight of 10 tablets exceeds the weight specified on the USP certificate by more than 3%, drying shall be performed. Dry at 250 ± 5° for 1–2 h, and cool in a desiccator for at least 2 h before use. Store desiccant in a tightly closed container in the driest conditions possible after being removed from original container.▲ (USP 1-Dec-2020)

### PROCEDURE

**Method ▲5:**▲ (USP 1-Dec-2020) Select 12 containers of a uniform size and type. Clean the sealing surfaces with a lint-free cloth, and close and open each container 30 times within the range of tightness specified in *Table 2*. Add desiccant to 10 of the containers, designated "test containers", filling each to within 13 mm of the closure if the container volume is 20 mL or more, or filling each to two-thirds of ▲its nominal volume▲ (USP 1-Dec-2020) if the container volume is less than 20 mL. If the interior of the container is more than 63 mm in depth, an inert filler or spacer ▲(e.g., glass beads)▲ (USP 1-Dec-2020) may be placed in the bottom to minimize the total weight of the container and desiccant; the layer of desiccant in such a container must be NLT 5 cm in depth. Close each container immediately after adding desiccant, and apply the torque designated in *Table 2* when closing screw-capped containers. To each of the remaining two containers, designated "controls", add a sufficient number of glass beads to attain a weight approximately equal to that of each of the test containers, and close, applying the torque designated in *Table 2* when closing screw-capped containers. Record the weight of the individual containers to the nearest 0.1 mg if the container volume is less than 20 mL, to the nearest milligram if the container volume is 20 mL or more but less than 200 mL, or to the nearest centigram (10 mg) if the container volume is 200 mL or more, and store at 75 ± 3% RH and a temperature of 23 ± 2°. [NOTE—A saturated system of 35 g of sodium chloride with each 100 mL of water placed in the bottom of a desiccator maintains the specified humidity. Other methods may be employed to maintain these conditions.] After 336 ± 1 h (14 days), record the weight of the individual containers in the same manner. Completely fill 5 empty containers of the same size and type as that of the containers under test with water or a noncompressible, free-flowing solid, such as well-tamped fine glass beads, to the level indicated by the closure surface when in place. Transfer the contents of each to a graduated cylinder, and determine the average container volume, in milliliters.

**Method ▲6:**▲ (USP 1-Dec-2020) Proceed as directed under *Method ▲5*,▲ (USP 1-Dec-2020) except fit containers with impervious seals obtained by heat-sealing the bottles with an aluminum foil–polyethylene laminate or other suitable seal. If there is a need to increase the precision of the method, the user can test the system without the closure as long as an impervious seal remains on the container. Keeping the cap on causes variation and the absorption of water by the cap liner is not part of the moisture permeation.

**Method ▲7:**▲ (USP 1-Dec-2020) Use this procedure for packs (e.g., punch-out cards) and blister cards that incorporate one or more separately sealed unit-dose containers or blisters. Seal a sufficient number of packs, such that NLT 4 packs and a total of NLT 10 unit-dose containers or blisters filled with 1 pellet in each unit are tested. Seal a corresponding number of empty packs, each pack containing the same number of unit-dose containers or blisters as used in the test packs, to provide the controls. Store all of the containers at 75 ± 3% RH and at a temperature of 23 ± 2°. [NOTE—A saturated system of 35 g of sodium chloride with each 100 mL of water placed in the bottom of a desiccator maintains the specified humidity. Other methods may be employed to maintain these conditions.] After 24 h, and at each multiple thereof (see *Classification*), remove the packs from the chamber, and allow them to equilibrate for about 45 min. Record the weights of the individual packs, and return them to the chamber. Weigh the control packs as a unit, and divide the total weight by the number of control packs to obtain the average empty pack weight. [NOTE—If any indicating pellets turn pink during the procedure, or if the average pellet weight increase in any

[3] Suitable 4- to 8-mesh, anhydrous calcium chloride is available from VWR International.

https://pharmacopeia.cn/v29240/

pack exceeds 10%, terminate the test, and regard only earlier determinations as valid.] The test and control containers are weighed after every 24 h and after suitable test intervals for the final weighings. $W_F$ and $C_F$ are as follows: 24 h for Class D, 48 h for Class C, 7 days for Class B, and NLT 28 days for Class A.

CALCULATIONS

**Methods ▲5 and 6:▲** (USP 1-Dec-2020) Calculate the rate of moisture vapor transmission, in mg/day/L:

$$(1000/14V)[(T_F - T_I) - (C_F - C_I)]$$

$V$ = volume of the container (mL)
$T_F$ = final weight of each test container (mg)
$T_I$ = initial weight of each test container (mg)
$C_F$ = average final weight of the two controls (mg)
$C_I$ = average initial weight of the two controls (mg)

**Method ▲7:▲** (USP 1-Dec-2020) Calculate, to two significant figures, the average rate of moisture vapor transmission, in mg/day, for each unit-dose container or blister in each pack taken:

$$[1/(N \times X)][(W_F - W_I) - (C_F - C_I)]$$

$N$ = number of days expired in the test period (beginning after the initial 24-h equilibration period)
$X$ = number of separately sealed units per pack
$W_F$ = final weight of each test pack (mg)
$W_I$ = initial weight of each test pack (mg)
$C_F$ = final weight of the control packs (mg)
$C_I$ = initial weight of the control packs (mg)

▲CLASSIFICATION▲ (USP 1-Dec-2020)

**Method ▲5:▲** (USP 1-Dec-2020) Packaging systems are ▲classified as▲ (USP 1-Dec-2020) "tight" if NMT 1 of the 10 test containers exceeds 100 mg/day/L in moisture vapor transmission, and none exceeds 200 mg/day/L. Packaging systems are ▲classified as▲ (USP 1-Dec-2020) "well-closed" if NMT 1 of the 10 test containers exceeds 2000 mg/day/L in moisture vapor transmission, and none exceeds 3000 mg/day/L.
**Method ▲6:▲** (USP 1-Dec-2020) Packaging systems are classified as ▲"tight"▲ (USP 1-Dec-2020) if the moisture vapor transmission exceeds 10 mg/day/L in NMT 1 of the 10 test containers, and none exceeds 25 mg/day/L.
**Method ▲7:▲** (USP 1-Dec-2020) Class A: No pack tested exceeds 0.5 mg/day/unit in average blister MVTR; Class B: No pack tested exceeds 5 mg/day/unit in average blister MVTR; Class C: No pack tested exceeds 20 mg/day/unit in average blister MVTR; and Class D: None of the packs tested meet any of the above average blister MVTR requirements.

## Classification Based on Water Method ▲for Liquid Oral Dosage Forms▲ (USP 1-Dec-2020)

The following procedure and classification scheme ▲(*Method 8*)▲ (USP 1-Dec-2020) is provided to ▲classify multiple-unit containers as "tight" for liquid oral dosage forms.▲ (USP 1-Dec-2020)

[NOTE—Determine the weights of individual container–closure systems (bottle; inner seal, if used; and closure), both as tare weights and fill weights, to the nearest 0.1 mg if the bottle capacity is less than 200 mL, to the nearest milligram if the bottle capacity is 200 mL or more but less than 1000 mL, or to the nearest ▲0.1 g▲ (USP 1-Dec-2020) if the bottle capacity is 1000 mL or more.]

PROCEDURE

**▲Method 8:▲** (USP 1-Dec-2020) Select 12 bottles of a uniform size and type, and clean the sealing surfaces with a lint-free cloth. Fit each bottle with a seal, closure liner (if applicable), and closure. Number each container–closure system, and record the tare weight.

Remove the closures and, using a pipet, fill 10 bottles with water to the fill capacity. Fill two containers with glass beads, to the same weight as the filled test containers. If using screw closures, apply a torque that is within the range specified in *Table 2*, and store the sealed containers at a temperature of 25 ± 2° and 40 ± 2% RH. After 336 ± 1 h (14 days), record the weight of the individual containers, and calculate the water weight loss rate, in %/year, for each bottle taken:

$$\frac{\left[\left(W_{1i} - W_T\right) - \left(W_{14i} - W_T\right) - \left(W_{C1} - W_{C14}\right)\right]}{\left(W_{1i} - W_T\right) \times 14} \times 365 \times 100$$

$W_{1i}$ = initial weight of each individual bottle ($i$) (mg)
$W_T$ = tare weight (mg)
$W_{14i}$ = weight of each individual bottle ($i$) at 14 days (mg)
$W_{C1}$ = initial weight of the control container at day 1 (mg)
$W_{C14}$ = weight of the control container at 14 days (mg)

## SPECTRAL TRANSMISSION ▲FOR LIGHT-RESISTANT PACKAGING COMPONENTS OR SYSTEMS

A packaging component or system intended to provide protection from light or offered as a light-resistant container meets the requirements for *Spectral Transmission for Light-Resistant Packaging Components or Systems*, where such protection or resistance is by virtue of the specific properties of the material of which the plastic component or system is composed, including any coating. A clear and colorless or a translucent packaging system that has light protection by means of an opaque enclosure by application of a suitable coating or wrapping (see *General Notices*) is exempt from the requirements for *Spectral Transmission for Light-Resistant Packaging Components or Systems*.▲ (USP 1-Dec-2020)

### Apparatus

▲If the suitability of the packaging system is demonstrated through stability testing, spectral transmission testing is not required; otherwise, use a UV-visible spectrophotometer of suitable sensitivity and accuracy (see ⟨857⟩), adapted for measuring the amount of light transmitted by plastic materials used for pharmaceutical containers.▲ (USP 1-Dec-2020)

### Procedure

Select a section representing the average ▲▲ (USP 1-Dec-2020) thickness. Cut a circular section from ▲the packaging component or system,▲ (USP 1-Dec-2020) and trim as necessary to get a segment convenient for mounting in the spectrophotometer. After cutting, wash and dry the specimen, taking care to avoid scratching the surfaces. If the specimen is too small to cover the opening in the specimen holder, mask the uncovered portion of the opening with opaque paper or masking tape, provided that the length of the specimen is greater than that of the slit in the spectrophotometer. Immediately before mounting in the specimen holder, wipe the specimen with lens tissue. Mount the specimen with the aid of a tacky wax, or by other convenient means, taking care to avoid leaving fingerprints or other marks on the surfaces through which light must pass. Place the section in the spectrophotometer with its cylindrical axis parallel to the plane of the slit and approximately centered with respect to the slit. When properly placed, the light beam is normal to the surface of the section and reflection losses are at a minimum.

Continuously measure the transmittance of the section with reference to air in the spectral region of interest with a recording instrument or at intervals of about 20 nm with a manual instrument, in the region of 290–450 nm.

### ▲Acceptance Criteria▲ (USP 1-Dec-2020)

The observed spectral transmission does not exceed the limits given in *Table 3* for ▲plastic components and systems▲ (USP 1-Dec-2020) for parenteral use. The observed spectral transmission for plastic containers for products intended for oral or topical administration does not exceed 10% at any wavelength in the range of 290–450 nm.

**Table 3. ▲Spectral Transmission Limits for Plastic Packaging Components or Systems▲** (USP 1-Dec-2020)

| Nominal Size (mL) | Maximum Percentage of Spectral Transmission at Any Wavelength Between 290 and 450 nm |
|---|---|
| 1 | ▲25▲ (USP 1-Dec-2020) |
| 2 | ▲20▲ (USP 1-Dec-2020) |
| 5 | ▲15▲ (USP 1-Dec-2020) |
| 10 | ▲13▲ (USP 1-Dec-2020) |
| 20 | ▲12▲ (USP 1-Dec-2020) |
| ▲50▲ (USP 1-Dec-2020) | ▲10▲ (USP 1-Dec-2020) |

## ▲GLOSSARY

**Blister:** Formed, lidded, and sealed plastic or foil dome that contains the capsule or tablet (usually a single unit or unit dose).

**Low-barrier blister:** Blisters made from low-barrier materials, formed and sealed so that the moisture vapor transmission rate when tested at 40°/75% RH is greater than 1.0 mg/cavity/day.

**High-barrier blister:** Blisters made from high-barrier material, formed and sealed so that the moisture vapor transmission rate when tested at 40°/75% RH is less than 1.0 mg/cavity/day.

Official

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99430_03_01
@2024 USPC

**Ultra-high barrier blister:** Blisters made from ultra-high barrier material, formed and sealed so that the moisture vapor transmission rate when tested at 40°/75% RH is less than 0.01 mg/cavity/day.

**Blister card:** A contiguous group of blisters formed and sealed with lid in place. The number of blisters per card commonly ranges from 1 to 10 but may be more. The blister card may sometimes be referred to as a packaging system.

**Cavity:** Formed, lidded, and sealed plastic or foil dome (see *Blister*).

**Moisture vapor transmission rate:** The steady-state moisture vapor transmission (in unit time) through a packaging system, under specific conditions of temperature and humidity. These test methods use gravimetric measurement to determine the rate of weight gain as a result of moisture vapor transmission into the packaging system and subsequent uptake by a desiccant enclosed within the packaging system.

**Test specimen** (or specimen)**:** For multiple-unit containers, the bottle is the test specimen, and for single-unit or unit-dose containers, the blister card containing multiple blister cavities is the test specimen. For blisters, more than 1 card (or specimen) may be grouped into a test unit for conducting the test.

**Test unit:** For multiple-unit containers, the bottle is the test unit as well as being the test specimen, and for single-unit or unit-dose containers, the test unit is a group of test specimens (blister cards) processed together for temperature and humidity exposure and for weighing at each time point. The purpose of the test unit for single-unit or unit-dose containers is to gain the advantage of additive weight gain resulting from more blister cavities than are present on a single card. The test unit, when applied to bottles, is used to maintain naming congruence among test methods 1, 2, and 3.▲ (USP 1-Dec-2020)

# ⟨695⟩ CRYSTALLINITY

This test is provided to determine compliance with the crystallinity requirement where stated in the individual monograph for a drug substance.

## PROCEDURE

A detailed test procedure is described under *Optical Microscopy* ⟨776⟩.

Official

https://pharmacopeia.cn/

# ⟨696⟩ CHARACTERIZATION OF CRYSTALLINE SOLIDS BY MICROCALORIMETRY AND SOLUTION CALORIMETRY

*For the purpose of this chapter, crystalline material, partially crystalline material, and amorphous material are considered as solids.*

## INTRODUCTION—THE CONCEPT OF CRYSTALLINITY

The perfectly ordered crystal lattice with every molecule in its expected lattice position is an ideal that is seldom, if ever, achieved. The other extreme is the amorphous state, in which a solid contains the maximum possible density of imperfections (defects of various dimensionalities), such that all long-range order is lost while only the short-range order, imposed by its nearest neighbors, remains. Real crystals lie somewhere between these two extremes. A crystal's position on a scale bounded by these two extremes is termed *crystallinity*.

All real crystals, even in the pure state, possess some lattice imperfections or defects, which increase both the energy (enthalpy under conditions of constant atmospheric pressure) and the disorder (expressed as the entropy) of the crystal lattice. A crystal with a relatively low density of imperfections is said to be highly crystalline and to possess a high crystallinity. By contrast, a particle with a relatively high density of imperfections is said to be partially amorphous and to possess a low crystallinity. In ideal terms, a totally amorphous particle corresponds to zero crystallinity. Amorphous particles may contain somewhat ordered domains that can act as nuclei for crystallization; such so-called amorphous particles are said to possess a low-level, but finite, crystallinity.

The ability to detect and quantify the amount of amorphous material within a highly crystalline substance is of great importance during the development and subsequent manufacture of a pharmaceutical preparation.

In reality, a powder probably contains particles with different degrees of crystallinity, just as it may contain particles with varying sizes and shapes. The lower the crystallinity of a solid, the greater its enthalpy and entropy. The increase in enthalpy is never totally compensated by the increase in entropy; therefore, the Gibbs free energy, which reflects the balance between them, actually increases. Hence, the lower the crystallinity of a material (powder), and consequently the greater its amorphous character, the greater its apparent intrinsic solubility and dissolution rate, but the lower its thermodynamic stability. Because of the great relevance of these properties, crystallinity is also an important property and requires measurement by a suitable method.

In the following chapter, the crystallinity or the content of amorphous parts of a powder are measured by calorimetric methods such as microcalorimetry or solution calorimetry, although other methods could be used (e.g., see general chapter *Characterization of Crystalline and Partially Crystalline Solids by X-ray Powder Diffraction (XRPD)* ⟨941⟩).

Many substances are capable of crystallizing in more than one type of crystal lattice, which is known as polymorphism. If water or a solvent is incorporated in the crystal lattice, the crystals are termed hydrates or solvates. Because of the different crystal packing, and/or molecular conformation and lattice energy, they usually exhibit different physical properties. For simplicity, calorimetry measurements for degree of crystallinity determination discussed here assume only one solid crystalline form present in the material of interest. The theory and experimental technique can be easily expanded to polymorphic systems with proper consideration of the enthalpy differences among the polymorphs.

## METHOD 1—MICROCALORIMETRY (DETERMINATION OF AMORPHOUS CONTENT)

Most chemical, physical, and biological processes are associated with the exchange of heat. Microcalorimetry is a highly sensitive technique to monitor and quantify both exothermic (heat producing) and endothermic (heat absorbing) changes associated with those processes. The technique allows the determination of the rate and extent of chemical reactions, changes of phase, or changes of structure.

Thermal events producing only a fraction of a microwatt can be observed using microcalorimetry. This means that temperature differences less than $10^{-6}$ K must be detectable. Microcalorimetry typically uses the heat flow (heat leakage) principle, where, in a thermally defined vessel, the heat produced (or absorbed) flows away from (or into) the vessel in an effort to re-establish thermal equilibrium with its surroundings. Exceptional thermal stability with its surrounding has to be achieved either by a heat sink or an electronically regulated surrounding.

Heat energy from an active sample in the reaction vessel is channeled typically through Peltier elements; they act as thermoelectric generators using the Seebeck effect. The heat energy is converted into a voltage signal proportional to the heat flow.

Results are typically presented as a measure of the thermal energy produced per unit of time (Watt) as a function of time.

### Apparatus

Microcalorimeters are typically designed as twin systems with a measuring vessel and a reference vessel. Vessels are typically made of glass or stainless steel. For certain applications, specially designed vessels that allow the addition of a gas, a liquid, or a solid material may be used.

### Calibration

The microcalorimeter is calibrated for heat flow (energy per time unit) using either calibrated external or internal electrical heat sources or a suitable standard reaction.

https://pharmacopeia.cn/v-download/

## Sensitivity

The sensitivity of the microcalorimetric method can be assessed on the basis of an appropriate standard sample analyzed according to the corresponding method in conjunction with the determination of the instrument baseline noise.

## Procedure

Weigh an appropriate quantity of the material in a suitable vessel. Close the vessel carefully, to avoid any evaporation of solvents, and place the vessel in the sample holder. If appropriate, allow the vessel to equilibrate at the temperature of the measurement before placing it in the measuring position.

Begin the analysis, and record the heat flow with the time on the abscissa and the heat flow on the ordinate (specify the direction of exothermic or endothermic heat flow).

## Detection and Quantification of Amorphous Content in Powders

The amorphous state is metastable with respect to the crystalline state; recrystallization may therefore occur. The measurement of the heat of recrystallization enables the amorphous content to be determined by the area of the recrystallization peak. By relating the output from the microcalorimeter for a sample to that obtained from an amorphous standard, it is possible to quantify the amorphous content of the sample. The range of amorphous content covered by this method depends on the individual substance to be tested. In favorable cases, limits of detection below 1% can be reached.

Recrystallization can be initiated by subjecting the sample to higher relative humidity or an atmosphere containing organic vapor. The sample is typically placed in an ampul that also contains a small test tube containing an aqueous saturated salt solution, an organic solvent, or a solvent mixture.

The heat of recrystallization is typically measured using a fixed sample mass placed in a glass or steel vessel. The test tube containing a saturated salt solution or an organic solvent is chosen large enough to allow a full saturation of the atmosphere above the sample. The mass of the sample and the nature of the vapor atmosphere above the sample is chosen so that recrystallization occurs in such a way that a distinct peak is observed, clearly separated from initial thermal events caused by introduction of the sample.

The conditions under which the transition of the amorphous phase to a thermodynamically more stable crystalline state occurs will have a significant impact on the time of recrystallization. In particular, physical mixtures of purely amorphous and crystalline material will behave differently from a partially crystalline material. These effects should be considered when developing a method.

A typical response for the recrystallization of a mainly amorphous material is shown in *Figure 1*. The first part of the curve represents several concurrent processes taking place simultaneously, such as the absorption of water vapor into the amorphous parts of the powder and by the generation of water vapor from the test tube. After this initial response, there is a large exothermic response caused by the recrystallization of the amorphous material. Also included, but not seen, is the expulsion of excess water from the recrystallized parts and its condensation. Thus, the area under this exothermic recrystallization response is proportional to the heat of recrystallization.

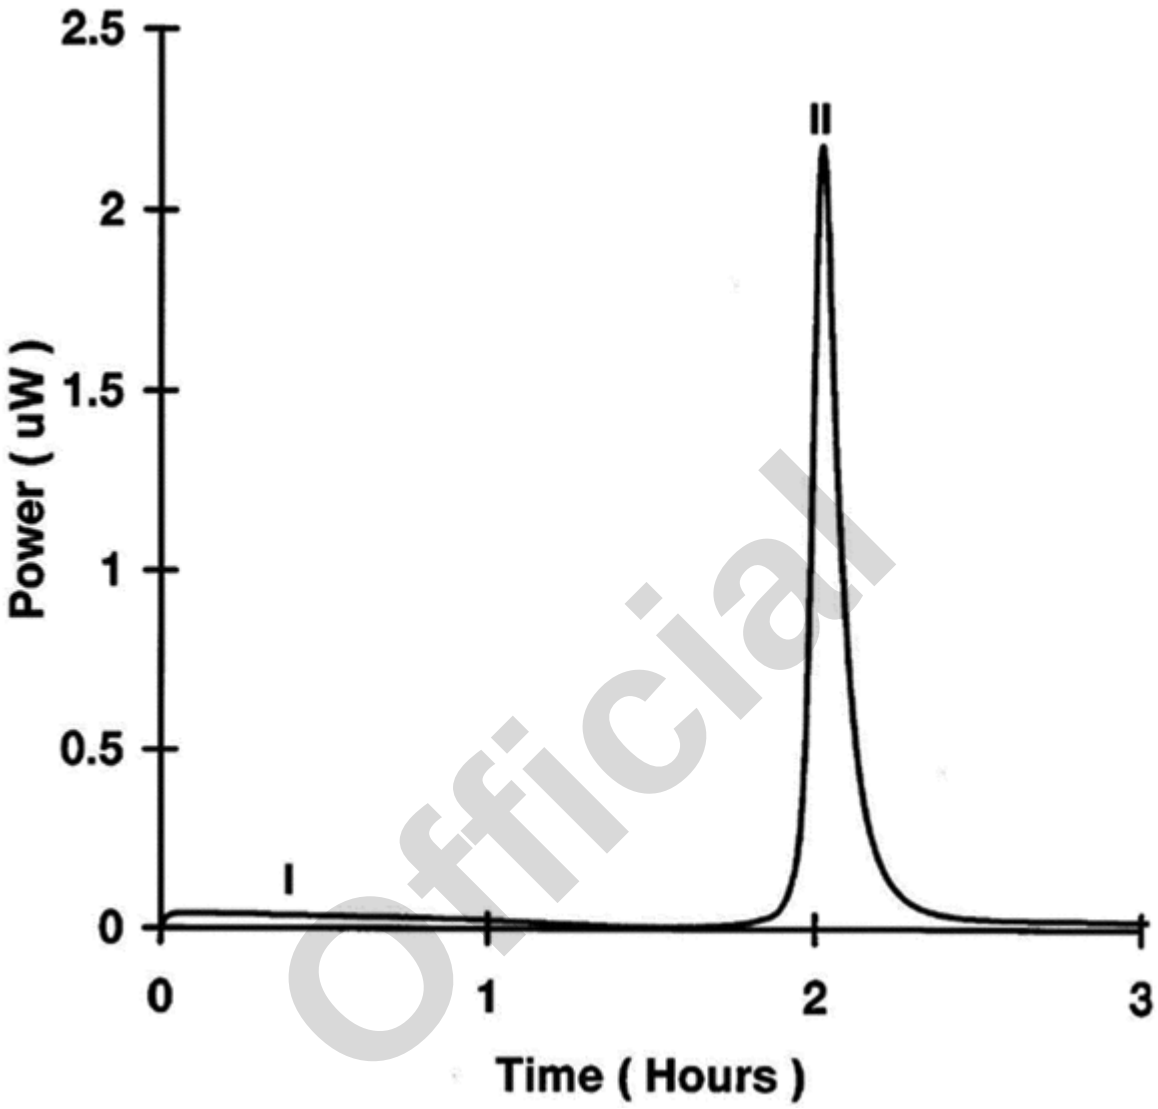

Figure 1. Typical microcalorimetric output of power (in µW) as a function of time (in h): amorphous collapse peak (I) and crystallization peak (II) for mainly amorphous lactose at 25° and 75% relative humidity.

## METHOD 2—SOLUTION CALORIMETRY (DETERMINATION OF CRYSTALLINITY)

Solution calorimetry provides a means of determining enthalpy of solution (i.e., heat of solution under constant atmospheric pressure) of a substance. Enthalpy of solution is defined as the enthalpy of the substance dissolved in the solution to a defined concentration minus the enthalpy of the original substance. The solvent for the dissolution process must be such that the mass of solid dissolves within a time frame that matches the response time of the calorimeter, as discussed below. The enthalpy of solution is proportional to the amount of solid being dissolved. This amount may be defined as one mole for molar enthalpy or as one gram for specific enthalpy. If the substance possesses adequate purity (as determined by the degree of accuracy required) and if its molecular mass is known, the molar enthalpy is preferred; otherwise the specific enthalpy must be used. The enthalpy of solution is weakly dependent on both the temperature, which is usually 25.0°, and the final concentration of the dissolved solute.

It is usually preferred to express the crystallinity, $P_c$, of a substance on a percentage scale. This procedure requires two reference standards, namely a highly crystalline sample assuming 100% crystallinity and having a measured enthalpy of solution of $\Delta H^s_c$, and an amorphous sample assuming 0% crystallinity and having a measured enthalpy of solution of $\Delta H^s_a$. From these values and from the measured enthalpy, $\Delta H^s_s$, of solution of the solid under study, the percentage crystallinity of the solid, $P_c$, may be calculated as follows:

$$P_c\,(\%) = 100(\Delta H^s_s - \Delta H^s_a)/(\Delta H^s_c - \Delta H^s_a)$$

Clearly, crystallinity expressed on a percentage scale depends on three measured values, and the enthalpies of solution may be replaced by other corresponding physical quantities that depend on crystallinity. The value of the percentage crystallinity

https://pharmacopeia.cn/v-download/

of a sample, however, depends not only on the nature and method of preparation of the two reference standards, but also on the choice of the physical quantity that is measured.

The enthalpy of solution is measured either by an isoperibol (constant perimeter, i.e., jacket) solution calorimeter or by an isothermal (constant temperature) solution calorimeter. Typically, at least three measurements are made with each sample. The mean of these values is then calculated. The exact requirements will depend on the equipment capability and degree of accuracy needed.

## Isoperibol Solution Calorimetry

In the isoperibol solution calorimeter, the heat change during the solution process causes a corresponding change in temperature of the solvent–solute system (i.e., solution). This temperature change is measured by a temperature sensor, which is wired to an electrical circuit that records an electrical signal corresponding to the temperature change. Typically, this temperature change in an electronic form is measured at precisely defined time intervals to produce temperature–time data that are collected, analyzed by a computer, and then plotted. A blank run without addition of the solid solute to the solvent normally shows no discernible change in the slope of the temperature–time plot.

For isoperibol solution calorimeters, response is fairly rapid, but corrections must be made for any heat losses to or heat gains from the bath. Therefore, isoperibol solution calorimeters are more advantageous than isothermal solution calorimeters when the solution process is relatively fast. For all measurements of enthalpy of solution using isoperibol solution calorimeters, the choice of solvent is critical. The nature and mass of the solvent and the mass of sample allow the total heat change, corresponding to total dissolution of the solid, to proceed to completion within five min under vigorous stirring at a constant rotational speed within the range of 400–600 revolutions/min.

The effective heat capacity of the calorimeter cell and its contents is determined for every calorimeter run. This determination is accomplished by electrical heating of the contents of the calorimeter cell. The effective heat capacity is determined according to one of two protocols—either by making one determination after ampul breakage or by making one determination before and a second determination after ampul breakage, and then averaging the two results. The accuracy and reliability of the electrical heating are established by the accuracy and reliability of the aforementioned chemical calibrations.

## Isothermal Solution Calorimetry

In the isothermal (constant temperature) solution calorimeter, the heat change during the solution process is compensated for by an equal but opposite energy change, such that the temperature of the solvent–solute system (i.e., solution) remains essentially constant. This equal but opposite energy change is measured and, when its sign is reversed, provides the enthalpy of solution. For isothermal calorimeters, response is relatively slow, but the compensation process eliminates the effects of heat losses to or heat gains from the bath. Therefore, isothermal calorimeters are more advantageous than isoperibol calorimetry when the solution process is relatively slow.

## Solution Calorimeter Calibration

To ensure the accuracy of the calorimeter, chemical calibrations must be performed on a regular basis. For an endothermic solution process, the calibration of the calorimeter is checked by measuring the heat absorbed during the dissolution of potassium chloride in distilled water at 298.15 K (25.0°). The established enthalpy change in this endothermic process is 235.5 J/g (17.56 kJ/mol). For an exothermic solution process, the calorimeter is checked by measuring the heat evolved during the dissolution of 5 g/L of tromethamine [tris(hydroxymethyl)aminomethane, THAM] in a 0.1 mol/L aqueous hydrochloric acid solution at 298.15 K (25.0°). The established heat for the aforementioned process is –246.0 J/g (–29.80 kJ/mol).

## Sample Handling

The chemical and physical stability of solids may decrease with decreasing crystallinity. In particular, solids of low crystallinity, especially amorphous solids, tend to sorb water vapor from the atmosphere, leading to crystallization and a corresponding gain in crystallinity. For these reasons, anhydrous samples whose crystallinity is to be determined must be stored at zero humidity or below critical humidity levels in sealed chambers containing a desiccant, preferably containing an indicator of effectiveness. If crystallinity–humidity studies are to be carried out, the sample is stored in a sealed chamber containing a saturated salt solution to provide a defined relative humidity.

# ⟨697⟩ CONTAINER CONTENT FOR INJECTIONS

Each container of an injection contains sufficient excess to allow withdrawal of the labeled quantity of drug (see *Pharmaceutical Dosage Forms* ⟨1151⟩*, Excess Volume in Injections*). Such withdrawal shall be performed according to labeled directions, if provided.

## DETERMINATION OF VOLUME OF INJECTION IN CONTAINERS

This section is harmonized with the corresponding texts of the *European Pharmacopoeia* and/or the *Japanese Pharmacopoeia*. These pharmacopeias have undertaken not to make any unilateral change to this harmonized section. A portion of the present text (see below) is national *USP* text, and therefore not part of the harmonized text; it is marked with symbols (♦,♦) to specify this fact.

Suspensions and emulsions must be shaken before withdrawal of the contents and before the determination of the density. Oily and viscous preparations may be warmed according to the instructions on the label, if necessary, and thoroughly shaken immediately before removing the contents. The contents are then cooled to 20°–25° before measuring the volume. ♦Sterile solid formulations must be constituted according to labeled directions before removing the contents. Contents are then to be measured following the procedures for suspensions, emulsions, or solutions, as appropriate.♦

### Single-Dose Containers

Select 1 container if the volume of the container is 10 mL or more, 3 containers if the nominal volume is more than 3 mL and less than 10 mL, or 5 containers if the nominal volume is 3 mL or less. Take up individually the total contents of each container selected into a dry syringe of a capacity not exceeding three times the volume to be measured and fitted with a 21-gauge needle NLT 2.5 cm (1 inch) in length. Expel any air bubbles from the syringe and needle, and then discharge the contents of the syringe, without emptying the needle, into a standardized, dry cylinder (graduated to contain rather than to deliver the designated volumes) of such size that the volume to be measured occupies at least 40% of its graduated volume. Alternatively, the volume of the contents in mL may be calculated as the mass, in g, divided by the density. For containers with a nominal volume of 2 mL or less, the contents of a sufficient number of containers may be pooled to obtain the volume required for the measurement, provided that a separate, dry syringe assembly is used for each container. The contents of containers holding 10 mL or more may be determined by means of opening them and emptying the contents directly into the graduated cylinder or tared beaker.

The volume is NLT the nominal volume in the case of containers examined individually or, in the case of containers with a nominal volume of 2 mL or less, is NLT the sum of the nominal volumes of the containers taken collectively.

### Multi-Dose Containers

For Injections in multiple-dose containers labeled to yield a specific number of doses of a stated volume, select 1 container, and proceed as directed for single-dose containers, using the same number of separate syringe assemblies as the number of doses specified. The volume is such that each syringe delivers NLT the stated dose.

### Injections in Cartridges or Prefilled Syringes

Select 1 container if the volume is 10 mL or more, 3 containers if the nominal volume is more than 3 mL and less than 10 mL, or 5 containers if the nominal volume is 3 mL or less. If necessary, fit the containers with the accessories required for their use (needle, piston, syringe) and transfer the entire contents of each container without emptying the needle into a dry tared beaker by slowly and constantly depressing the piston. Determine the volume, in mL, calculated as the mass, in g, divided by the density.

The volume measured for each of the containers is NLT the nominal volume.

### Large-Volume Intravenous Solutions

For intravenous solutions, select 1 container. Transfer the contents into a dry measuring cylinder of such a capacity that the volume to be determined occupies at least 40% of the nominal volume of the cylinder. Measure the volume transferred.

The volume is NLT the nominal volume.

# ⟨698⟩ DELIVERABLE VOLUME

## PURPOSE

The following tests are designed to provide assurance that oral liquids will, when transferred from the original container, deliver the volume of dosage form that is declared on the label.

***Change to read:***

## SCOPE

These tests are applicable to products that are dispensed by pouring from the container. The tests apply whether the products are supplied as liquid preparations or liquid preparations that are constituted from solids upon the addition of a designated volume of a specific diluent. ▲When the container includes a flow restrictor or orifice reducer (e.g., a coupler for an oral syringe), the volume for this test should be discharged according to the labeling advice. These tests▲ (USP 1-Dec-2020) are not required for an article packaged in single-unit containers when the monograph includes the test for *Uniformity of Dosage Units* ⟨905⟩.

## DENSITY DETERMINATION

Because of the tendency of oral liquids to entrain air when shaken or transferred, a more accurate method for determining the delivered volume is to first determine the delivered mass, and then, using the density of the material, to convert the mass to delivered volume. In order to do that, a determination of the density of the material is required. The following is one method to determine density:

1. Tare a 100-mL volumetric flask containing 50.0 mL of water.
2. Add approximately 25 g of well-shaken product, and gently swirl the contents to mix.
3. Reweigh the flask.
4. From a buret, add an accurately measured amount of water to bring the flask contents to volume while gently swirling the contents of the flask. Record the volume taken from the buret.
5. Calculate the density of the sample:

$$\text{Result} = W/V$$

$W$ = weight of the material taken (g)
$V$ = 50.0 minus the volume, in mL, of the water necessary to adjust the contents of the flask to volume

Other methods of determining the density may be employed depending on the formulation (e.g., substantially nonaqueous formulations).

## TEST PREPARATIONS

For the determination of deliverable volume, select NLT 30 containers, and proceed as follows for the dosage form designated.

### Oral Solutions and Oral Suspensions

Shake the contents of 10 containers individually.

### Powders That Are Labeled to State the Volume of Oral Liquid That Results When the Powder Is Constituted with the Volume of Diluent Stated in the Labeling

Constitute 10 containers with the volume of diluent stated in the labeling, accurately measured, and shake individually.

***Change to read:***

## PROCEDURE

The deliverable volume can be determined by weight as follows:

1. Discharge the container contents into a suitable tared container (allowing drainage for NMT 5 s for single-▲unit▲ (USP 1-Dec-2020) containers and NMT 10 min for multiple-unit containers).
2. Determine the mass of the contents.
3. Calculate the volume using the density.

Alternatively, the following by-volume procedure may be used:

Official

https://pharmacopeia.com/

1. Under conditions of use or as instructed in the labeling, carefully discharge the contents of each container into separate dry graduated cylinders of a rated capacity not exceeding 2.5 times the volume to be measured and calibrated "to contain" (see *Volumetric Apparatus* ⟨31⟩). Care must be taken to avoid the formation of air bubbles during the process. In the absence of labeling instructions, support the containers at about a 30° angle to the horizontal, and gently discharge the contents into the graduated cylinder.
2. Allow each container to drain for a period not to exceed 10 min for multiple-unit containers and 5 s for single-unit containers, unless otherwise specified in the monograph.
3. When free from bubbles, measure the volume of each mixture.

## ACCEPTANCE CRITERIA

Use the following criteria to determine compliance with this test.

### For Multiple-Unit Containers (see *Figure 1*)

The average volume of liquid obtained from the 10 containers is NLT 100%, and the volume of no container is less than 95% of the volume declared in the labeling. If (A), the average volume is less than 100% of that declared in the labeling, but the volume of no container is less than 95% of the labeled amount, or if (B), the average volume is NLT 100% and the volume of NMT 1 container is less than 95%, but is NLT 90% of the labeled volume, perform the test on 20 additional containers. The average volume of liquid obtained from the 30 containers is NLT 100% of the volume declared in the labeling; the volume of liquid obtained from NMT 1 of the 30 containers is less than 95%, but NLT 90% of that declared in the labeling.

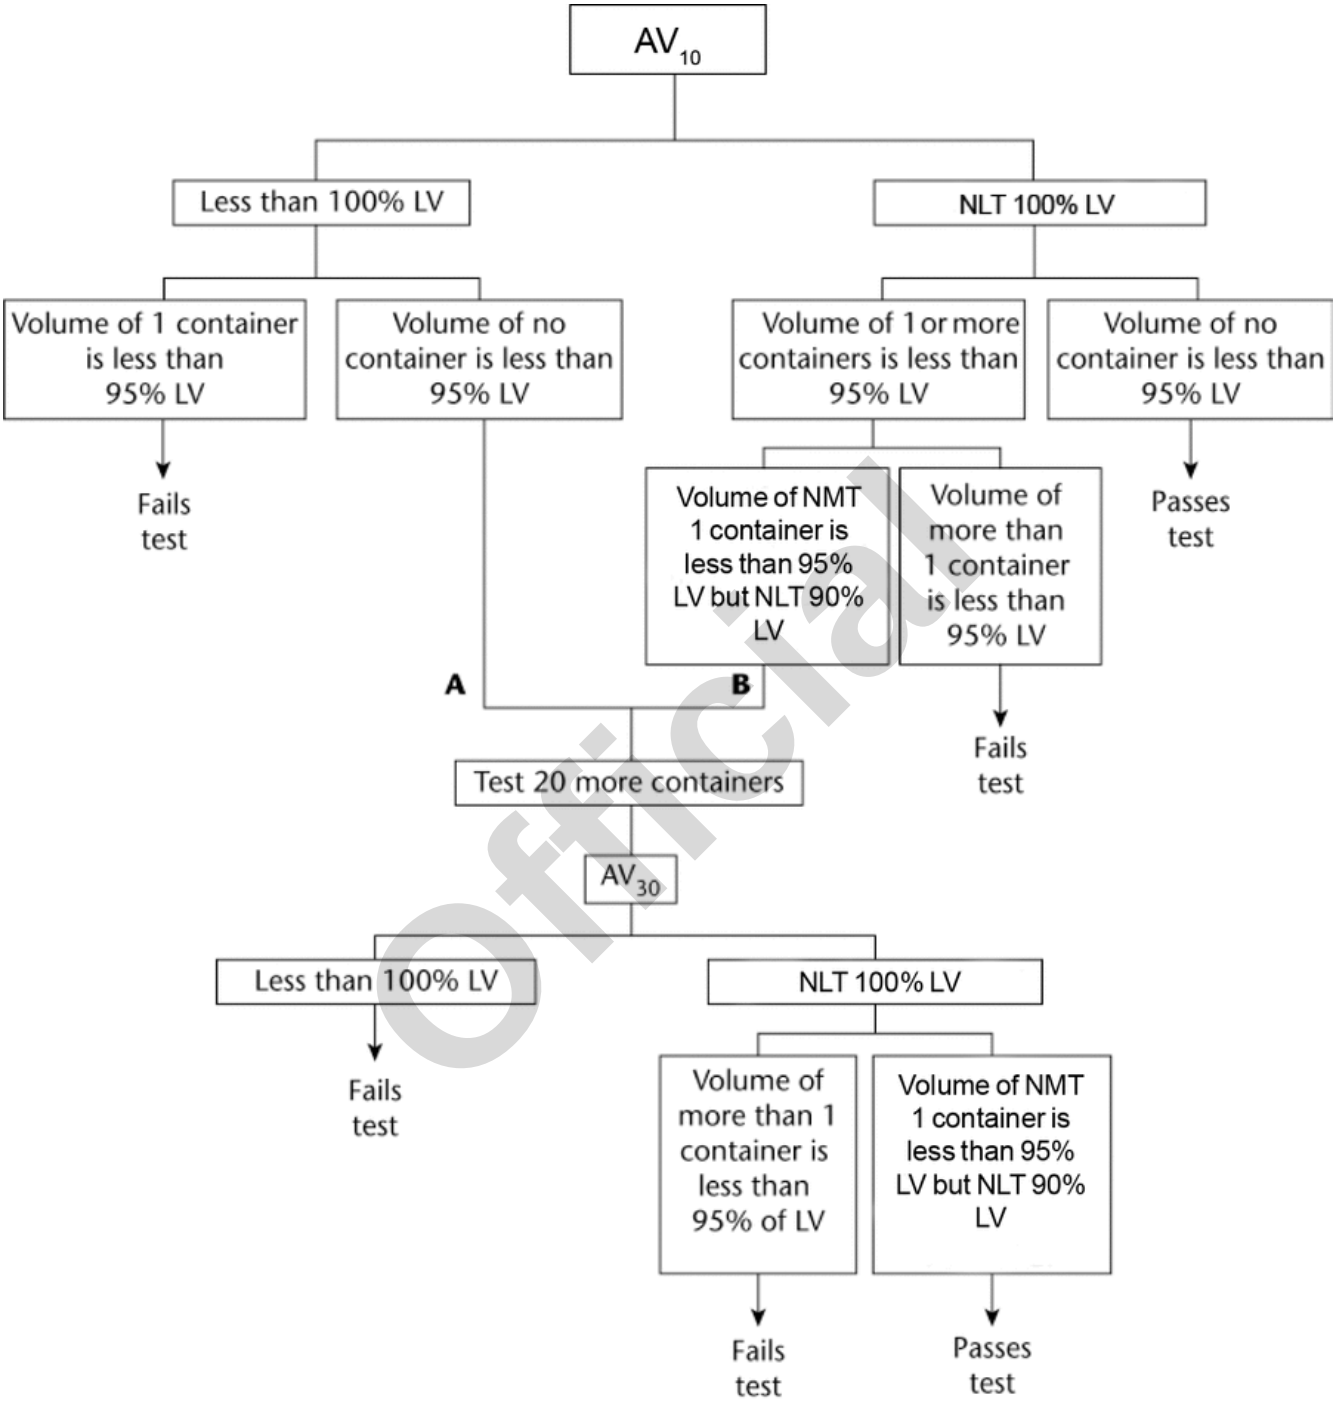

Figure 1. Decision scheme for multiple-unit containers (AV = average volume; LV = labeled volume).

## For Single-Unit Containers (see *Figure 2*)

The average volume of liquid obtained from the 10 containers is NLT 100%, and the volume of each of the 10 containers lies within the range of 95%–110% of the volume declared in the labeling. If (A), the average volume is less than 100% of that declared in the labeling, but the volume of no container is outside the range of 95%–110%, or if (B), the average volume is NLT 100% and the volume of NMT 1 container is outside the range of 95%–110%, but within the range of 90%–115%, perform the test on 20 additional containers. The average volume of liquid obtained from the 30 containers is NLT 100% of the volume declared in the labeling; the volume obtained from NMT 1 of the 30 containers is outside the range of 95%–110%, but within the range of 90%–115% of the volume declared on the labeling.

# ⟨699⟩ DENSITY OF SOLIDS

## TERMS AND DEFINITIONS

Density refers to the average spatial distribution of mass in a material. The density of solids typically is expressed in g per $cm^3$, in contrast to fluids, where the density is commonly expressed in g per mL at a stated reference temperature.

The density of a solid particle can assume different values depending on the method used to measure the volume of the particle. It is useful to distinguish among three different possibilities.

The *true density* of a substance is the average mass per unit volume, exclusive of all voids that are not a fundamental part of the molecular packing arrangement. It is a property of a particular material, and hence should be independent of the method of determination. The true density of a perfect crystal can be determined from the size and composition of the unit cell.

The *pycnometric density*, as measured by gas pycnometry, is a convenient density measurement for pharmaceutical powders. In a gas pycnometer, the volume occupied by a known mass of powder is determined by measuring the volume of gas displaced by the powder. The quotient of the mass and volume is the pycnometric density. The pycnometric density equals the true density unless the material contains impenetrable voids, or sealed pores, that are inaccessible to the gas used in the pycnometer.

The *granular density* includes contributions to particle volume from open pores smaller than some limiting size. The size limit depends on the method of measurement. A common measurement technique is mercury porosimetry, where the limiting pore size depends upon the maximum intrusion pressure. Because of the additional contribution from pore volume, the granular density will never be greater than the true density. A related concept is the *aerodynamic density*, which is the density of the particle with a volume defined by the aerodynamic envelope of the particle in a flowing stream. Both the closed and open pores contribute to this volume, but the open pores fill with the permeating fluid. The aerodynamic density, therefore, depends on the density of the test fluid if the particle is porous.

For brevity, the pycnometric density and the true density are both referred to as density. If needed, these quantities may be distinguished based on the method of measurement.

The density of a material depends on the molecular packing. For gases and liquids, the density will depend only on temperature and pressure. For solids, the density will also vary with the crystal structure and degree of crystallinity. If the solids are amorphous, the density may further depend upon the history of preparation and treatment. Therefore, unlike fluids, the densities of two chemically equivalent solids may be different, and this difference reflects a difference in solid-state structure. The density of constituent particles is an important physical characteristic of pharmaceutical powders.

Beyond these definitions of particle density, the *bulk density* of a powder includes the contribution of interparticulate void volume. Hence, the bulk density depends on both the density of powder particles and the packing of powder particles.

## GAS PYCNOMETRY FOR THE MEASUREMENT OF DENSITY

Gas pycnometry is a convenient and suitable method for the measurement of the density of powder particles. A simple schematic of one type of gas pycnometer is shown in *Figure 1.*

DOI: https://doi.org/10.31003/USPNF_M99458_02_01

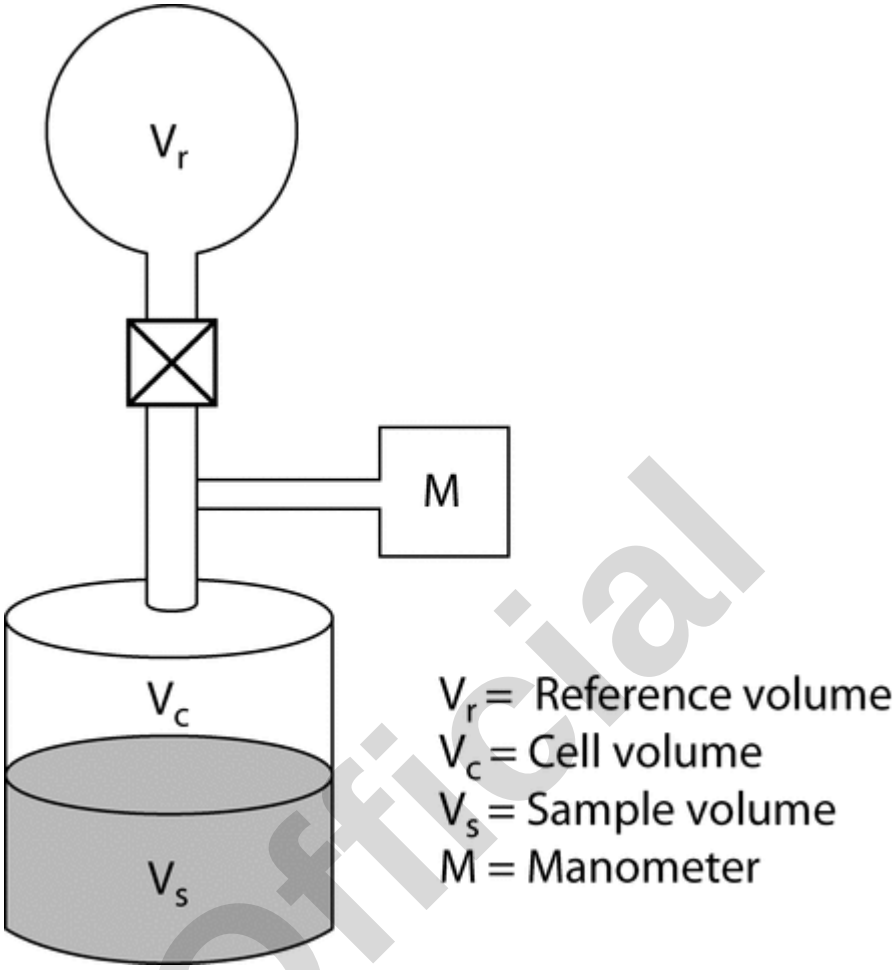

Figure 1. Schematic of gas pycnometer.

The sample, with mass *w* and volume $V_s$, is placed inside a sealed test cell with an empty cell volume of $V_c$. The system reference pressure, $P_r$, is determined at the manometer while the valve that connects the reference volume with the test cell is open. The valve is closed to separate the reference volume, $V_r$, from the test cell. The test cell is pressurized with the measurement gas to an initial pressure, $P_i$. Then the valve is opened to connect the reference volume, $V_r$, with the test cell, and the pressure drops to the final pressure, $P_f$. If the measurement gas behaves ideally under the conditions of measurement, the sample volume, $V_s$, is given by the following expression:

$$V_s = V_c - \frac{V_r}{\left[\frac{P_i - P_r}{P_f - P_r}\right] - 1} \quad (1)$$

The density, ρ, is given by the equation:

$$\rho = \frac{w}{V_S} \quad (2)$$

Details of the instrumental design may differ, but all gas pycnometers rely on the measurement of pressure changes as a reference volume is added to, or deleted from, the test cell.

The measured density is a volume-weighted average of the densities of individual powder particles. The density will be in error if the test gas sorbs onto the powder or if volatile contaminants are evolved from the powder during the measurement. Sorption is prevented by an appropriate choice of test gas. Helium is the common choice. Volatile contaminants in the powder are removed by degassing the powder under a constant purge of helium prior to the measurement. Occasionally, powders may have to be degassed under vacuum. Two consecutive readings should yield sample volumes that are equal within 0.2% if volatile contaminants are not interfering with the measurements. Because volatiles may be evolved during the measurement, the weight of the sample should be taken after the pycnometric measurement of volume.

Official

https://pharmacopeia.cn/v-download/

## Method

Ensure that the reference volume and the calibration volume have been determined for the gas pycnometer by an appropriate calibration procedure. The test gas is helium, unless another gas is specified in the individual monograph. The temperature of the gas pycnometer should be between 15° and 30° and should not vary by more than 2° during the course of the measurement. Load the test cell with the substance under examination that has been prepared according to the individual monograph. Where ⟨699D⟩ is indicated, dry the substance under examination as directed for *Loss on drying* in the monograph unless other drying conditions are specified in the monograph *Density of solids* test. Where ⟨699U⟩ is indicated, the substance under examination is used without drying. Use a quantity of powder recommended in the operating manual for the pycnometer. Seal the test cell in the pycnometer, and purge the pycnometer system with the test gas according to the procedure given in the manufacturer's operating instructions. If the sample must be degassed under vacuum, follow the recommendations in the individual monographs and the instructions in the operating manual for the pycnometer.

The measurement sequence above describes the procedure for the gas pycnometer shown in *Figure 1*. If the pycnometer differs in operation or in construction from the one shown in *Figure 1*, follow the operating procedure given in the manual for the pycnometer.

Repeat the measurement sequence for the same powder sample until consecutive measurements of the sample volume, $V_s$, agree to within 0.2%. Unload the test cell and measure the final powder weight, $w$. Calculate the pycnometric density, $\rho$, of the sample according to *Equation 2*.

# ⟨701⟩ DISINTEGRATION

***Change to read:***

This general chapter is harmonized with the corresponding texts of the *European Pharmacopoeia* and/or the *Japanese Pharmacopoeia*. The texts of these pharmacopeias are therefore interchangeable, and the methods of the *European Pharmacopoeia* and/or the *Japanese Pharmacopoeia* may be used for demonstration of compliance instead of the present general chapter. These pharmacopeias have undertaken not to make any unilateral change to this harmonized chapter.

Portions of the present general chapter text that are national *USP* text, and therefore not part of the harmonized text, are marked with symbols (⬥⬥) to specify this fact.

This test is provided to determine whether tablets, capsules, ▲⬥or granules⬥▲ (USP 1-Aug-2019) disintegrate within the prescribed time when placed in a liquid medium at the experimental conditions presented below. ⬥Compliance with the limits on *Disintegration* stated in the individual monographs is required. ▲▲ (USP 1-Aug-2019) Determine the type of units under test from the labeling and from observation, and apply the appropriate procedure to 6 or more dosage units.⬥

For the purposes of this test, disintegration does not imply complete solution of the unit or even of its active constituent. Complete disintegration is defined as that state in which any residue of the unit, except fragments of insoluble coating or capsule shell, remaining on the screen of the test apparatus or adhering to the lower surface of the disk, if used, is a soft mass having no palpably firm core.

***Change to read:***

## APPARATUS

The apparatus consists of a basket-rack assembly, a 1000-mL low-form beaker 138–160 mm in height and having an inside diameter of 97–115 mm for the immersion fluid, a thermostatic arrangement for heating the fluid 35°–39°, and a device for raising and lowering the basket in the immersion fluid at a constant frequency rate 29–32 cycles/min through a distance of NLT 53 mm and NMT 57 mm. The volume of the fluid in the vessel is such that at the highest point of the upward stroke, the wire mesh remains at least 15 mm below the surface of the fluid and descends to NLT 25 mm from the bottom of the vessel on the downward stroke. At no time should the top of the basket-rack assembly become submerged. The time required for the upward stroke is equal to the time required for the downward stroke, and the change in stroke direction is a smooth transition, rather than an abrupt reversal of motion. The basket-rack assembly moves vertically along its axis. There is no appreciable horizontal motion or movement of the axis from the vertical.

### Basket-Rack Assembly

The basket-rack assembly consists of 6 open-ended transparent tubes, each ▲75.0–80.0▲ (USP 1-May-2020) mm long and having an inside diameter of 20.7–23 mm and a wall 1.0–2.8 mm thick; the tubes are held in a vertical position by two plates, each 88–92 mm in diameter and 5–8.5 mm in thickness, with 6 holes, each 22–26 mm in diameter, equidistant from the center of the plate and equally spaced from one another. Attached to the under surface of the lower plate is a woven stainless steel wire cloth, which has a plain square weave with 1.8–2.2-mm apertures and with a wire diameter of 0.57–0.66 mm. The parts of the apparatus are assembled and rigidly held by means of 3 bolts passing through the 2 plates. A suitable means is provided to suspend the basket-rack assembly from the raising and lowering device using a point on its axis.

The design of the basket-rack assembly may be varied somewhat, provided the specifications for the glass tubes and the screen mesh size are maintained. The basket-rack assembly conforms to the dimensions found in *Figure 1*.

### Disks

The use of disks is permitted only where specified or allowed ⬥in the monograph. If specified in the individual monograph,⬥ each tube is provided with a cylindrical disk ▲9.35–9.65▲ (USP 1-May-2020) mm thick and ▲20.55–20.85▲ (USP 1-May-2020) mm in diameter. The disk is made of a suitable transparent plastic material having a specific gravity of 1.18–1.20. Five parallel ▲1.9–2.1▲ (USP 1-May-2020)-mm holes extend between the ends of the cylinder. One of the holes is centered on the cylindrical axis. The other holes are ▲parallel to the cylindrical axis and▲ (USP 1-May-2020) centered ▲5.8–6.2▲ (USP 1-May-2020) mm from the axis on imaginary lines perpendicular to the axis and ▲▲ (USP 1-May-2020) to each other. Four identical trapezoidal-shaped planes are cut into the wall of the cylinder, nearly perpendicular to the ends of the cylinder. The trapezoidal shape is symmetrical; its parallel sides coincide with the ends of the cylinder and are parallel to an imaginary line connecting the centers of two adjacent holes 6 mm from the cylindrical axis. The parallel side of the trapezoid on the bottom of the cylinder has a length of ▲1.5–1.7▲ (USP 1-May-2020) mm, and its bottom edges lie at a depth of 1.5–1.8 mm from the cylinder's circumference. The parallel side of the trapezoid on the top of the cylinder has a length ▲9.2–9.6▲ (USP 1-May-2020) mm, and its center lies at a depth ▲2.5–2.7▲ (USP 1-May-2020) mm from the cylinder's circumference. All surfaces of the disk are smooth. If the use of disks is specified ⬥in the individual monograph,⬥ add a disk to each tube, and operate the apparatus as directed under *Procedure*. The disks conform to dimensions found in *Figure 1*.[1]

[1] The use of automatic detection employing modified disks is permitted where the use of disks is specified or allowed. Such disks must comply with the requirements for density and dimension given in this chapter.

# PROCEDURE ◆▲AND CRITERIA

## Procedure and Criteria for▲ (USP 1-Aug-2019) Uncoated ▲or Plain-Coated▲ (USP 1-Aug-2019) Tablets

▲PROCEDURE FOR UNCOATED OR PLAIN-COATED TABLETS▲ (USP 1-Aug-2019)◆

Place 1 dosage unit in each of the 6 tubes of the basket▲◆-rack assembly◆▲ (USP 1-Aug-2019) and, if prescribed, add a disk. Operate the apparatus, using ◆water or◆ the specified medium as the immersion fluid, maintained at 37 ± 2°. At the end of the time limit specified ◆in the monograph,◆ lift the basket▲◆-rack assembly◆▲ (USP 1-Aug-2019) from the fluid, and observe the tablets. All of the tablets ▲◆should◆▲ (USP 1-Aug-2019) have disintegrated completely. If 1 or 2 tablets fail to disintegrate completely, repeat the test on 12 additional tablets.

▲◆CRITERIA FOR UNCOATED OR PLAIN-COATED TABLETS

1. If 6 tablets are tested, all 6 of the tablets are disintegrated.
2. If 18 tablets are tested,◆ the requirement is met if not fewer than 16 of the total of 18 tablets are disintegrated.▲ (USP 1-Aug-2019)

## ◆▲Procedure and Criteria for Delayed-Release Tablets and Capsules (tablets or capsules that are formulated with acid-resistant or enteric coatings)

PROCEDURE FOR DELAYED-RELEASE TABLETS AND CAPSULES▲ (USP 1-Aug-2019)

Place 1 ▲dosage unit▲ (USP 1-Aug-2019) in each of the 6 tubes of the basket. ▲If the dosage units are not sugar-coated, proceed to the *Acid stage*. If testing tablets that have a soluble external sugar coating, immerse the basket in water at room temperature for 5 min and then immediately proceed to the *Acid stage*. If specified in the monograph, add 1 disk to each tube.

**Acid stage**

**Immersion fluid:** 0.1 M hydrochloric acid, or simulated gastric fluid TS, or as specified in the monograph
**Temperature:** 37 ± 2°
**Time:** 1 h

If after 1 h no dosage unit shows evidence of disintegration, cracking, or softening, proceed with the *Buffer stage*.

**Buffer stage**

**Immersion fluid:** pH 6.8 phosphate buffer, or simulated intestinal fluid TS, or as specified in the monograph
**Temperature:** 37 ± 2°
**Time:** As specified in the individual monograph

CRITERIA FOR DELAYED-RELEASE TABLETS AND CAPSULES

**Acid stage:** No dosage unit shows evidence of disintegration, cracking, or softening.
**Buffer stage:** Apply the *Criteria for Uncoated or Plain-Coated Tablets*.

## Procedure and Criteria for Buccal Tablets, Sublingual Tablets, Capsules, Tablets for Oral Suspension, Tablets for Oral Solution, Tablets for Topical Solution, Orally Disintegrating Tablets, and Chewable Tablets

Apply the *Procedure and Criteria for Uncoated or Plain-Coated Tablets*.

## Procedure and Criteria for Effervescent Tablets for Oral Solution

PROCEDURE FOR EFFERVESCENT TABLETS FOR ORAL SOLUTION

Place 1 tablet in each of 6 beakers containing 200 mL of water. A suitable beaker will have a nominal volume of 250–400 mL.
**Time:** 5 min or as specified in the individual monograph

CRITERIA FOR EFFERVESCENT TABLETS FOR ORAL SOLUTION

Numerous bubbles of gas are evolved. After 5 min or as specified in the individual monograph, the evolution of gas around each tablet or its fragments has ceased. Each tablet has dissolved or disintegrated and has been dispersed in the water so that no appreciable agglomerates remain.

Official

https://pharmacopeia.com/

# Procedure and Criteria for Effervescent Granules

## PROCEDURE FOR EFFERVESCENT GRANULES

In each of 6 beakers containing 200 mL of water place 1 dose of the effervescent granules. A suitable beaker will have a nominal volume of 250–400 mL.
**Time:** 5 min or as specified in the individual monograph

## CRITERIA FOR EFFERVESCENT GRANULES

Numerous bubbles of gas are evolved. After 5 min or as specified in the individual monograph, the evolution of gas around the granules in each beaker has ceased. The granules have dissolved or disintegrated and have been dispersed in the water. ▲ (USP 1-Aug-2019) ◆

# ⟨705⟩ QUALITY ATTRIBUTES OF TABLETS LABELED AS HAVING A FUNCTIONAL SCORE

## PURPOSE

This chapter provides quality attributes for products with approved labeling indicating that the tablets can be split to produce multiple portions that have an accurate fractional dose (labeled as functionally scored). The label claim of the split portions should be a simple fractional part of the claim for the intact tablet based on the number of scores and the size of the split portion (e.g., one-half, one-third, or one-quarter). At the time of splitting, the intact tablets should conform to the monograph specification. With the exception of dose, each split portion from tablets labeled as having a functional score are expected to conform to the quality attributes of the whole tablets. The split portions resulting from subdividing a functionally scored tablet should conform to the tests for *Splitting Tablets with Functional Scoring* and *Dissolution* or *Disintegration* given in this chapter.

## SCOPE

This chapter applies to tablets labeled as having a functional score and to the split portions that represent any labeled fraction of the whole functionally scored tablet dose. Tablets should be split as part of the test procedure and the storage conditions for the split portions should be defined in the test procedure. For *Dissolution* or *Disintegration* testing, analysts should use only split portions from tablets determined to be acceptable by the *Splitting Tablets with Functional Scoring* test.

## SPLITTING TABLETS WITH FUNCTIONAL SCORING

### Test Procedure

1. Take a random sample of 30 intact tablets, and proceed as follows.
2. Accurately weigh each tablet, and record its weight.
3. For each intact tablet, determine the expected weight of the split portions by dividing the whole-tablet weight by the designated number of split portions indicated on the labeling.
4. Split each tablet by hand (without mechanical assistance) into the designed number of split portions, and weigh each split portion.
5. For each tablet, determine the percent of the expected weight in each split portion.

An acceptable tablet breaks into the designed number of segments, and each split portion has NLT 75% and NMT 125% of the expected weight of the split tablet portion. [NOTE—Set aside split tablet portions derived from acceptable tablets for subsequent testing for dissolution or disintegration.]

**Acceptance criteria:** NLT 28 of the 30 tablets are acceptable.

## DISSOLUTION

Use split portions from tablets that are acceptable according to the *Splitting Tablets with Functional Scoring* test.

### Immediate-Release Tablets

Dissolution for immediate-release tablets is performed at the $S_2$ stage (see *Dissolution* ⟨711⟩). Test 12 split tablet portions according to the specified *Medium, Apparatus, Times*, and *Analysis*. The average of the 12 results is NLT *Q,* and no result is less than $Q - 15\%$.

### Extended-Release Tablets

Perform dissolution testing of split tablet portions from extended-release tablets by one of the two alternative procedures. The procedure to be used is specified in the monograph.

**Procedure 1** (*Procedure for Extended-Release Dosage Forms, Dissolution* ⟨711⟩)**:** Individually test 12 split tablet portions and 12 intact tablets.

**Medium, Apparatus,** and **Analysis:** As given in the monograph following the appropriate test number found on the labeling. Dissolution profile test time points are determined as follows. From the appropriate dissolution test in the monograph, use the time points given. At a minimum, use three time points with no more than one time point where the results exceed 85% dissolved.

Calculate the similarity factor ($f_2$) for the intact-tablet results and the split-tablet portion results:

$$f_2 = 50 \cdot \log\left\{\left[1 + (1/n)\sum_{t=1}^{n}\left(R_t - T_t\right)^2\right]^{-0.5} \cdot 100\right\}$$

@2024 USPC
DOI: https://doi.org/10.31003/USPNF_M7826_02_01

$R_t$ = cumulative percentage of the labeled drug dissolved at each of the selected *n* time points of the intact tablets
$T_t$ = cumulative percentage of the labeled drug dissolved at each of the selected *n* time points of the split tablet portions

**Acceptance criteria:** The calculated $f_2$ is NLT 50 (acceptable range: 50–100).

**Procedure 2** (*Procedure for Extended-Release Dosage Forms, Dissolution* ⟨711⟩)**:** Use a split-tablet portion as the dosage unit. Individually test 12 dosage units.

**Medium, Apparatus, Times,** and **Analysis:** As given in the monograph following the appropriate test number found on the labeling.

**Acceptance criteria:** The percentages of the labeled amount released at the times specified conform to the $L_2$ level criteria of *Acceptance Table 2* in ⟨711⟩.

## DISINTEGRATION

Disintegration testing is necessary only when used as a surrogate for dissolution testing as specified in the monograph. Follow the procedure using split portions from tablets that are acceptable according to the *Splitting Tablets with Functional Scoring* test as the dosage unit (see *Disintegration* ⟨701⟩).

Official

https://pharmacopeia.com/

# ⟨711⟩ DISSOLUTION

This general chapter is being harmonized with the corresponding texts of the *European Pharmacopoeia* and/or the *Japanese Pharmacopoeia*. These pharmacopeias have undertaken to not make any unilateral change to this harmonized chapter.

Portions of the present general chapter text that are national *USP* text, and therefore not part of the harmonized text, are marked with symbols (•,) to specify this fact.

This test is provided to determine compliance with the dissolution requirements •where stated in the individual monograph,• for dosage forms administered orally. In this general chapter, a dosage unit is defined as 1 tablet or 1 capsule or the amount specified. •Of the types of apparatus designs described herein, use the one specified in the individual monograph. Where the label states that an article is enteric coated and a dissolution or disintegration test does not specifically state that it is to be applied to delayed-release articles and is included in the individual monograph, the procedure and interpretation given for *Delayed-Release Dosage Forms* are applied, unless otherwise specified in the individual monograph.•

## •FOR DOSAGE FORMS CONTAINING OR COATED WITH GELATIN

If the dosage form containing gelatin does not meet the criteria in the appropriate *Acceptance Table* (see *Interpretation*, *Immediate-Release Dosage Forms*, *Extended-Release Dosage Forms*, or *Delayed-Release Dosage Forms*) because of evidence of the presence of cross-linking, the dissolution procedure should be repeated with the addition of enzymes to the medium, as described below, and the dissolution results should be evaluated starting at the first stage of the appropriate *Acceptance Table*. It is not necessary to continue testing through the last stage (up to 24 units) when criteria are not met during the first stage testing, and evidence of cross-linking is observed.

Gelatin, in the presence of certain compounds and/or in certain storage conditions, including but not restricted to high humidity and temperature, may present cross-linking. A pellicle may form on the external and/or internal surface of the gelatin capsule shell or on the dosage form that prevents the drug from being released during dissolution testing (see more information in *Capsules—Dissolution Testing and Related Quality Attributes* ⟨1094⟩).

[NOTE—All references to a chapter above ⟨1000⟩ are for information purposes only and for use as a helpful resource. These chapters are not mandatory unless explicitly called out for this application.]

### Dissolution Medium with pH ≤4.0

**Enzyme:** Pepsin, activity determined by the procedure in *purified pepsin*, in the *Reagent Specifications* section
**Amount:** A quantity of pepsin that results in an activity of not more than 750,000 units/L of dissolution medium

### Dissolution Medium with pH >4.0 and <6.8

**Enzyme:** Papain, activity determined by the *Assay* test in the monograph for *Papain*; or bromelain, activity determined by the procedure in *bromelain*, in the *Reagent Specifications* section
**Amount:** A quantity of papain that results in an activity of not more than 550,000 units/L of dissolution medium, or a quantity of bromelain that results in an activity of not more than 30 gelatin-digesting units (GDU)/L of dissolution medium

### Dissolution Medium with pH ≥6.8

**Enzyme:** Pancreatin, protease activity determined by the procedure in *Assay for protease activity* (*Casein digestive power*) in the monograph for *Pancreatin*
**Amount:** A quantity of pancreatin that results in a protease activity of not more than 2000 units/L of dissolution medium

## Dissolution Medium Containing Surfactant or Other Ingredients Known to Denature the Enzyme

If the dissolution medium contains surfactant or other ingredients that are known to denature the enzyme used, a pretreatment step in the dissolution testing of the dosage form may be applied. This pretreatment step is done using the specified dissolution medium without the surfactant or the ingredient and with the addition of the appropriate amount of enzyme according to the medium pH. The amount of enzyme added is appropriate to the volume of dissolution medium used in the pretreatment. To achieve the specified medium volume for the final dissolution testing, the pretreatment step may be conducted with a smaller volume of medium without the ingredient such that the final volume is obtained when the ingredient is added at the end of the pretreatment step. All of the other conditions of the test (apparatus, rotation, or flow rate) should remain as described in the method or monograph. Typically, the duration of the pretreatment step is not more than 15 min. The required pretreatment time should be evaluated on a case-by-case basis and should be scientifically justified. This time should be included in the total time of the test. As an example, if the total time of the test is 45 min and 15 min are used in the pretreatment step, the test will continue for 30 min after the addition of the ingredient.•

# APPARATUS

## Apparatus 1 (Basket Apparatus)

The assembly consists of the following: a vessel, which may be covered, and made of glass or other inert, transparent material[1] ; a motor; a metallic drive shaft; and a cylindrical basket. The vessel is partially immersed in a suitable water bath of any convenient size or heated by a suitable device, such as a heating jacket. The water bath or heating device permits holding the temperature inside the vessel at 37 ± 0.5° during the test and keeps the bath fluid in constant, smooth motion. No part of the assembly, including the environment in which the assembly is placed, contributes significant motion, agitation, or vibration beyond that due to the smoothly rotating, stirring element. An apparatus that permits observation of the specimen and of the stirring element during the test is preferable. The vessel is cylindrical, with a hemispherical bottom and •with one of the following dimensions and capacities: for a nominal• capacity of 1 L, the height is 160–210 mm, and its inside diameter is 98–106 mm; •for a nominal capacity of 2 L, the height is 280–300 mm, and its inside diameter is 98–106 mm; and for a nominal capacity of 4 L, the height is 280–300 mm, and its inside diameter is 145–155 mm•. Its sides are flanged at the top. A fitted cover may be used to retard evaporation.[2] The shaft is positioned so that its axis is not more than 2 mm at any point from the vertical axis of the vessel and rotates smoothly and without significant wobble that could affect the results. A speed-regulating device is used that allows the shaft rotation speed to be selected and maintained at the specified rate •given in the individual monograph• within ±4%.

Shaft and basket components of the stirring element are fabricated of stainless steel, type 316, or other inert material, to the specifications shown in *Figure 1*. A basket having a gold coating of about 0.0001 inch (2.5 µm) thick may be used. A dosage unit is placed in a dry basket at the beginning of each test. The distance between the inside bottom of the vessel and the bottom of the basket is maintained at 25 ± 2 mm during the test.

Official

[1] The materials should not sorb, react, or interfere with the specimen being tested.
[2] If a cover is used, it provides sufficient openings to allow ready insertion of the thermometer and withdrawal of specimens.

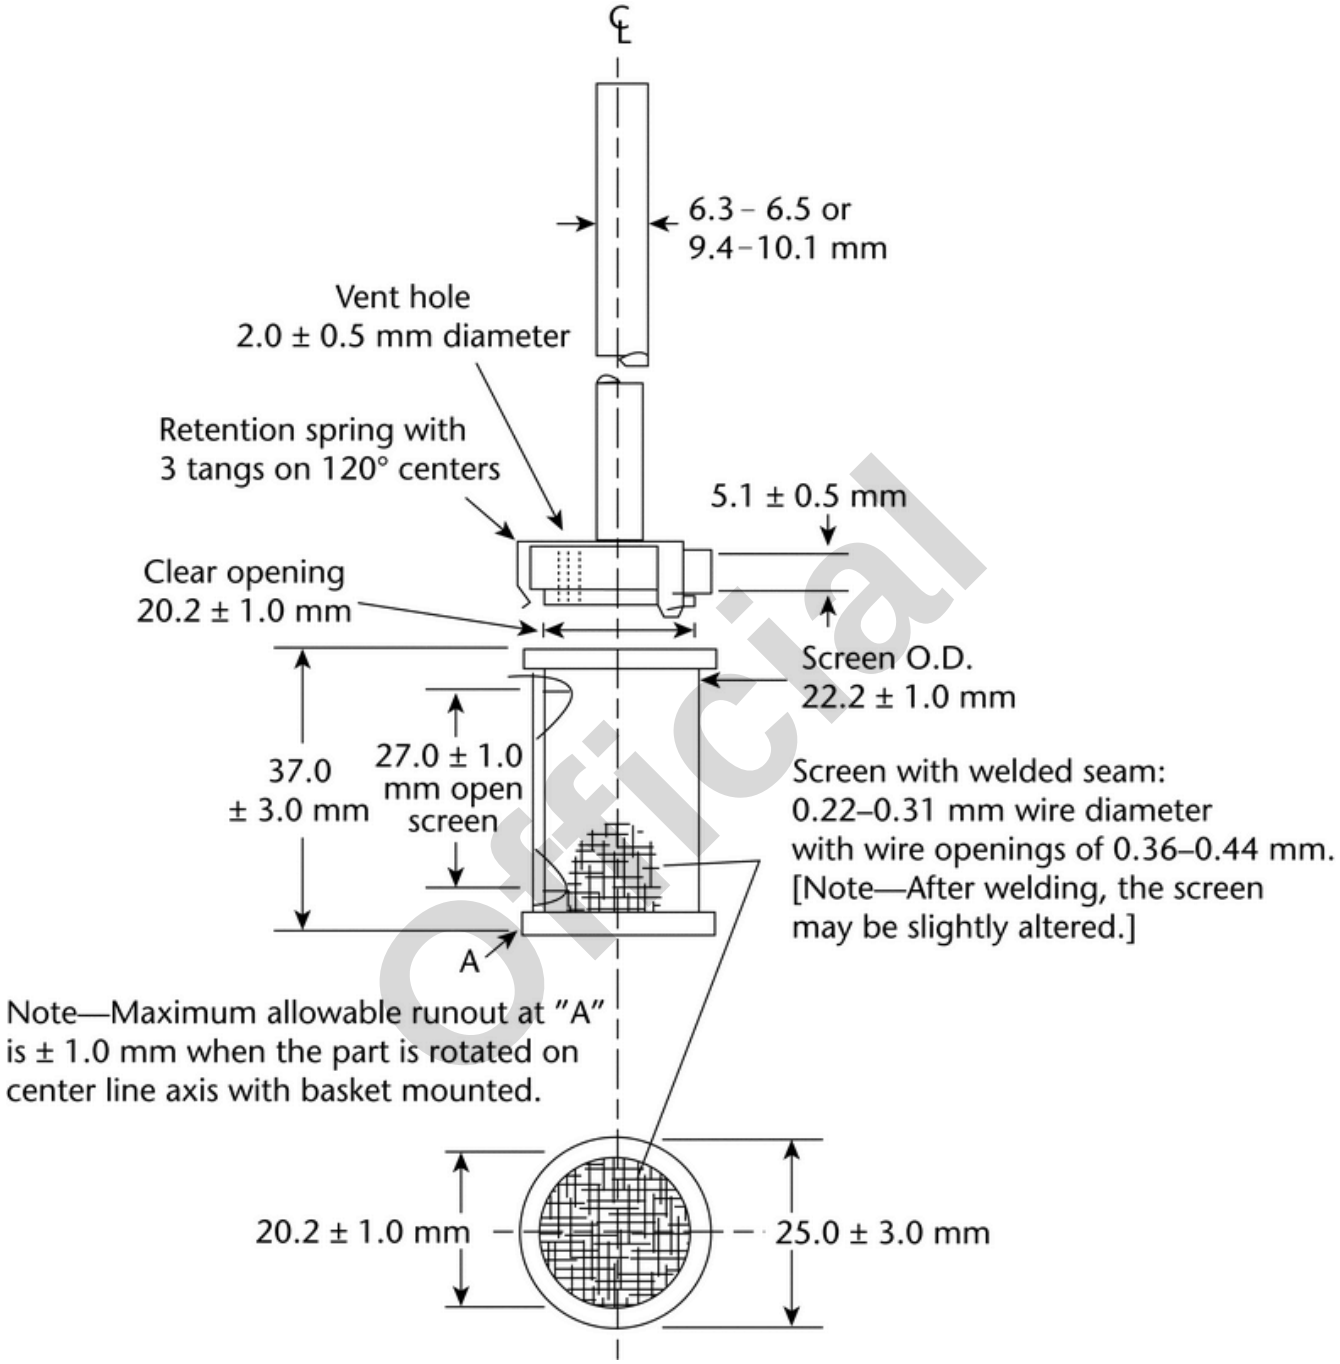

Figure 1. Basket stirring element.

## Apparatus 2 (Paddle Apparatus)

Use the assembly from *Apparatus 1*, except that a paddle formed from a blade and a shaft is used as the stirring element. The shaft is positioned so that its axis is not more than 2 mm from the vertical axis of the vessel at any point and rotates smoothly without significant wobble that could affect the results. The vertical center line of the blade passes through the axis of the shaft so that the bottom of the blade is flush with the bottom of the shaft. The paddle conforms to the specifications shown in *Figure 2*. The distance of 25 ± 2 mm between the bottom of the blade and the inside bottom of the vessel is maintained during the test. The metallic or suitably inert, rigid blade and shaft compose a single entity. A suitable two-part, detachable design may be used, provided that the assembly remains firmly engaged during the test. The paddle blade and shaft may be coated with a suitable coating so as to make both of them inert. The dosage unit is allowed to sink to the bottom of the vessel before rotation of the blade is started. A small, loose piece of nonreactive material, such as not more than a few turns of wire helix, may be attached to dosage units that would otherwise float. An alternative sinker device is shown in *Figure 2a*. Other validated sinker devices may be used.

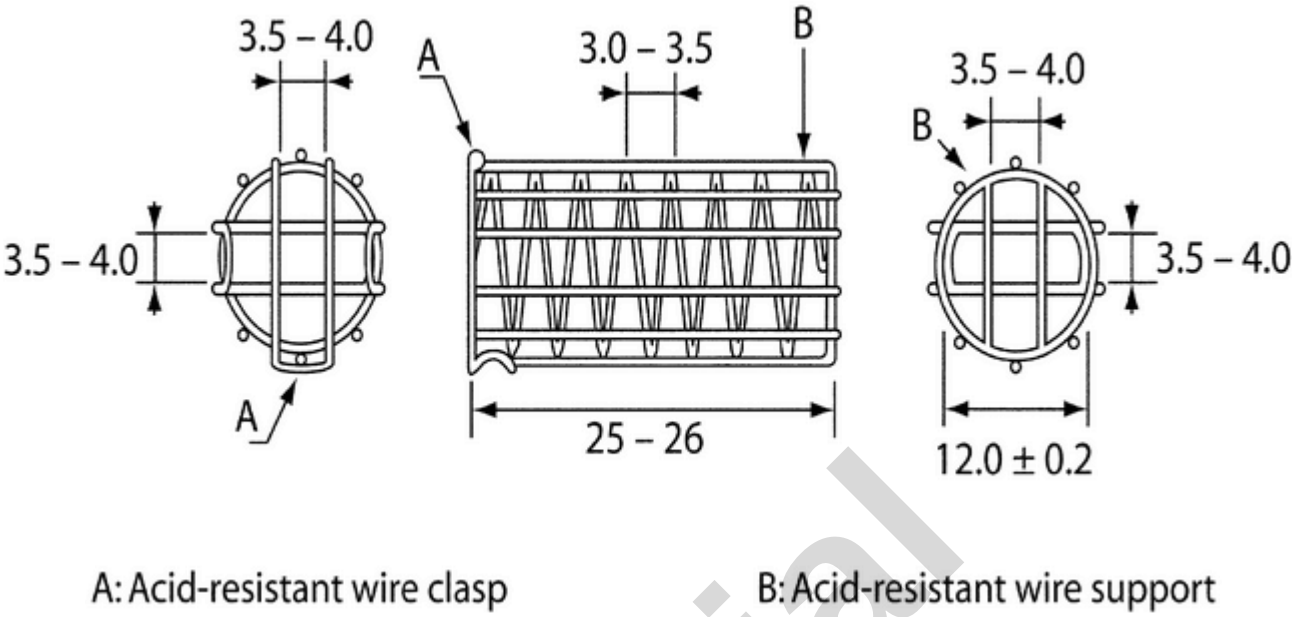

Figure 2a. Alternative sinker. All dimensions are expressed in millimeters.

•An alternative to sinkers is the stationary basket. The dosage form is placed in a quadrangular basket made of stainless steel wire mesh, soldered in one of its upper, narrow sides and attached to the end of a stainless steel connecting rod (see *Figure 2b*). The cover is placed in the horizontal diagonal of the basket. The rod assembly is attached to the cover of the dissolution vessel via an adjustable threaded steel rod, and is fixed by means of two Teflon nuts, about 3.2 cm from the center of the vessel, or by another appropriate means. The lower corner of the bottom of the basket is adjusted to about 1 cm above the top of the paddle blade (see *Figure 2c*). The axis of the connecting rod is parallel to the axis of the paddle shaft along the vertical length of the connecting rod and the largest face of the basket lies in a vertical plane perpendicular to the radius of the cylinder of the vessel.

## Apparatus 4 (Flow-Through Cell)

The assembly consists of a reservoir and a pump for the *Dissolution medium*; a flow-through cell; and a water bath that maintains the *Dissolution medium* at 37 ± 0.5°. Use the specified cell size •as given in the individual monograph•.

The pump forces the *Dissolution medium* upward through the flow-through cell. The pump has a delivery range between 240 and 960 mL/h, with standard flow rates of 4, 8, and 16 mL/min. It must deliver a constant flow (±5% of the nominal flow rate); the flow profile is sinusoidal with a pulsation of 120 ± 10 pulses/min. A pump without pulsation may also be used. Dissolution test procedures using a flow-through cell must be characterized with respect to rate and any pulsation.

The flow-through cell (see *Figure 4* and *Figure 5*), of transparent and inert material, is mounted vertically with a filter system (specified in the individual monograph) that prevents escape of undissolved particles from the top of the cell; standard cell diameters are 12 and 22.6 mm; the bottom cone is usually filled with small glass beads of about 1-mm diameter with one bead of about 5 mm, positioned at the apex to protect the fluid entry tube; and a tablet holder (see *Figure 4* and *Figure 5*) is available for positioning of special dosage forms, e.g., inlay tablets. The cell is immersed in a water bath, and the temperature is maintained at 37 ± 0.5°.

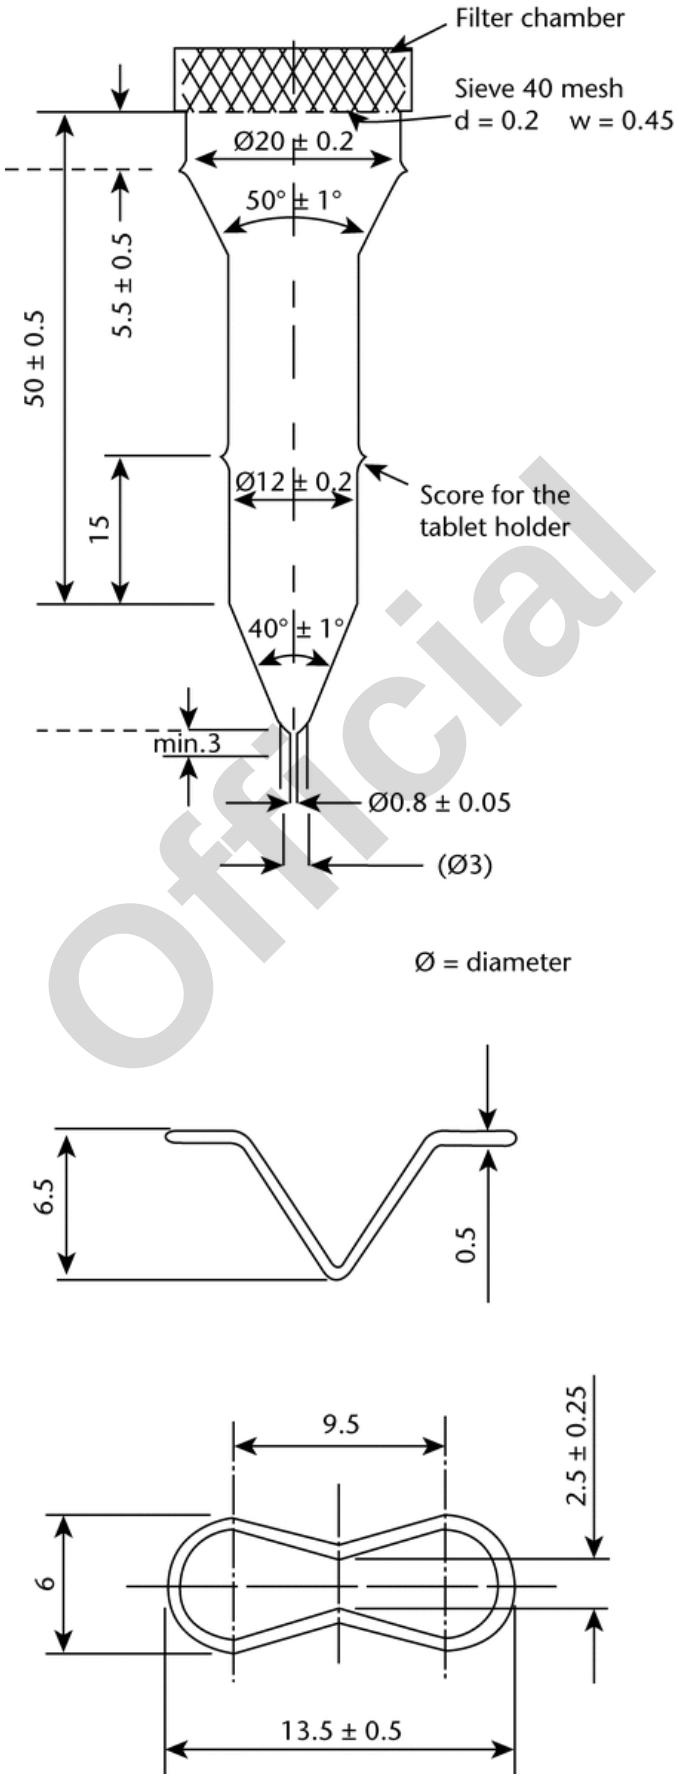

Figure 5. Apparatus 4: small cell for tablets and capsules (top); tablet holder for the small cell (bottom). (All measurements

https://pharmacopeia.cn/v29240/

are expressed in millimeters unless noted otherwise.)

The apparatus uses a clamp mechanism and two O-rings to assemble the cell. The pump is separated from the dissolution unit to shield the latter against any vibrations originating from the pump. The position of the pump should not be on a level higher than the reservoir flasks. Tube connections are as short as possible. Use suitably inert tubing, such as polytef, with about a 1.6-mm inner diameter and chemically inert, flanged-end connections.

### APPARATUS SUITABILITY

The determination of suitability of a test assembly to perform dissolution testing must include conformance to the dimensions and tolerances of the apparatus as given above. In addition, critical test parameters that have to be monitored periodically during use include volume and temperature of the *Dissolution medium*, rotation speed (*Apparatus 1* and *Apparatus 2*), dip rate (*Apparatus 3*), and flow rate of medium (*Apparatus 4*).

Determine the acceptable performance of the dissolution test assembly periodically. •The suitability for the individual apparatus is demonstrated by the *Performance verification test*.

**USP Reference Standards** ⟨11⟩: ▲USP Dissolution Performance Verification Standard-Prednisone RS▲ (IRA 1-May-2023)

**Performance verification test, Apparatus 1 and Apparatus 2:** Test ▲USP Dissolution Performance Verification Standard-Prednisone RS▲ (IRA 1-May-2023) according to the operating conditions specified. The apparatus is suitable if the results obtained are within the acceptable range stated in the technical data sheet specific to the lot used and the apparatus tested.

**Performance verification test, Apparatus 3:** [To come]

**Performance verification test, Apparatus 4:** [To come]•

## PROCEDURE

## Apparatus 1 and Apparatus 2

### IMMEDIATE-RELEASE DOSAGE FORMS

Place the stated volume of the *Dissolution medium* (±1%) in the vessel of the specified apparatus •given in the individual monograph•, assemble the apparatus, equilibrate the *Dissolution medium* to 37 ± 0.5°, and remove the thermometer. Place 1 dosage unit in the apparatus, taking care to exclude air bubbles from the surface of the dosage unit, and immediately operate the apparatus at the specified rate •given in the individual monograph•. Within the time interval specified, or at each of the times stated, withdraw a specimen from a zone midway between the surface of the *Dissolution medium* and the top of the rotating basket or blade, not less than 1 cm from the vessel wall.

[NOTE—Where multiple sampling times are specified, replace the aliquots withdrawn for analysis with equal volumes of fresh *Dissolution medium* at 37° or, where it can be shown that replacement of the medium is not necessary, correct for the volume change in the calculation. Keep the vessel covered for the duration of the test, and verify the temperature of the mixture under test at suitable times.]

Perform the analysis •as directed in the individual monograph• using a suitable assay method.[4] Repeat the test with additional dosage form units.

If automated equipment is used for sampling or the apparatus is otherwise modified, verification that the modified apparatus will produce results equivalent to those obtained with the standard apparatus described in this general chapter is necessary.

**Dissolution medium:** A suitable dissolution medium is used. Use the solvent specified •in the individual monograph•. The volume specified refers to measurements made between 20° and 25°. If the *Dissolution medium* is a buffered solution, adjust the solution so that its pH is within 0.05 unit of the specified pH •given in the individual monograph•. [NOTE—Dissolved gases can cause bubbles to form, which may change the results of the test. If dissolved gases influence the dissolution results, dissolved gases should be removed before testing.[5]]

**Time:** Where a single time specification is given, the test may be concluded in a shorter period if the requirement for the minimum amount dissolved is met. Specimens are to be withdrawn only at the stated times, within a tolerance of ±2%.

**•Procedure for a pooled sample for immediate-release dosage forms:** Use this procedure where *Procedure for a Pooled Sample* is specified in the individual monograph. Proceed as directed for *Immediate-Release Dosage Forms* in *Apparatus 1 and Apparatus 2* in the *Procedure* section. Combine equal volumes of the filtered solutions of the 6 or 12 individual specimens withdrawn, and use the pooled sample as the test specimen. Determine the average amount of the active ingredient dissolved in the pooled sample.•

### EXTENDED-RELEASE DOSAGE FORMS

Proceed as directed for *Immediate-Release Dosage Forms*.

**Dissolution medium:** Prepare as directed for *Immediate-Release Dosage Forms*.

**Time:** The test time points, generally three, are expressed in hours.

[4] Test specimens are filtered immediately upon sampling unless filtration is demonstrated to be unnecessary. Use an inert filter that does not cause adsorption of the active ingredient or contain extractable substances that would interfere with the analysis.

[5] One method of deaeration is as follows: Heat the medium, while stirring gently, to about 41°, immediately filter under vacuum using a filter having a porosity of 0.45 µm or less, with vigorous stirring, and continue stirring under vacuum for about 5 min. Other validated deaeration techniques for removal of dissolved gases may be used.

https://nhathuocngocanh.com/

DELAYED-RELEASE DOSAGE FORMS[3]

Use *Method A Procedure* or *Method B Procedure* and the apparatus specified •in the individual monograph•. All test times stated are to be observed within a tolerance of ±2%, unless otherwise specified.

## Method A Procedure •(unless otherwise directed in the individual monograph)•

ACID STAGE

Place 750 mL of 0.1 N hydrochloric acid in the vessel, and assemble the apparatus. Allow the medium to equilibrate to a temperature of 37 ± 0.5°. Place 1 dosage unit in the apparatus, cover the vessel, and operate the apparatus at the specified rate •given in the monograph•.

After 2 h of operation in 0.1 N hydrochloric acid, withdraw an aliquot of the fluid, and proceed immediately as directed in the *Buffer Stage*.

Perform an analysis of the aliquot using a suitable assay method. •The procedure is specified in the individual monograph.•

BUFFER STAGE

[NOTE—Complete the operations of adding the buffer and adjusting the pH within 5 min.] With the apparatus operating at the rate specified •in the monograph•, add to the fluid in the vessel 250 mL of 0.20 M tribasic sodium phosphate that has been equilibrated to 37 ± 0.5°. Adjust, if necessary, with 2 N hydrochloric acid or 2 N sodium hydroxide to a pH of 6.8 ± 0.05. Continue to operate the apparatus for 45 min, or for the specified time •given in the individual monograph•. At the end of the time period, withdraw an aliquot of the fluid, and perform the analysis using a suitable assay method. •The procedure is specified in the individual monograph. The test may be concluded in a shorter time period than that specified for the *Buffer Stage* if the requirement for the minimum amount dissolved is met at an earlier time.•

## Method B Procedure •(unless otherwise directed in the individual monograph)•

ACID STAGE

Place 1000 mL of 0.1 N hydrochloric acid in the vessel, and assemble the apparatus. Allow the medium to equilibrate to a temperature of 37 ± 0.5°. Place 1 dosage unit in the apparatus, cover the vessel, and operate the apparatus at the rate specified •in the monograph•. After 2 h of operation in 0.1 N hydrochloric acid, withdraw an aliquot of the fluid, and proceed immediately as directed in the *Buffer Stage*.

Perform an analysis of the aliquot using a suitable assay method. •The procedure is specified in the individual monograph.•

BUFFER STAGE

[NOTE—For this stage of the procedure, use buffer that previously has been equilibrated to a temperature of 37 ± 0.5°.] Drain the acid from the vessel, and add to the vessel 1000 mL of pH 6.8 phosphate buffer, prepared by mixing 0.1 N hydrochloric acid with 0.20 M tribasic sodium phosphate (3:1) and adjusting, if necessary, with 2 N hydrochloric acid or 2 N sodium hydroxide to a pH of 6.8 ± 0.05. [NOTE—This may also be accomplished by removing from the apparatus the vessel containing the acid, then replacing it with another vessel containing the buffer, and transferring the dosage unit to the vessel containing the buffer.]

Continue to operate the apparatus for 45 min, or for the specified time •given in the individual monograph•. At the end of the time period, withdraw an aliquot of the fluid, and perform the analysis using a suitable assay method. •The procedure is specified in the individual monograph. The test may be concluded in a shorter time period than that specified for the *Buffer Stage* if the requirement for minimum amount dissolved is met at an earlier time.•

## Apparatus 3 (Reciprocating Cylinder)

IMMEDIATE-RELEASE DOSAGE FORMS[3]

Place the stated volume of the *Dissolution medium* in each vessel of the apparatus, assemble the apparatus, equilibrate the *Dissolution medium* to 37 ± 0.5°, and remove the thermometer. Place 1 dosage form unit in each of the six reciprocating cylinders, taking care to exclude air bubbles from the surface of each dosage unit, and immediately operate the apparatus as specified •in the individual monograph•. During the upward and downward strokes, the reciprocating cylinder moves through a total distance of 9.9–10.1 cm. Within the time interval specified, or at each of the times stated, raise the reciprocating cylinders and withdraw a portion of the solution under test from a zone midway between the surface of the *Dissolution medium* and the bottom of each vessel. Perform the analysis as directed •in the individual monograph•. If necessary, repeat the test with additional dosage-form units.

**Dissolution medium:** Prepare as directed for *Immediate-Release Dosage Forms* in *Apparatus 1 and Apparatus 2*.

**Time:** Proceed as directed for *Immediate-Release Dosage Forms* in *Apparatus 1 and Apparatus 2*.

EXTENDED-RELEASE DOSAGE FORMS

Proceed as directed for *Immediate-Release Dosage Forms* in *Apparatus 3*.
**Dissolution medium:** Prepare as directed for *Extended-Release Dosage Forms* in *Apparatus 1 and Apparatus 2*.
**Time:** Proceed as directed for *Extended-Release Dosage Forms* in *Apparatus 1 and Apparatus 2*.

DELAYED-RELEASE DOSAGE FORMS

Proceed as directed for *Delayed-Release Dosage Forms, Method B Procedure* in *Apparatus 1 and Apparatus 2*, using one row of vessels for the acid stage media and the following row of vessels for the buffer stage media, and using the volume of medium specified (usually 300 mL).
**Time:** Proceed as directed for *Immediate-Release Dosage Forms* in *Apparatus 1 and Apparatus 2*.

## Apparatus 4 (Flow-Through Cell)

IMMEDIATE-RELEASE DOSAGE FORMS

Place the glass beads into the cell specified ♦in the monograph♦. Place 1 dosage unit on top of the beads or, if specified ♦in the monograph♦, on a wire carrier. Assemble the filter head, and fix the parts together by means of a suitable clamping device. Introduce by the pump the *Dissolution medium* warmed to 37 ± 0.5° through the bottom of the cell to obtain the flow rate specified ♦in the individual monograph♦ and measured with an accuracy of 5%. Collect the eluate by fractions at each of the times stated. Perform the analysis as directed ♦in the individual monograph♦. Repeat the test with additional dosage form units.
**Dissolution medium:** Prepare as directed for *Immediate-Release Dosage Forms* in *Apparatus 1 and Apparatus 2*.
**Time:** Proceed as directed for *Immediate-Release Dosage Forms* in *Apparatus 1 and Apparatus 2*.

EXTENDED-RELEASE DOSAGE FORMS

Proceed as directed for *Immediate-Release Dosage Forms* in *Apparatus 4*.
**Dissolution medium:** Prepare as directed for *Immediate-Release Dosage Forms* in *Apparatus 4*.
**Time:** Proceed as directed for *Immediate-Release Dosage Forms* in *Apparatus 4*.

DELAYED-RELEASE DOSAGE FORMS

Proceed as directed for *Delayed-Release Dosage Forms* in *Apparatus 1 and Apparatus 2*, using the specified media.
**Time:** Proceed as directed for *Delayed-Release Dosage Forms* in *Apparatus 1 and Apparatus 2*.

# INTERPRETATION

## Immediate-Release Dosage Forms

Unless otherwise specified ♦in the individual monograph♦, the requirements are met if the quantities of active ingredient dissolved from the dosage units tested conform to *Acceptance Table 1*. Continue testing through the three stages unless the results conform at either $S_1$ or $S_2$. The quantity ($Q$) is the amount of dissolved active ingredient ♦specified in the individual monograph♦, expressed as a percentage of the labeled content of the dosage unit; the 5%, 15%, and 25% values in *Acceptance Table 1* are percentages of the labeled content so that these values and $Q$ are in the same terms.

**Acceptance Table 1**

| Stage | Number Tested | Acceptance Criteria |
|---|---|---|
| $S_1$ | 6 | Each unit is NLT $Q$ + 5%. |
| $S_2$ | 6 | Average of 12 units ($S_1$ + $S_2$) is $\geq Q$, and no unit is $< Q$ − 15%. |
| $S_3$ | 12 | Average of 24 units ($S_1$ + $S_2$ + $S_3$) is $\geq Q$, NMT 2 units are $< Q$ − 15%, and no unit is $< Q$ − 25%. |

## ♦Immediate-Release Dosage Forms Pooled Sample

Unless otherwise specified in the individual monograph, the requirements are met if the quantities of active ingredient dissolved from the pooled sample conform to the accompanying *Acceptance Table for a Pooled Sample*. Continue testing through the three stages unless the results conform at either $S_1$ or $S_2$. The quantity ($Q$) is the amount of dissolved active ingredient specified in the individual monograph, expressed as a percentage of the labeled content.

Official

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:36:03 AM (EST)

**Acceptance Table for a Pooled Sample**

| Stage | Number Tested | Acceptance Criteria |
|---|---|---|
| $S_1$ | 6 | Average amount dissolved is NLT $Q$ + 10%. |
| $S_2$ | 6 | Average amount dissolved ($S_1$ + $S_2$) is ≥$Q$ + 5%. |
| $S_3$ | 12 | Average amount dissolved ($S_1$ + $S_2$ + $S_3$) is ≥$Q$. |

## Extended-Release Dosage Forms

Unless otherwise specified in the individual monograph, the requirements are met if the quantities of active ingredient dissolved from the dosage units tested conform to *Acceptance Table 2*. Continue testing through the three levels unless the results conform at either $L_1$ or $L_2$. Limits on the amounts of active ingredient dissolved are expressed in terms of the percentage of labeled content. The limits embrace each value of $Q_i$, the amount dissolved at each specified fractional dosing interval. Where more than one range is specified in the individual monograph, the acceptance criteria apply individually to each range.

**Acceptance Table 2**

| Level | Number Tested | Acceptance Criteria |
|---|---|---|
| $L_1$ | 6 | No individual value lies outside each of the stated ranges, and no individual value is less than the stated amount at the final test time. |
| $L_2$ | 6 | The average value of the 12 units ($L_1$ + $L_2$) lies within each of the stated ranges and is not less than the stated amount at the final test time; none is >10% of labeled content outside each of the stated ranges; and none is >10% of the labeled content below the stated amount at the final test time. |
| $L_3$ | 12 | The average value of the 24 units ($L_1$ + $L_2$ + $L_3$) lies within each of the stated ranges and is not less than the stated amount at the final test time; NMT 2 of the 24 units are more than 10% of labeled content outside each of the stated ranges; NMT 2 of the 24 units are >10% of labeled content below the stated amount at the final test time; and none of the units are >20% of labeled content outside each of the stated ranges or >20% of the labeled content below the stated amount at the final test time. |

## Delayed-Release Dosage Forms[3]

### ACID STAGE

Unless otherwise specified in the individual monograph, the requirements of this portion of the test are met if the quantities, based on the percentage of the labeled content, of active ingredient dissolved from the units tested conform to *Acceptance Table 3*. Continue testing through all levels unless the results of both the *Acid Stage* and *Buffer Stage* conform at an earlier level.

**Acceptance Table 3**

| Level | Number Tested | Acceptance Criteria |
|---|---|---|
| $A_1$ | 6 | No individual value exceeds 10% dissolved. |
| $A_2$ | 6 | Average of the 12 units ($A_1$ + $A_2$) is NMT 10% dissolved, and no individual unit is >25% dissolved. |
| $A_3$ | 12 | Average of the 24 units ($A_1$ + $A_2$ + $A_3$) is NMT 10% dissolved, and no individual unit is >25% dissolved. |

### BUFFER STAGE

Unless otherwise specified in the individual monograph, the requirements are met if the quantities of active ingredient dissolved from the units tested conform to *Acceptance Table 4*. Continue testing through the three levels unless the results of both stages conform at an earlier level. The value of $Q$ in *Acceptance Table 4* is 75% dissolved unless otherwise specified in the individual monograph. The quantity ($Q$) specified in the individual monograph is the total amount of active ingredient dissolved in both the *Acid Stage* and the *Buffer Stage*, expressed as a percentage of the labeled content. The 5%, 15%, and 25% values in *Acceptance Table 4* are percentages of the labeled content so that these values and $Q$ are in the same terms.

Official

https://pharmacopeia.cn/v29240/

**Acceptance Table 4**

| Level | Number Tested | Acceptance Criteria |
|---|---|---|
| $B_1$ | 6 | Each unit is NLT $Q$ + 5%. |
| $B_2$ | 6 | Average of 12 units ($B_1$ + $B_2$) is $\geq Q$, and no unit is $< Q$ − 15%. |
| $B_3$ | 12 | Average of 24 units ($B_1$ + $B_2$ + $B_3$) is $\geq Q$, NMT 2 units are $< Q$ − 15%, and no unit is $< Q$ − 25%. |

# ⟨721⟩ DISTILLING RANGE

To determine the range of temperatures within which an official liquid distills, or the percentage of the material that distills between two specified temperatures, use Method I or Method II as directed in the individual monograph. The *lower limit* of the range is the temperature indicated by the thermometer when the first drop of condensate leaves the tip of the condenser, and the *upper limit* is the Dry Point, i.e., the temperature at which the last drop of liquid evaporates from the lowest point in the distillation flask, without regard to any liquid remaining on the side of the flask, or the temperature observed when the proportion specified in the individual monograph has been collected.

[NOTE—Cool all liquids that distill below 80° to between 10° and 15° before measuring the sample to be distilled.]

## METHOD I

### Apparatus

Use apparatus similar to that specified for *Method II*, except that the distilling flask is of 50- to 60-mL capacity, and the neck of the flask is 10 to 12 cm long and 14 to 16 mm in internal diameter. The perforation in the upper insulating board, if one is used, should be such that when the flask is set into it, the portion of the flask below the upper surface of the insulating material has a capacity of 3 to 4 mL.

### Procedure

Proceed as directed for *Method II*, but place in the flask only 25 mL of the liquid to be tested.

## METHOD II

### Apparatus

Use an apparatus consisting of the following parts:

DISTILLING FLASK

A round-bottom distilling flask, of heat-resistant glass, of 200-mL capacity, and having a total length of 17 to 19 cm, and an inside neck diameter of 20 to 22 mm. Attached about midway on the neck, approximately 12 cm from the bottom of the flask, is a side-arm 10 to 12 cm long and 5 mm in internal diameter, which forms an angle of 70° to 75° with the lower portion of the neck.

CONDENSER

A straight glass condenser 55 to 60 cm in length with a water jacket about 40 cm in length, or a condenser of other design having equivalent condensing capacity. The lower end of the condenser may be bent to provide a delivery tube, or it may be connected to a bent adapter that serves as a delivery tube.

INSULATING BOARDS

Two pieces of insulating board, 5 to 7 mm thick and 14 to 16 cm square, suitable for confining the heat to the lower part of the flask. Each board has a hole in its center, and the two boards differ only with respect to the diameter of the hole, i.e., the diameters are 4 cm and 10 cm, respectively. In use, the boards are placed one upon the other, and rest on a tripod or other suitable support, with the board having the larger hole on top.

RECEIVER

A 100-mL cylinder graduated in 1-mL subdivisions.

THERMOMETER

In order to avoid the necessity for an emergent stem correction, an accurately standardized, partial-immersion thermometer having the smallest practical subdivisions (not greater than 0.2°) is recommended. Suitable thermometers are available as the ASTM E-1 series 37C through 41C, and 102C through 107C (see *General Notices, 6.80.30. Temperature Reading Devices*). When placed in position, the stem is located in the center of the neck, and the top of the contraction chamber (or bulb, if 37C or 38C is used) is level with the bottom of the outlet to the side-arm.

HEAT SOURCE

A small Bunsen burner or an electric heater or mantle capable of adjustment comparable to that possible with a Bunsen burner.

Official

https://pharmacopeia.cn/v-about/

## Procedure

Assemble the apparatus, and place in the flask 100 mL of the liquid to be tested, taking care not to allow any of the liquid to enter the side-arm. Insert the thermometer, shield the entire burner and flask assembly from external air currents, and apply heat, regulating it so that between 5 and 10 minutes elapse before the first drop of distillate falls from the condenser. Continue the distillation at a rate of 4 to 5 mL of distillate per minute, collecting the distillate in the receiver. Note the temperature when the first drop of distillate falls from the condenser, and again when the last drop of liquid evaporates from the bottom of the flask or when the specified percentage has distilled over. Unless otherwise specified in the individual monograph, apply when necessary the emergent stem correction and report the temperatures adjusting the barometric pressure by the following formula:

$$t = t_0 + [(t_0 10^{-4} + 0.033)(760 - p)]$$

in which t is the corrected boiling temperature, in Celsius scale; $t_0$ is the measured boiling temperature, in Celsius scale; and p is the barometric pressure at the time of measurement, in mm Hg.

# ⟨724⟩ DRUG RELEASE

## SCOPE

This test is provided to determine compliance with drug release or dissolution requirements where stated in the individual monographs for transdermal systems (TDS) and other dosage forms. From the types of apparatus described herein, use the one specified in the individual monograph.

## GENERAL DRUG RELEASE STANDARDS

### Apparatus 5 (Paddle over Disk)

APPARATUS

Use the paddle and vessel assembly as described in *Dissolution* ⟨711⟩, *Apparatus, Apparatus 2*, with the addition of a disk assembly designed to hold the TDS at the bottom of the vessel. This disk assembly is designed to minimize any "dead" volume between the assembly and the bottom of the vessel. The disk assembly holds the TDS flat and is positioned such that the release surface is parallel with the bottom of the paddle blade (see *Figure 1a*, *Figure 1b*, and *Figure 1c*). A distance of 25 ± 2 mm between the paddle blade and the surface of the disk assembly is maintained during the test. Other appropriate devices may be used (see *Figure 2*), provided they do not sorb, react with, or interfere with the specimen being tested. [NOTE—A suitable device is catalog number TRANDE-SC from www.qla-llc.com.]

## APPARATUS SUITABILITY

Proceed as directed for *Apparatus 2* in Dissolution ⟨711⟩, *Apparatus, Apparatus 4, Apparatus Suitability, Performance verification test, Apparatus 1 and Apparatus 2*.

## MEDIUM

Proceed as directed for *Dissolution medium* in *Dissolution* ⟨711⟩, *Procedure, Apparatus 1 and Apparatus 2, Immediate-Release Dosage Forms*.

## PROCEDURE

Place the stated volume of *Medium* in the vessel, and equilibrate to 32 ± 0.5°.

Apply the TDS to the disk assembly, assuring that the release surface is as smooth as possible and the TDS is completely and firmly attached to the disk. The TDS, with release surface side up, may be attached to the disk by an appropriate and validated procedure such as use of an adhesive, double-face adhesive tape, screen, or membrane. Care must be taken to avoid the presence of air bubbles between the membrane, if used, and the TDS, or the presence of wrinkles on the surface of the TDS. Carefully remove the protective liner from the TDS without causing damage to the surface of the TDS.

Place the disk assembly flat at the bottom of the vessel with the release surface facing up and parallel to the edge of the paddle blade and surface of the *Medium*. Ensure that the surface of the TDS is devoid of air bubbles. The bottom edge of the paddle is 25 ± 2 mm from the surface of the disk assembly. The vessel may be covered during the test to minimize evaporation.

Immediately operate the apparatus at the rate specified in the monograph.

At each sampling time interval, withdraw a specimen from a zone midway between the surface of the *Medium* and the top of the blade, not less than 1 cm from the vessel wall.

Perform the analysis on each sample aliquot as directed in the individual monograph, correcting for any volume losses, as necessary. Repeat the test with additional TDS as needed.

### TIME

The test time points, at least three, are expressed in hours. Specimens are to be withdrawn within a tolerance of ±15 min or ±2% of the stated time, selecting the tolerance that results in the narrowest time interval.

### INTERPRETATION

Unless otherwise specified in the individual monograph, the requirements are met if the quantities of active ingredient released from the system conform to *Acceptance Table 1* below. Continue testing through the three levels unless the results conform at either $L_1$ or $L_2$.

**Acceptance Table 1**

| Level | Number Tested | Criteria |
|---|---|---|
| $L_1$ | 6 | No individual value lies outside the stated range. |
| $L_2$ | 6 | The average value of the 12 units ($L_1 + L_2$) lies within the stated range. No individual value is outside the stated range by more than 10% of the average of the stated range. |
| $L_3$ | 12 | The average value of the 24 units ($L_1 + L_2 + L_3$) lies within the stated range. Not more than 2 of the 24 units are outside the stated range by more than 10% of the average of the stated range; and none of the units is outside the stated range by more than 20% of the average of the stated range. |

## Apparatus 6 (Cylinder)

### APPARATUS

Use the vessel assembly as described in *Dissolution* ⟨711⟩, *Apparatus, Apparatus 1*, except replace the basket and shaft with a stainless steel cylinder stirring element with the specifications shown in *Figure 3*. This cylinder stirring element is composed of two parts, one comprising the shaft and the upper cylinder, and the other being the extension cylinder. Since both parts are serially numbered, it is recommended that they be kept paired because the friction fitting is done individually for each cylinder, allowing a very tight fit. The distance between the inside bottom of the vessel and the cylinder is maintained at 25 ± 2 mm during the test.

MEDIUM

See *Dissolution medium* in *Dissolution* ⟨711⟩*, Procedure, Apparatus 1 and Apparatus 2, Immediate-Release Dosage Forms*.

PROCEDURE

Place the stated volume of *Medium* in the vessel, and equilibrate to 32 ± 0.5°.

Apply the TDS to the cylinder, assuring that the release surface is as smooth as possible and the TDS is completely and firmly attached to the cylinder. The TDS, with release side facing the *Medium*, may be attached to the cylinder by an appropriate and validated procedure such as use of an adhesive, double-face adhesive tape, membrane, or nylon net. Care must be taken to avoid the presence of air bubbles between the membrane, if used, and the TDS, or the presence of wrinkles on the surface of the TDS. Carefully remove the protective liner from the TDS without causing damage to the surface. If additional reinforcement of the TDS to the cylinder is needed, inert metal wire or a polymer ring may be used.

Place the cylinder in the apparatus, and immediately rotate at the rate specified in the individual monograph. The vessel may be covered during the test to minimize evaporation.

At each sampling time interval, withdraw a specimen from a zone midway between the surface of the *Medium* and the top of the rotating cylinder, not less than 1 cm from the vessel wall.

Perform the analysis on each sample aliquot as directed in the individual monograph, correcting for any volume losses, as necessary. Repeat the test with additional TDS, as needed.

TIME

The test time points, at least three, are expressed in hours. Specimens are to be withdrawn within a tolerance of ±15 min or ±2% of the stated time, selecting the tolerance that results in the narrowest time interval.

INTERPRETATION

Unless otherwise specified in the individual monograph, the requirements are met if the quantities of active ingredient released from the system conform to *Acceptance Table 1* above. Continue testing through the three levels unless the results conform at either $L_1$ or $L_2$.

***Change to read:***

## Apparatus 7 (Reciprocating Holder)

APPARATUS

The assembly consists of (1) a set of volumetrically calibrated or tared solution containers made of glass or other suitable inert material that should not sorb, react with, or interfere with the specimen being tested; (2) a motor and drive assembly to reciprocate the system vertically and to index the system horizontally to a different row of vessels, automatically if desired; and (3) a set of suitable sample holders (see *Figure 4*, *Figure 5a*, *Figure 5b*, *Figure 5c*, and *Figure 5d*).

▲ (ERR 1-May-2018)

During the test, the solution containers are partially immersed in a suitable water bath of any convenient size that permits maintaining the temperature inside the containers at 32 ± 0.5° for TDS or at 37 ± 0.5° for other dosage forms during the test.

No part of the assembly, including the environment in which the assembly is placed, contributes significant motion, agitation, or vibration beyond that due to the smooth, vertically reciprocating sample holder.

Apparatus that permits observation of the system and holder during the test is preferable.

Use the size container and sample holder as specified in the individual monograph.

## MEDIUM

See *Dissolution medium* in *Dissolution* ⟨711⟩, *Procedure, Apparatus 1 and Apparatus 2, Immediate-Release Dosage Forms*.

## SAMPLE PREPARATION A (FOR OSMOTIC PUMP TABLETS)

Attach each unit to be tested to a suitable holder by an appropriate and validated procedure such as use of an adhesive to adhere the edge of the tablet to a holder (e.g., *Figure 5c*), the spring holder (*Figure 5d*), a small nylon net bag, or a membrane.

## SAMPLE PREPARATION B (FOR TDS)

Apply the TDS to the appropriate holder, assuring that the release surface is as smooth as possible and the TDS is completely and firmly attached to the holder. The TDS, with release side facing the *Medium*, may be attached to the holder by an appropriate and validated procedure such as use of an adhesive, double-face adhesive tape, membrane, or nylon net. Care must be taken to avoid the presence of air bubbles between the membrane, if used, and the TDS, or the presence of wrinkles on the surface of the TDS. Carefully remove the protective liner from the TDS without causing damage to the surface of the TDS. If additional reinforcement of the TDS to the holder is needed, inert metal wire or a polymer ring may be used.

## SAMPLE PREPARATION C (FOR OTHER DOSAGE FORMS)

Attach each dosage form to be tested to a suitable holder.

## PROCEDURE

Place the stated volume of *Medium* in the solution containers, and equilibrate to the test temperature.

Suspend each prepared sample holder from a vertically reciprocating shaker such that each system is continuously immersed in *Medium* during the entire test.

Reciprocate at a frequency of about 30 cycles/min with an amplitude of about 2 cm, or as specified in the individual monograph, for the specified time.

At each sampling time interval, remove the solution containers from the bath, cool to room temperature, and add sufficient solvent (i.e., water in most cases) to correct for evaporative losses.

Perform the analysis on each sample as directed in the individual monograph. Repeat the test with additional TDS, as needed.

# ⟨729⟩ GLOBULE SIZE DISTRIBUTION IN LIPID INJECTABLE EMULSIONS

## INTRODUCTION

Lipid injectable emulsions for intravenous administration are sterile oil-in-water emulsions of soybean oil, used to provide an ample supply of essential fatty acids, linoleic and linolenic, dispersed with the aid of an emulsifying agent in *Water for Injection*. Alternatively, soybean oil can be mixed with other suitable oils (neutral triglycerides), such as safflower oil, medium-chain triglycerides (MCT) derived from coconut or palm kernel oils, olive oil, or a marine oil, such as menhaden oil. The size of the lipid droplets is critical: because of mechanical filtration, larger-size fat globules (>5 µm) can be trapped in the lungs. The essential size characteristics of a lipid injectable emulsion for intravenous use include the mean diameter of the lipid droplets and the range of the various droplet diameters distributed around the mean diameter, expressed as the standard deviation. In particular, the amounts of fat globules comprising the large-diameter tail of the globule size distribution are especially important with respect to infusion safety. These two regions of the globule size distribution (mean droplet size and large-diameter tail) must be controlled within specified limits.

The two methods described below are used for determination of the mean lipid droplet diameter and the distribution of large-diameter globule sizes in lipid injectable emulsions. *Method I* and *Method II* must be validated. The methods described below to assess the quality of lipid injectable emulsions are to be performed in two stages.

***Change to read:***

## METHOD I—▲MEASUREMENT OF MEAN DROPLET DIAMETER BY DYNAMIC LIGHT SCATTERING OR CLASSICAL LIGHT SCATTERING▲ (USP 1-AUG-2019)

For the determination of the mean droplet size of lipid injectable emulsions, either of two common light-scattering techniques may be employed: (1) dynamic light scattering (DLS), also known as photon correlation spectroscopy (PCS), or (2) classical light scattering ▲[laser diffraction (LD)],▲ (USP 1-Aug-2019) based on Mie scattering theory. The DLS, or PCS, technique is based on analyzing the rapid temporal fluctuations in the scattered light intensity that occur due to the random Brownian motion, or diffusion, of any particles, including lipid droplets, suspended in liquid. The intensity is measured at a given angle (usually 90°) by a suitable detector (e.g., photomultiplier tube) able to measure the rapidly fluctuating scattered light intensity produced by the suspended, diffusing droplets. These scattered intensity data are typically used to calculate the intensity autocorrelation function, which is a simple decaying exponential function in time for droplets of uniform size. A distribution of droplet sizes expresses itself by ▲the superposition, or summation, of▲ (USP 1-Aug-2019) exponential functions of different decay times, ▲each representative of a given droplet size.▲ (USP 1-Aug-2019) The autocorrelation function generated by the scattered intensity data obtained from a given emulsion can be "inverted" by means of an appropriate deconvolution algorithm in order to obtain the approximate distribution of intensity-weighted diffusion coefficients. From the latter, the distribution of small-diameter droplets is calculated, using the Stokes–Einstein equation and the rules of classical (Mie) light scattering.

By contrast, classical light scattering based on Mie theory analyzes the spatial ▲(angular),▲ (USP 1-Aug-2019) rather than temporal, variation of the scattered light intensity by measuring the latter as a function of the scattering angle, typically over a large range of detected angles. The temporal fluctuations in the scattering intensity due to Brownian motion are averaged out in time for each angular measurement. This angular variation occurs as a consequence of the mutual interference of individual scattered waves arriving at the detector with different phases from different points within ▲each of the▲ (USP 1-Aug-2019) lipid droplets, ▲summed over all of the▲ (USP 1-Aug-2019) different particles. The extent of the angular variation is significant whenever the droplet diameter is not small compared with the wavelength of the laser light (typically ▲633–▲ (USP 1-Aug-2019)635 nm). Droplets of a given size and refractive index yield a unique curve of scattering intensity versus angle. A distribution of droplet sizes gives rise to a final angular dependence that represents the superposition, or summation, of ▲all of the▲ (USP 1-Aug-2019) individual (different) intensity versus angle curves. The measured angular dependence of the scattering intensity obtained from a given emulsion sample, ▲in principle,▲ (USP 1-Aug-2019) can be inverted by means of an appropriate deconvolution algorithm ▲in combination with▲ (USP 1-Aug-2019) Mie scattering theory in order to obtain the approximate droplet size distribution.

Thus, light scattering, using either dynamic light scattering (i.e., ▲varying▲ (USP 1-Aug-2019) temporal fluctuations due to droplet diffusion) or classical light scattering/Mie theory (i.e., ▲varying,▲ (USP 1-Aug-2019) average intensity versus angle), can provide acceptable results for both the mean diameter and, ▲to a lesser degree, the▲ (USP 1-Aug-2019) standard deviation of the droplet size distribution. For purposes of illustrating the method used in *Method I*, a dynamic light-scattering technique is described. For guidance regarding instruments employing classical Mie-theory light scattering, see *Light Diffraction Measurement of Particle Size* ⟨429⟩.

### Apparatus

A suitable DLS/PCS instrument with or without the capability of automatic sample dilution is controlled by validated software and is used to perform the measurement, with the scattering angle typically set at 90°. The intensity-weighted results (mean diameter and standard deviation) are reported, provided it is clearly stated which values are given and that the necessary parameter values required for all requisite calculations are also given.

## Water

Pass distilled water through a filter of 0.2-µm pore size, and degas by sonication, or use *Sterile Water for Injection* stored in a glass container.

## Standard Preparation

To a pre-established volume of *Water* add an appropriate amount of concentrated suspension, containing National Institute of Standards and Technology (NIST)-traceable polystyrene latex standard particles or other suitable nanospheres. Gently mix the fluids to achieve a homogeneous suspension. The diluted suspension will be slightly turbid in appearance. If the DLS/PCS instrument is equipped with an automatic dilution system, the starting concentrated sample can be analyzed by injection directly into the instrument via a syringe, with further dilution occurring automatically to optimize the droplet concentration for analysis. Alternatively, the sample would require greater manual dilution with *Water* (typically by at least a factor of 10 over the first dilution), and then this sample would be instilled into a "drop-in" cuvette. The optimum dilution scheme that achieves the proper scattering intensity for the cuvette-based analysis will be determined by the instrument specifications. Thus, the concentration of latex in the final sample must be optimized for the DLS/PCS instrument used. This should be performed separately for three different size standards of approximately 100, 250, and 400 nm (triplicate analyses per size), and the corresponding results of intensity-weighted mean diameter and standard deviation should coincide with the expected values within acceptable errors.

## Test Preparation

To a pre-established volume of *Water* add an appropriate volume of sample from the lipid injectable emulsion. Gently mix the fluids to achieve a homogeneous suspension. The diluted suspension will be slightly turbid in appearance. If the DLS/PCS instrument is equipped with an automatic dilution system, the starting concentrated sample can be analyzed by injection directly into the instrument via a syringe. Further dilution of the sample then occurs automatically to optimize the droplet concentration for analysis, ensuring that it is not so high as to cause artifacts due to multiple scattering or interdroplet interactions. Alternatively, the sample would require greater manual dilution with *Water* (typically by at least a factor of 10 over the first dilution), and then this sample would be instilled into a "drop-in" cuvette. The optimum dilution scheme that achieves the proper scattering intensity for the cuvette-based analysis will be determined by the instrument specifications. Thus, the concentration of lipid injectable emulsion in the final sample must be optimized for the DLS/PCS instrument used. ▲Testing should be done in triplicate or, as appropriate, based on method validation data.▲ (USP 1-Aug-2019)

## System Suitability

Using the *Standard Preparation,* measure the intensity-weighted mean particle diameter and the corresponding standard deviation. The system is suitable once the sample temperature has reached equilibration and the results have stabilized and triplicate mean droplet diameter measurements are obtained. The coefficient of variation (CV) should not exceed ▲15% (see below)▲ (USP 1-Aug-2019) of the NIST-traceable mean droplet diameter. A larger CV value indicates that the latex microspheres are not suitable as a standard because they either inherently lack uniformity or have become agglomerated to an unacceptable extent. In this case, another standard latex suspension must be selected and tested.

▲[NOTE—The recommended 15% CV limit is increased here because of the differences in the way the mean droplet size is determined by DLS versus classical light scattering.]▲ (USP 1-Aug-2019)

## Procedure and Interpretation

If the DLS/PCS instrument is equipped with an automatic dilution system, use a disposable syringe to load the *Standard preparation* or *Test preparation*. If no automatic dilution system is used, transfer the appropriately diluted preparation to a cuvette, and place the cuvette in the ▲temperature-regulated sample holder of the instrument.▲ (USP 1-Aug-2019) Allow the sample to equilibrate to a preset controlled temperature close to ambient (between 20° and 25°, as in the USP definition found in *Packaging and Storage Requirements* ⟨659⟩). Set the instrument scattering angle to 90°, and carry out the measurements. As long as the chi-square ($\chi^2$) goodness-of-fit parameter remains acceptably low (per instrument specifications), the results for the *Test preparation* are acceptable. Excessive values of the $\chi^2$ parameter suggest that the droplet distribution is not normal and may indicate an unstable emulsion. The intensity-weighted mean droplet diameter (MDD) for lipid injectable emulsions must be less than 500 nm or 0.5 µm, irrespective of the concentration of the dispersed lipid phase.

▲Submicron results from the DLS method and classical (Mie) light scattering method may vary due to the different physical principles of the mechanism of testing and the different mathematical procedures used to analyze the underlying data.▲ (USP 1-Aug-2019)

***Change to read:***

# METHOD II—MEASUREMENT OF LARGE GLOBULE CONTENT BY LIGHT OBSCURATION OR EXTINCTION METHOD

For determination of the extent of the large-diameter droplet tail (>5 µm) of lipid injectable emulsions, a light obscuration (LO) or light extinction (LE) method that employs a single-particle (globule) optical sizing (SPOS) technique is used. ▲DLS

https://pharmacopeia.cn/
Printed on: Fri Jan 05 2024 06:38:01 AM(EST)

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99505_02_01
@2024 USPC

methodology is effective only for characterizing smaller particle sizes in the nominal size range of about 1–1000 nm; therefore, DLS is complimentary to LE and is particularly effective in sizing droplets smaller than 500 nm. Importantly, DLS is only a sizing method and provides only semi-quantitative information on the relative droplet size distribution. DLS does not count particles or droplets; thus, it is mainly a qualitative method. In contrast, LE both sizes (1.3–400 µm) and counts fat globules providing "reliable" count values at a size threshold of 5 µm.▲ (USP 1-Aug-2019)

During application of the LE/SPOS technique, passage of a droplet through a thin optical sensing zone results in ▲effective▲ (USP 1-Aug-2019) blockage of a portion of the incident light beam, causing a momentary decrease in the light intensity reaching the ▲distant▲ (USP 1-Aug-2019) "extinction" detector. The magnitude of this decrease in the signal is ▲related▲ (USP 1-Aug-2019) to the cross-sectional area of the droplet (assumed smaller than the sensing zone thickness), i.e., to the square of the droplet diameter. ▲The larger the droplet diameter, the larger the height (voltage) of the signal pulse produced by the momentary decrease in the detected light intensity.▲ (USP 1-Aug-2019) During optimization of the LE/SPOS instrument for a given emulsion sample, a series of dilutions should be tested to achieve consistency between samples. The goal is to identify a standard range of dilutions that yield consistent data and are most applicable to the formulation tested. Ideally, when comparing different emulsions, the same approximate number of globules are sized each time, and once a standard is achieved, it should be incorporated into the routine sampling plan for validation testing. As long as the fat globule concentration is below the "coincidence limit" of the sensor (determined by the flow cell and optical design, ▲verified experimentally),▲ (USP 1-Aug-2019) only one globule at most will pass through the sensing zone at any given time, allowing it to be counted and accurately sized (with less than 1% ▲particle or globule▲ (USP 1-Aug-2019) coincidence events). Both the coincidence ▲(concentration)▲ (USP 1-Aug-2019) limit and the optimal flow rate must be known for the LE/SPOS sensor used. Furthermore, it is prudent to perform the large-diameter measurements at a reduced emulsion concentration such that the measurable droplet concentration ▲from the▲ (USP 1-Aug-2019) threshold of detection (e.g., >1.8 µm) to an ▲appropriate▲ (USP 1-Aug-2019) upper ▲size▲ (USP 1-Aug-2019) limit (e.g., 50 µm) is only approximately one-third of the nominal coincidence limit for the sensor used. The resulting single pulse heights are converted to droplet diameters using a standard calibration curve previously constructed from NIST-traceable monosized polystyrene microspheres of known diameters. For additional guidance in the use of the light obscuration methodology, see *Particulate Matter in Injections* ⟨788⟩.

## Apparatus

A suitable light obscuration instrument with or without the capability of automatic sample dilution and controlled by a personal computer (PC) is used for the measurement. The number- and volume-weighted particle size distribution data are reported, provided that it is clearly stated which values are given and that the necessary parameter values required for all necessary calculations are also given.

## Water

Pass distilled water through a filter of 0.2-µm pore size ▲and degas by sonication,▲ (USP 1-Aug-2019) or use *Sterile Water for Injection* stored in a glass container.

## Standard Preparation

To a pre-established volume of *Water* add an appropriate amount of concentrated suspension, containing NIST-traceable polystyrene latex standard particles or other suitable microspheres. Gently mix the fluids to achieve a homogeneous suspension. If the light obscuration instrument is equipped with an automatic dilution system, the starting concentrated sample can be analyzed by injection directly into the instrument via a syringe or Teflon sample line. Further dilution of the sample then occurs automatically to optimize the particle concentration for analysis. Alternatively, the sample would require greater manual dilution with water (typically by at least a factor of 10 over the first dilution). The resulting diluted sample is then instilled in an appropriate, clean container, such as a sterile Type I glass container, before being passed through the sensor. In either case the final particle concentration is caused to lie below the coincidence limit of the sensor. The sizing and counting accuracy of the light obscuration instrument should be obtained using two different size standards of approximately 5 and 10 µm (triplicate analyses per size). For the standards after system calibration, set the instrument threshold of detection at 1.8 µm, extended to an upper limit of 50 µm. The corresponding results for the mean diameter should coincide with the expected values, within 10% of the relative standard deviation and 90%–110% size accuracy. In addition, the number of particle counts obtained per milliliter should also agree within ±10% with the concentration values certified in the documentation provided with each NIST-traceable size standard.

## Test Preparation

To a pre-established volume of *Water* add an appropriate volume of sample from the lipid injectable emulsion (triplicate analyses per sample). Gently mix the fluids to achieve a homogeneous suspension. The diluted emulsion will be slightly turbid in appearance. If the light obscuration instrument is equipped with an automatic dilution system, the starting concentrated sample can be analyzed by injection directly into the instrument via a syringe or nonreactive[1] Teflon sample line. Further dilution then occurs automatically to optimize the droplet/globule concentration for analysis. Alternatively, the sample would require greater manual dilution with water (typically by at least a factor of 10 over the first dilution). The resulting diluted sample is then instilled in an appropriate, clean container such as a sterile Type I glass container. In either case the final droplet/globule concentration is caused to lie below the coincidence limit of the sensor.

[1] Polyvinyl chloride (PVC) with diethylhexylphthalate (DEHP) has been shown to induce breakdown of lipid injectable emulsions (Drug Product Problem Reporting System. USP File Access No. 11173, May 15, 1991).

@2024 USPC

## System Suitability

Perform prior to the test procedure, using the *Standard preparation* of a 5- and 10-µm NIST-traceable particle. Measure in triplicate the number-weighted particle diameter and the counts/mL of the standard. The system is suitable when the triplicate mean number-weighted particle diameter measurements are within 10% of the target value, both in terms of repeatability (CV) and closeness to the certified size on the label of the NIST-traceable standard.

## Procedure and Interpretation

If the light obscuration instrument is equipped with an automatic dilution system, use a disposable syringe or Teflon sample line to load the *Standard Preparation* or *Test Preparation.* If no automatic dilution system is used, transfer the sample to an appropriate large-volume, clean container such as a sterile Type I glass vessel containing an appropriate volume of water. Allow the sample and water to mix thoroughly to achieve a homogeneous suspension. Set the instrument threshold of detection at 1.8 µm, extended to an upper ▲size▲ (USP 1-Aug-2019) limit of 50 µm, and vary the concentration and/or data collection times such that there is at least a factor of two in the difference of the total number of globules that measure >5 µm between at least two sample runs. In any case, the number of globules that measure >5 µm should be large enough so that it represents an adequate number of globules that are statistically representative of the large-diameter tail population of the native emulsion. The volume-weighted, large-diameter fat globule limits of the dispersed phase, expressed as the percentage of fat residing in globules larger than 5 µm (PFAT5) for a given lipid injectable emulsion, must not exceed 0.05%. ▲Most commonly used instruments provide calculation in software (HIAC Royco, PSS AccuSizer, Klotz). However, the general equation applied is based on the sum of the number of droplets per milliliter of sample per channel multiplied by the volume of a sphere of the geometric mean of each channel, i.e., $\Sigma(\#/mL/channel)\ (\pi D3/6)$.▲ (USP 1-Aug-2019)

# ⟨730⟩ PLASMA SPECTROCHEMISTRY

## INTRODUCTION

Plasma-based instrumental techniques, which are useful for pharmaceutical analyses, fall into two major categories: those based on the inductively coupled plasma, and those where a plasma is generated at or near the surface of the sample. The inductively coupled plasma (ICP) is a high-temperature excitation source that desolvates, vaporizes, and atomizes aerosol samples and ionizes the resulting atoms. The excited analyte ions and atoms can then subsequently be detected by observing their emission lines, a method termed inductively coupled plasma–optical emission spectroscopy (ICP–OES; also referred to as inductively coupled plasma–atomic emission spectroscopy), or the excited or ground state ions can be determined by a technique known as inductively coupled plasma–mass spectrometry (ICP–MS). ICP–OES and ICP–MS may be used for either single- or multi-element analysis and used for either sequential or simultaneous analyses with good sensitivity over an extended linear range.

For additional information and discussion of the theory and principles of measurements, see *Plasma Spectrochemistry—Theory and Practice* ⟨1730⟩.

## QUALIFICATION OF PLASMA SPECTROPHOTOMETERS

Qualification of the ICP–OES or the ICP–MS can be divided into three elements: installation qualification (IQ), operational qualification (OQ), and performance qualification (PQ)—see also the general chapter *Analytical Instrument Qualification* ⟨1058⟩.

### Installation Qualification

The IQ requirements provide evidence that the hardware and software are properly installed in the desired location, and that the environment, in which the instrument will be used, is adequate.

### Operational Qualification

The purpose of OQ is to demonstrate that instrument performance is suitable. In OQ, an instrument's performance is characterized using standards of known spectral properties to verify that the system operates within target specifications. OQ is a check of the key operational parameters performed after installation and after repairs and/or maintenance. Instrument vendors often have samples and test parameters available as part of the IQ/OQ package.

### Performance Qualification

PQ determines whether the instrument is capable of meeting the user's requirements for all the parameters that may affect the quality of the measurement. Depending on typical use, the specifications for PQ may be different from the manufacturer's specifications. For validated methods, specific PQ tests, also known as system suitability tests, can be used in lieu of PQ requirements. A solution used in the initial standard curve of an ICP–OES or ICP–MS instrument must be reassayed as a check standard at appropriate, pre-established intervals throughout the analysis of the sample set.

For single-element ICP–OES analyses, when analytical wavelengths are between 200 and 500 nm, or concentrations are >1 µg/mL, the reassayed standard should agree with its expected value to within ±10%, or as specified in an individual monograph. For multi-element ICP–OES analyses, when analytical wavelengths are <200 nm or >500 nm, or at concentrations of <1 µg/mL, the reassayed standard should agree with its theoretical value to within ±20%, or as specified in an individual monograph. For single-element ICP–MS analyses, when analytical masses that are free of interferences and when concentrations are >1 ng/mL, the reassayed standard should agree with its expected value to within ±10%, or as specified in an individual monograph.

For multi-element ICP–MS analyses, or when concentrations are <1 ng/mL, or for single-element analyses where interferences may be present, the reassayed standard should agree with its expected value to within ±20%, or as specified in an individual monograph.

In cases where an individual monograph provides different guidance regarding the reassayed check standard for ICP–OES or ICP–MS, the requirements of the monograph take precedence. Specific procedures, acceptance criteria, and time intervals for characterizing ICP–OES or ICP–MS performance depend on the instrument and intended application.

## PROCEDURE

Users must evaluate and select the type of material of construction, pretreatment, and cleaning of analytical labware used in ICP–OES and ICP–MS analyses. The material must be inert and, depending on the specific application, resistant to caustics, acids, and/or organic solvents. For some analyses, diligence must be exercised to prevent the adsorption of analytes onto the surface of a vessel; contamination of the sample solutions from metal and ions present in the container also can lead to inaccurate results. For the analysis of a ubiquitous element, it is often necessary to use the purist grade of reagent or solvent available. Check all solutions for elemental contamination before they are used in an analysis.

### Standard Solution

Standard solutions are used to standardize the instrument at the time-of-use, and prepare these solutions as directed in the individual monograph. [NOTE—Commercially available single- or multi-element standard solutions, traceable to the National Institute of Standards and Technology or to an equivalent national metrology organization, can be used in the preparation of standard solutions.] Standard solutions, especially those used for ultra-trace analyses, may have limited shelf-life. Stability of standard solutions can vary depending on concentration, analyte of interest, storage container type, and storage conditions. For these reasons, standard solutions with concentrations <10 ppm (w/v) should be retained for NMT 24 h, unless stability is demonstrated experimentally.

The method of standard additions can be used for instrument standardization. This method involves adding a known concentration of the analyte element to the sample at NLT two concentration levels against an unspiked sample preparation. The instrument response is plotted against the concentration of the added analyte element, and a linear regression line is drawn through the data points. The absolute value of the *x*-intercept multiplied by any dilution factor is the concentration of the analyte in the sample, and many instruments will perform the analyte calculation automatically. Once a method has been developed and is in routine use, it is common practice to calibrate with a blank and a single standard. One-point standardizations are suitable for conducting limit tests on production materials and final products, provided that the methodology has been rigorously validated for sufficient specificity, sensitivity, linearity, accuracy, precision, ruggedness, and robustness.

### Sample Solution

Although solid samples and slurried samples may be analyzed, it is generally necessary to prepare solutions of samples for analyses as directed in the individual monograph. Samples may be dissolved in any solvent, including organic solvents or acids/bases, that are compatible with the instrument system. Samples that are not soluble in a solvent require digestion. A variety of digestion techniques could be used to dissolve a sample. These include hot-plate and microwave-assisted digestions, including open-vessel and closed-vessel approaches. Note that open-vessel digestion generally is not recommended for the analysis of volatile metals, e.g., selenium and mercury.

### Analysis

The instrument must be standardized for quantitation at the time of use, following the procedure as directed in the individual monograph for the instrumental parameters. The response of standard solutions that bracket the target concentration of an analyte in a sample is determined against an appropriate blank. The detector response is plotted as a function of the analyte concentration. When an analysis is performed at or near the detection limit, the analyst cannot always use a bracketing standard. In such a case, a standard prepared at or near (within ±10% of) the detection limit should be run in triplicate, with an acceptance criteria of ±10% of the theoretical value for the standard for single-element standards, and ±20% of the theoretical value for the standard for multi-element standards.

To demonstrate the stability of the system's initial standardization, the analyst must reassay a solution used in the initial standard curve as a check standard at appropriate, pre-established intervals throughout the analysis of the sample set. Unless otherwise indicated in the individual monograph, the reassayed standard should meet the same acceptance criteria as those outlined in the PQ section above. Sample concentrations are calculated versus the working curve generated by plotting the detector response versus the concentration of the analyte in the standard solutions, and most instruments perform this calculation automatically.

## VALIDATION AND VERIFICATION

### Validation

Validation is required when the ICP–OES or ICP–MS method is intended for use as an alternative to the official procedure for testing an official article. The objective of the ICP–OES or the ICP–MS procedure validation is to demonstrate that the measurement is suitable for its intended purpose, including quantitative determination of the main component in a drug substance or a drug product (Category I assays), quantitative determination of impurities or limit tests (Category II), and identification tests (Category IV). [NOTE—For definition of different categories, see *Validation of Compendial Procedures* ⟨1225⟩.] Depending on the category of the test, analytical procedure validation for the ICP–OES or ICP–MS requires the testing of linearity, range, accuracy, specificity, precision, detection limit, quantitation limit, and robustness. These analytical performance characteristics apply to externally standardized methods and to the method of standard additions.

General chapter ⟨1225⟩ provides definitions and general guidance on the procedures for analytical validation without indicating specific validation criteria for each characteristic. The intention of the following sections is to provide the user with specific validation criteria that represent the minimum expectations for this technology.

#### ACCURACY

For Category I assays or Category II tests, accuracy can be determined by conducting recovery studies with the appropriate matrix spiked with known concentrations of elements. It is also an acceptable practice to compare assay results obtained using the ICP–OES or ICP–MS procedure under validation to those of an established analytical procedure. In standard addition methods, accuracy assessments are based on the final intercept concentration, not the recovery calculated from the individual standard additions.

Official

https://pharmacopeia.cn/

**Validation criteria:** 95.0%–105.0% mean recovery for the assay, and 70.0%–150.0% mean recovery for the impurity analysis. These criteria apply throughout the intended range.

## Precision

### REPEATABILITY

The analytical procedure is assessed by measuring the concentrations of six independently prepared sample solutions at 100% of the assay test concentration.
**Validation criteria:** The relative standard deviation is NMT 5.0% for the drug substance assay, NMT 5.0% for the drug product assay, and NMT 20% for the impurity analysis.

### INTERMEDIATE PRECISION

The effect of random events on the analytical precision of the procedure should be established. Typical variables include performing the analysis on different days, using different instrumentation, or having the method performed by two or more analysts. As a minimum, any combination of these factors totaling three experiments will provide an estimation of intermediate precision. For example, this could be one analyst on each of 3 days, or one analyst on two sets of equipment on two different days for one instrument; three analysts could be on the same piece of equipment.
**Validation criteria:** The relative standard deviation is NMT 8.0% for the drug substance assay, NMT 8.0% for the drug product assay, and NMT 25.0% for the impurity analysis.

### SPECIFICITY

The procedure must be able to unequivocally assess each analyte element in the presence of components that are expected to be present, including any matrix components.
**Validation criteria:** Demonstrated by meeting the accuracy requirement

### QUANTITATION LIMIT

The limit of quantitation (QL) is estimated by calculating the standard deviation of NLT 10 replicate measurements of a blank solution and multiplying by 10. When validating a procedure using the method of standard additions, the slope of standards applied to a solution of the test material is used. Other suitable approaches can be used (see ⟨1225⟩).

A measurement of a test solution prepared from a representative sample matrix spiked at the estimated QL concentration must be performed to confirm accuracy. When validating a procedure using the method of standard additions, the validation criterion applies to the final experimental result, not the spike recovery of the individual standard addition levels.
**Validation criteria:** The analytical procedure should be capable of determining the analyte precisely and accurately at a level equivalent to 50% of the specification.

### LINEARITY

A response curve between the analyte concentration and absorbance is prepared from NLT two standard solutions and a blank (for a total of three data points), at concentrations that encompass the anticipated concentration of the test solution. The standard curve is then evaluated using appropriate statistical methods, such as a least-squares regression.

For experiments that do not yield a linear relationship between analyte concentration and the ICP–OES or ICP–MS response, appropriate statistical methods must be applied to describe the analytical response.
**Validation criteria:** Correlation coefficient (*R*), NLT 0.995 for Category I assays and NLT 0.99 for Category II quantitative tests

### RANGE

Range is the interval between the upper and lower concentrations (amounts) of analyte in the sample (including these concentrations) for which it has been demonstrated that the analytical procedure has a suitable level of precision, accuracy, and linearity that is demonstrated by meeting the precision, accuracy, and linearity requirements.
**Validation criteria:** For Category I tests, the validation range for 100.0% centered acceptance criteria is 80.0%–120.0%. For noncentered acceptance criteria, the validation range is 10.0% below the lower limit to 10.0% above the upper limit. For content uniformity, the validation range is 70.0%–130.0%. For Category II tests, the validation range covers 70.0%–130.0% of the acceptance criteria.

### ROBUSTNESS

The reliability of an analytical measurement is demonstrated by deliberate changes to experimental parameters. Because certain changes to experimental parameters could result in potential safety issues or damage to equipment, robustness is demonstrated by meeting the intermediate precision requirements set forth above.

## Verification

U.S. Current Good Manufacturing Practices regulations [21 CFR 211.194(a)(2)] indicate that users of the analytical procedures, as described in *USP–NF*, are not required to validate these procedures if they are provided in a monograph. Instead, users must simply verify their suitability under actual conditions of use.

The objective of ICP–OES or ICP–MS procedure verification is to demonstrate that the procedure, as prescribed in a specific monograph, should be executed by the user with suitable accuracy, specificity, and precision using the instruments, analysts, and sample matrices available. According to *Verification of Compendial Procedures* ⟨1226⟩, if the verification of the compendial procedure by following the monograph is not successful, the procedure may not be suitable for use with the article under test. It may be necessary to develop and validate an alternative procedure as allowed in *General Notices, 6.30 Alternative and Harmonized Methods and Procedures*.

Verification of compendial ICP–OES or ICP–MS methods should, at a minimum, include the execution of the validation parameters for specificity, accuracy, precision, linearity, and limit of quantitation, when appropriate, as indicated in *Validation*.

# ⟨731⟩ LOSS ON DRYING

***Change to read:***

The procedure set forth in this chapter determines the amount of volatile matter of any kind that is driven off under the conditions specified, ▲which is defined as Loss on Drying value.▲ (USP 1-Aug-2020) For substances appearing to contain water as the only volatile constituent, the procedure given in *Water Determination* ⟨921⟩ is appropriate, and is specified in the individual monograph.

Unless otherwise directed in the individual monograph, conduct the determination of Loss on Drying on a 1- to 2-g test specimen. Mix the substance to be tested and, if it is in the form of large particles, reduce the particle size to about 2 mm by ▲▲ (USP 1-Aug-2020) crushing before weighing ▲it▲ (USP 1-Aug-2020) out. ▲▲ (USP 1-Aug-2020) Tare an appropriate glass-stoppered▲▲ (USP 1-Aug-2020) weighing bottle that has been dried for about 30 min under the same conditions to be employed in the determination and cooled to room temperature in a desiccator. Put the test specimen in the bottle, replace the ▲stopper,▲ (USP 1-Aug-2020) and accurately weigh the ▲stoppered▲ (USP 1-Aug-2020) bottle and the contents. By gentle, sidewise shaking, distribute the test specimen as evenly as practicable to a depth of about 5 mm generally, and NMT 10 mm in the case of ▲low bulk density▲ (USP 1-Aug-2020) materials. Place the loaded bottle in the drying chamber, ▲remove▲ (USP 1-Aug-2020) the stopper and ▲leave▲ (USP 1-Aug-2020) it also in the chamber. Dry the test specimen at the▲specified▲ (USP 1-Aug-2020) temperature and time ▲conditions.

[NOTE—The Loss on Drying value is a function of both temperature and time. Therefore, these values must be identified and reported.▲ (USP 1-Aug-2020) The temperature specified in the monograph is to be regarded as being within the range of ±2° of the stated ▲value.▲ (USP 1-Aug-2020)]

When "dry to constant weight" is specified in a monograph, drying shall be continued until two consecutive weighings do not differ by more than 0.50 mg/g of ▲specimen taken, where the second weighing follows▲ (USP 1-Aug-2020) an additional hour of drying. Upon opening the chamber, ▲reapply the same stopper to the bottle,▲ (USP 1-Aug-2020) and allow it to come to room temperature in a desiccator before weighing ▲accurately.▲ (USP 1-Aug-2020)

If the substance melts at a lower temperature than that specified for the determination of Loss on Drying, maintain the bottle with its contents for 1–2 h at a temperature 5°–10° below the melting temperature, then dry at the specified temperature.

Where capsules are to be tested, use a ▲representative sample mixture, excluding the capsule shell, from not▲ (USP 1-Aug-2020) fewer than 4 capsules.

Where tablets are to be tested, use ▲a representative sample mixture▲ (USP 1-Aug-2020) from NLT 4 crushed tablets.

Where the individual monograph directs that Loss on Drying be determined by thermogravimetric analysis, a ▲suitable▲ (USP 1-Aug-2020) balance is to be used ▲(see *Balances* ⟨41⟩.▲ (USP 1-Aug-2020)

Where drying under vacuum over a desiccant is directed in the individual monograph, a vacuum desiccator or a vacuum drying pistol, or other suitable vacuum drying apparatus, is to be used.

Where drying in a desiccator is specified, exercise particular care to ensure that the desiccant is ▲▲ (USP 1-Aug-2020) fully effective. ▲▲ (USP 1-Aug-2020)

Where drying in a capillary-stoppered bottle[1] under vacuum is directed in the individual monograph, use a bottle or tube fitted with a stopper having a 225 ± 25-µm diameter capillary, and maintain the heating chamber at a pressure of 5 mm or less of mercury. At the end of the heating period, admit dry air to the heating chamber, remove the bottle, and with the capillary stopper still in place allow it to cool to room temperature in a desiccator before weighing.

[1] Available as an "antibiotic moisture content flask" from Kimble ▲Chase Life Science and Research Products,▲ (USP 1-Aug-2020) 1022 Spruce St., Vineland, NJ ▲08360.▲ (USP 1-Aug-2020)

# ⟨733⟩ LOSS ON IGNITION

***Change to read:***

This procedure is provided for the purpose of determining the percentage of test material that is volatilized and driven off under the conditions specified.

Perform the test on finely powdered material, and break up lumps, if necessary, with the aid of a mortar and pestle before weighing the specimen. Weigh the specimen to be tested without further treatment, unless a preliminary drying at a lower temperature, or other special pretreatment, is specified in the individual monograph. Unless other equipment is designated in the individual monograph, conduct the ignition in a suitable muffle furnace or oven that is capable of maintaining a temperature within 25° of that required for the test, and use a suitable crucible, complete with cover, previously ignited for 1 h at the temperature specified for the test, cooled in a desiccator, and accurately weighed.

Unless otherwise directed in the individual monograph, transfer to the tared crucible an accurately weighed quantity, in g, of the substance to be tested, about equal to that calculated by the formula:

$$10/L$$

in which $L$ is the limit (or the mean value of the limits) for Loss on Ignition, in percentage. Ignite the loaded uncovered crucible, and cover at the temperature (±25°) and for the period of time designated in the individual monograph. When "ignition to constant weight" is specified in a monograph, ignite for successive 1-h periods until two consecutive weighings do not differ by more than 0.50 mg/g of specimen. Upon completion of each ignition, cover the crucible, and allow it to cool in a desiccator to room temperature before weighing ▲accurately▲ (ERR 1-Nov-2020).

# ⟨735⟩ X-RAY FLUORESCENCE SPECTROMETRY

## INTRODUCTION

X-ray fluorescence (XRF) spectrometry is an instrumental method based on the measurement of characteristic X-ray photons caused by the excitation of atomic inner-shell electrons by a primary X-ray source. The XRF method can be used for both qualitative and quantitative analysis of liquids, powders, and solid materials. The X-rays produced by an X-ray tube include characteristic lines that correspond to the anode material and a continuum known as Bremsstrahlung radiation. Both types of X-rays can be used to excite atoms and thus induce X-rays. XRF instrumentation can be divided into one of two categories: Wavelength Dispersive X-ray Fluorescence (WDXRF) and Energy Dispersive X-ray Fluorescence (EDXRF). The main factor distinguishing these technologies is the method used to separate the spectrum emitted by the atoms in the sample. The energy of the X-ray photon is characteristic for a given electron transition in an atom and is *qualitative* in nature. The *intensity* of the emitted radiation is indicative of the number of atoms in the sample and constitutes the *quantitative* nature of the method.

## QUALIFICATION OF XRF SPECTROMETERS

### Installation Qualification

See also *USP* general information chapter *Analytical Instrument Qualification* ⟨1058⟩.

### Operational Qualification

The purpose of operational qualification (OQ) is to verify that the system operates within target tolerances using appropriate samples with known spectral properties. OQ is a check of the key operating parameters and should be performed following installation, repairs, or major maintenance that can affect the performance of the instruments. Note that all calibration samples must be handled with cotton or nitrile gloves and must be stored in sealed plastic containers. Alternatively, they may be fixed in the instrument.

The OQ tests and specifications in the following sections are typical examples only (see *Tables 1* and *3*). Other tests and standards can be used to establish tolerances for these purposes. The instrument vendor often makes samples and test parameters available as part of the IQ package.

**Table 1. EDXRF OQ Specifications**

| Test | Procedure | Acceptance Criteria |
|---|---|---|
| Peak position | Acquire a spectrum of the Al–Cu energy calibration sample. | The spectrum should have at least 3000 counts at the top of both the Al Kα and the Cu Kα peaks. The energy corresponding to the peaks of Al Kα and Cu Kα should differ less than 0.1% from the tabulated values. |
| Detector resolution | Calculate the resolution (full width, half maximum) at the same energy and at the same count rate that was used at IQ. | The resolution value should not change more than 10% from the value determined at IQ. |
| Count rate | Measure the count rate of Al and Cu Kα lines from the energy calibration sample. | <10% change from initial measurements at IQ, for each peak |

The Al–Cu energy calibration sample is a disc of Al–Cu alloy (EN AW-AlCu6BiPb; Alloy 2011, ASTM B211) that has been selected for use in EDXRF spectrometers. This alloy is generally available, is resistant to corrosion, and provides adequate intensities for both Al Kα and Cu Kα. These characteristic lines cover the typical energies used for XRF analysis. Also, sufficient information can be obtained from spectra recorded on this material to assess detector resolution. A more complete compositional specification for this calibration sample is given in *Table 2*.

**Table 2. Specification of the Concentration of the Alloying Elements in Al–Cu Alloy (the Remaining Balance Is Aluminum)**

| Element | Concentration Limits (in % by Weight) |
|---|---|
| Cu | 5–6 |
| Zn | 0.3 maximum |
| Fe | 0.7 maximum |
| Bi | 0.2–0.6 |
| Pb | 0.2–0.6 |
| Si | 0.4 maximum |

Official

https://nhathuocngocanh.com/

When the energy range of the analytical lines for which the spectrometer will be used includes energies above 50 keV, a pure W metal (99.5% minimum) should be used instead of the Al–Cu alloy. This metal is stable, is generally available, and provides well-defined characteristic lines at 8.40 keV (L-lines) and 59.3 keV (K-lines).

**Table 3. WDXRF OQ Specifications**

| Test | Procedure | Acceptance Criteria |
|---|---|---|
| Peak angle | Perform according to the manufacturer's procedure. Repeat for each crystal. | The angle corresponding to the peak maximum should differ less than 0.10 degree 2θ of the angle measured at IQ. |
| Detector resolution | Full width half maximum at specified wavelengths and at the same measurement conditions at the time of IQ. Repeat for each detector available. | NMT 20% change |
| Count rate | Measure count rate from the specified monitor specimen at a specified wavelength at the same measurement conditions at the time of IQ. Repeat for each detector available. | <10% change from initial measurements at IQ |

Use Inconel 625 (Special Metals Corporation, New Hartford, NY) as a sample for WDXRF spectrometers. Other designations for this alloy are UNS N06625, DIN 2.4856, ASTM B443, ASME SB-443, and AMS 5599. This is a nickel-based alloy that includes chromium, molybdenum, and niobium as the most important alloying elements. A more complete compositional specification is given in *Table 4*.

**Table 4. Elemental Concentrations in Inconel 625**

| Element | Concentration Limits (in % by Weight) |
|---|---|
| Ni | 58.0 minimum |
| Cr | 20.0–23.0 |
| Fe | 5.0 maximum |
| Mo | 8.0–10.0 |
| Nb[a] | 3.15–4.15 |

[a] This could include Ta.

A polished piece of Inconel 625 should never require resurfacing when stored and used appropriately.

The radiation characteristics of nickel can be detected by all detectors that are used in sequential WDXRF, whether they are flow proportional, sealed gas, or scintillation detectors. In combination with Mo K (and L) radiation, the tests regarding peak position and detector response of WDXRF spectrometers can be completed readily. *Table 5* includes the typical wavelengths or energies that are used for XRF analysis.

**Table 5. Energies and Wavelengths[a] for Al, Ni, Cu, Mo, and W**

| | Al | Ni | Cu | Mo | W |
|---|---|---|---|---|---|
| $K\alpha_1$ Line transition | $K–L_{2,3}$ | $K–L_{2,3}$ | $K–L_{2,3}$ | $K–L_3$ | $K–L_3$ |
| $K\alpha_1$ Energy (eV) | 1487 | 7473 | 8041 | 17479 | 59310 |
| $K\alpha_1$ Wavelength (Å) | 8.340 | 1.659 | 1.542 | 0.709 | 0.209 |
| $L\alpha_1$ Line transition | N/A[b] | N/A | N/A | $L_3–M_5$ | $L_3–M_5$ |
| $L\alpha_1$ Energy (eV) | N/A | N/A | N/A | 2293.2 | 8398.2 |
| $L\alpha_1$ Wavelength (Å) | N/A | N/A | N/A | 5.4066 | 1.47632 |

[a] From: Deslattes RD, Kessler EG, Indelicato P, et al. X-ray transition energies: new approach to a comprehensive evaluation. *Rev Mod Phys*. 2003;75(1):35–99. For Al, Ni, and Cu, the $K\alpha_1$ and $K\alpha_2$ energies from *Table V* were averaged with 2:1 weighting. Wavelength conversion uses the *hc*/*E* value from page 94. Values for Mo and W are taken from *Table VI*.
[b] N/A = not applicable.

## Performance Qualification

The purpose of performance qualification (PQ) is to determine that the instrument is capable of meeting the user's requirements for all critical-to-quality measurements.

Depending on typical use, the specifications for PQ may be different from the manufacturer's specifications. Method-specific PQ tests, also known as system suitability tests, may be used in lieu of PQ requirements for validated methods.

Specific procedures, acceptance criteria, and time intervals for characterizing XRF performance depend on the instrument and its intended application. Demonstrating stable instrument performance over extended periods of time provides some assurance that reliable measurements can be obtained from sample spectra using previously validated XRF experiments.

# PROCEDURE

## General Recommendations

Analysts should check the suitability of all reagents and materials for contamination before using depending on the method used. The analysis of a ubiquitous element often requires the use of the purest grade of reagent or material available. Sample holders and support windows should be appropriate for the analysis and the instrument configuration. Analysts should evaluate the cleaning of equipment used to prepare samples for XRF analysis in order to avoid cross-contamination of samples.

### SAMPLES

**Liquids:** Liquid samples can be introduced directly to the XRF spectrometer provided that the solution consists of a single phase and has sufficiently low volatility. Analysis of liquid samples requires use of a special liquid sample holder and a commercially available support window composed of a suitable polymer film. Alternatively, liquid samples can be transferred onto the surface of a disk and dried before analysis. The experiment typically is conducted using a purge gas. The liquid sample can be spiked directly with solution standards at appropriate concentrations to facilitate accuracy, precision, and specificity tests as required for method validation.

**Powders:** Prepared powders may be measured directly in a liquid sample holder. Alternatively, they may be pressed into pellets. If the powder has poor self-binding properties, it may require a binder such as a wax or ethyl cellulose.

Powders also can be prepared for XRF analysis by fusing the sample material into a glass using a flux, typically sodium tetraborate, lithium tetraborate, and lithium metaborate. Because the temperatures required to melt the flux and dissolve the sample are relatively high (800°–1300°), this procedure is not suitable for the analysis of volatile elements such as mercury and arsenic.

Powder samples can be mixed with appropriate quantities of a certified reference material to facilitate accuracy, precision, and specificity tests as required for method validation. Alternatively, powder samples can be spiked with appropriate quantities of solution-based standards and then dried, ground if necessary, and thoroughly mixed before analysis. Standard additions can be used in instances when physical or chemical properties of the powder may introduce an analyte response bias.

## Standards

Appropriate reference materials that are traceable to the National Institute of Standards and Technology, or equivalent, can be used in the preparation of XRF standards.

## Analysis

For the instrumental parameters (if applicable) follow the procedure in the individual monograph. Because of differences in manufacturers' equipment configurations, analysts can use the manufacturer's suggested default conditions. At the time of use, the instrument must be standardized for the intended use. Analysts should use calibration standards to bracket the expected range of typical analyte concentrations. When they perform an analysis at or near the detection limit, analysts cannot always use a bracketing standard, which is an acceptable strategy for limit tests. Analysts should use regression analysis of the standard plot to evaluate the linearity of detector response, and individual monographs may set criteria for the residual error of the regression line.

To demonstrate the stability of the system's initial standardization, at appropriate intervals throughout their tests on the sample set analysts must re-assay the calibration standard used in the initial standard curve as a check standard. The use of an independently prepared standard also is acceptable. Unless otherwise indicated in the individual monograph, the re-assayed standard should agree with its expected value to within ±2% for *Assay* or ±20% for an impurity analysis.

Sample concentrations are calculated versus the working curve generated by plotting the instrument response versus the concentration of the analyte in the standard solutions.

# VALIDATION AND VERIFICATION

Current Good Manufacturing Practice regulations [21 CFR 211.194(a)(2)] indicate that users of analytical methods described in *USP–NF* are not required to validate the accuracy and reliability of these methods but rather must verify their suitability under actual conditions of use. In this context, and according to these regulations, validation is required when an XRF procedure is used to test a nonofficial article and when this procedure is used as an alternative to the official procedure for testing an official article (see *USP–NF General Notices, 6.30 Alternative and Harmonized Methods and Procedures*). On the other hand, verification must be performed the first time an official article is tested using a *USP* procedure (for informational purposes only, refer to *Verification of Compendial Procedures* ⟨1226⟩).

## Validation

The objective of an XRF method validation is to demonstrate that the measurement procedure is suitable for its intended purpose, including quantitative determination of the main component in a drug substance or a drug product (Category I assays), quantitative determination of impurities or limit tests (Category II), and identification tests (Category IV). Depending on the category of the test (see *Table 2* in *Validation of Compendial Procedures* ⟨1225⟩), the analytical method validation process for XRF requires the testing of linearity, range, accuracy, specificity, precision, quantitation limit, and robustness.

Official

https://pharmacopeia.cn/

Performance characteristics that demonstrate the suitability of an XRF method are similar to those required for any analytical procedure. A discussion of the applicable general principles is found in ⟨1225⟩. Specific acceptance criteria for each validation parameter must be consistent with the intended use of the method. The samples for validation should be independent of the calibration set.

## ACCURACY

For Category I assays or Category II tests, analysts can determine accuracy by conducting recovery studies using the appropriate matrix spiked with known concentrations of elements. An appropriate certified standard material provided by USP also can be used. It also is an acceptable practice to compare assay results obtained using the XRF method under validation to those from an established analytical method. When analysts use the method of standard additions, accuracy assessments are based on the final intercept concentration, not the recovery calculated from the individual standard additions.
**Acceptance Criteria:** 98.0%–102.0% recovery for drug substances and drug product assay, 70.0%–150.0% recovery for impurity analysis. These acceptance criteria should be met throughout the validated range.

## PRECISION

**Repeatability:** Analysts should assess the analytical method by measuring the concentrations of six separate standards at 100% of the assay test concentration. Alternatively, they can measure the concentrations of three replicates of three separate samples at different concentrations. The three concentrations should be close enough so that the repeatability is constant across the concentration range. In this case, the repeatability at the three concentrations is pooled for comparison to the acceptance criteria.

*Acceptance Criteria:* The relative standard deviation is NMT 1.0% for drug substance assay, NMT 2.0% for drug product assay, and NMT 20.0% for impurity analysis.
**Intermediate Precision:** Analysts should establish the effect of random events on the method's analytical precision. Typical variables include performing the analysis on different days, using different instrumentation, or having two or more analysts perform the method. As a minimum, any combination of at least two of these factors totaling six experiments will provide an estimation of intermediate precision.

*Acceptance Criteria:* The relative standard deviation is NMT 1.0% for drug substance assay, NMT 3.0% for drug product assay, and NMT 25.0% for impurity analysis.

## SPECIFICITY

The procedure must unequivocally assess each analyte element in the presence of components that may be expected to be present, including any matrix components.
**Acceptance Criteria:** Demonstrated by meeting the *Accuracy* requirement.

## QUANTITATION LIMIT

The limit of quantitation (LOQ) can be estimated by calculating the standard deviation of NLT 6 replicate measurements of a blank and multiplying by 10. Other suitable approaches may be used (see ⟨1225⟩). A measurement of a test sample prepared from a representative sample matrix and spiked so that the concentration is similar to the estimated LOQ concentration must be performed to confirm accuracy.
**Acceptance Criteria:** The analytical procedure should be capable of determining the analyte precisely and accurately at a level equivalent to 50% of the specification.

## LINEARITY

Analysts should demonstrate a linear relationship between the analyte concentration and corrected XRF response by preparing no fewer than five standards at concentrations that encompass the anticipated concentration of the test sample. The standard curve then should be evaluated using appropriate statistical methods such as a least squares regression. The correlation coefficient ($R$), $y$-intercept, and slope of the regression line must be determined.

For experiments that do not have a linear relationship between analyte concentration and XRF response, appropriate statistical methods must be applied to describe the analytical response.
**Acceptance Criteria:** $R$ is NLT 0.995 for Category I assays and NLT 0.99 for Category II quantitative tests.

## RANGE

The range is the interval between the upper and lower concentration (amounts) of analyte in the sample (including the upper and lower concentrations) for which it has been demonstrated that the analytical procedure has a suitable level of precision, accuracy, and linearity. Range is demonstrated by meeting the linearity and accuracy requirement.
**Acceptance Criteria:** For 100.0% centered acceptance criteria: 80.0%–120.0%. For non-centered acceptance criteria: 10% below the lower limit of the specification to 10% above the upper limit of the specification. For content uniformity: 70.0–130.0%. For Category II the range requirements are 50.0%–120.0% of the acceptance criteria.

## ROBUSTNESS

The reliability of an analytical measurement should be demonstrated by deliberate changes to experimental parameters. For XRF this can include measuring the stability of the analyte under specified storage conditions.

Official

https://pharmacopeia.cn/

**Acceptance Criteria:** The measurement of a standard or sample response following a change in experimental parameters should differ from the same standard measured using established parameters by NMT ±2.0% for a drug product assay and NMT ±20.0% for an impurity analysis.

## Verification

The objective of an XRF method verification is to demonstrate that the procedure as prescribed in a specific monograph is being executed with suitable accuracy, sensitivity, and precision. According to ⟨1226⟩, if the verification of the compendial procedure according to the monograph is not successful, the procedure may not be suitable for use with the article under test. It may be necessary to develop and validate an alternative procedure as allowed in *USP–NF General Notices, 6.30 Alternative and Harmonized Methods and Procedures*.

Although complete revalidation of a compendial XRF method is not required, verification of compendial XRF methods should at minimum include the execution of the validation parameters for specificity, accuracy, precision, and limit of quantitation, when appropriate, as indicated under *Validation* (above).

# ⟨736⟩ MASS SPECTROMETRY

## INTRODUCTION

Mass spectrometry (MS) is an analytical technique based on the measurement of the mass-to-charge ratio of ionic species related to the analyte under investigation. MS can be used to determine the molecular mass and elemental composition of an analyte as well as provide an in-depth structural elucidation of the analyte.

In addition to being recognized as a powerful structure-elucidation tool, MS is also extensively used for quantitative measurements. For additional information, see general information chapter *Applications of Mass Spectrometry* ⟨1736⟩, which provides a detailed discussion of MS.

Currently available MS instrumentation offers a wide range of capabilities for qualitative and quantitative analysis, which results in a wide range of potential MS experimental approaches for a given measurement need. Because of the diversity of approaches, this chapter does not present specific procedures but instead provides experimental and system suitability information for MS procedures.

## QUALITATIVE ANALYSIS

MS is a sensitive and highly specific technique for the identification of analytes. Identification or verification of structure (i.e., comparison against an authentic standard) by MS is particularly powerful when used in conjunction with a separation technique such as gas chromatography (GC) or high-performance liquid chromatography (HPLC). Additional degrees of specificity can be obtained by the use of tandem mass spectrometry (MS/MS) or high-resolution mass spectrometry (HRMS). Also, tighter tolerances on mass accuracy are also afforded using high-resolution mass spectrometry (HRMS).

### Experimental Parameters

The following MS experimental parameters should be defined for a qualitative (e.g., identification) procedure.

#### MASS RESOLUTION

Unit mass resolution is sufficient for most identification tests. When higher resolution is required, the resolution is specified in the procedure, and demonstration of adequate resolution is included in the system suitability tests for the procedure.

#### MASS ACCURACY

A mass accuracy or agreement of ±0.50 mass units for singly charged ions from a known standard should be sufficient for most applications. A mass accuracy or agreement of ±0.05% from a standard should be sufficient for the identification of large molecules (above 2000 m/z) when multiply charged ions are employed for the identification test.

When higher mass accuracy is required, the required mass accuracy is specified in the procedure. A demonstration of the mass accuracy then is included in the system suitability tests for the procedure or as part of the instrument's established performance qualification (PQ) procedure discussed later in this chapter.

#### MASS RANGE

The mass range to be scanned is also presented in the procedure. The mass range must encompass all ions used as part of the identification confirmation.

### System Suitability

The system suitability for the MS procedure should include demonstration of adequate performance for the following experimental attributes.

#### MASS RESOLUTION

A demonstration of the appropriate resolution is included in the system suitability tests for a procedure. The performance test in the instrument's established PQ, executed daily or prior to the time of use, may suffice. When resolutions greater than unit mass are required for a procedure, the system suitability test includes demonstration of adequate resolution along with acceptance criteria.

#### MASS ACCURACY

A demonstration of the mass accuracy is included in the system suitability tests for the procedure or is part of the instrument's established PQ procedure. A mass accuracy or agreement of ±0.50 mass units for singly charged ions from a known standard should be sufficient for most applications. If higher mass accuracy is required for a given procedure, the appropriate acceptance criteria are specified.

Official

https://pharmacopeia.com/

## Interpretation Directions

An identification or verification experiment involves comparison of the compound of interest to an authentic standard (e.g., a USP Reference Standard). For this form of identification or verification, the standard and the sample are run under identical conditions and should have results that are within acceptable experimental error for the procedure. Applications of MS for identification purposes in a compendial monograph may incorporate the mass spectral data alone or may combine this spectral identification with the chromatographic retention time if more specificity is dictated by the particular monograph identification needs.

The procedure should also provide specific instructions that define a successful mass spectral match. If the procedure represents the only spectroscopic identification test or if no other identification tests (e.g., peptide mapping or amino acid analysis) provide structural information, the spectrum of the standard should closely resemble that of the sample and a minimum of three structurally relevant ions, preferably one of which is an ion representing the molecular mass of the analyte, should be used for the comparison. In the case where only the ion representing the intact molecule is produced, the accurate mass or MS/MS spectrum of the molecular ion may be used to strengthen the identification. If other structurally relevant identification tests are also conducted, the comparison can be conducted with fewer ions as long as one of the ions represents the molecular mass of the analyte. For example, the MS identification test for a protein may examine only an ion that represents the molecular mass if several other tests are conducted to confirm the protein structure.

# QUANTITATIVE ANALYSIS

The sensitivity and specificity of MS also make it a suitable analytical tool for the quantification of analytes. Quantification is particularly powerful when used in conjunction with a separation technique such as GC or HPLC. Further degrees of specificity can be obtained by the use of MS/MS or HRMS.

## Experimental Parameters

The following experimental parameters should be defined within a quantitative (e.g., identification) MS procedure.

### MASS RESOLUTION

Unit mass resolution is sufficient for most quantitative tests. When higher resolution is required, the resolution is specified in the procedure, and demonstration of the mass accuracy is included in the system suitability tests for the procedure.

### MASS ACCURACY

The mass accuracies listed in the previous qualitative section should be sufficient for most quantitative applications. When higher mass accuracy is required, it is specified in the procedure. A demonstration of the mass accuracy is included in the system suitability tests for the procedure or as part of the instrument's established PQ procedure.

### MASS SELECTION

The masses to be monitored (e.g., mass range, individual masses, or MS/MS transitions) are presented in the procedure.

## System Suitability

The system suitability for the MS procedure should include demonstration of adequate performance for the following experimental attributes, as appropriate for the procedure.

### MASS RESOLUTION

A demonstration of the appropriate resolution is included in the system suitability tests for the procedure or is part of the instrument's established PQ procedure. When resolutions greater than unit mass are required for a procedure, the system suitability test includes demonstration of adequate resolution along with acceptance criteria.

### MASS ACCURACY

A demonstration of the mass accuracy is included in the system suitability tests for the procedure or is part of the instrument's established PQ procedure. A mass accuracy or agreement of ±0.50 mass units for singly charged ions from a known standard should be sufficient for most applications. If higher mass accuracy is required for a given procedure, the appropriate acceptance criteria are specified.

### PRECISION

The system suitability includes a demonstration of adequate precision. See *Table 1* for maximum limits for precision. Typically, system suitability limits are set to tighter limits than those employed to ensure adequate precision for the validation experiments. (See also the section on *Validation and Verification of Mass Spectrometry Analytical Procedures*.)

Official

https://pharmacopeia.com/

LINEARITY

The system suitability includes a demonstration of adequate linearity. See *Table 1* for appropriate linearity limits. (See also the section on *Validation and Verification of Mass Spectrometry Analytical Procedures*.)

ACCURACY

In certain situations, quality control (or check) samples may also be appropriate for inclusion in the procedure to ensure the quality of the measurement. Typically, these quality control samples are of known analyte concentration and are prepared identically to the test samples. If used, quality control (or check) samples are also prepared as a verification of time-of-application method accuracy. The procedure specifies the number or analysis order of quality control (or check) samples needed. Acceptance criteria for calibration and quality control (or check) sample results should be aligned with the validation requirements as required by the application type (i.e., Category I or II) as outlined in *Table 1*.

QUANTITATION LIMIT

In certain applications (e.g., limits tests), it may be necessary to include demonstration of the ability to detect the analyte at a prescribed level. For these applications, the procedure specifies the limit and success criteria (e.g., signal-to-noise ratio).

## QUALIFICATION OF MASS SPECTROMETRY INSTRUMENTS

Qualification of an MS instrument can be divided into three elements: installation qualification (IQ), operational qualification (OQ), and PQ. For additional information, see *Analytical Instrument Qualification* ⟨1058⟩, which may be a helpful, but not mandatory resource.

### Installation Qualification

IQ provides evidence that the hardware and software are installed to accommodate safe and effective use of the instrument at the desired location.

### Operational Qualification

In OQ, an instrument's performance is characterized using standards to verify that the system operates within target specifications. The purpose of OQ is to demonstrate that instrument performance is suitable for a given application. Because so many different approaches are available for measuring MS spectra, OQ using standards with known spectral properties is recommended. Because of the diversity of MS instrumentation, interfaces, and experimental approaches, MS instruments should be qualified against target specifications for the intended application, not simply the specifications supplied by the manufacturer.

### Performance Qualification

PQ helps to determine that the instrument is capable of meeting the user's requirements for all critical-to-quality measures. PQ documentation should describe the following:

- the definition of the specific performance criteria and detailed test procedures, including test samples and instrument parameters;
- the elements that will be measured to evaluate the criteria and the predefined specifications;
- the test interval, which may be daily or time-of-use measurements;
- the use of bracketing samples or groups of samples; and
- corrective actions that will be implemented if the spectrometer does not pass the specifications.

Periodic PQ should include a subset of the OQ tests to ensure that the instrument as supplied is performing at a level that produces data that are suitable for their intended use. Depending on typical use, the specifications for PQ may be higher or lower than the manufacturer's installation specifications. Method-specific PQ tests, also known as system suitability tests, may be used in lieu of PQ requirements for validated procedures.

Because of the diversity of MS instrumental configurations and experimental designs, a standard sample or experiment for all PQ assessments may not be available. Thus, method-specific PQ tests or system suitability tests often are needed. The PQ experimental design should be sufficiently robust to ensure proper instrument performance for the intended application, including the specifications associated with the measurement. At minimum, PQ experiments should include the following.

- For qualitative applications, the PQ experiment includes a check of the mass accuracy of the instrumentation. A mass accuracy or agreement of ±0.50 mass units for singly charged ions from a known standard should be sufficient for most applications.
- For quantitative applications, the PQ experiment includes checks of mass accuracy and precision. A mass accuracy or agreement of ±0.50 mass units for singly charged ions from a known standard should be sufficient for most applications. The success criteria for precision is established via consideration of the instrument and method capability, and provides sufficient controls relative to the specification for the measurement in question.

## Characterizing Instrument Performance

Specific procedures, acceptance criteria, and time intervals for characterizing MS spectrometer performance depend on the instrument and its intended applications. Many MS applications use previously validated experiments that relate MS spectra to a chemical property of interest. Analysts typically demonstrate stable instrument performance over extended periods of time. This practice provides some assurance that reliable measurements can be taken from sample spectra using previously validated MS experiments.

# VALIDATION AND VERIFICATION OF MASS SPECTROMETRY ANALYTICAL PROCEDURES

Validation is required only when an MS procedure is an alternative to the official procedure for testing an official article.

The objective of validating an MS procedure is to demonstrate that the measurement is suitable for its intended purpose, including quantitative determination of the main component in a drug substance or a drug product (Category I assays), quantitative determination of impurities (Category II), and identification tests (Category IV). [NOTE—For additional information on the different category definitions, see *Validation of Compendial Procedures* ⟨1225⟩.] Depending on the category of the test, analytical procedure validation requires the testing of linearity, range, accuracy, specificity, precision, quantitation limit, and robustness. These analytical performance characteristics apply to externally standardized methods and to the method of standard additions.

Chapter ⟨1225⟩ provides definitions and general guidance about analytical procedures validation without indicating specific validation criteria for each characteristic. The intention of the following sections is to provide the user with specific validation criteria that represent the minimum expectations for this technology. For each particular application, tighter criteria may be needed in order to demonstrate suitability for the intended use.

## Measurement Categories for Mass Spectrometry Analytical Procedures

The required validation performance characteristics of an MS analytical procedure, assuming the typical Category I USP specifications of 98.0%–102.0% for drug substances and 95.0%–105.0% for drug products, are listed in *Table 1*. The actual validation performance characteristics would be dependent upon the specifications in place and should provide sufficient evidence that the measurement capability is sufficient for those specifications. A procedure validation protocol must specify the required validation experiments and validation criteria. These criteria are determined according to the intended purpose of the analytical procedure.

**Table 1. Analytical Measurement Requirements**

| Analytical Performance Characteristics | Category I | Category II Quantitative |
|---|---|---|
| Specificity | Ensured by use of a reference standard when possible and demonstrable lack of interference from other components | |
| Linearity | Correlation coefficient *(R)* NLT 0.995 | Correlation coefficient *(R)* NLT 0.99 |
| Range | For 100.0% centered acceptance criteria: 80.0%–120.0%. For noncentered acceptance criteria: 10.0% below the lower limit to 10.0% above the upper limit. For content uniformity: 70.0%–130.0% | 50%–120% |
| Accuracy | 98.0%–102.0% (drug substance) 95.0%–105.0% (drug product) | 80.0%–120.0% |
| Repeatability | NMT 1.0% (drug substance) NMT 2.0% (drug product) | NMT 20.0% |
| Intermediate precision | NMT 1.0% (drug substance) NMT 3.0% (drug product) | NMT 25.0% |
| Quantitation limit | — | The analytical procedure should be capable of determining the analyte precisely and accurately at a level equivalent to 50% of the specification. |
| Robustness | The reliability of an analytical measurement should be demonstrated by deliberate changes to experimental parameters. | |

## Analytical Procedure Validation

The objective of analytical procedure validation is to demonstrate that the analytical procedure is suitable for its intended purpose by conducting experiments and obtaining results that meet predefined acceptance criteria. MS analytical procedures can include quantitative tests for major component and impurities content, limit tests for the presence of impurities, quantification of a component in a product or formulation, or identification tests.

VALIDATION PARAMETERS

Performance characteristics that demonstrate the suitability of an analytical procedure are similar to those required for any analytical procedure. For additional information on the applicable general principles, see ⟨1225⟩. Specific acceptance criteria for each validation parameter must be consistent with the intended use of the analytical procedure.

The performance characteristics that are required as part of a validation for each of the analytical procedure categories are given in *Table 1*.

**Specificity:** The purpose of a specificity test is to demonstrate that measurements of the intended analyte signals are free of interference from components and impurities in the test material. Specificity tests can be conducted to compare spectra of components and impurities that are known from synthetic processes, formulations, and test preparations. Specificity is also to be demonstrated for any materials added as part of the procedure (e.g., specificity versus isotope-labeled internal standards).

For an identification MS analytical procedure (Category I and II), validation experiments may include multidimensional MS experiments to validate correct assignments of an ion's structure or origin.

**Linearity:** A linear relationship is exhibited between the analyte concentration and instrument response. This is demonstrated by measuring analyte responses from NLT five standard solutions at concentrations that encompass the anticipated concentration range of analyte(s) in the test solution. For Category I, standard solutions can be prepared from reference materials in appropriate solvents. For Category II (MS analytical procedures that are used to quantitate impurities), linearity samples are prepared by spiking suitable test samples that contain low amounts of analyte or by spiking matrix samples at concentrations of the expected range. The standard curve then is constructed using appropriate statistical analytical procedures such as a least-squares regression. The correlation coefficient ($R$), $y$-intercept, slope of the regression line, and residual root mean square are then determined. Absolute values determined for these factors are appropriate for the procedure being validated.

**Range:** The range between the low and high concentrations of analyte is given by the quantitative MS analytical procedure. This typically is based on test article specifications in the *USP* monograph. It is the range within which the analytical procedure can demonstrate an acceptable degree of linearity, accuracy, and precision and can be obtained from an evaluation of that analytical procedure.

Recommended ranges for various MS analytical procedures are as follows.

- For Category I—assay of a drug substance (or a finished product): 80%–120% of the test concentration;
- For Category I—content uniformity: a minimum of 70%–130% of the test concentration;
- For Category II—determination of an impurity: 50%–120% of the acceptance criteria.

**Accuracy:** The accuracy of a quantitative MS analytical procedure is determined across the required analytical range. Typically, three levels of concentrations are evaluated using triplicate preparations at each level.

*Preparation of accuracy samples:* For drug substance assays (Category I), accuracy is determined by analyzing a reference standard of known purity. For drug product assays (Category I), a composite sample of reference standard and other components in a pharmaceutical finished product should be used for analytical procedure validation. The assay results are compared to the theoretical value of the reference standard to estimate errors or percent recovery. For the quantitation of impurities (Category II), the accuracy of the analytical procedure can be determined by conducting studies with drug substances or products spiked with known concentrations of the analyte under test.

Assay results from the analytical procedure being validated may be compared to those of an established alternative analytical procedure.

**Precision:**

*Repeatability:* The analytical procedure is assessed by measuring the concentrations of three replicates of separate standard solutions at three different concentrations that encompass the analytical range. Alternatively, the concentrations of six separate standard solutions at 100% of the test concentration can be measured. The relative standard deviation from the replicate measurements is then evaluated to determine if the solutions meet the acceptance criteria.

*Intermediate precision:* The effect of random events on the analytical precision of the analytical procedure is to be established. Typical variables include performing the analysis on different days, using different instruments that are suitable as specified in the analytical procedure, or having the analytical procedure performed by two or more analysts.

**Quantitation limit:** The quantitation limit is validated by measuring six replicates of test samples spiked with analyte at 50% of specification.

From these replicates, analysts are then able to determine accuracy and precision. Examples of specifications for Category II quantitative determinations are that the measured concentration is within 70%–130% of the spike concentration and the relative standard deviation is NMT 15%.

**Robustness:** The reliability of an analytical measurement is demonstrated with deliberate changes to critical experimental parameters. These can include measuring the stability of the analyte under specified storage, chromatographic, or ionization conditions.

## Analytical Procedure Verification

U.S. Current Good Manufacturing Practices regulations [21 CFR 211.194(a)(2)] indicate that users of analytical procedures described in *USP–NF* do not need to validate procedures that are provided in a monograph. Instead, they must simply verify the suitability of the procedures under actual conditions of use.

The objective of an MS procedure verification is to demonstrate that the procedure as prescribed in a specific monograph can be executed by the user with suitable accuracy, specificity, and precision using the instruments, analysts, and sample matrices available. According to the general information chapter *Verification of Compendial Procedures* ⟨1226⟩, if the verification of the compendial procedure by following the monograph is not successful, the procedure may not be suitable for use with the article under test. It may be necessary to develop and validate an alternative procedure as allowed in *General Notices, 6.30 Alternative and Harmonized Methods and Procedures*.

Official

https://pharmacopeia.cn/

Verification of a compendial MS procedure includes at minimum the execution of the validation parameters for specificity, accuracy, precision, and limit of quantitation, when appropriate, as indicated in the *Validation and Verification of Mass Spectrometry Analytical Procedures* section in this chapter.

# ⟨741⟩ MELTING RANGE OR TEMPERATURE

The terms melting range, melting point, or melting temperature are all used in pharmacopeial contexts. Most substances exhibit a melting transition, spanning the temperatures at which the first detectable change of phase or liquid phase is detected to the temperature at which no solid phase is apparent. The transition may appear instantaneous for a highly pure material, but usually a range is observed from the beginning to the end of the process. Factors influencing this transition include the sample size, the particle size, the efficiency of heat diffusion within the sample, and the heating rate, among other variables, that are controlled by procedure instructions.

For pharmacopeial purposes, the temperatures of the beginning (onset temperature) and end of transition (clear temperature) represent the melting range, except as defined otherwise for *Procedure for Class II* and *Procedure for Class III* below. The terms melting point and melting temperature are considered to be equivalent.

Substances which melt with no decomposition or chemical change are known to melt congruently. In these cases, the melting point is taken to be the end of the melting range, i.e., the temperature at which no solid phase is apparent. In some articles, the melting process is accompanied by simultaneous decomposition, which is visually evidenced as a side event like darkening of the material, charring, bubbling, or other incident. These transitions are known to be non-congruent. The visual impact of this side reaction frequently obscures the end of the melting process, which may be impossible to accurately determine. In those circumstances, only the beginning of the melting can be accurately established, and it is to be reported as the melting point.

Since there may be a thermal lag between the heating medium and the sample within the capillary tube, in order to achieve consistency and repeatability, it is important to perform the melting determination at a heating rate, also referred to as ramp rate, of 1°/min.

The accuracy of the apparatus to be used as described below should be checked at suitable intervals by the use of one or more of the available USP Melting Point Standards, preferably those that melt nearest the melting temperatures of the compounds being tested (see *USP Reference Standards* ⟨11⟩). The USP Melting Point Standards are intended to check the accuracy of the device and may be suitable to calibrate.

Eight procedures for the determination of melting range or temperature are given herein, varying in accordance with the nature of the substance. When no class is designated in the monograph, use the *Procedure for Class Ia* for crystalline or amorphous substances and the *Procedure for Class II* for waxy substances.

The procedure known as the mixed-melting point determination, whereby the melting range or temperature of a solid under test is compared with that of an intimate mixture of equal parts of the solid and an authentic specimen of it, e.g., the corresponding USP Reference Standard, if available, may be used as a confirmatory identification test. Agreement of the observations on the original and the mixture constitutes reliable evidence of chemical identity.

Official

## APPARATUS

Apparatus with cameras or other computerized equipment to improve accuracy, sensitivity, or precision may be used provided that the apparatus is properly qualified.

### Apparatus I

An example of a suitable melting range *Apparatus I* consists of a glass container for a bath of transparent fluid, a suitable stirring device, an accurate thermometer, and a controlled source of heat. The bath fluid is selected with a view to the temperature required, but light paraffin is used generally and certain liquid silicones are well adapted to the higher temperature ranges. The fluid is deep enough to permit immersion of the thermometer to its specified immersion depth so that the bulb is still about 2 cm above the bottom of the bath. The heat may be supplied by an open flame or electrically. The capillary tube is about 10 cm long and 0.8–1.2 mm in internal diameter with walls 0.2–0.3 mm in thickness.

### Apparatus II

An instrument may be used in the *Procedure for Class I*, *Procedure for Class Ia*, and *Procedure for Class Ib*. An example of a suitable melting range *Apparatus II* consists of a block of metal that may be heated at a controlled rate, with its temperature being monitored by a sensor. The block accommodates the capillary tube containing the test substance and permits monitoring of the melting process, typically by means of a beam of light and a detector. The detector signal may be processed by a microcomputer to determine and display the melting point or range, or the detector signal may be plotted to allow visual estimation of the melting point or range. Some approaches broadly used by automated systems employ optical methods such as light absorption or bulk reflection.

## PROCEDURES

### Procedure for Class I, Apparatus I

Reduce the substance under test to a very fine powder, and, unless otherwise directed, render it anhydrous when it contains water of hydration by drying it at the temperature specified in the monograph, or, when the substance contains no water of hydration, dry it over a suitable desiccant for NLT 16 h (or at the conditions stated in *Loss on Drying* ⟨731⟩, if appropriate).

https://pharmacopeia.com/

Charge a capillary glass tube, one end of which is sealed, with a sufficient amount of the dry powder to form a column in the bottom of the tube to a nominal height of 3 mm high when packed down as closely as possible by moderate tapping on a solid surface. Due to the instrument design, alternative sample sizes may be used as instructed by the instrument manufacturer.

Heat the bath until the temperature is about 10° below the expected melting point. Remove the thermometer, and quickly attach the capillary tube to the thermometer by wetting both with a drop of the liquid of the bath or otherwise, and adjust its height so that the material in the capillary is level with the thermometer bulb. Replace the thermometer, and continue the heating, with constant stirring, sufficiently to achieve the ramp rate of about 3°/min. When the temperature is about 3° below the lower limit of the expected melting range, reduce the heating so that the ramp rate of about 1°/min is achieved. Continue heating until melting is complete.

The temperature at which the column of the substance under test is observed to collapse definitely against the side of the tube at any point indicates the beginning of melting, and the temperature at which the test substance becomes liquid throughout corresponds to the end of melting or the melting point. The two temperatures fall within the limits of the melting range. If melting occurs with decomposition, the melting temperature corresponding to the beginning of the melting (melting point) is within the range specified.

## Procedure for Class Ia, Apparatus I

Prepare the test substance and charge the capillary as directed in *Procedure for Class I*, *Apparatus I.* Heat the bath until the temperature is about 10° below the expected melting point and is rising at a rate of about 1°/min. Insert the capillary as directed in *Procedure for Class I*, *Apparatus I* when the temperature is about 5° below the lower limit of the expected melting range, and continue heating until melting is complete. Record the melting range as directed in *Procedure for Class I*, *Apparatus I*.

## Procedure for Class Ib, Apparatus I

Place the test substance in a closed container and cool to 10°, or lower, for at least 2 h. Without powdering, charge the cooled material into the capillary tube as directed in *Procedure for Class I*, *Apparatus I*, then immediately place the charged tube in a vacuum desiccator and dry at a pressure not exceeding 20 mm of mercury for 3 h. Immediately upon removal from the desiccator, fire-seal the open end of the tube, and as soon as practicable proceed with the determination of the melting range as follows. Heat the bath until the temperature is about 10° below the expected melting range, then introduce the charged tube, and heat at a rate of rise of about 1°/min until melting is complete. Record the melting range as directed in *Procedure for Class I*, *Apparatus I.*

If the particle size of the material is too large for the capillary, precool the test substance as directed above, then with as little pressure as possible gently crush the particles to fit the capillary, and immediately charge the tube.

## Procedure for Class I, Apparatus II

Prepare the substance under test and charge the capillary tube as directed in *Procedure for Class I, Apparatus I*. Operate the apparatus according to the manufacturer's instructions. Heat the block until the temperature is about 10° below the expected melting point. Insert the capillary tube into the heating block, and continue heating at a rate of temperature increase of about 1°/min until melting is complete.

The temperature at which the detector signal first leaves its initial value indicates the beginning of melting, and the temperature at which the detector signal reaches its final value corresponds to the end of melting, or the melting point. The two temperatures fall within the limits of the melting range. If melting occurs with decomposition, the melting temperature corresponding to the beginning of the melting (melting point) is within the range specified.

## Procedure for Class Ia, Apparatus II

Prepare the test substance and charge the capillary as directed in *Procedure for Class I*, *Apparatus I*. Operate the apparatus according to the manufacturer's instructions. Heat the block until the temperature is about 5° below the expected melting point and is rising at a rate of about 1°/min. Insert the capillary as directed in *Procedure for Class I*, *Apparatus I*, and continue heating until melting is complete. Record the melting range as directed in *Procedure for Class I*, *Apparatus I*. If melting occurs with decomposition, the melting temperature corresponding to the beginning of the melting (melting point) is within the range specified.

## Procedure for Class Ib, Apparatus II

Place the test substance in a closed container and cool to 10°, or lower, for at least 2 h. Without previous powdering, charge the cooled material into the capillary tube as directed in *Procedure for Class I*, *Apparatus I*, then immediately place the charged tube in a vacuum desiccator, and dry at a pressure not exceeding 20 mm of mercury for 3 h. Immediately upon removal from the desiccator, fire-seal the open end of the tube, and as soon as practicable proceed with the determination of the melting range as follows. Operate the apparatus according to the manufacturer's instructions. Heat the block until the temperature is about 10° below the expected melting range, then introduce the charged tube, and heat at a rate of rise of about 1°/min until melting is complete. Record the melting range as directed in *Procedure for Class I*, *Apparatus I*.

If the particle size of the material is too large for the capillary, precool the test substance as directed above, then with as little pressure as possible gently crush the particles to fit the capillary, and immediately charge the tube.

Official

https://pharmacopeia.com/

## Procedure for Class II

Carefully melt the material to be tested at as low a temperature as possible, and draw it into a capillary tube, which is left open at both ends, to a depth of about 10 mm. Cool the charged tube at 10°, or lower, for 24 h, or in contact with ice for at least 2 h. Then attach the tube to the thermometer by suitable means, adjust it in a water bath so that the upper edge of the material is 10 mm below the water level, and heat as directed in *Procedure for Class I*, *Apparatus I* except, within 5° of the expected melting temperature, to regulate the rate of rise of temperature of about 1.0°/min. The temperature at which the material is observed to rise in the capillary tube is the melting temperature.

## Procedure for Class III

While stirring, melt a quantity of the test substance slowly until it reaches a temperature of 90°–92°. Remove the source of the heat, and allow the molten substance to cool to a temperature of 8°–10° above the expected melting point. Chill the bulb of a suitable thermometer to 5°, wipe it dry, and while it is still cold dip it into the molten substance so that approximately the lower half of the bulb is submerged. Withdraw it immediately, and hold it vertically away from the heat until the wax surface dulls, then dip it for 5 min into a water bath having a temperature NMT 16°.

Fix the thermometer securely in a test tube so that the lower point is 15 mm above the bottom of the test tube. Suspend the test tube in a water bath adjusted to about 16°, and raise the temperature of the bath at the rate of about 2°/min to 30°, then change to a rate of about 1°/min, and note the temperature at which the first drop of melted substance leaves the thermometer. Repeat the determination twice on a freshly melted portion of the test substance. If the variation of three determinations is less than 1°, take the average of the three as the melting point. If the variation of three determinations is 1° or greater than 1°, make two additional determinations and take the average of the five.

# ⟨755⟩ MINIMUM FILL

***Change to read:***

## SCOPE

The following tests and ▲acceptance criteria▲ (USP 1-Dec-2020) apply to articles such as creams, gels, lotions, ointments, pastes, powders, aerosols, ▲foams,▲ (USP 1-Dec-2020) and sprays that are packaged in containers. To minimize the impact of entrained air for products labeled by volume, the fill determination is performed by mass from which the volume is calculated by use of the density of the preparation.

## PURPOSE

The test for minimum fill ensures that the amount of material filled into the product conforms to the labeled amount.

***Change to read:***

## PROCEDURE FOR DOSAGE FORMS OTHER THAN AEROSOLS,▲SPRAYS, AND FOAMS▲ (USP 1-DEC-2020)

### For Containers Labeled by Weight

Select a sample of 10 filled containers, and remove any labeling that might be altered in weight during the removal of the container contents. Thoroughly cleanse and dry the outside of the containers by a suitable means, and weigh individually. Quantitatively remove the contents from each container, cutting the latter open and washing with a suitable solvent, if necessary, taking care to retain the closure and other parts of each container that were present during the initial weighing. Dry and reweigh each empty container, together with its corresponding parts. Determine the net weight of the contents of the container by difference.

### For Containers Labeled by Volume

Proceed as indicated above for products labeled by weight, but convert the mass to volume using the density of the preparation. A suggested approach to determine the density of the materials is as follows:

1. Tare a 100-mL volumetric flask containing 50.0 mL of liquid that is miscible with the formulation.
2. Add approximately 25 mL of a representative sample of the product and gently swirl the contents to mix.
3. Reweigh the flask.
4. From a buret, add an accurately measured amount of the miscible liquid to bring the flask contents to volume while gently swirling the contents of the flask. Record the volume taken from the buret.
5. Calculate the density of the sample:

$$\text{Result} = W/V$$

$W$ = weight of the material taken (g)
$V$ = 50.0 minus the volume, in mL, of the miscible fluid necessary to adjust the contents of the flask to 100 mL

Other methods of determining the density may be employed depending on the formulation (e.g., substantially nonaqueous formulations). Similarly, if the container contents are less than 25 mL, smaller graduated vessels may be used, with the quantities of miscible liquid adjusted accordingly.

Alternatively, pour the contents of 10 containers into 10 suitable graduated cylinders, and allow to drain completely. Record the volume of the contents of each of the 10 containers.

### Acceptance Criteria

This test meets the acceptance criteria either at *Stage 1* or *Stage 2*:

Stage 1:

1. The average net content of the 10 containers is NLT the labeled amount, and the net content of any single container is NLT 90% of the labeled amount where the labeled amount is 60 g or 60 mL or less, or NLT 95% of the labeled amount where the labeled amount is more than 60 g or 60 mL. If these criteria are not met, and the net content of NMT 1 container is less than 90% of the labeled amount where the labeled amount is 60 g or 60 mL or less, or ▲less than▲ (USP 1-Dec-2020) 95% of the labeled amount where the labeled amount is more than 60 g or 60 mL, proceed to *Stage 2*.

Stage 2:

1. Determine the content of 20 additional containers.

Official

https://pharmacopeia.cn/v29240/

2. The average content of the 30 containers is NLT the labeled amount, and the net content of NMT 1 of the 30 containers is less than 90% of the labeled amount where the labeled amount is 60 g or 60 mL or less, or less than 95% of the labeled amount where the labeled amount is more than 60 g or 60 mL.

***Change to read:***

## PROCEDURE FOR AEROSOLS, SPRAYS, AND ▲FOAMS▲ (USP 1-DEC-2020)

Select a sample of 10 filled containers, and remove any labeling that might be altered in weight during the removal of the container contents. Thoroughly cleanse and dry the ▲outside▲ (USP 1-Dec-2020) of the containers by suitable means, and weigh individually. Remove the contents from each container by employing any safe technique (e.g., chill to reduce the internal pressure, remove the valve, and pour). Remove any residual contents with suitable solvents, then rinse with a few portions of methanol. Retain as a unit the container, the valve, and all associated parts, and heat them at 100° for 5 min. Cool, and again weigh each of the containers together with its corresponding parts. The difference between the original weight and the weight of the empty aerosol container is the net fill weight. Determine the net fill weight for each container tested.

### Acceptance Criteria

The requirements are met if the net weight of the contents of each of the 10 containers is NLT the labeled amount.

Official

# ⟨761⟩ NUCLEAR MAGNETIC RESONANCE SPECTROSCOPY

## INTRODUCTION

Nuclear magnetic resonance (NMR) spectroscopy is an analytical method based on the magnetic properties of certain atomic nuclei. As is the case with other types of spectroscopy, absorption or emission of electromagnetic energy at characteristic frequencies provides structural information. NMR differs from other types of spectroscopy because the discrete energy levels between which the transitions take place are present only when the nuclei are placed in a magnetic field.

Although widely recognized as one of the most powerful structure-elucidation tools available, with proper experimental design, it can also be used for accurate qualitative and quantitative measurements. See general information chapter *Applications of Nuclear Magnetic Resonance Spectroscopy* ⟨1761⟩. [NOTE—Above 1000 chapters are for informational purposes only.]

## QUALIFICATION OF NMR INSTRUMENTS

Qualification of an NMR instrument can be divided into three elements: Installation Qualification (IQ), Operational Qualification (OQ), and Performance Qualification (PQ). For further discussion, see general information chapter *Analytical Instrument Qualification* ⟨1058⟩.

### Installation Qualification

The IQ requirements provide evidence that the hardware and software are installed to accommodate safe and effective use of the instrument at the desired location.

### Operational Qualification

In OQ, an instrument's performance is characterized using standards to verify that the system operates within target specifications. The purpose of OQ is to demonstrate that instrument performance is suitable for a given application. Because so many different approaches are available for measuring NMR spectra, OQ using standards with known spectral properties is recommended. Generally, sealed NMR tubes are available as reference standards for measuring signal-to-noise (S/N) and lineshape.

### Performance Qualification

PQ helps to determine that the instrument is capable of meeting the user's requirements for all critical-to-quality (CTQ) measures. PQ documentation should describe the following:

1. The definition of the specific performance criteria and detailed test procedures including test samples and instrument parameters.
2. The elements that will be measured to evaluate the criteria and the predefined specifications.
3. The test interval, which may be time-of-use.
4. The use of bracketing samples or groups of samples.
5. The defined corrective actions that will be implemented if the spectrometer does not pass the specifications.

Periodic PQ should include a subset of the OQ tests to ensure that those aspects of the instrument that are being supplied are performing at a level that produces data that are suitable for its intended use. Depending on typical use, the specifications for PQ may be higher or lower than the manufacturer's installation specifications. Typical CTQs include S/N ratio and resolution tests for all nuclei of interest. Method-specific PQ tests, also known as system suitability tests, may be used in lieu of PQ requirements for validated procedures.

The PQ samples and tests in the following subsections are typical examples only. Other tests and samples may be used to establish specifications for specific purposes. Instrument vendors often provide samples and test parameters that can be used as part of the PQ package.

RESOLUTION AND LINESHAPE MEASUREMENT—$^{1}$H NMR (see *Figure 1*)

**Sample:** 1% chloroform in acetone-$d_6$ (≥ 500 MHz), 3% chloroform in acetone-$d_6$, degassed and sealed
**Spectral width:** < 1 KHz
**Data acquisition time:** NLT 10 s
**Tip angle:** 90°
**Relaxation time:** 60 s
**Spinning rate:** Static or 20 Hz
**Pulse sequence:** Delay-pulse-acquire with no decoupling
**Processing:** No line broadening, zero-filling to 128 k

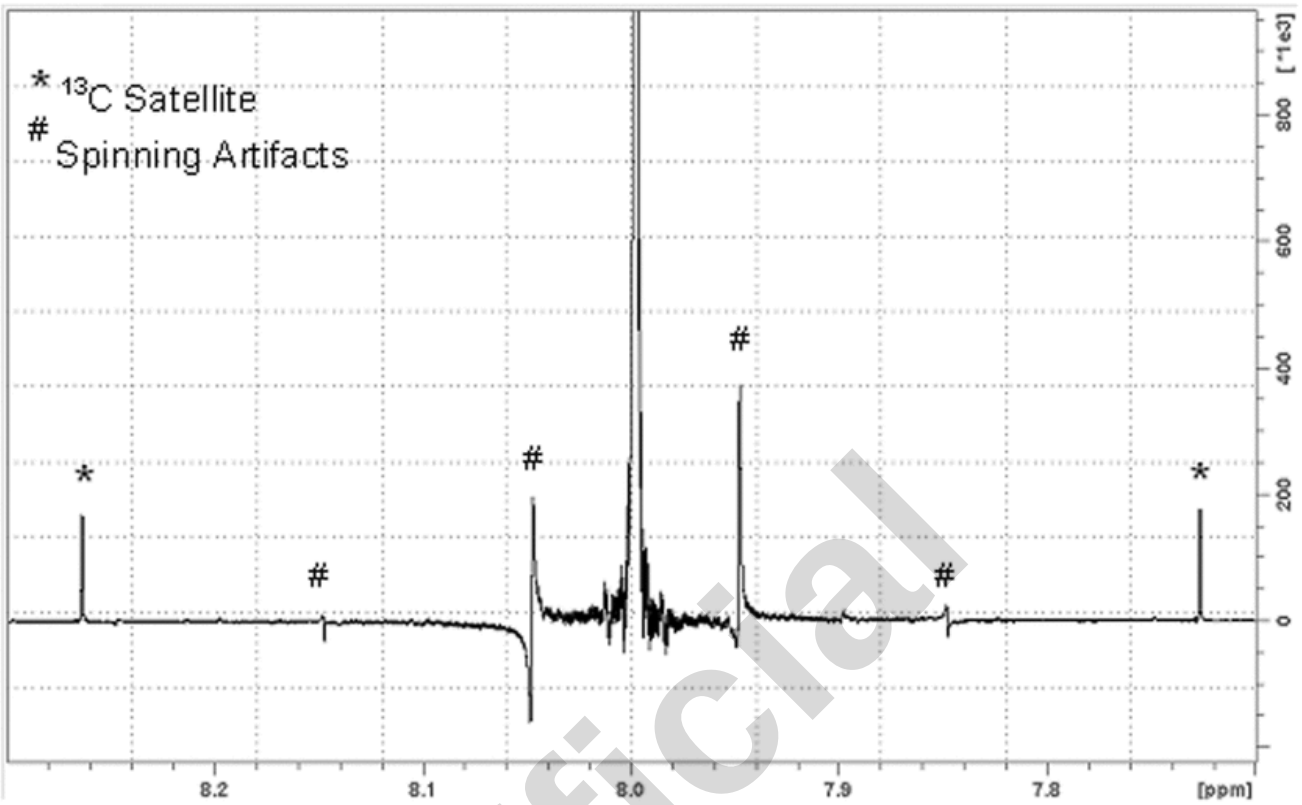

Figure 1. $^{1}$H NMR spectrum of chloroform in acetone-$d_6$ obtained at 400 MHz. The linewidth measured at 0.55% and 0.11% of the $^{13}$C satellites was 2.7 and 5.5 Hz, respectively.

Shim the magnet with special attention to the off-axis shims, acquire a single acquisition, phase to pure absorption, and measure the linewidth at 50%, 0.55%, and 0.11% maximum intensity. The linewidth should pass specifications at these positions, and, in addition, the lineshape should be Lorentzian. On modern NMR spectrometers, the lineshape is frequently obtained on a nonspinning sample because the off-axis shims can be set so well that there is essentially no difference between spectra obtained spinning and nonspinning. In addition, two-dimensional spectra should be obtained on a static sample.

S/N MEASUREMENTS—$^{1}$H NMR (see *Figure 2*)

**Sample:** 0.1% ethylbenzene in chloroform-d, 1% ethylbenzene in chloroform-d (< 200 MHz) degassed and sealed
**Spectral width:** 10 ppm
**Data acquisition time:** 400 ms
**Tip angle:** 90°
**Relaxation delay:** 60 s
**Spinning rate:** 0 or approximately 20 Hz
**Pulse sequence:** Delay-pulse-acquire with no decoupling
**Processing:** Exponential with 1-Hz line broadening
**Referencing:** Tetramethylsilane (TMS) = 0.0 ppm or the center of the quartet = 2.65 ppm

DOI: https://doi.org/10.31003/USPNF_M99550_04_01

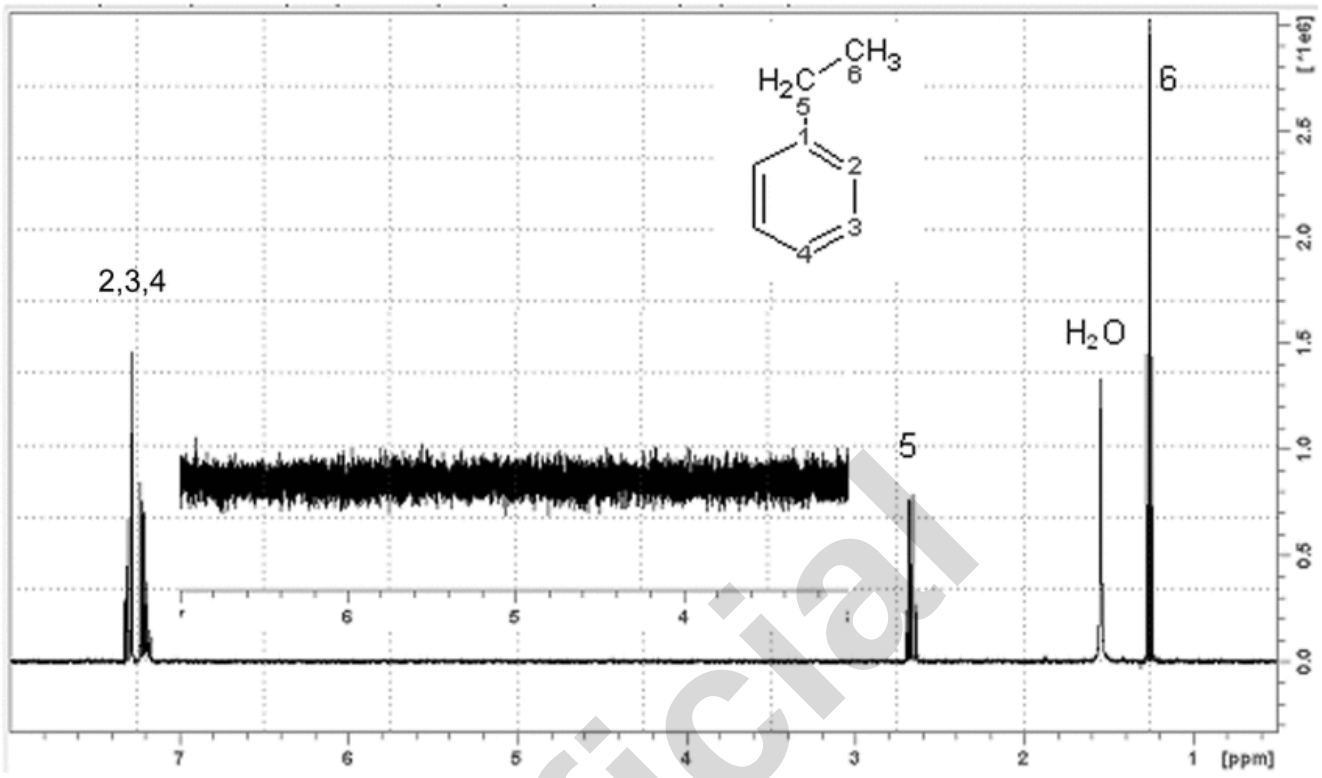

Figure 2. $^{1}$H NMR spectrum of 0.1% ethylbenzene obtained at 400 MHz with an S/N ratio of 550:1.

The concentration of ethylbenzene should be chosen to achieve S/N ratio specifications in the range of 20–1000. Concentrations that typically result in measurements outside that range are of limited utility in assessing the performance of the instrument. Nevertheless, established standard solutions are conventionally used. The magnet should be shimmed as well as possible. Ideally, this test should be run immediately after the lineshape test because most of the shims will be nearly maximized. Acquire a single acquisition, phase the spectrum in pure absorption mode, and measure the S/N of the ethylbenzene quartet. This experiment can be run with or without sample spinning. With a spinning sample, the S/N value that is measured should be only about 10% higher than that obtained with a nonspinning sample if the off-axis shims are well adjusted. A higher ratio would indicate that the determination would benefit from further shimming with the off-axis shims.

Most modern spectrometers have software that perform the S/N measurement after the operator has identified the signal and noise regions. Manual calculations can also be made. Measure the amplitude (*A*) from the center of the baseline to the peak of the highest of the central two lines in the quartet. Measure the peak-to-peak noise height (*H*) from the lowest noise peak to the highest noise peak in the 3–5 ppm region. The noise may be vertically multiplied by a factor for accurate measurement of high S/N spectra. Calculate the S/N as follows:

$$S/N = k \times 2.5 \times A/H \quad [1]$$

where *k* is the vertical expansion factor of the noise region used. The factor of 2.5 converts the peak-to-peak S/N to root-mean-squared (rms) noise, which is the standard convention for reporting S/N in NMR spectroscopy. Computerized S/N calculations can be used provided the specifications are set and tested by the same procedure. At the discretion of the spectroscopist, an S/N value lower than that specified by the manufacturer may be used if it is judged to be sufficient for the current application.

### S/N MEASUREMENTS $^{13}$C NMR (see *Figure 3*)

**Sample:** 40% *p*-dioxane in benzene-$d_6$ (v/v) (degassed and sealed)
**Spectral width:** Approximately 200 ppm
**Tip angle:** 90°
**Relaxation delay:** 300 s
**Spinning rate:** Approximately 20 Hz
**Pulse sequence:** Delay-pulse-acquire with no decoupling
**Processing:** Exponential with 3.5-Hz line broadening, zero-filling to 32k
**Referencing:** TMS = 0.0 ppm or the center of the benzene triplet = 128.4 ppm

DOI: https://doi.org/10.31003/USPNF_M99550_04_01

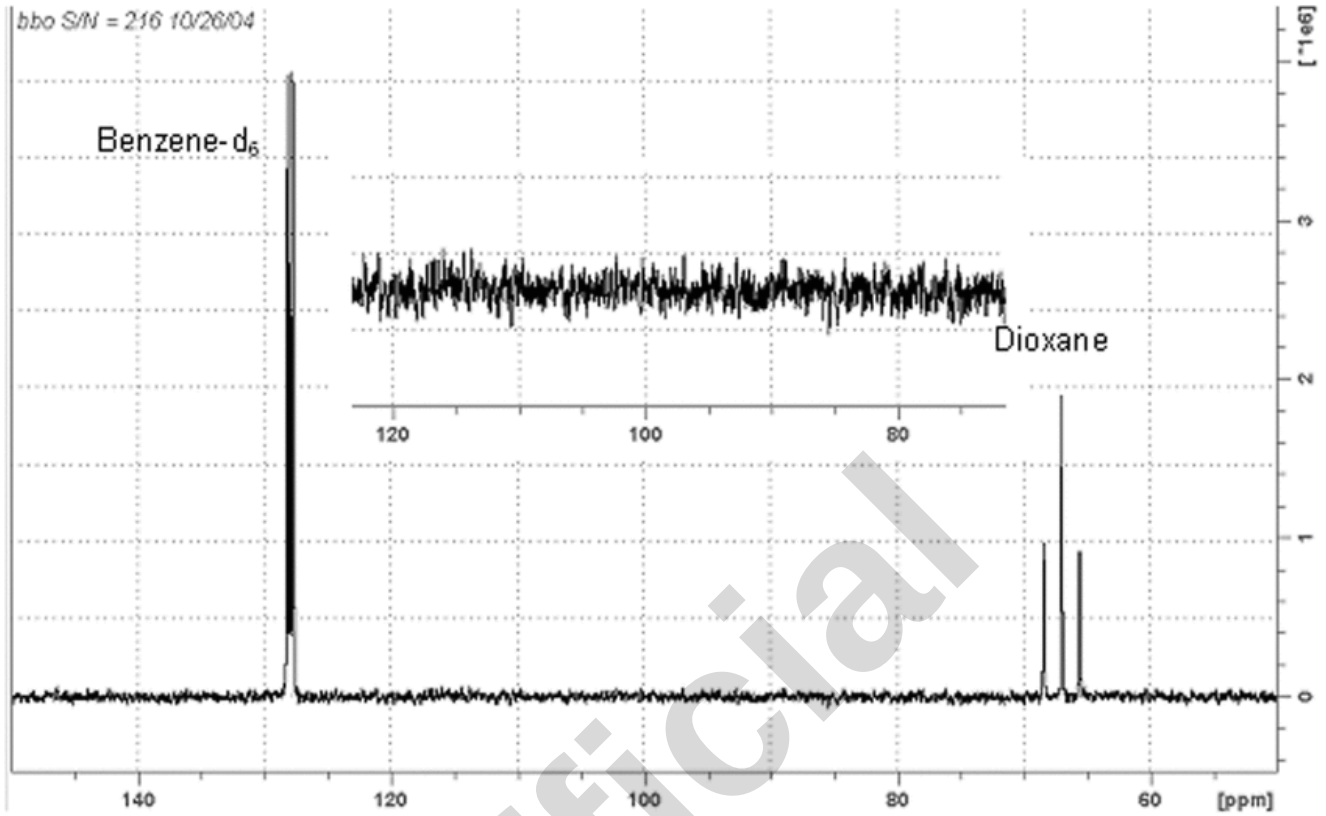

Figure 3. $^{13}C$ NMR spectrum of the ASTM standard 40% *p*-dioxane in benzene-$d_6$ (v/v) obtained at 100.6 MHz, with an S/N ratio of 140:1.

With a well-shimmed magnet, acquire a single acquisition following a minimum delay of 300 s, phase the spectrum in pure absorption mode, and measure the height of the benzene triplet at approximately 128.4 ppm from the center of the baseline. The peak-to-peak noise can be measured as above with appropriate vertical expansion of 80–120 ppm. S/N calculations can be made as in *Equation 1* or by computer calculation.

The benzene-$d_6$ triplet has no nuclear Overhauser enhancement (NOE). Consequently, this test verifies the performance of only the $^{13}C$ channel.

## PERFORMANCE OF BOTH OF THE $^{13}C$ AND $^{1}H$ CHANNELS (see *Figure 4*)

**Sample:** up to 10% ethylbenzene in chloroform-d (degassed and sealed)
**Spectral width:** 200 ppm
**Data acquisition length:** 64k points
**Tip angle:** 90°
**Relaxation delay:** 300 s
**Spinning rate:** Approximately 20 Hz
**Pulse sequence:** Delay-pulse-acquire with composite pulse decoupling set to the center of the $^{1}H$ spectrum
**Processing:** Exponential with 0.3-Hz line-broadening
**Referencing:** TMS = 0.0 ppm or the center of the chloroform-d, triplet = 77.23 ppm

@2024 USPC
DOI: https://doi.org/10.31003/USPNF_M99550_04_01

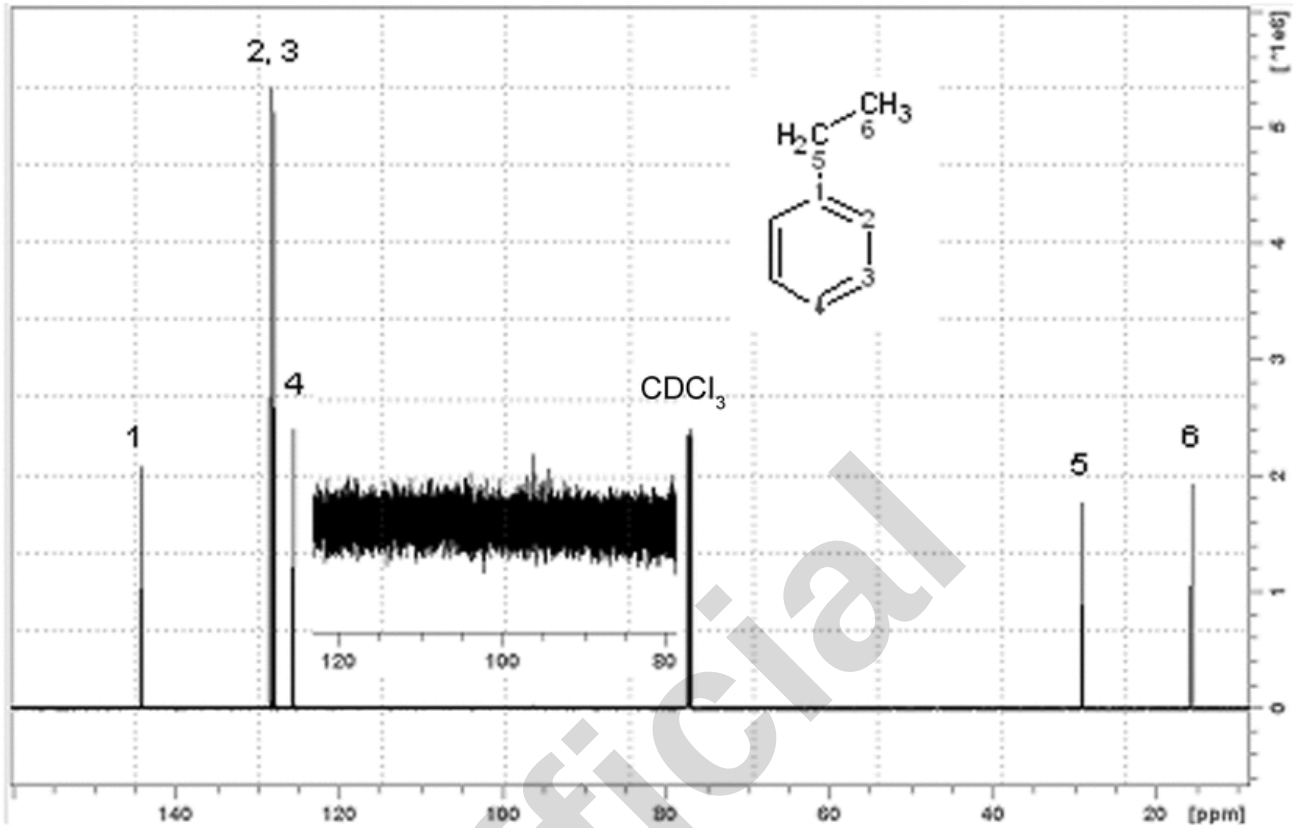

Figure 4. $^{13}C$ NMR spectrum of 10% ethylbenzene obtained using a cryogenically cooled dual $^{1}H/^{13}C$ probe at 150.9 MHz, with an S/N ratio of 640:1.

The shimming should be sufficient to pass the resolution and lineshape tests described above. The measurement of S/N is done from the peak height of the larger resonance of the two near 128 ppm. The noise is measured as above in the region of 80–120 ppm, with appropriate vertical expansion. S/N is calculated by the computer or as in *Equation 1*.

RELAXOMETRY MEASUREMENTS—LOW FIELD-NMR (LF-NMR)

The PQ should be performed before the collection of experimental data.

Dissolve an accurately weighed quantity of manganese (II) chloride tetrahydrate (MW 197.91) in water, and quantitatively dilute with water to obtain check solutions that have known concentrations of 0.9, 2.7, and 4.5 mM.

Place a portion of each of the solutions into sample holders suitable for the configuration of the specific model of the LF-NMR spectrometer. Warm to 40° for NLT 10 min, and measure the spin-lattice relaxation time ($T_1$) of water. The average $T_1$ for replicate measurements must be within 5% of 156, 52, and 32 ms for the 0.9, 2.7, and 4.5 mM solutions, respectively.

## Characterizing Instrument Performance

Specific procedures, acceptance criteria, and time intervals for characterizing NMR spectrometer performance depend on the instrument and its intended application. Many NMR applications use previously validated experiments that relate NMR spectra to a physical or chemical property of interest. Stable instrument performance over extended periods of time should be demonstrated. This practice provides some assurance that reliable measurements can be taken from sample spectra using previously validated NMR experiments.

# QUALITATIVE AND QUANTITATIVE NMR ANALYSIS

NMR spectroscopy has been used for a wide range of applications such as structure elucidation; thermodynamic, kinetic, and mechanistic studies; and quantitative analysis. Some of these applications are beyond the scope of compendial methods.

All characteristics of the signal—chemical shift, multiplicity, linewidth, coupling constants, relative intensity, and relaxation time—contribute analytical information.

## Qualitative Applications

Comparison of a spectrum from the literature or from an authentic standard with that of a test sample may be used to confirm the identity of a compound and to detect the presence of impurities that generate extraneous signals. The NMR spectra of simple structures can be adequately described by the value of the chemical shifts and coupling constants, and by the relative number of nuclei represented by the integral of each signal. (The software of modern instruments have available programs that generate simulated spectra using these data.) Experimental details, such as the solvent used, and the chemical shift reference, must also be provided.

For unknown samples, NMR analysis, usually coupled with other analytical techniques, is a powerful tool for structure elucidation. Chemical shifts provide information on the chemical environment of the nuclei. Extensive literature is available with correlation charts and rules for predicting chemical shifts. The multiplicity of the signals provides important structural information. The magnitude of the scalar coupling constant, *J*, between residual protons on substituted aromatic, olefinic, or cycloalkyl structures is used to identify the relative position of the substituents. Routine $^{13}C$ spectra are obtained under proton decoupling conditions that remove all heteronuclear $^{13}C$-$^{1}H$ couplings. As a result of this decoupling, the carbon signals appear as singlets, unless other nuclei that are not decoupled are present (e.g., $^{19}F$, $^{31}P$).

*Chemical exchange* is an example of the effect of intermolecular and intramolecular rate processes on NMR spectra. If a proton can experience different environments by virtue of such a process (tautomerism, rotation about a bond, exchange equilibria, ring inversion, etc.), the appearance of the spectrum will be a function of the rate of the process. Slow processes (on an NMR time scale) result in more than one signal from the interconverting species; fast processes average these signals to one line; and intermediate processes produce broad signals, which sometimes cannot be easily found in the spectra.

The software of modern FT-NMR spectrometers allows for sequences of pulses much more complex than the repetitive accumulation of transients described above. Such experiments include homonuclear or heteronuclear *multidimensional analysis*, which determines the correlation of couplings and may simplify the interpretation of otherwise complex spectra.

See chapter ⟨1761⟩ for detailed descriptions of common two-dimensional experiments.

## Quantitative Applications

I. General considerations of quantitative NMR: see ⟨1761⟩.

II. The scope of this section is limited to quantitation by one-dimensional NMR. Although any of the NMR active nuclei can be used to obtain quantitative data, the discussion here will be limited to $^{1}H$. There are two kinds of quantitation by NMR: relative and absolute.

1. **Relative quantitation** involves measurement of relative amounts of species in a sample based on integration of peaks due to each of the components measured. The integrals are normalized by factor *N*, that is, the integral is divided by the number of equivalent nuclei represented by that peak to give the relative molar concentration of each component.
2. **Absolute quantitation** is the direct measurement of the actual amount of analyte independent of other components contained in that sample. There are two basic methods for absolute quantitation based on the kind of reference standard that is used to calibrate the NMR signal.
    A. **Internal reference standard**
        I. **Definition:** The reference standard is co-dissolved in the analyte test solution.
        II. **Procedure**

**Typical NMR solution preparation:** An NMR solution is prepared with exact weights of both the analyte and reference standard. The largest source of error in this quantitative NMR method is from weighing, so the use of larger weights is recommended to minimize this error. This quantitative method is based on a comparison of the reference standard and analyte NMR peaks and their respective concentrations. Since the analyte and reference standard are in the same solution, the analyte and reference standard are contained in the same volume, and only their masses are compared. Therefore, the exact volume is not required. Typically, at least three replicates are prepared.

**Data acquisition:** Data is acquired under quantitative conditions, see ⟨1761⟩. For example, the pulse repetition time should be at least 5 times the longest $T_1$ when a 90° pulse is used.

**Data processing:** Process the data, using zero-filling if necessary, such that a sufficient number of points define a peak. For example, experience has shown that at least 16 points gives a good quantitative representation of a peak.

**Analysis:** Integrate appropriate peaks. For example, avoid using peaks that are overlapped, or due to hydrogens capable of exchanging. The determination of the amount of analyte derives from the basic proportionality between the peak intensity and the concentration of the solute.

$$\frac{[A]_{1H}}{I_A/N_A} = \frac{[RS]_{1H}}{I_{RS}/N_{RS}} \qquad [2]$$

where *I* = integral; *N* = normalization factor; and $[\,]_{^1H} = {}^1H$ relative molar concentration, and the subscripts *A* and *RS* represent the analyte and reference standard, respectively. The mass of the analyte is thus calculated according to the following equation.

DOI Ref: 94huv
DocId: GUID-B980A615-B451-42FF-AC40-4CB8B64163E3_4_en-US
DOI: https://doi.org/10.31003/USPNF_M99550_04_01
@2024 USPC

$$M_A = \frac{I_A}{I_{RS}} \times \frac{N_{RS}}{N_A} \times \frac{MM_A}{MM_{RS}} \times M_{RS} \times P \qquad [3]$$

where $M_A$ = mass of the analyte, $MM$ = molar mass, and $P$ = purity of the reference standard.

III. A common application of absolute quantitation is the determination of the purity of a sample. The weight % purity is given by

$$weight\,\%\,purity = \frac{M_A}{M_S} \times 100\,\% \qquad [4]$$

where $M_S$ is the total mass of the sample with contributions from the analyte plus any contaminants that may be present in the sample such as water and salts. Combining *Equations 3* and *4*, the weight % purity is given by

$$weight\,\%\,purity = \frac{I_A}{I_{RS}} \times \frac{N_{RS}}{N_A} \times \frac{MM_A}{MM_{RS}} \times \frac{M_{RS}}{M_S} \times P \times 100 \qquad [5]$$

B. **External reference standard**

I. **Definition:** The classical external reference standard method consists of solutions of a reference standard and analyte that are each in separate NMR tubes. One variation of an external reference standard is the standard test solution contained in a coaxial tube and is inserted into an analyte test solution contained in an NMR tube. Another variation is the introduction of a computer-generated signal into the spectrum of a reference standard solution of known concentration to calibrate the signal's response (intensity per $^1$H molar concentration, in the case of $^1$H NMR), followed by insertion of that calibrated computer-generated signal into the spectrum of an analyte test solution. This section will address the use of an external reference in the classical sense.

II. **Procedure**

**NMR solution preparation:** NMR solutions of known concentrations of each of the analyte and reference standard are prepared using exact weights and volumes. Again, the use of larger weights is recommended to minimize the weighing error. Typically replicates of the analyte solutions and reference standard solutions are prepared. The analyte and reference must be prepared in the same solvent to minimize probe tuning differences.

**Data acquisition and processing:** Same as in II.B.1.b, internal reference standard. Apply the same acquisition and processing parameters to the analyte and reference standard spectra.

**Analysis:** Integrate appropriate peaks in the spectra of the analyte and reference standard. The amount of analyte is calculated according to the following equation:

$$M_A = \frac{I_A}{I_{RS}} \times \frac{N_{RS}}{N_A} \times \frac{V_A}{V_{RS}} \times \frac{MM_A}{MM_{RS}} \times M_{RS} \times P \qquad [6]$$

where $V$ = volume.

Application to weight % purity: Weight % purity values may be similarly calculated as in *Equation 5*.

3. The internal and external reference standard methods each have their own set of advantages and disadvantages.

A. **Chemical interactions:** Preparation of the reference standard and the test material in separate solutions avoids chemical interactions between the test sample and reference standard that may otherwise occur with an internal reference standard.

B. **Spectral overlap:** The use of an external reference standard also avoids potential overlap between peaks of the reference standard and test sample that can occur with an internal standard.

C. **Calibration:** Once an NMR response has been calibrated with external reference standard solutions, this calibration may be applied to any other sample in the same solvent given that i) the instrument has been demonstrated to be stable over the time between when the calibration is done and when data is acquired on the test material, ii) system suitability has been established on the day that the measurement on the test material is made, and iii) absolute integrals are compared. In the case of internal reference standards, the measurement on the reference standard and test sample is made under absolutely identical conditions.

D. **Accuracy and precision:** Multiple external reference standard solutions may be prepared to average the errors in the mass and volume measurements during sample preparation, thereby improving the accuracy of the calibrated NMR response. In the case of internal reference standards, single measurements of the reference standard and analyte are made for each replicate test solution. The combined errors from the mass measurements of the reference standard and test sample as well as instrumental electronic variations determine the standard deviation of the average $M_A$ or weight % purity values.

# VALIDATION AND VERIFICATION OF NMR ANALYTICAL PROCEDURES

If an NMR procedure is provided in a monograph, verification of suitability (see ⟨1226⟩) under actual conditions of use is required. Validation is required only when an NMR method is an alternative to the official procedure for testing an official article. The objective of validation of a procedure relying on the NMR method is to demonstrate that the measurement is suitable for its intended purpose, including the following: quantitative determination of the main component in a drug substance or a drug product (Category I assays), quantitative determination of impurities (Category II), and identification tests (Category IV). [NOTE—For a definition of the different categories, see *Validation of Compendial Procedures* ⟨1225⟩.] Depending on the category of the test, analytical procedure validation requires the testing of specificity, linearity, range, accuracy, precision, quantitation limit, and robustness. These analytical performance characteristics apply to externally standardized methods and to the method of standard additions.

Chapter ⟨1225⟩ provides definitions and general guidance on analytical procedures validation without indicating specific validation criteria for each characteristic. The intention of the following sections is to provide the user with specific validation criteria that represent the minimum expectations for this technology. For each particular application, tighter criteria may be needed in order to demonstrate suitability for the intended use.

## Analytical Procedure Validation

The objective of an analytical procedure validation is to demonstrate that the analytical procedure is suitable for its intended purpose by conducting experiments and obtaining results that meet predefined acceptance criteria. NMR analytical procedures can include the following: quantitative tests for major component and impurities content, limit tests for the presence of impurities, quantification of component in a product or formulation, and/or identification tests.

Performance characteristics that demonstrate the suitability of an analytical procedure are similar to those required for any analytical procedure. A discussion of the applicable general principles is found in chapter ⟨1225⟩. Specific acceptance criteria for each validation parameter must be consistent with the intended use of the analytical procedure.

The performance characteristics that are required as part of a validation for each of the analytical procedure categories is given below.

### SPECIFICITY

The purpose of a specificity test is to demonstrate that measurements of the intended analyte signals are free of interference from components and impurities in the test material. Specificity may be applied to all categories and is a requirement for Category IV. Specificity tests can be conducted to compare NMR spectra of other components and impurities that are known from synthetic processes and formulations and test preparations. For an identification NMR analytical procedure (Category IV), validation experiments may include multidimensional NMR experiments to validate correct assignments of chemical shifts and to confirm the structure of the analyte.

**Validation criteria:** Specificity is ensured by use of a reference standard wherever possible and demonstrable lack of interference from other components.

### LINEARITY

A linear relationship is exhibited between the analyte concentration and instrument response; this should be demonstrated by measuring responses of analyte from NLT five standard solutions at concentrations encompassing the anticipated concentration range of analyte(s) of the test solution. For Category I, standard solutions can be prepared from reference materials in an appropriate NMR solvent. For Category II, NMR analytical procedures that are used to quantitate impurities, linearity samples can be prepared by spiking suitable test samples that contain low amounts of analyte or by spiking matrix samples at concentrations of the expected range. The standard curve should then be constructed using appropriate statistical analytical procedures such as a least squares regression. The correlation coefficient ($R$), $y$-intercept, and slope of the regression line should be determined. Absolute values determined for these factors should be appropriate for the procedure being validated.

**Validation criteria:** The correlation coefficient ($R$) must be NLT 0.995 for Category I assays and NLT 0.99 for Category II quantitative tests.

### RANGE

The range between the low and high concentrations of analyte is given by the quantitative NMR analytical procedure. This is normally based on test article specifications in the *USP* monograph. It is the range within which the analytical procedure can demonstrate an acceptable degree of linearity, accuracy, and precision, and may be obtained from an evaluation of that analytical procedure. Recommended ranges for various NMR analytical procedures are given below.

**Validation criteria:** For Category I tests, the validation range for 100.0% centered acceptance criteria is 80.0%–120.0%. For noncentered acceptance criteria, the validation range is 10.0% below the lower limit to 10.0% above the upper limit. For content uniformity, it is 70.0%–130.0%. For Category II quantitative tests, the validation range covers 50.0%–120.0% of the acceptance criteria.

### ACCURACY

The accuracy of a quantitative NMR analytical procedure should be determined across the required analytical range. Typically, three levels of concentrations are evaluated using triplicate preparations at each level.

DOI: https://doi.org/10.31003/USPNF_M99550_04_01
@2024 USPC

For drug substance assays (Category I), accuracy can be determined by analyzing a reference standard of known purity. For drug product (Category I), a composite sample of reference standard and other components in a pharmaceutical finished product should be used for analytical procedure validation. The assay results are compared to the theoretical value of the reference standard to estimate errors or percent recovery. For the quantitation of impurities (Category II), the accuracy of the analytical procedure can be determined by conducting studies with drug substances or products spiked with known concentrations of the analyte under test. It is also acceptable to compare assay results from the analytical procedure being validated to those of an established, alternative analytical procedure.
**Validation criteria:** 98.0%–102.0% recovery for drug substances, 95.0%–105.0% recovery for compounded pharmaceutical finished products assay, and 80.0%–120.0% recovery for the quantitative impurity analysis. These criteria should be met throughout the intended range.

PRECISION

**Repeatability:** The analytical procedure should be assessed by measuring the concentrations of six separate standard solutions at 100% of the test concentration. The relative standard deviation from the replicate measurements should be evaluated to meet acceptance criteria. Alternatively they can measure the concentrations of three replicates of three separate sample solutions at different concentrations. The three concentrations should be close enough so that the repeatability is constant across the concentration range. If this is done, the repeatability at the three concentrations is pooled for comparison to the acceptance criteria.

*Validation criteria:* The relative standard deviation is NMT 1.0% for drug substances, NMT 2.0% for compounded pharmaceutical finished products, and NMT 20.0% for the quantitative impurity analysis.

*Intermediate precision:* The effect of random events on the analytical precision of the analytical procedure should be established. Typical variables include performing the analysis on different days, using different instrumentation that are suitable as specified in the analytical procedure, and/or having the analytical procedure performed by two or more analysts. As a minimum, any combination of at least two of these factors totaling six experiments will provide an estimation of intermediate precision.

*Validation criteria:* The relative standard deviation is NMT 1.0% for drug substances, NMT 3.0% for compounded pharmaceutical finished products, and NMT 25.0% for quantitative impurity analysis.

QUANTITATION LIMIT (QL)

The QL can be validated by measuring six replicates of test samples spiked with analyte at 50% of specification.

From these replicates, accuracy and precision can be determined. Examples of specifications for Category II quantitative determinations are that the measured concentration is within 70.0%–130.0% of the spike concentration and the relative standard deviation is NMT 15%.

ROBUSTNESS

The reliability of an analytical measurement should be demonstrated with deliberate changes to critical experimental parameters. This can include measuring the stability of the analyte under specified storage conditions, slightly varied inter-pulse delay, probe temperature, and possible interfering species, to list a few examples. Robustness is required for Category I and Category II, quantitative methods.

## Analytical Procedure Verification

U.S. Current Good Manufacturing Practices regulations [21 CFR 211.194(a)(2)] indicate that users of analytical procedures described in *USP–NF* do not need to validate these procedures if provided in a monograph. Instead, they must simply verify their suitability under actual conditions of use.

The objective of an NMR procedure verification is to demonstrate that the procedure as prescribed in a specific monograph can be executed by the user with suitable accuracy, specificity, and precision using the instruments, analysts, and sample matrices available. According to general information chapter *Verification of Compendial Procedures* ⟨1226⟩, if the verification of the compendial procedure by following the monograph is not successful, the procedure may not be suitable for use with the article under test. It may be necessary to develop and validate an alternative procedure as allowed in *General Notices, 6.30 Alternative and Harmonized Methods and Procedures*.

Verification of a compendial NMR procedure should at minimum include the execution of the validation parameters for specificity, accuracy, precision, and limit of quantitation, when appropriate, as indicated in this section.

## GLOSSARY

**Internal standard:** An internal standard (IS) is a substance added to a sample solution at a known concentration. One should select an IS with at least a single NMR resonance that does not overlap with those of the analyte. The ratio of a specific internal standard peak area and that of an analyte peak area is used to determine the concentration of the analyte. The number of nuclei corresponding to the integrated peaks in the IS and analyte spectra must be known.

**NMR reference:** An NMR reference, also known as an NMR shift reference, is a substance added to a sample and from which the chemical shift for the δ scale is established. Common examples for proton and carbon NMR analyses are tetramethylsilane (TMS) for use in organic solvents and the sodium salt of 2,2-dimethyl-2-silapentane-5-sulfonic acid (DSS) or sodium-3-trimethylsilylpropionate (TMSP) for use in aqueous media. In both cases, the chemical shift of the methyl peaks is defined as 0.0 ppm.

**Reference standard:** A reference standard is a substance authenticated by appropriate experimental means to be of a specific chemical structure. In NMR spectroscopy, a reference standard is typically used for the qualitative analysis of a test

Official

https://pharmacopeia.cn/v-pharm/

material. Structure can be confirmed if one directly compares the chemical shifts and multiplicities of the peaks in the NMR spectrum of the test material against the spectrum of the reference standard acquired under comparable experimental conditions.

# ⟨771⟩ OPHTHALMIC PRODUCTS—QUALITY TESTS

***Change to read:***

## INTRODUCTION

Ophthalmic products are sterile products that are intended for application to any ocular structure, including any space adjacent to an ocular structure and its immediate surrounding spaces.

The routes of administration of ophthalmic products fall into three general categories: topical, intraocular injections, and extraocular injections. Topical drug products are intended to be administered to an ocular surface component, such as the eyelid, conjunctiva, or cornea, and can produce local or systemic effects. Intraocular and extraocular injections are administered through external boundary tissue. ▲Due to the potential sensitivity of some ocular tissues, injections have additional requirements for subvisible particulate matter content (see *Particulate and Foreign Matter*, *Subvisible Particulate Matter in Ophthalmic Solutions* ⟨789⟩, and *Visible Particulates in Injections* ⟨790⟩).▲ (USP 1-Dec-2022) The ophthalmic routes of administration include, but are not limited to: topical, subconjunctival, sub-Tenons, subretinal, subchoroidal, intracorneal, intrascleral, suprachoroidal, intravitreal, intracameral, juxtascleral, and retrobulbar routes (see *Figure 1*). Ophthalmic products are administered to the eye in a wide variety of dosage forms, including but not restricted to: solutions, suspensions, ointments, gels, emulsions, strips, injections, inserts, and implants.

▲

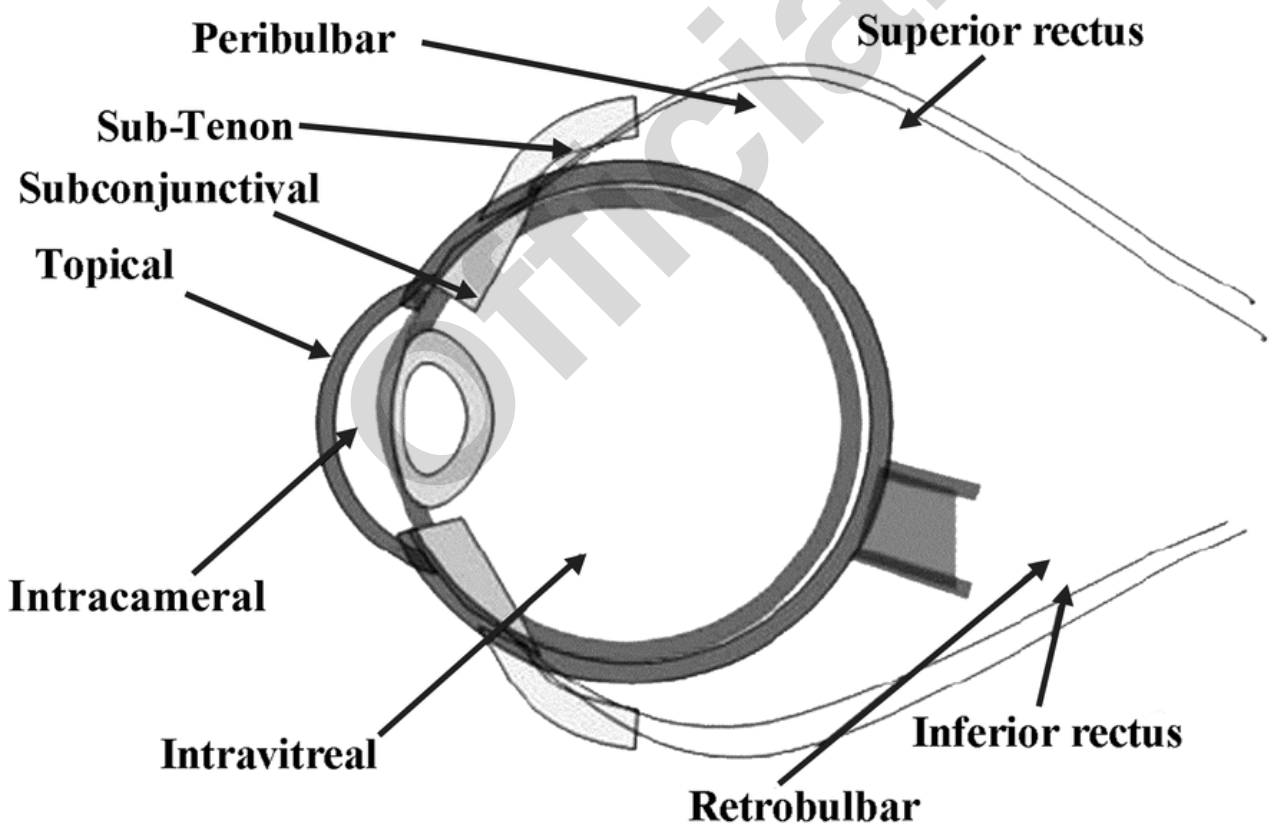

Figure 1. Examples of ocular routes of administration.

▲ (USP 1-Dec-2022)

This chapter provides lists of consolidated common product quality test requirements in a concise and coherent fashion. This chapter applies, in part or in its entirety, when referenced in a drug product monograph (see *General Notices, 3.10 Applicability of Standards*). This chapter includes the quality tests for the specific route of administration. The quality tests listed can be used, as appropriate, by manufacturers toward the development of new drug product monographs for submission to the *USP–NF*.▲▲ (USP 1-Dec-2022)

***Change to read:***

# OPHTHALMIC DOSAGE FORMS

This chapter discusses the specific characteristics of dosage forms that are administered to any structure in the eye. See *Pharmaceutical Dosage Forms* ⟨1151⟩ for additional information pertaining to the description and manufacturing of pharmaceutical dosage forms.

Ophthalmic products have the same or similar requirements as injectables and implants. For more information on the requirements for these dosage forms, see *Injections and Implanted Drug Products* ⟨1⟩.

▲Degradation and/or morphological changes of the drug product can occur during the sterilization step of the manufacturing process depending on the formulation, container-closure system, and sterilization process. These changes should be minimized.▲ (USP 1-Dec-2022) Temperatures required for autoclaving can cause irreversible damage to certain dosage forms such as suspensions, semisolids, emulsions, and others, whereas filtration is applicable only to formulations containing particulates with particle sizes <0.2 µm. An alternative ▲approach▲ (USP 1-Dec-2022) is to manufacture the ▲drug▲ (USP 1-Dec-2022) product from sterile ingredients ▲maintained within▲ (USP 1-Dec-2022) an aseptic environment.

▲Multi-dose products shall contain a suitable antimicrobial preservative, and the effectiveness of the preservative over the shelf life of the product must be verified. Alternatively, preservative-free multi-dose products require a packaging system that has been demonstrated to maintain sterility over the shelf-life of the product.▲ (USP 1-Dec-2022)

## Solutions

[NOTE—Included in this section are ▲solutions and▲ (USP 1-Dec-2022) those solid products that, when reconstituted according to the ▲instructions in the labeling,▲ (USP 1-Dec-2022) result in a solution.]

The corneal contact time of topical ophthalmic solutions increases with the viscosity of the formulations. Several synthetic polymers, including but not limited to polyvinyl alcohol, polyvinylpyrrolidone, polyethylene glycol, poly(acrylic acid), and ▲▲ (USP 1-Dec-2022) cellulose derivatives such as hypromellose and hydroxyethyl cellulose, are commonly used as viscosity enhancers because of their physiologic compatibility and ▲desirable▲ (USP 1-Dec-2022) physicochemical properties.

Another approach to increase the corneal contact time involves the use of polymers that provide the liquid formulation with semisolid consistency only when ▲the liquid formulation▲ (USP 1-Dec-2022) is placed in the conjunctival or corneal area. In this way, ▲▲ (USP 1-Dec-2022) instillation of the solution is followed by prolonged permanence as a result of the viscoelastic properties of the formed hydrogel. "Hydrogel", or "water-based gels", are three-dimensional networks of polymer chains containing water within the network. ▲The structure of the polymer network can be physically crosslinked (e.g., via ionic or hydrogen bonds) or chemically crosslinked (via a covalent bond).▲ (USP 1-Dec-2022) The water content of hydrogels can be adjusted by modulating the composition and conformation of polymers, such as the hydrophilic/hydrophobic balance of polymer chains and pendant groups, and the degree of cross-linking. The in-situ gelling phenomenon is caused ▲upon delivery to the eye▲ (USP 1-Dec-2022) by a change in the conformation of the polymer(s) that can be triggered by external stimuli such as temperature, pH, ionic content, and lacrimal fluid. ▲▲ (USP 1-Dec-2022) Additionally, some polymers can interact, via noncovalent bonds, with conjunctival mucin and maintain the formulation in contact with corneal tissues.

Solutions can be injected not only by the intravitreal route but also by other routes, such as subconjunctival, sub-Tenons, retrobulbar, suprachoroidal, and subretinal routes.

## Suspensions

[NOTE—Included in this section are ▲suspensions and▲ (USP 1-Dec-2022) those solid products that, when reconstituted according to the ▲instructions in the labeling,▲ (USP 1-Dec-2022) result in a suspension.]

Use of aqueous or oily suspensions may be considered for a number of reasons such as the following: 1) ▲a drug is▲ (USP 1-Dec-2022) poorly ▲▲ (USP 1-Dec-2022) soluble ▲in water▲ (USP 1-Dec-2022), 2) ▲a drug has poor stability in water▲ (USP 1-Dec-2022), and 3) in cases where there is a need to increase contact time with the eye and to increase wetting of the eye. ▲A▲ (USP 1-Dec-2022) drug particle size ▲of <10 µm is desirable to reduce irritation.▲ (USP 1-Dec-2022)

After topical instillation, particles are expected to be retained in the cul-de-sac, and the drug slowly dissolves or is released from the polymeric structures by diffusion, dissolution, polymer degradation, or ion-exchange.

Suspensions can be injected not only by the intravitreal route but also through other routes, such as subconjunctival, sub-Tenons, retrobulbar, suprachoroidal, and subretinal.

## Ointments

Eye ointments are semisolid products usually intended for application to the conjunctiva, cornea, or eyelid. They have longer contact time when compared to many solutions. A suitable ophthalmic ointment base is nonirritating to the eye and permits diffusion of the drug substance throughout the secretions bathing the eye.

The majority of water-free, oleaginous eye ointment bases are composed of white petrolatum and liquid petrolatum (mineral oil), or the eye ointment base is a modification of the petrolatum-based formula. They are designed to melt at body temperature. Other types of lipophilic ointment bases can also be used. An anhydrous vehicle can be advantageous for moisture-sensitive drugs.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99560_05_01
@2024 USPC

## Gels

Semisolid ▲gel▲ (USP 1-Dec-2022) products are an alternative to traditional ointments and are based on the effect of increasing the viscosity to prolong the retention of the drug in the eye. Several types of gelling agents can be used, such as poly(acrylic acid) derivatives (e.g., carbomer) ▲or▲ (USP 1-Dec-2022) hypromellose.

## Emulsions

Topical ophthalmic emulsions are generally prepared by dissolving or dispersing the drug substance into an oil phase, adding suitable emulsifying and suspending agents, and ▲vigorously mixing these components with water▲ (USP 1-Dec-2022) to form a uniform oil-in-water emulsion. Each phase is typically sterilized before or during charging into the mixing vessel. High-shear homogenization may be used to reduce oil droplet size to submicron size, which may improve the physical stability of the oil micelles so that they do not coalesce. The resulting dosage form should contain small oil droplets, uniformly suspended.

Limited aqueous solubility of the drug substance(s) is the most common rationale for developing an ophthalmic emulsion. The drug substance(s) can be added to the phase in which it is soluble at the beginning of the manufacturing process, or the drug substance can be added after the emulsion is prepared by a suitable dispersion process.

The physical stability of the emulsion can be measured by light-scattering techniques that characterize oil-phase, globule-size distribution. Suitable surfactants may be added to improve emulsion stability.

## Strips

Ophthalmic strips can have different ophthalmic uses including, but not limited to, use as a diagnostic tool to visualize defects or aberrations in the corneal epithelium or to measure the amount of tear production. They are made of filter paper, and they can contain compounds such as fluorescein sodium. They are individually packed to preserve sterility until the moment of use.

## Injections

Although injections are considered a dosage form for nomenclature purposes, they are ▲referred to in this chapter by other dosage forms such as solution, suspension, emulsion, and other appropriate terminology based on physical form.▲ (USP 1-Dec-2022)

## Inserts

Ophthalmic inserts and ocular systems are solid dosage forms of appropriate size and shape that are placed in the conjunctival fornix, in the lacrimal punctum (*Figure 2*), or on the cornea. Inserts can usually be removed, if adverse effects develop, and ▲can▲ (USP 1-Dec-2022) provide extended release of the drug over a certain period of time. Inserts can be classified as ▲bioabsorbable▲ (USP 1-Dec-2022) (soluble) or ▲non-bioabsorbable▲ (USP 1-Dec-2022) (insoluble). Drug release from soluble inserts involves two steps: 1) fast release of a portion of the drug as the tear fluid penetrates into the system and 2) slow release as a gel layer is formed on the surface of the insert. Collagen shields made from porcine sclera collagen or bovine corium tissue—and devices obtained by molding, extrusion, or compression (minitablets) of gelling polymers—belong to this category of soluble inserts. ▲Bioabsorbable▲ (USP 1-Dec-2022) polymers (e.g., cross-linked gelatin derivatives and polyesters) can be used to prepare ▲bioabsorbable▲ (USP 1-Dec-2022) inserts; these matrices act as reservoirs or interact with the drug molecules through labile bonds.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99560_05_01
@2024 USPC

▲

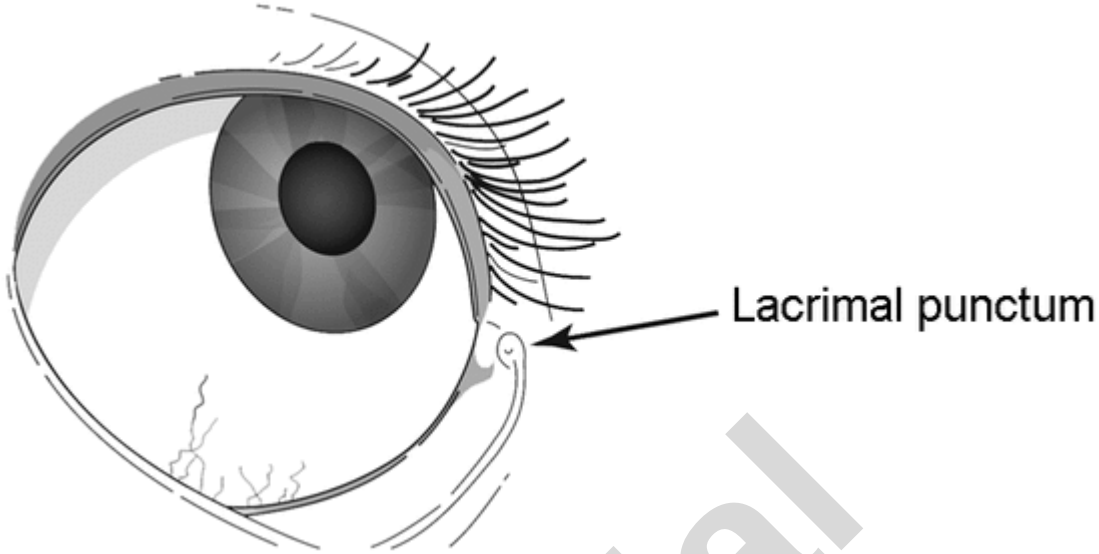

Figure 2. Lacrimal punctum.

▲ (USP 1-Dec-2022)

Soluble inserts can have the drug incorporated into ▲a bioabsorbable▲ (USP 1-Dec-2022) matrix, such as hydroxypropyl cellulose, hyaluronic acid, ▲or poly(acrylic acid) matrices.▲ (USP 1-Dec-2022) Soluble inserts may be placed in the lower cul-de-sac and generally dissolve within 12–24 h. ▲Bioabsorbable▲ (USP 1-Dec-2022) polymeric products undergo gradual dissolution while releasing the drug, and the patient does not have to remove the ▲bioabsorbable▲ (USP 1-Dec-2022) polymeric insert after use.

Insoluble inserts can have a reservoir or matrix structure. Their mechanism of action is based on diffusion of a fluid ▲from the eye▲ (USP 1-Dec-2022) into the device, ▲dissolution▲ (USP 1-Dec-2022) of the drug, and the creation of a saturated solution released to the medium by diffusion out of the insert. ▲▲ (USP 1-Dec-2022)Insoluble inserts need to be removed after a certain period of time.

## Implants

Implants are injected or implanted into the anterior segment (intracameral, subconjunctival, sub-Tenon, or other parts of the anterior segment) or intravitreal cavities, and the implants can be in different shapes, such as a disk or a thin rod. Implants can be made of ▲non-bioabsorbable▲ (USP 1-Dec-2022) or ▲bioabsorbable▲ (USP 1-Dec-2022) polymers.

Among the types of ▲non-bioabsorbable▲ (USP 1-Dec-2022) solid (polymer) implants are reservoir-type implants anchored to the sclera, in which the drug is released across a ▲non-bioabsorbable▲ (USP 1-Dec-2022), semipermeable polymer. The reservoir-type implants can be made of a variety of materials, including ▲poly(vinyl alcohol–ethylene vinyl acetate). Bioabsorbable▲ (USP 1-Dec-2022) polymers can be used to form injectable solid implants.

## Drug–Device Combination Products

An ophthalmic drug–device combination product is constituted, in most cases, of two components. One is a pharmaceutical dosage form containing the drug substance(s), and the other is a device that will activate or facilitate the penetration of the drug substance(s) from the dosage form into a particular region of the eye. Some examples of the devices are those that generate waveforms (heat or light). ▲Light sources can activate photoresponsive drugs.▲ (USP 1-Dec-2022)

This chapter is applicable only to the pharmaceutical dosage form component of the ophthalmic drug–device combination product. The appropriate FDA regulations regarding medical devices should be used for the device component.

***Change to read:***

# DRUG PRODUCT QUALITY

Procedures and acceptance criteria for testing ophthalmic products are divided into two categories: 1) those that assess general quality attributes, e.g., identification, potency, purity (and impurities), sterility, and particulate matter; and 2) those that assess in vitro product performance, ▲i.e.▲ (USP 1-Dec-2022), dissolution or drug release of the drug substance from the drug product. Quality tests assess the integrity of the dosage form, whereas the performance tests assess drug release and other attributes that relate to in vivo drug performance. Taken together, quality and performance tests ensure the identity, strength, quality, purity, and efficacy of the drug product. This chapter addresses the quality tests for ophthalmic products. The performance tests (dissolution/drug release) are addressed by *Ophthalmic Products—Performance Tests* ⟨1771⟩.

https://pharmacopeia.cn/

# Universal Tests

In this chapter, the division of the product quality tests into universal and specific tests does not strictly follow the ICH guidance *Q6A Specifications: Test Procedures and Acceptance Criteria for New Drug Substances and New Drug Products: Chemical Substances* (available at www.ich.org). Universal tests in this chapter mean the tests that are applicable to all ophthalmic products, regardless of the dosage form type.

## DESCRIPTION

A qualitative description of the drug product should be provided. The acceptance criteria should contain the final acceptable appearance, including clarity and color, of the dosage form and packaging. If the color changes during storage, a quantitative procedure may be appropriate. This is not a compendial test but is part of the manufacturer's specification of the drug product.

## IDENTIFICATION

Identification tests are discussed in *General Notices, 5.40 Identification*. Identification tests should establish the identity of the drug or drugs present in the article and should discriminate between compounds of closely related structures that are likely to be present. Identity tests should be specific for the drug substance(s). ▲▲ (USP 1-Dec-2022) If the test is nonspecific, at least two orthogonal nonspecific tests should be used. ▲▲ (USP 1-Dec-2022) Identification by use of a single chromatographic retention time does not constitute a specific test.

## ASSAY

A specific and stability-indicating test should be used to determine the strength (content) of the drug product. In cases where the use of a nonspecific assay test is justified, other supporting analytical procedures should be used to achieve overall specificity. A specific procedure should be used when there is evidence of excipient interference with the nonspecific assay test. Additional information on specific assays may be found in *Antibiotics—Microbial Assays* ⟨81⟩, *Chromatography* ⟨621⟩, and *Ion Chromatography* ⟨1065⟩.

## IMPURITIES

Process impurities, synthetic byproducts, and other inorganic and organic impurities may be present in the drug substance and excipients used in the manufacture of the drug product. These impurities are controlled by the drug substance and excipient monographs. Organic impurities arising from the degradation of the drug substance in the drug product and those impurities arising during the manufacturing process of the drug product should be monitored. All articles meet the requirements in *Elemental Impurities—Limits* ⟨232⟩ and *Residual Solvents* ⟨467⟩.

## pH

See *pH* ⟨791⟩. Normal tears have a pH of about 7.4. The eye can tolerate products over a range of pH values from about 3.0 to about 8.6, depending on the buffering capacity of the formulation. The pH value of the formulation should be the one where the drug product is the most stable. Formulations that target the extremes of the acceptable pH range will have better patient acceptability if the formulations have a low buffering capacity.

## OSMOLARITY

See *Osmolality and Osmolarity* ⟨785⟩. Ophthalmic products may be tolerated over a ▲▲ (USP 1-Dec-2022) wide range of tonicity (0.5%–5% sodium chloride, equivalent to about 171–1711 mOsm/kg). Hypotonic solutions are better tolerated than hypertonic solutions. Precautions should be taken to ensure that the product maintains its osmolarity during shelf life. Any possible contributions or interferences from the packaging system should be considered.

## PARTICULATE AND FOREIGN MATTER

▲As described in *Visual Inspection of Injections* ⟨1790⟩*, 4.1 Extrinsic, Intrinsic, or Inherent Particles*, unwanted particulate matter is categorized as extrinsic (foreign matter) and intrinsic (formulation-, process-, or container-related matter or particulate matter due to product instability or product package interactions). A third category, inherent, describes a physical state that is an expected attribute of the product, such as a suspension or emulsion. It is expected that the manufacturer has established an acceptable control level for any inherent attribute, such as solution color, haze, or drug/excipient-related particle content.

The term 100% unit inspection is defined in ⟨1790⟩*, 3.1 100% Inspection* as the complete nondestructive inspection of the container–closure system and its contents. Therefore, evaluation of package and fill acceptability is shown by using the methodology in *Visible Particulates in Injections* ⟨790⟩, and this methodology is applied to all ophthalmic products: topical, intraocular injections or ophthalmic products used in association with a surgical procedure, and extraocular injections.

Intraocular administration includes all ophthalmic products that cross (penetrate) boundary tissue such as the cornea and sclera. Extraocular administration of ophthalmic products includes all the other ocular components and spaces.

For all intraocular solutions, conformance to ⟨790⟩ and *Particulate Matter in Ophthalmic Solutions* ⟨789⟩ is required. Additionally, for extraocular (nontopical) solution products, conformance to ⟨790⟩ and evaluation by *Particulate Matter in Injections* ⟨788⟩ is required. For topical products, conformance to ⟨790⟩ is required. See the summary of this information in *Table 1*.

**Table 1. Particulate and Foreign Matter Requirements for Ophthalmic Solutions**

| Route of Administration (See *Figure 1*) | Must comply with[a] |
|---|---|
| Topical | ⟨790⟩ |
| Peribulbar | ⟨790⟩, ⟨788⟩ |
| Superior rectus | ⟨790⟩, ⟨788⟩ |
| Sub-Tenon | ⟨790⟩, ⟨788⟩ |
| Subconjunctival | ⟨790⟩, ⟨788⟩ |
| Inferior rectus | ⟨790⟩, ⟨788⟩ |
| Retrobulbar | ⟨790⟩, ⟨788⟩ |
| Suprachoroidal | ⟨790⟩, ⟨789⟩ |
| Juxtascleral | ⟨790⟩, ⟨788⟩ |
| Intrascleral | ⟨790⟩, ⟨789⟩ |
| Intracorneal | ⟨790⟩, ⟨789⟩ |
| Subchoroidal | ⟨790⟩, ⟨789⟩ |
| Subretinal | ⟨790⟩, ⟨789⟩ |
| Intracameral | ⟨790⟩, ⟨789⟩ |
| Intravitreal | ⟨790⟩, ⟨789⟩ |

[a] Chapter ⟨787⟩ may be used instead of ⟨788⟩ for protein biotherapeutic formulas. For further information on difficult-to-inspect products, see ⟨1790⟩.

For nonsolution dosage forms (e.g., ointments, gels, suspensions, and emulsions) and dosage forms packaged in opaque containers (e.g., opaque bottles, metal tubes), the approach must be modified because these products are not directly amenable to the tests listed in *Table 1*. It is recommended to use 100% unit inspection per ⟨790⟩ for package acceptability (including but not limited to integrity, form, dimensions, cleanliness, label); whereas, an alternate testing strategy may be used for foreign particles where the dosage form hinders or precludes the use of these tests. For these products, a statistically relevant sample, examined by a destructive or other alternative method, will determine batch acceptability for visible particles as required by ⟨790⟩ and further described in ⟨1790⟩.

All ophthalmic products will benefit from evaluation of unwanted particulate matter content through the control strategy discussed in ⟨1790⟩ and in the FDA's current good manufacturing practices guidance. The final product, therefore, benefits from a control strategy including comprehensive evaluation of excipient and active ingredient quality, processing effects, package quality, and fill control. These concepts are discussed in ⟨1790⟩.▲ (USP 1-Dec-2022)

## STERILITY

Ophthalmic dosage forms must meet the requirements of *Sterility Tests* ⟨71⟩. If the specific ingredients used in the formulation do not lend themselves to routine sterilization techniques, ingredients that meet the sterility requirements described in ⟨71⟩, along with aseptic manufacture, may be used. The immediate container for ophthalmic products shall be sterile at the time of filling and closing. See also *Universal Tests, Container–Closure Integrity*.

## ANTIMICROBIAL PRESERVATIVES

Antimicrobial agents must be added to products that are packaged in containers that allow for the withdrawal or administration of multiple doses, unless one of the following conditions prevails: 1) there are different directions in the individual monograph; 2) the ▲radiopharmaceutical drug product▲ (USP 1-Dec-2022) contains a radionuclide with a physical half-life of <24 h; ▲▲ (USP 1-Dec-2022) 3) the drug product, without additional agents, is sufficiently microbicidal to meet the requirements of *Antimicrobial Effectiveness Testing* ⟨51⟩, ▲or 4) the container–closure system is capable of maintaining sterility of the product throughout its shelf life until opened or accessed. Once opened or accessed, it must maintain antimicrobial effectiveness during the intended use period. Antimicrobial agents▲ (USP 1-Dec-2022) must meet the requirements of ⟨51⟩ and *Antimicrobial Agents—Content* ⟨341⟩. Acceptance criteria for antimicrobial preservative content in ▲multi-dose▲ (USP 1-Dec-2022) products should be established.

## BACTERIAL ENDOTOXINS

All injected ophthalmic drug products shall be prepared in a manner designed to minimize bacterial endotoxins as defined in *Bacterial Endotoxins Test* ⟨85⟩. The limits are not more than 0.5 EU/mL for ophthalmic irrigation products and not more than 2.0 EU/dose/eye for injected or implanted drug products. Typically, this test is not required for topically applied ophthalmic products. This chapter does not address the endotoxin limits for devices that are injected or implanted.

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Dec-2022
DOI Ref: q2u74
DocId: GUID-5C58E1A2-6BE7-4011-9776-64687B306810_5_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99560_05_01
@2024 USPC

### UNIFORMITY OF DOSAGE UNITS

This test is applicable to dosage forms packaged in single-unit containers. It includes both the mass of the dosage form and the content of the drug substance(s) in the dosage form. The test can be performed by either content uniformity or weight variation (see *Uniformity of Dosage Units* ⟨905⟩).

### CONTAINER CONTENTS

Container contents of ophthalmic products should be determined (see *Minimum Fill* ⟨755⟩).

### LEACHABLES AND EXTRACTABLES

The packaging system should not interact physically or chemically with the product in any manner to alter the strength, quality, or purity of the drug product. The packaging system should meet the requirements in *Elastomeric Components in Injectable Pharmaceutical Product Packaging/Delivery Systems* ⟨381⟩, *Containers—Glass* ⟨660⟩, ▲and, depending on which standards the manufacturer has implemented, *Plastic Packaging Systems and Their Materials of Construction* ⟨661⟩ or ▲ (USP 1-Dec-2022) *Plastic Materials of Construction* ⟨661.1⟩ and *Plastic Packaging Systems for Pharmaceutical Use* ⟨661.2⟩. Further information regarding packaging systems testing can be found in *Assessment of Extractables Associated with Pharmaceutical Packaging/Delivery Systems* ⟨1663⟩ and *Assessment of Drug Product Leachables Associated with Pharmaceutical Packaging/Delivery Systems* ⟨1664⟩. The assessment of possible leachables and/or extractables and the establishment of any acceptance criteria for these compounds should ▲consider▲ (USP 1-Dec-2022) the risk assessment of the product, its indication, and its packaging system. This assessment is done in a case-by-case approach during product development and re-evaluated when any changes are made to the product including, but not restricted to, changes in manufacturing process, formulation, and packaging material.

Furthermore, it should be noted that a risk assessment of extractable/leachable impact on ▲the▲ (USP 1-Dec-2022) topical or intraocular route of administration is a challenging undertaking. Toxicological or safety assessments of primary or secondary packaging component extractables and leachables are not typically available for ophthalmic routes of administration. A risk assessment may include evaluation of toxicology and safety from other routes of administration and an assessment of the total daily intake of the extractable/leachable being evaluated. The preponderance of such assessments leads to an estimate of extractable/leachable risk via ocular delivery to the patient.

### CONTAINER–CLOSURE INTEGRITY

The packaging system should be closed or sealed in such a manner as to prevent contamination or loss of contents and should ▲incorporate a tamper-evident design.▲ (USP 1-Dec-2022) Validation of container integrity must demonstrate no penetration of microbial contamination or of chemical or physical impurities (see *Package Integrity Evaluation—Sterile Products* ⟨1207⟩).

## Specific Tests

### VISCOSITY

An increase in viscosity increases the residence time ▲of ocular formulations.▲ (USP 1-Dec-2022) However, drug diffusion out of ▲these formulations▲ (USP 1-Dec-2022) into the ▲ocular tissue▲ (USP 1-Dec-2022) may be ▲modified▲ (USP 1-Dec-2022) due to high product viscosity. Ophthalmic ointments are designed to be of very high viscosity to prolong the residence time ▲of the formulation▲ (USP 1-Dec-2022) in the eye. The inclusion of viscosity evaluation in the specification of the product should be based on the type of dosage form and whether changes in product viscosity will affect its performance. This is not a compendial test but is part of the manufacturer's specification of the drug product. See *Viscosity—Capillary Methods* ⟨911⟩, *Viscosity—Rotational Methods* ⟨912⟩, and *Viscosity—Rolling Ball Method* ⟨913⟩.

### ANTIOXIDANT CONTENT

If antioxidants are present in the drug product, tests of their content should be established, unless oxidative degradation can be detected by another test method such as impurity testing. Acceptance criteria for antioxidant content should be established. They should be based on the levels of antioxidant necessary to maintain the product's stability at all stages throughout its proposed usage and shelf life.

### RESUSPENDABILITY/REDISPERSIBILITY

Consideration must be given to establishing good physical stability of a suspension. If the particles settle and eventually produce a cake at the bottom of the container, they must redisperse readily at the time of use to achieve dosage uniformity. ▲Quantitative demonstration of the active ingredient's resuspendability/redispersibility during product development is also recommended.▲ (USP 1-Dec-2022)

### PARTICLE SIZE AND PARTICLE SIZE DISTRIBUTION

The potential for any changes in the particle size of ophthalmic suspensions and emulsions needs to be evaluated through stability testing (see *Light Diffraction Measurement of Particle Size* ⟨429⟩).

Official

https://pharmacopeia.cn/v-prod/

## DROP SIZE

For ophthalmic drug products dispensed as drops, drop sizes may typically range from 20–70 µL. Drop size can be controlled by weight or by volume, and it is typically evaluated during product development. Drop size can be determined by any appropriate validated procedure.

## ADDED SUBSTANCES

Suitable substances may be added to ophthalmic products to increase stability, unless proscribed in the individual monograph, provided they are harmless in the amounts administered and do not interfere with therapeutic efficacy or with responses to the specified assays and tests. Typically, ▲these substances▲ (USP 1-Dec-2022) should be evaluated during product development. The use of ingredients solely to impart ▲▲ (USP 1-Dec-2022) an odor or flavor is prohibited. ▲The use of ingredients solely to impart a color is prohibited unless coloring is needed to visualize the administration location of the product.▲ (USP 1-Dec-2022)

# ⟨776⟩ OPTICAL MICROSCOPY

Optical microscopy for particle characterization can generally be applied to particles 1 µm and greater. The lower limit is imposed by the resolving power of the microscope. The upper limit is less definite and is determined by the increased difficulty associated with the characterization of larger particles. Various alternative techniques are available for particle characterization outside the applicable range of optical microscopy. Optical microscopy is particularly useful for characterizing particles that are not spherical. This method may also serve as a base for the calibration of faster and more routine methods that may be developed.

## APPARATUS

Use a microscope that is stable and protected from vibration. The microscope magnification (product of the objective magnification, ocular magnification, and additional magnifying components) must be sufficient to allow adequate characterization of the smallest particles to be classified in the test specimen. The greatest numerical aperture of the objective should be sought for each magnification range. Polarizing filters may be used in conjunction with suitable analyzers and retardation plates. Color filters of relatively narrow spectral transmission should be used with achromatic objectives, are preferable with apochromats, and are required for appropriate color rendition in photomicrography. Condensers corrected at least for spherical aberration should be used in the microscope substage and with the lamp. The numerical aperture of the substage condenser should match that of the objective under the conditions of use and is affected by the actual aperture of the condenser diaphragm and by the presence of immersion oils.

## ADJUSTMENT

The precise alignment of all elements of the optical system and proper focusing are essential. The focusing of the elements should be done in accordance with the recommendations of the microscope manufacturer. Critical axial alignment is recommended.

## ILLUMINATION

A requirement for good illumination is a uniform and adjustable intensity of light over the entire field of view; Kohler illumination is preferred. With colored particles, choose the color of the filters used so as to control the contrast and detail of the image.

## VISUAL CHARACTERIZATION

The magnification and numerical aperture should be sufficiently high to allow adequate resolution of the images of the particles to be characterized. Determine the actual magnification using a calibrated stage micrometer to calibrate an ocular micrometer. Errors can be minimized if the magnification is sufficient that the image of the particle is at least 10 ocular divisions. Each objective must be calibrated separately. To calibrate the ocular scale, the stage micrometer scale and the ocular scale should be aligned. In this way, a precise determination of the distance between ocular stage divisions can be made. Several different magnifications may be necessary to characterize materials having a wide particle size distribution.

## PHOTOGRAPHIC CHARACTERIZATION

If particle size is to be determined by photographic methods, take care to ensure that the object is sharply focused at the plane of the photographic emulsion. Determine the actual magnification by photographing a calibrated stage micrometer, using photographic film of sufficient speed, resolving power, and contrast. Exposure and processing should be identical for photographs of both the test specimen and the determination of magnification. The apparent size of a photographic image is influenced by the exposure, development, and printing processes as well as by the resolving power of the microscope.

## PREPARATION OF THE MOUNT

The mounting medium will vary according to the physical properties of the test specimen. Sufficient but not excessive contrast between the specimen and the mounting medium is required to ensure adequate detail of the specimen edge. The particles should rest in one plane and be adequately dispersed to distinguish individual particles of interest. Furthermore, the particles must be representative of the distribution of sizes in the material and must not be altered during preparation of the mount. Care should be taken to ensure that this important requirement is met. Selection of the mounting medium must include a consideration of the analyte solubility.

Official

https://pharmacopeia.cn/

## CRYSTALLINITY CHARACTERIZATION

The crystallinity of a material may be characterized to determine compliance with the crystallinity requirement where stated in the individual monograph of a drug substance. Unless otherwise specified in the individual monograph, mount a few particles of the specimen in mineral oil on a clean glass slide. Examine the mixture using a polarizing microscope: the particles show birefringence (interference colors) and extinction positions when the microscope stage is revolved.

## LIMIT TEST OF PARTICLE SIZE BY MICROSCOPY

Weigh a suitable quantity of the powder to be examined (for example, 10 to 100 mg), and suspend it in 10 mL of a suitable medium in which the powder does not dissolve, adding, if necessary, a wetting agent. A homogeneous suspension of particles can be maintained by suspending the particles in a medium of similar or matching density and by providing adequate agitation. Introduce a portion of the homogeneous suspension into a suitable counting cell, and scan under a microscope an area corresponding to not less than 10 µg of the powder to be examined. Count all the particles having a maximum dimension greater than the prescribed size limit. The size limit and the permitted number of particles exceeding the limit are defined for each substance.

## PARTICLE SIZE CHARACTERIZATION

The measurement of particle size varies in complexity depending on the shape of the particle, and the number of particles characterized must be sufficient to ensure an acceptable level of uncertainty in the measured parameters. Additional information on particle size measurement, sample size, and data analysis is available, for example, in ISO 9276. For spherical particles, size is defined by the diameter. For irregular particles, a variety of definitions of particle size exist. In general, for irregularly shaped particles, characterization of particle size must also include information on the type of diameter measured as well as information on particle shape. Several commonly used measurements of particle size are defined below (see *Figure 1*):

Figure 1. Commonly used measurements of particle size.

*Feret's Diameter*—The distance between imaginary parallel lines tangent to a randomly oriented particle and perpendicular to the ocular scale.
*Martin's Diameter*—The diameter of the particle at the point that divides a randomly oriented particle into two equal projected areas.
*Projected Area Diameter*—The diameter of a circle that has the same projected area as the particle.
*Length*—The longest dimension from edge to edge of a particle oriented parallel to the ocular scale.
*Width*—The longest dimension of the particle measured at right angles to the length.

## PARTICLE SHAPE CHARACTERIZATION

For irregularly shaped particles, characterization of particle size must also include information on particle shape. The homogeneity of the powder should be checked using appropriate magnification. The following defines some commonly used descriptors of particle shape (see *Figure 2*):

https://pharmacopeia.cn/

@2024 USPC

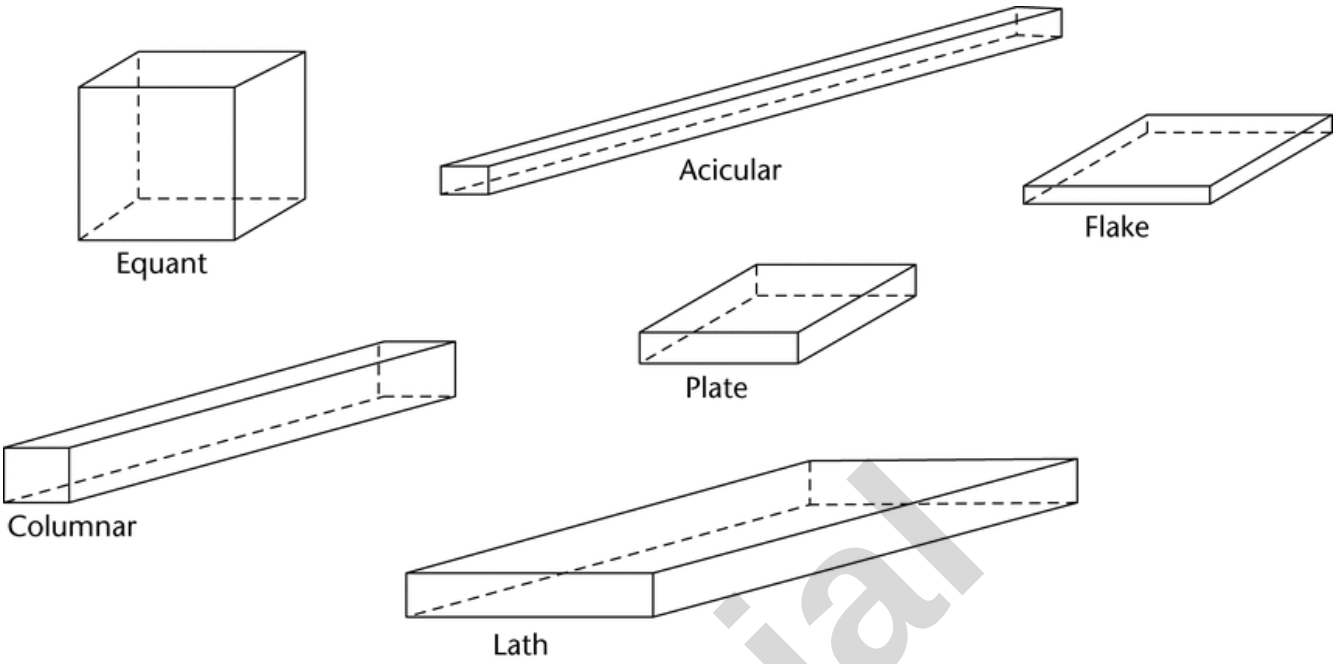

Figure 2. Commonly used descriptions of particle shape.

*Acicular*—Slender, needle-like particle of similar width and thickness.
*Columnar*—Long, thin particle with a width and thickness that are greater than those of an acicular particle.
*Flake*—Thin, flat particle of similar length and width.
*Plate*—Flat particles of similar length and width but with greater thickness than flakes.
*Lath*—Long, thin, and blade-like particle.
*Equant*—Particles of similar length, width, and thickness; both cubical and spherical particles are included.

## GENERAL OBSERVATIONS

A particle is generally considered to be the smallest discrete unit. A particle may be a liquid or semisolid droplet; a single crystal or polycrystalline; amorphous or an agglomerate. Particles may be associated. This degree of association may be described by the following terms:

*Lamellar*—Stacked plates.
*Aggregate*—Mass of adhered particles.
*Agglomerate*—Fused or cemented particles.
*Conglomerate*—Mixture of two or more types of particles.
*Spherulite*—Radial cluster.
*Drusy*—Particle covered with tiny particles.

Particle condition may be described by the following terms:

*Edges*—Angular, rounded, smooth, sharp, fractured.
*Optical*—Color (using proper color-balancing filters), transparent, translucent, opaque.
*Defects*—Occlusions, inclusions.

Surface characteristics may be described as:

*Cracked*—Partial split, break, or fissure.
*Smooth*—Free of irregularities, roughness, or projections.
*Porous*—Having openings or passageways.
*Rough*—Bumpy, uneven, not smooth.
*Pitted*—Small indentations.

# ⟨781⟩ OPTICAL ROTATION

***Change to read:***

## INTRODUCTION

Many pharmaceutical substances are optically active in the sense that they rotate an incident plane of polarized light so that the transmitted light emerges at a measurable angle to the plane of the incident light. This property is characteristic of some crystals and of many pharmaceutical liquids or solutions of solids. Where the property is possessed by a liquid or by a solute in solution, it is generally the result of the presence of one or more asymmetric centers, usually a carbon atom with four different substituents. The number of optical isomers is $2^n$, where $n$ is the number of asymmetric centers. Polarimetry, the measurement of optical rotation, of a pharmaceutical ▲substance▲ (USP 1-Dec-2022) may be the only convenient means for distinguishing optically active isomers from each other and thus is an important criterion of identity and purity.

Substances that may show optical rotatory properties are "chiral". Those that rotate light in a clockwise direction ▲▲ (USP 1-Dec-2022) are "dextrorotatory" or "(+) optical isomers", and those that rotate light in a counterclockwise direction are called "levorotatory" or "(–) optical isomers". (The symbols *d*- and *l*-, formerly used to indicate dextrorotatory and levorotatory isomers, are no longer sanctioned owing to confusion with D- and L-, which refer to configuration relative to D-glyceraldehyde. The symbols *R* and *S*, or α and β, are also used to indicate configuration, the arrangement of atoms or groups of atoms in space.)

The physicochemical properties of nonsuperimposable chiral substances rotating plane-polarized light in opposite directions to the same extent, "enantiomers", are identical, except for this property and in their reactions with other chiral substances. Enantiomers often exhibit profound differences in pharmacology and toxicology, owing to the fact that biological receptors and enzymes themselves are chiral. Many ▲pharmaceutical substances▲ (USP 1-Dec-2022) from natural sources such as amino acids, proteins, alkaloids, antibiotics, glycosides, and sugars exist as chiral compounds. Synthesis of such compounds from nonchiral materials usually results in equal amounts of the enantiomers, i.e., "racemates". Racemates have a net null optical rotation, and their physical properties may differ from those of the component enantiomers. Use of stereoselective or stereospecific synthetic methods or separation of racemic mixtures can be used to obtain individual optical isomers.

Measurement of optical rotation is performed using a polarimeter. ▲For a neat, undiluted liquid, the specific rotation is a function of the density of the liquid at the temperature of interest:

$$[\alpha]_{\lambda}^{t} = \frac{\alpha}{l\rho}$$

When measuring the specific rotation of an analyte in solution, it may be convenient to prepare the *Sample solution* in a volume containing a mass of the analyte, with a concentration of the analyte per unit of volume (g analyte/mL solution), $c_v$, or per unit of mass (g analyte/g solution), $c_w$. The equations for determining the specific rotation of a *Sample solution* are:

For *Sample solution* (g/mL):

$$[\alpha]_{\lambda}^{t} = \frac{\alpha}{lc_v}$$

For *Sample solution* (g/g):

$$[\alpha]_{\lambda}^{t} = \frac{\alpha}{l\rho c_w}$$

$[\alpha]_{\lambda}^{t}$ = specific rotation at wavelength λ and temperature $t$ (°C). The units of specific rotation are $[(^\circ) \cdot mL \cdot dm^{-1} \cdot g^{-1}]$, which is typically expressed just as degrees (°).
α = observed rotation in degrees (°)
$l$ = path length (dm)
ρ = density of the solution or liquid at temperature $t$ (g/mL)
$c_v$ = concentration of the analyte per unit of volume (g analyte/mL solution)
$c_w$ = concentration of the analyte per unit of mass (g analyte/g solution)

For some pharmaceutical substances, especially liquids such as essential oils, the optical rotation requirement is expressed in terms of the observed angle of optical rotation, α, measured under conditions defined in the monograph.▲ (USP 1-Dec-2022)

Historically, polarimetry was performed using an instrument where the extent of optical rotation is estimated by visual matching of the intensity of split fields. For this reason, the D-line of the sodium lamp at the visible wavelength of 589 nm was most often employed.[1] Specific rotation determined at the D-line ▲at 25° C or 20° C▲ (USP 1-Dec-2022) is expressed by the symbol:

$$[\alpha]_{D}^{25} \text{ or } [\alpha]_{D}^{20}$$

Much of the data available are expressed in this form. Use of lower wavelengths, such as those available with the mercury lamp lines isolated by means of filters of maximum transmittance at approximately 546, 436, 405, and 365 ▲▲ (USP 1-Dec-2022) nm in a

[1] All references of wavelengths are in vacuum. The sodium D-line is 589.44 nm in vacuum and 589.3 nm in air.

@2024 USPC

photoelectric polarimeter, has been found to provide advantages in sensitivity with a consequent reduction in the concentration of the test compound. In general, the observed optical rotation at 436 nm is about double, and at 365 nm, about 3 times that at 589 nm.[1] ▲ (USP 1-Dec-2022)

It is now common practice to use other light sources such as ▲light emitting diodes (LEDs)▲ (USP 1-Dec-2022) or xenon or tungsten halogen ▲lamps,▲ (USP 1-Dec-2022) with appropriate filters, instead of traditional light sources because these ▲contemporary light sources▲ (USP 1-Dec-2022) may offer advantages of cost, long life, and broad wavelength emission range.

***Add the following:***

## ▲QUALIFICATION OF POLARIMETERS

Qualification of polarimeters can be divided into three elements: installation qualification (IQ), operational qualification (OQ), and performance qualification (PQ). For a more detailed discussion, see *Analytical Instrument Qualification* ⟨1058⟩.

### Installation Qualification (IQ)

The IQ requirements provide evidence that the hardware and software are properly installed in the desired location and ambient conditions (temperature and humidity).

### Operational Qualification (OQ)

The OQ for the polarimeter should verify the temperature control of the sample, the wavelength accuracy and bandwidth of the light source, the accuracy and repeatability of the optical rotation measurements at the operating wavelengths, and for quantitative applications, the linearity of the instrument response.

#### TEMPERATURE CONTROL

The optical rotation is affected by the temperature of the sample. Therefore, proper temperature control of the sample will be critical for maintaining suitable accuracy and repeatability of the optical rotation measurements. The polarimeter should report the temperature of measurement to at least ±0.1° C or better and should be capable of maintaining constant temperature during the measurement. The OQ of a polarimeter's temperature control is performed by demonstrating that the operating temperature is within ±0.5° C to a temperature recorded on a temperature reading device that is traceable to a National Institute of Standards and Technology (NIST) standard or equivalent (see *General Notices, 6.80.30. Temperature Reading Devices*).

#### WAVELENGTH ACCURACY AND BANDWIDTH

For polarimeters that employ continuum light sources (e.g., LED or tungsten halogen lamps), bandpass filters are typically used to select the wavelength for measurement. It is recommended to record attributes of the wavelength and the bandwidth. If other light sources are employed (e.g., sodium emission lamps), it is recommended to record the wavelength.

#### ACCURACY OF OPTICAL ROTATION

To verify accuracy of the polarimeter, the polarimeter must be capable of reporting the optical rotation to ±0.01° or better and the certified optical rotation reference material must be certified to ±0.01° or better. Verify the accuracy of the polarimeter at the operating wavelength(s) by measuring a certified optical rotation reference material having an associated expanded uncertainty. Typically, quartz plate reference standards with certified optical rotation values are used.[2] Alternatively, other suitable certified reference materials or reference standards may be used.[3] The result should agree with the stated certified value within the limits of the expanded uncertainty of the reference material added to the accuracy specification of the instrument (as provided by the manufacturer).

#### REPEATABILITY

Perform at least five replicate measurements of a reference material at the operating wavelength. Calculate the relative standard deviation (% RSD) of the replicates. The result should be equal to or less than the stated repeatability performance specification of the instrument (as provided by the manufacturer).

#### LINEARITY

Linearity should be verified if the optical rotation measurement is used for quantitation of an enantiomer. For quantitative applications, linearity is verified if optical rotation at three or more values representing the operational range meet the criteria for accuracy.

---

[2] Qualification may be performed using a polarization reference standard, which consists of a plate of quartz mounted in a holder perpendicular to the light path. Acceptable periodic calibrations may be made by a National Metrology Institute (NMI) that is signatory to the International Committee for Weights and Measures Mutual Recognition Arrangement (CIPM MRA) or an ISO/IEC 17025 accredited laboratory for calibration where the accreditation body is a signatory to the International Laboratory Accreditation Cooperation Mutual Recognition Arrangement (ILAC MRA).

[3] A certified reference material is available from the Office of Standard Reference Materials, National Institute of Standards and Technology (NIST), Gaithersburg, MD 20899, as a current lot of Standard Reference Material, Sucrose.

## Performance Qualification (PQ)

PQ consists of periodic qualification of optical rotation accuracy and repeatability as well as temperature control, along with performance checks performed as needed by the instrument user.▲ (USP 1-Dec-2022)

***Change to read:***

## PROCEDURES

▲When polarimetry is used to differentiate an optically active material (e.g., a pure chiral isomer) from an optically inactive material (e.g., a racemic mixture of substances), the polarimeter may provide a small, measurable optical rotation that is close to 0°, which may require interpretation to determine whether the result indicates that a material is classified as dextrorotatory, levorotatory, or optically inactive. The term "dextrorotatory" should be interpreted to mean that the observed angle of optical rotation is a positive, optically active value of optical rotation. The term "levorotatory" should be interpreted to mean that the observed angle of optical rotation is a negative, optically active value of optical rotation. The term "optically inactive" should be interpreted to mean the observed angle of rotation is not significantly different from 0°.

For a neat, undiluted liquid, follow the procedure for *Angular Rotation* in this chapter unless otherwise indicated in the monograph. (In some cases, a drug product is treated as a neat, undiluted liquid.) For *Test solutions* or *Sample solutions* prepared by diluting the analyte in a solvent, follow the procedure for *Specific Rotation* in this chapter unless otherwise indicated in the monograph.

Temperature, which applies to the solution or the liquid under test, should be maintained to ±0.5° C of the stated value.▲ (USP 1-Dec-2022)

## Specific Rotation

The reference ▲"⟨781S⟩"▲ (USP 1-Dec-2022)in a monograph signifies that specific rotation is to be calculated from observed optical rotations in the *Test solution* or *Sample solution* obtained as directed therein. Unless otherwise directed, measurements of optical rotation are made in a 1.0-dm ▲measurement cell▲ (USP 1-Dec-2022) at 589 nm at 25° ▲C ± 0.5° C corrected for the reading of the solvent blank.▲ (USP 1-Dec-2022)[1] Unless otherwise specified, specific rotation is calculated on the dried basis where *Loss on Drying* ▲⟨731⟩▲ (USP 1-Dec-2022) is specified in the monograph or on the anhydrous basis where *Water Determination* ▲⟨921⟩▲ (USP 1-Dec-2022) is specified.

Optical rotation of solutions should be determined within 30 min of preparation. In the case of substances known to undergo racemization or mutarotation, care should be taken to standardize the time between adding the solute to the solvent and introduction of the solution into the polarimeter ▲measurement cell.▲ (USP 1-Dec-2022)

## Angular Rotation

The reference ▲"⟨781A⟩"▲ (USP 1-Dec-2022)in a monograph signifies, unless otherwise directed, that the optical rotation of the neat, ▲undiluted▲ (USP 1-Dec-2022) liquid is measured in a 1.0-dm ▲measurement cell▲ (USP 1-Dec-2022) at 589 nm at 25° ▲C ± 0.5° C▲ (USP 1-Dec-2022) corrected for the reading of the dry, empty ▲measurement cell blank.[1] The result is reported as the observed angle of optical rotation.▲ (USP 1-Dec-2022)

    4.2 Precision
    4.3 Verification

## 1. INTRODUCTION

Vibrational circular dichroism (VCD) is a form of chiroptical spectroscopy for which chiral molecules have non-zero spectra with intensities that are identical for mirror-image pairs (enantiomers) of chiral molecules but with signs that are opposite with respect to zero intensity. For a chiral molecular substance, two important properties are 1) absolute configuration (AC), which indicates which of two mirror-image forms of the molecule is present; and 2) enantiomeric excess (EE, also called enantiomeric purity), the fractional excess of one enantiomer of a chiral molecule over its mirror-image enantiomer. The principal chapter in *USP–NF* that addresses molecular chirality is *Optical Rotation* ⟨781⟩. Optical rotation (OR) and electronic circular dichroism (ECD) are the traditional forms of chiroptical spectroscopy, whereas VCD is a newer form of chiroptical spectroscopy that contains more molecular structure information and recently has been adopted more broadly for use in the pharmaceutical industry.

In this chapter, the required methodology for the use of VCD is described in terms of instrument qualification; sign and intensity calibration; procedures, validation, and verification of VCD measurement; calculation; and statistical analysis as needed for the determination of AC and EE of chiral pharmaceutical products. VCD is the extension of ECD from the region of electronic transitions in the UV and visible regions of the spectrum to vibrational transitions in the infrared (IR) region.

VCD is defined as:

$$\Delta A = A_L - A_R$$

$\Delta A$ = difference in the IR absorbance
$A_L$ = sample absorbance for left circularly polarized (LCP) radiation
$A_R$ = sample absorbance for right circularly polarized (RCP) radiation

Unpolarized IR intensity is defined as the average of LCP and RCP intensities:

$$A = (A_L + A_R)/2$$

$A$ = IR absorbance
$A_L$ = sample absorbance for left circularly polarized (LCP) radiation
$A_R$ = sample absorbance for right circularly polarized (RCP) radiation

The IR intensities of enantiomers are identical, whereas enantiomers have equal and opposite-signed VCD intensities.

For discussion of the theory and principles of VCD measurements, as well as a more detailed explanation of the application of VCD to problems of pharmaceutical interest, see *Vibrational Circular Dichroism Spectroscopy—Theory and Practice* ⟨1782⟩.

## 2. QUALIFICATION OF VCD SPECTROMETERS

This section on qualification is divided into three subsections: *2.1 Installation Qualification* (IQ), *2.2 Operational Qualification* (OQ), and *2.3 Performance Qualification* (PQ) of a Fourier transform (FT)-VCD instrument. Although a VCD instrument can be based on a scanning dispersive spectrometer, no such VCD spectrometers are commercially available, and hence they will not be considered. Additional details on the qualification of instruments can be found in *Analytical Instrument Qualification* ⟨1058⟩.

### 2.1 Installation Qualification

The IQ requirements provide evidence that the hardware and software are properly installed in the desired location. An FT-VCD instrument is a sensitive, circular-polarization-difference, FT-infrared (FT-IR) spectrometer. Its installation requires a stable bench-top surface, access to dry air or nitrogen for purging of water vapor, and standard electrical outlets. Evidence for IQ involves ensuring that the IR interferometer is scanning, that its photoelastic modulator(s) [PEM(s)] is operating, and that

https://mathuseonly.com/

the electronics hardware is interacting with both the FT-IR main bench and the PEM. The final evidence for IQ is that the software display for acquisition of a VCD spectrum is ready for operator use.

## 2.2 Operational Qualification

In OQ, an instrument's performance is characterized using a qualification standard of known spectral properties to verify that the system operates within target specifications. The purpose of OQ is to demonstrate that instrument performance is suitable. OQ is a check of the key operational parameters and should be performed after installation and after repairs and/or maintenance.

The OQ tests described in the following sections are typical examples only. Other tests and samples can be used to establish specifications for OQ. Instrument vendors often have samples and test parameters available as part of the IQ/OQ package. The acceptance criteria provided in this section are applicable for general use, whereas specifications for particular instruments and applications may vary, depending on analytical methods used and desired accuracy of the final result.

### CHARACTERIZING INSTRUMENT PERFORMANCE

FT-VCD spectrometers measure simultaneously the VCD spectrum and the parent IR spectrum. The VCD spectrum is obtained from a VCD interferogram arising from the combined high-frequency PEM polarization modulation and the Fourier frequencies, whereas the parent IR spectrum arises from the conventional FT-IR interferogram based only on the instrument's Fourier frequencies. Part of the instrument performance is from the underlying FT-IR operation, and the remaining part of the instrument performance is from those components that are uniquely associated with the FT-VCD operation. The combined FT-IR and FT-VCD criteria are wavenumber accuracy and absorbance linearity, whereas those uniquely associated with the VCD operation are VCD sign and intensity calibration, empty-beam baseline accuracy, sample-associated baseline deviations and artifact levels, baseline stability and spectral reproducibility, and signal-to-noise ratio. As described in ⟨1782⟩, two standard samples are commonly used for specifying VCD performance. For sign and intensity calibration, neat α-pinene is used as a validation standard, whereas for baseline characteristics, a solution of camphor in carbon tetrachloride ($CCl_4$) is used as the qualification standard. VCD spectra presented in ⟨1782⟩ serve as examples of performance characteristics of typical spectra for VCD sign and intensity calibration, baseline stability, and signal-to-noise ratio.

### WAVENUMBER ACCURACY

The wavenumber accuracy of FT-VCD instruments is based on the corresponding wavenumber accuracy of the parent FT-IR operation. This accuracy is determined by fringe counting of the visible laser co-operating with the FT-IR interferometer. The frequency calibration is accurate to within the spectral resolution of the instrument and requires no calibration standard. The accuracy of wavenumber frequency should be checked by measuring the IR spectrum of a 35-µm-thick polystyrene film, as described in the *USP–NF* chapter on mid-IR spectroscopy, *Mid-Infrared Spectroscopy* ⟨854⟩, with additional information in *Mid-Infrared Spectroscopy—Theory and Practice* ⟨1854⟩. Because the FT-VCD and FT-IR spectra are simultaneously measured by the action of the same interferometer, the wavenumber accuracy of the VCD spectrum is the same as that of the FT-IR operation of the instrument.

### LINEARITY AND STABILITY

Commercial FT-IR instruments have excellent linearity, provided that the infrared detector remains unsaturated. FT-IR spectra are particularly prone to detector saturation, because the intensity of the entire spectrum is present simultaneously at the detector. Detector saturation can be avoided by the use of a long-wavelength pass filter or appropriate adjustment of the gain of the preamplifier to ensure that the maximum of the FT-IR interferogram lies within the range of preamplifier voltage capability. The hallmark of the onset of nonlinearity is distortion of the FT-IR interferogram that can lead to negative FT-IR absorbance values at the endpoint frequency of the spectral coverage, which is clearly incorrect for an absorbing sample. Aperture reduction, insertion of screens, or neutral density filters can be used to avoid detector saturation.

These same considerations apply to the linearity of FT-VCD measurements. The linearity of VCD is more sensitive to the onset of detector saturation than is the parent IR spectrum. VCD spectra are unstable and distorted when the parent FT-IR spectrum has any saturation, and in some cases linearity in the VCD is not restored until the FT-IR intensity is well below saturation. Saturation can be tested by varying the throughput of the instrument by changing the sample path length and making sure that all of the points across the spectrum are changed by the same factor, i.e., there are no relative shape changes in the spectrum. These relative shape changes should be less than the apparent noise level or, at most, 2% (1.00 ± 0.02), depending on the accuracy needed for the VCD measurements.

### PHASE CORRECTION, SIGN, AND INTENSITY CALIBRATION

The raw VCD spectrum is measured as the ratio of the FT of the VCD interferogram to that of the FT of the IR interferogram. Both of these interferograms must be phase-corrected before performing the FT. The phase correction for the IR is straightforward, but the phase correction of the VCD interferogram requires transfer of a phase file from a VCD interferogram representing only positive intensities. Most commercial FT-VCD instruments provide such phase files for the measurement of VCD.

Next, the measured raw VCD spectrum must be calibrated such that VCD spectra with the correct signs and intensities are produced. The signs can be determined by measuring the qualification standard of (–)-camphor or (+)-camphor in carbon tetrachloride solution and comparing it to a previously published standard VCD spectrum of this molecule, such as that provided in ⟨1782⟩. Either all of the signs agree, in which case the sign is correctly set, or all of the signs are opposite, in which

Official

https://mathuseglobal.com/

case the phase of the VCD synchronous detection (lock-in amplifier or numerical processing) must be changed by 180° to reverse the signs of all VCD bands, positive-to-negative and negative-to-positive.

Calibration of VCD intensities is performed by dividing the raw VCD by a calibration curve representing the magnitude of unit VCD intensity for the VCD spectrometer. The shape of the calibration curve follows a first-order Bessel function, which in turn depends on the settings of the PEM generating LCP and RCP radiation. The maximum of the calibration curve corresponds to the maximum wavenumber value set on the PEM controller. The calibration curve for a given PEM setting can be obtained from the crossing points of curves generated by placing a multiple-wave plate followed by a polarizer in place of the sample and measuring the VCD spectrum in the usual manner. Commercial VCD instruments provide such curves, and the correct calibration curve must be used for each wavenumber setting of the PEM. For an example of a calibration curve for the PEM setting at 1200 $cm^{-1}$, see ⟨1782⟩.

After calibration of the intensities of the VCD instrument, a measurement of a 0.9 M solution of (+)-*R*-camphor in carbon tetrachloride measured in a 100-µm path-length cell should be approximately $2 \times 10^{-4}$. After baseline subtraction, described below and in ⟨1782⟩, this difference should be a positive peak $\Delta A$ value of $+1 \times 10^{-4}$ absorbance units at 1240 $cm^{-1}$ and a negative $\Delta A$ peak value of $-1 \times 10^{-4}$ at 1040 $cm^{-1}$.

### EMPTY BEAM BASELINE CHARACTERISTICS

To avoid significant levels of baseline deviations from the absorbance features of a sample, the empty beam baseline for a VCD instrument should be as close as possible to the true zero of the measurement. A minimum standard for FT-VCD spectrometers is to have empty beam baselines sufficiently close to zero so that deviations from true zero are <25% of the span of maximum positive-to-negative absorbance intensity of a 0.9 M solution of (+)-*R*-camphor in carbon tetrachloride, measured in a 100-µm path-length cell. This magnitude, noted above, is approximately $2 \times 10^{-4}$ as determined from a positive peak value of $+1 \times 10^{-4}$ at 1240 $cm^{-1}$ and a negative peak value of $-1 \times 10^{-4}$ at 1040 $cm^{-1}$. The value of 25% of this intensity range is approximately $5 \times 10^{-5}$. VCD empty beam baseline deviations (maximum to minimum), over the mid-IR range from 900 to 1800 $cm^{-1}$, should not exceed $\pm 5 \times 10^{-4}$ and should not deviate more than $+5 \times 10^{-4}$ or $-5 \times 10^{-4}$ from the zero of VCD intensity over this wavenumber range.

### SAMPLE BASELINES AND ABSORPTION ARTIFACTS

An important test for a VCD measurement is the VCD spectrum of a racemic sample relative to that of the baseline of the empty instrument or the VCD spectrum of a nonchiral solvent, such as carbon tetrachloride. Because of possible baseline changes due to the sample cell, it is preferable to compare the VCD of the solvent with that of a solution of the racemic sample of the chiral molecule in the same solvent. Both should have zero VCD, but the racemic solution may have baseline artifacts (offsets) at the location of the absorption bands. Absorption bands change the index of refraction of the sample and can cause baseline deviations that are particular to the sample molecule. If such absorption artifacts are present, the only way to recover the artifact-free VCD spectrum is by subtraction of the racemic mixture (equal quantities of both enantiomers) from that of the measured VCD spectrum. Alternatively, subtraction of the VCD spectrum of the opposite enantiomer is divided by 2, because the VCD intensity doubles if the VCD spectrum of one enantiomer is subtracted from that of the other. The qualification standard used for measuring the VCD baseline with an absorbing sample present is racemic camphor in carbon tetrachloride solution versus the VCD spectrum of neat carbon tetrachloride in the range 900–1800 $cm^{-1}$, where there are only absorption bands from camphor and none for carbon tetrachloride. Both samples should have zero VCD and a baseline that is featureless with respect to the camphor absorption bands.

### SIGNAL-TO-NOISE RATIO

The signal-to-noise ratio of a VCD measurement can be determined from the noise curve generated by subtracting one-half of the FT scans of a measurement from the other half, thus cancelling the signal and exposing the noise level. The noise level varies across the spectrum and increases when the light level reaching the detector decreases, either due to the overall throughput of the instrument in a particular spectral region or directly within the absorption bands of the sample. The level of noise in the noise curve can be reduced by increasing the measurement time of the spectrum. The noise level is inversely proportional to the square root of the measurement time. This is illustrated with a particular example in *Figures 9* and *10* of ⟨1782⟩.

Smoothing a VCD spectrum without increasing the measurement time will reduce the size of the peak-to-peak noise excursions but will not reduce the overall accuracy of a VCD measurement, because the VCD baseline, and hence the VCD intensity relative to the zero baseline, will undergo the same level of variations, although the VCD spectrum appears to have less noise after smoothing. To know the true level of the noise and hence the uncertainty level of a VCD spectrum, all smoothing functions, if any, should be turned off. Noise can legitimately be reduced by lowering the spectral resolution. In evaluating the noise level of the VCD measurement, the resolution and interferogram apodization must be specified.

## 2.3 Performance Qualification

PQ determines if the instrument is capable of meeting the user's requirements for all the parameters that may affect the quality of the measurement. Depending on typical use, the specifications for PQ may be different from the manufacturer's OQ specifications; however, for general use across a range of typical chiral molecules and sampling conditions, the specifications for OQ will be the same as those needed for PQ. For validated methods, specific PQ tests, also known as system suitability tests, can be used in lieu of PQ requirements.

Specific procedures, acceptance criteria, and time intervals for characterizing performance depend on the instrument and intended application. Demonstrating stable instrument performance over extended periods of time provides some assurance that reliable measurements can be taken from test sample spectra.

@2024 USPC

Particular long-term stability tests that can be carried out for PQ evaluation beyond those carried out for IQ or OQ are as follows. It is recommended that a 60-min measurement of a 0.9 M solution of (+)-*R*-camphor in carbon tetrachloride, measured in a 100-µm path-length cell, be performed between different applications of the VCD spectrometer to ensure that the signs, intensities, and signal-to-noise ratio of the VCD spectrum established as a qualification test during OQ are maintained. This is particularly important if there has been an interruption in power or a long hiatus between measurements.

If averaging over long periods of time, such as overnight, it is important that the stability of both the VCD baseline and the sample VCD spectrum are stable over time and that the signal-to-noise ratio improves as expected with the square-root of measurement time or number of interferometer scans, as illustrated by the example in ⟨1782⟩. In general, stability should be maintained to within the noise level of the VCD measurement. Because VCD intensities are generally three to four orders of magnitude smaller than the parent IR intensity, the instrument stability for the FT-IR performance of the instrument is typically larger over time relative to the noise level of the VCD spectrum.

## 3. PROCEDURE

The measurement of the VCD spectrum of a sample follows the same general rules as the measurement of an IR spectrum as for mid-IR spectroscopy described in ⟨854⟩.

### 3.1 Sample

A VCD spectrum can be measured in all types of standard IR transmission cells, either for neat liquids or solutions. For solids, such as in potassium bromide (KBr) pellets, mulls, or thin films, it is recommended that additional steps be taken to ensure that artifacts arising from sample linear birefringence are not present as described in ⟨1782⟩ for advanced instrumentation methods, such as dual PEM modulation or rotating sample cells.

Because of the importance of noise control in a VCD measurement, the absorbance of a sample should not exceed $A = 1.0$ in the region of measurement interest. For absorbance >1.0, insufficient radiation is present at the detector, and noise dominates the VCD spectrum. The optimum level of absorbance relative to the sample reference (empty beam or solvent) is approximately 0.4. One should adjust the path length and/or concentration of the sample such that the average absorbance is approximately 0.4–0.5 over the region of interest, with limits of 0.1–1.0. For samples with a wide range of absorbance, more than one measurement can be carried out with differing average absorbance values to ensure that a VCD spectrum of adequate quality is obtained over the entire range of interest.

To perform a solution-state VCD measurement, first find a solvent that dissolves an adequate amount of solute to achieve a desired absorbance level. Solvents without CH bonds are the most desirable for this purpose; these include carbon tetrachloride, deuterated chloroform ($CDCl_3$), or deuterated dimethyl sulfoxide (DMSO-$d_6$). The IR cell should have windows that are transparent in the mid-IR region, with generally low levels of linear birefringence. Commonly used materials are barium fluoride ($BaF_2$), which has good transmission to 800 $cm^{-1}$, and calcium fluoride ($CaF_2$), which is used if coverage to only 1100–1200 $cm^{-1}$ is needed, such as for aqueous solutions.

### 3.2 Standard

To ensure that the analyst can use an IR cell for a transmission measurement of a solution, it is recommended that a standard OQ measurement of a 0.9 M solution of (+)-*R*-camphor in carbon tetrachloride using a 100-µm barium fluoride cell be performed. For different choices of concentration or path length, one can use the linear dependence of these quantities on the measured $\Delta A$ to ensure that an accurate measurement with the correct signs and intensities has been achieved.

### 3.3 Analysis

VCD spectra, once measured, can be analyzed in a variety of ways, depending on the intended application. The principal application of VCD in the pharmaceutical industry is the determination of absolute configuration (AC) in conjunction with a VCD calculation using a quantum chemistry computation software package. A second application is the determination of EE of a sample, either for the purpose of determining the EE of a sample or for monitoring the EE of one or more species during the course of the chemical reaction involving chiral species. Achievement of the highest level of accuracy in the determination of EE requires the use of a chemometric software package that uses the entire range of the VCD spectrum, as opposed to a single band or wavenumber frequency. Other applications of VCD are its use with a standard database of VCD and IR spectra to simultaneously ensure the correct identity, AC, and EE of a chiral substance, for example as a chiral raw material identification. VCD can also be used to specify the AC and EE of a drug product in the presence of either achiral or chiral excipients, such as carbohydrates. These applications are described in more detail in ⟨1782⟩.

## 4. VALIDATION AND VERIFICATION

### 4.1 Validation

The objective of VCD procedure validation, as with the validation of any analytical process, is to demonstrate that the measurement is suitable for its intended purpose. The application of VCD spectroscopy is somewhat different from that of conventional vibrational spectroscopic techniques because it is not a primary technique. Rather, it is the polarization difference spectroscopy of the parent IR spectroscopy that has been used by itself for decades as a primary identification and quantitation technique as described for mid-IR spectroscopy in ⟨854⟩. The differential VCD spectrum supplements the parent IR spectrum

@2024 USPC

with a new set of intensities at each position of an IR absorption band. The new set of intensities then reveals stereospecific properties of the sample molecules that must be chiral to have a non-zero VCD spectrum. There are two primary properties of a sample of a chiral molecule: one is the AC of the dominant chiral species (dominant enantiomer), and the second property is the EE of the dominant enantiomer over its lesser (mirror-image) enantiomer. In addition, the VCD spectrum carries additional information about the solution-state conformation, or conformational distribution, of the molecule that may be available in only lesser detail, if any, using the parent IR spectrum alone. Applications that require validation for the use of VCD spectroscopy also exist for the combined use of the measurement of the VCD of a substance for which there exists a reference spectrum with known AC and EE. Any subsequent measurement of the VCD spectrum, together with the simultaneous measurement of its parent IR spectrum, confirms in one measurement the molecular identity of the sample as well as the AC and EE. Such applications are useful, for example, for chiral raw-material identification of AC and EE, for which there is currently no established methodology for a single measurement. VCD can also confirm, in a single measurement, the AC and EE of a final drug product, including the chirality (if any) of the excipients.

Before validation of VCD for AC determination, an overall instrument validation should be carried out by the measurement of the VCD spectrum of neat (–)-*S*-α-pinene or (+)-*R*-α-pinene using a 75-µm cell. The calibrated, baseline-corrected VCD spectrum should yield a positive peak maximum of $\Delta A$ equal to approximately $+5 \times 10^{-4}$ absorbance units at 1220 $cm^{-1}$ and a negative peak value of approximately $-4 \times 10^{-4}$ at 1130 $cm^{-1}$. The noise level should be comparable to that established for the instrument during the OQ phase of instrumental qualification described above. Because the VCD spectrum of α-pinene is relatively large, sufficient signal-to-noise ratio is available with a 20-min collection to verify that the instrument is operating with correct VCD intensities, signs, and noise levels for the applications of VCD described below.

Validation for AC determination by VCD can be achieved by the successful comparison of the measured VCD spectrum of the validation standard, neat (–)-*S*-α-pinene, to its quantum-chemistry-calculated VCD spectrum. Success is achieved by measuring the baseline-corrected VCD spectrum with sufficient signal-to-noise ratio that the signs, frequencies, and relative intensities of the major VCD bands can be compared clearly to the corresponding VCD signs, frequencies, and relative intensities of the calculated VCD spectrum. If the signs, frequencies, and relative intensities agree, then the AC of the measured sample of (–)-α-pinene is the same as that for the model of *S*-α-pinene that has been constructed for the calculation of this standard molecule. If the frequencies and relative VCD intensities are opposite after instrument sign calibration, then the AC of the sample is opposite (the mirror image) of the enantiomer used for the calculation. A successful comparison requires pretreatment of the VCD data for baseline subtraction and intensity calibration. It also requires a computational procedure that is known to be accurate in calculating VCD spectra. Finally, a program should be used to impartially assess the degree of agreement between measured and calculated VCD spectra such that one relies on more than an analyst's visual assessment of the agreement, or lack of agreement, between a measured spectrum and a calculated spectrum. An example of this procedure can be found in ⟨1782⟩ as well as in the references cited in ⟨1782⟩.

Validation of VCD spectroscopy for the determination of EE is achieved by plotting the EE predicted by VCD versus the EE for a sample of neat (–)-*S*-α-pinene for a series of samples with differing values of %EE over the range from 100% EE to 0% EE. The EE predicted by VCD involves measurement of the VCD spectra at a chosen spectral resolution and time of collection to achieve a desired level of signal-to-noise ratio, followed by pretreatment of the measured VCD spectra for baseline subtraction. The prediction of EE could be based on a size of a single VCD band for the samples with differing VCD, normalized for constant IR intensity; but more generally and with better accuracy, the entire range of VCD bands across the spectrum is used for each spectrum by means of a chemometrics software package. Validation is accompanied by a measure of the %EE accuracy through a cross-correlation analysis, yielding a root mean square (RMS). An example of such a determination of %EE by VCD for neat (–)-*S*-α-pinene is provided, along with literature references, in ⟨1782⟩.

More generally, validation is required when a method is intended for use as an alternative to the official procedure for testing an official article. The objective is to demonstrate that the measurement of VCD is suitable for its intended purpose; for examples of various types of measurements, see *Validation of Compendial Procedures* ⟨1225⟩. For %EE determination, creation of a linear plot of actual versus VCD-predicted values of %EE establishes that the magnitude of IR-normalized VCD spectra, as evaluated with chemometrics, exhibits sufficient linearity, range, accuracy, specificity, precision, detection limit, quantitation limit, and robustness with respect to the detection of %EE.

Chapter ⟨1225⟩ provides definitions and general guidance on analytical procedures validation without indicating specific validation criteria for each characteristic. The intention of the following sections is to provide the user with specific validation criteria that represent the minimum expectations for VCD technology. For each particular application, tighter criteria may be needed to demonstrate suitability for the intended use.

#### ACCURACY

Accuracy can be determined by the measurement of a VCD spectrum of the established validation standard of neat (–)-α-pinene or (+)-α-pinene, as presented, for example, in ⟨1782⟩, and verifying that the measured signs and intensities of the VCD spectrum agree with the standard VCD spectrum to within the noise level of the measurement. In particular, the VCD spectrum should yield a positive peak maximum of $\Delta A$ equal to approximately $+5 \times 10^{-4}$ absorbance units at 1220 $cm^{-1}$ and a negative peak value of approximately $-4 \times 10^{-4}$ at 1130 $cm^{-1}$. This validation ensures that the VCD spectrometer is accurately calibrated and has the correct signs for the VCD bands.

### 4.2 Precision

#### REPEATABILITY

**Validation criteria:** Measurement of VCD spectra of the validation standard sample, neat (+)-α-pinene or (–)-α-pinene, in 20-min blocks with variations in the VCD spectra at or less than the noise level of each 20-min block that is approximately $\Delta A$ equal to or less than $1 \times 10^{-5}$

https://pharmacopeia.com/

INTERMEDIATE PRECISION

The effect of random events on the analytical precision of the validation criteria of VCD measurement should be established. Typical variables include performing the analysis on different days, using different instrumentation, or having the method performed by two or more analysts. As a minimum, any combination of at least two of these factors totaling six experiments will provide an estimation of intermediate precision. (For example, this could be two analysts on each of 3 days, or two analysts on two sets of equipment on 2 days for each analyst–equipment combination.)
**Validation criteria:** The *Validation criteria* are the same as those for *Repeatability*.

SPECIFICITY

Specificity is not a required metric for the determination of AC. For the measurement of EE for more than one chiral species in a single set of measurements, the analytical procedure, including chemometric analysis, must be able to unequivocally assess the EE of chiral species in the presence of components that may be expected to be present, i.e., solvent and other nonchiral species.
**Validation criteria:** The *Validation criteria* are demonstrated by meeting the *Accuracy* requirement.

QUANTITATION LIMIT

For the determination of AC, there is no quantitation limit (QL). The QL for EE can be determined by carrying out a determination of quantitation of %EE for the VCD validation standard of neat α-pinene for a series of EE values, performing a chemometric analysis of VCD-predicted EE values and performing a determination of RMS error, as illustrated, for example, in ⟨1782⟩.
**Validation criteria:** The analytical procedure should be capable of determining the analyte precisely and accurately at a level equivalent to approximately 1% EE for neat α-pinene.

LINEARITY

A linear relationship between the analyte concentration and response should be demonstrated by preparing NLT 5 standard solutions at concentrations encompassing the anticipated concentration of the test solution. The standard curve should then be evaluated using appropriate statistical methods, such as a least-squares regression, for the area of peak height of a selected VCD band, or for the entire spectrum, using chemometric analysis such as partial least squares. For experiments that do not yield a linear relationship between analyte concentration and response, appropriate statistical methods must be applied to describe the analytical response.
**Validation criteria:** The *Validation criteria* find the correlation coefficient above 0.95 for a linear plot of actual EE versus VCD-predicted EE.

ROBUSTNESS

The reliability of an analytical measurement should be demonstrated by deliberate changes to experimental parameters, such as changes in spectral resolution, concentration, or path length for measurement of VCD.

## 4.3 Verification

U.S. Current Good Manufacturing Practices regulations [21 CFR 211.194(a)(2)] indicate that users of the analytical procedures, as described in *USP–NF*, are not required to validate these procedures if provided in a monograph. Instead, they must simply verify their suitability under actual conditions of use.

The objective of procedure verification is to demonstrate that the procedure, as prescribed in a specific monograph, can be executed by the analysts with suitable accuracy, specificity, and precision using the instruments, and sample solutions of chiral molecules available. If the verification of the compendial procedure by following the monograph is not successful, the procedure may not be suitable for use with the article under test (for additional information, see *Verification of Compendial Procedures* ⟨1226⟩). It may be necessary to develop and validate an alternative procedure as allowed in *General Notices, 6.30 Alternative and Harmonized Methods and Procedures*.

Verification of compendial methods should, at a minimum, include the execution of the validation parameters for specificity, accuracy, precision, and limit of quantitation, when appropriate, as indicated in *4.1 Validation*.

# ⟨785⟩ OSMOLALITY AND OSMOLARITY

***Change to read:***

## INTRODUCTION

Osmotic pressure plays a critical role in all biological processes that involve diffusion of solutes or transfer of fluids through membranes.

▲Osmosis occurs when the osmotic pressure drives the solvent, but not solute, to cross a semipermeable membrane from regions of lower to higher solute concentrations until equilibrium is reached. Osmotic pressure is a colligative property that depends on the number, but not the identity, of moles of solutes present in solution. Quantitative measurement of the number of moles of solutes in solution is necessary for predicting and controlling the potential damage to biological tissues due to fluid transfer across biological tissue membranes.

The terms osmolality, osmolarity, and tonicity are often used to describe the number of solutes in the solution, however, it is incorrect to use these terms interchangeably. The measurement of the number of solutes in the solution, using colligative properties, allows the direct determination of the osmolality of the solution with units of moles of solutes per kilogram of solvent. This result can be converted into a value for osmolarity with units of moles of solutes per liter of solvent, typically water. Tonicity is a medical term that relates to the osmotic pressure difference between the internal and external sides of a cell membrane.▲ (USP 1-Dec-2020)

***Change to read:***

## ▲THEORETICAL BACKGROUND

The osmotic pressure of a solution depends on the number of solutes in a solution, and is therefore referred to as a colligative property. For an ideal solution with water as the solvent, the osmotic pressure, $\Pi$, is a function of the water activity, $a_W$:

$$\Pi = -\frac{RT}{V_m}\ln\ a_w$$
$$a_w = \gamma_w x_w$$

where $V_m$ is the molar volume of water at temperature $T$, $V_m$ = 18.018 $cm^3 mol^{-1}$ at 273.15 K (*1*); $R$ is the gas constant, $R$ = 8.3144598 J $mol^{-1}$ $K^{-1}$ (*2*); $T$ is the temperature in Kelvin; $\gamma_W$ is the activity coefficient of water; and $x_W$ is the mole fraction of water, $x_W = (1 - x_S)$, where $x_S$ is the mole fraction of solute. At low solute concentrations ($-\ln a_W \approx x_S \approx n_S/n_W$), the equation for osmotic pressure, above, can be simplified to the van't Hoff equation for osmotic pressure which states:

$$\Pi = RT\left(\frac{n_S}{V}\right) = RT\left(\frac{n_S}{n_W V_m}\right) = \frac{RTM_W}{V_m}\left(\frac{n_S}{n_W M_W}\right)$$

where

$$\left(\frac{n_S}{n_W M_W}\right) = v \times m = \xi_{m,\ ideal}$$

which yields

$$\Pi = \frac{RTM_W}{V_m}\xi_{m,\ ideal}$$

where $n_S$ is the moles of solute molecules; $n_W$ is the moles of water molecules; $V$ is the volume of water at temperature, $T$; $M_W$ is the molar mass of water, $M_W$ = 18.015268 g $mol^{-1}$ (*3*); $\xi_{m,ideal}$ is the osmolality of the solution in moles per kilogram of water; $v$ is the stoichiometric coefficient for the solute; and $m$ is the molal concentration of the solute in moles of solute per kilogram of water. For an ideal, non-dissociating solute, $v$ = 1 and the osmolality, $\xi_m$, is equal to the molal concentration of solute. For a dissociating solute, $v$ is equal to the stoichiometric number of moles into which one mole of solute will dissociate. For non-ideal solutes, an osmolality coefficient, $\Phi_m$, is introduced to correct for the difference between the predicted behavior of ideal solutions and the observed behavior of real solutions. The osmolality coefficient is defined as:

$$\Phi_m = \frac{-\ln a_W}{vmM_W} = \frac{\xi_{m,real}}{\xi_{m,ideal}}$$

The osmolality of a real solution is, therefore:

DOI: https://doi.org/10.31003/USPNF_M99580_03_01
@2024 USPC

$$\xi_{m,\,real} = \nu m \Phi_m$$

When multiple solutes are present, the osmolality may be approximated by summing the contributions from all individual solutes, *i*, as:

$$\xi_{m,real} = \sum_i \nu_i m_i \Phi_{m,i}$$

where $m_i$ is the molal concentration of the $i^{th}$ solute; $\nu_i$ is the number of ions into which the solute dissociates; and $\Phi_{m,i}$ is the osmolality coefficient for the $i^{th}$ solute at the molality, *m*. This simplified additive approach assumes that the osmolality coefficient for each solute in the mixture is not different from the osmolality coefficient determined for the individual solute (*4*).

In addition to osmotic pressure, other colligative properties can be used to measure the osmolality of solutions including dew-point depression, boiling-point elevation, and freezing-point depression. The most commonly used method for analysis of the osmolality of solutions is freezing-point depression. The freezing-point depression, $\Delta T_f$, of an aqueous solution relative to pure water is proportional to the change in the water activity, $a_W$:

$$\Delta T_f = \frac{RT_f^2}{\Delta H_{fus}} \Delta \ln a_W$$

where $\Delta H_{fus}$ is the enthalpy of fusion of water, and $T_f$ is the freezing point of the solution in Kelvin. At low solute concentrations, this can be simplified to express freezing-point depression in terms of osmolality as:

$$\Delta T_f = \frac{M_W RT_f^2}{\Delta H_{fus}} \xi_m = K_f \xi_m$$

where

$$K_f = \frac{M_W RT_f^2}{\Delta H_{fus}}$$

The value of $\Delta H_{fus}$ is temperature dependent (*3*) and so is $K_f$; however, $K_f$ is typically treated as a constant and set to the value for pure water at the freezing point. For water, the value of $\Delta H_{fus}$ at 273.15 K is 6006.78 J $mol^{-1}$ (*3*), which gives a value for $K_f$ of 1.86056 K kg $mol^{-1}$.

Vapor pressure osmometers measure the relative humidity of the air above the sample that is in equilibrium with the sample. The dew point is the temperature below which the water vapor in the air is above saturation and condensation occurs. The change in the dew point of the air, $\Delta T_D$, is given by the Clausius–Clapeyron equation:

$$\Delta T_D = \frac{RT_D^2}{\Delta H_{vap}} \frac{\left(p_{SW}^0 - p_{SW}\right)}{p_{SW}^0}$$

where $p_{sw}$ is the saturation vapor pressure of the solution; $p^0_{sw}$ is the vapor pressure of pure water; and $\Delta H_{vap}$ is the enthalpy of vaporization of water. The change in dew point can be expressed in terms of osmolality as:

$$\Delta T_D = \frac{M_W RT^2}{\Delta H_{vap}} \xi_m = K_D \xi_m$$

where

$$K_D = \frac{M_W RT^2}{\Delta H_{vap}}$$

The value of $\Delta H_{vap}$ is temperature dependent (*5*) and so is $K_D$. At 25° (298.15 K), the enthalpy of vaporization of water is $\Delta H_{vap}$ = 43.990 k J $mol^{-1}$ (*5*) and this results in a value of $K_D$ = 0.3027 K kg $mol^{-1}$. At the boiling point, 373.15 K, $\Delta H_{vap}$ = 40.657 k J $mol^{-1}$ (*5*) and $K_D$ = 0.5130 K kg $mol^{-1}$ and is equivalent to the ebullioscopic constant, $K_b$, for water which correlates the osmolality to boiling-point elevation.

To calibrate instruments for measurements of water activity and osmolality, it is necessary to have well-characterized solutions that are easy to prepare. The nonlinear relationship between the osmolality coefficient, $\Phi_m$, and the molality of the solute has been studied for many solutions of single salts and is most often represented by the Pitzer–Debye–Hückel equation (*1,4,6*) as a virial expansion in terms of molality as follows:

$$\Phi_m - 1 = f_\Phi + B_\Phi m + C_\Phi m^2$$

where

$$f_\Phi = -A_\Phi\left(\frac{\sqrt{I}}{1 + b\sqrt{I}}\right)$$

and

$$B_\Phi = \beta_0 + \beta_1 e^{-\alpha\sqrt{I}}$$

and

$$I = \frac{1}{2}\sum_i m_i z_i$$

where $A_\Phi$ is the Debye–Hückel slope; $I$ is the ionic strength; $z_i$ is the charge of $i$; $b$ is the empirical ion size parameter and equal to 1.2; and $\alpha$ is the empirical ionic strength dependence parameter and equal to 2.0. The parameters $\beta_0$, $\beta_1$, and $C_\Phi$ are constants that are specific to the particular solute.

For a simple 1:1 electrolyte, like sodium chloride (NaCl), the ionic strength, $I$, is equal to the molality, and the relationship between molality and osmolality coefficient simplifies to:

$$\Phi_m = 1 - A_\Phi\left(\frac{\sqrt{m}}{1 + b\sqrt{m}}\right) + \left(\beta_0 + \beta_1 e^{-\alpha\sqrt{m}}\right)m + C_\Phi m^2$$

For sodium chloride (NaCl), the value of $A_\Phi$ has been calculated as a function of temperature and pressure (*7*), and at 273.15 K and standard pressure, $A_\Phi = 0.37642$. Using this value for $A_\Phi$ and keeping $\alpha = 2$ and $b = 1.2$, the remaining values for sodium chloride (NaCl) ($\beta_0$, $\beta_1$, and $C_\Phi$) can be fit to the experimental results for the freezing-point depression of sodium chloride (NaCl) solutions from Scatchard and Prentiss (*8*) and Gibbard and Gossmann (*9*). The entire set of experimental results span the range from 2–7300 mOsmol/kg. The resulting best-fit parameters of $\beta_0 = 0.040933$, $\beta_1 = 0.26955$, $C_\Phi = 0.004506$ enable the calculation of recipes for sodium chloride calibration standard solutions for osmolalities within this experimental range. The resulting recipes for *Standard Solutions* are listed in *Table 1*.▲ (USP 1-Dec-2020)

***Change to read:***

## ▲TYPES OF OSMOLALITY INSTRUMENTS

The osmolality of a solution is commonly determined by measurement of the freezing-point depression or dew-point depression. A freezing-point depression instrument measures the osmolality of a solution at the freezing-point of the solution, whereas a dew-point depression instrument measures the osmolality of a solution at ambient temperatures. Significant changes in the solubility, solvation, and ionization of solutes may occur as temperature changes resulting in a temperature dependence of activity and osmotic coefficients. These factors may lead to significant differences in the osmolality results obtained by different types of osmometers on the same test solutions. Volatile solutes will evaporate during a measurement with vapor pressure osmometers and result in erroneous values. Other techniques need to be used when measuring osmolality in solutions containing volatile solutes.

### Freezing-point Depression Osmometer

A freezing-point depression osmometer typically consists of the following: a means of cooling the container used for the measurement, a thermocouple for measuring the temperature of the sample, and a means of initiating crystallization. The liquid sample (generally about 0.02–2 mL) is typically placed into a cooling bath or a cooling pit while being mixed to facilitate uniform cooling. In small volume freezing-point osmometers (with sample sizes smaller than 100 µL), mixing the liquid is not required for uniform cooling. The sample is supercooled to below the expected freezing point and then a short “buzz” (a brief pulse or shock to initiate crystallization of the water) is applied to the sample. As the sample freezes, the temperature of the thermocouple rises asymptotically toward the freezing point until the sample is completely frozen and the temperature stabilizes. The freezing-point depression is the difference between the freezing point of pure water and the freezing point of the sample.

### Vapor Pressure Osmometer

Vapor pressure osmometers use hygrometric (dew-point temperature depression) measurements for determining water activity. They require a smaller volume of specimen (generally about 5–20 µL). The hygrometric technique is based on measuring the temperature of a wet thermocouple junction in a sealed chamber containing the sample. A current is applied to cool the thermocouple, by means of the Peltier effect, below the dew-point temperature, resulting in condensation of water from the air onto that junction. As water condenses on the thermocouple, the temperature of the thermocouple rises asymptotically

@2024 USPC

toward the dew point. When the temperature of the thermocouple reaches the dew point, condensation ceases, causing the thermocouple temperature to stabilize. The dew-point temperature depression is the difference between the dew-point temperature for air in equilibrium with pure water and the dew-point temperature for air in equilibrium with the sample. In some instruments, the solution to be tested is pipetted onto a small, solute-free paper disk, which is then inserted into the sample chamber containing the thermocouple hygrometer. In other instruments, the solution is tested as a drop at the end of a micropipette inserted into the chamber containing the thermocouple hygrometer.▲ (USP 1-Dec-2020)

## ▲QUALIFICATION OF OSMOLALITY INSTRUMENTS

Osmometers are classified as Group B instruments as described in *Analytical Instrument Qualification* ⟨1058⟩. The qualification of an osmometer instrument should cover the intended operational range of the instrument, the required accuracy of the instrument, and the required precision of the instrument. For more details, see ⟨1058⟩. Acceptance criteria for fitness for purpose are based on the uncertainty of the reference material and the performance specification of the instrument. Any osmometer that is shown to be fit for the intended purpose, by meeting the qualification criteria, may be used to provide osmolality results according to the guidelines of this chapter.

### Installation Qualification (IQ)

The installation qualification (IQ) requirements provide evidence that the hardware and software are properly installed in the desired location.

### Operational Qualification (OQ)

The operational qualification (OQ) for the osmolality instrument should characterize the precision and accuracy of the osmolality measurements. Prior to characterizing the performance of the osmolality instrument, perform a full calibration of the instrument, as instructed by the instrument operation manual, and confirm the proper calibration with a calibration check (see *Procedure for Calibration Check*).

#### OPTIMIZATION OF ADJUSTABLE FREEZING PARAMETERS

Freezing-point depression osmometers may have user-adjustable parameters that affect the freezing of the *Test Solutions*. These parameters may include stirring amplitude (during cooling step), "buzz" point (amount of supercooling that precedes initiation of freezing), and "buzz" amplitude (amplitude used to initiate freezing). These test parameters may be optimized, following the manufacturer's recommendations, to reliably freeze the *Test Solutions*.

#### PRECISION/REPEATABILITY

The precision of the measurement system should be characterized as part of the operational qualification by performing repeated measurements on the mid-range osmolality standard solution that was used in the instrument calibration. Calculate the sample standard deviation using ($n$–1) degrees of freedom, σ, of six or more measurements, and express the repeatability as a percentage (%) relative to the mean value of the osmolality standard, $X_0$:

$$R_{\%} = \frac{100\sigma}{\overline{X}_0}$$

The precision of the instrument, in mOsmol/kg, at the osmolality of a test solution being analyzed is:

$$R_{osm} = \frac{R_{\%}}{100}\overline{X}$$

where $\overline{X}$ is the mean value for the test solution. After characterizing the precision of the measurement system, this result should be compared to the manufacturer's claimed repeatability. If the result is significantly greater than the claimed repeatability (e.g., more than twice the claimed repeatability), then the performance of the osmometer should be more fully investigated. The acceptance criterion is that the relative standard deviation should be NMT 2%.

#### ACCURACY

Verify the accuracy of the calibrated instrument by measurement of at least three replicates of the highest and lowest osmolality standard used during the calibration. The instrument reading should be within ±4 mOsmol/kg of the stated value for the standard solutions up to 400 mOsmol/kg and within ±1% of the stated value for the standard solutions >400 mOsmol/kg.

## Performance Qualification (PQ)

The performance qualification (PQ) should be evaluated by periodic recalibration of the instrument and a day-of-use calibration check. It is recommended that the result for the day-of-use calibration check be monitored over time to track performance of the instrument. ▲ (USP 1-Dec-2020)

***Change to read:***

# ▲OPERATION AND CALIBRATION OF OSMOMETERS

## Standard Solutions

Solutions for instrument calibration may be purchased (*10*) or may be prepared as specified in *Table 1*. Other concentrations not listed in *Table 1* are acceptable. They may be stored at 2°–30°, but should not be frozen. When using purchased solutions, follow the manufacturer's expiry date and use instructions. Purchased solutions are typically provided in single-use ampules and should be discarded after use. Solutions prepared as specified in *Table 1* should be stored in nonpermeable (e.g., glass) containers to prevent evaporation. Fresh solutions should be prepared at least monthly as they are often nonsterile unpreserved solutions.

**Table 1. Standard Solutions (STD) for Freezing-Point Depression Osmometer Calibration[a, b]**

| mOsmol/kg of STD | g of Sodium Chloride/kg of Water | mOsmol/kg of STD | g of Sodium Chloride/kg of Water |

| 1400 | 45.00 | 3900 | 121.60 |
| 1500 | 48.20 | 4000 | 124.48 |

[a] Calculated from experimental data from Scatchard and Prentiss (*8*) and Gibbard and Gossmann (*9*) with best-fit parameters of $A_\phi = 0.37642$; $\beta_0 = 0.040933$; $\beta_1 = 0.26955$; $C_\phi = 0.004506$; $\alpha = 2$, $b = 1.2$.

[b] The amount of sodium chloride (NaCl) specified is added to 1 kg of water (on weight basis). Weigh sodium chloride (NaCl), which has been previously dried at 110° for 2 h, to ±0.03 g and weigh water to ±0.2 g to ensure osmolality is accurate to correct whole number of mOsmol/kg. If correctly prepared, the accuracy of these *Standard Solutions* is ±1 mOsmol/kg. For purchased solutions, the accuracy is typically ±2 mOsmol/kg for concentrations up to 400 mOsmol/kg, and ±0.5% for concentrations >400 mOsmol/kg. Other *Standard Solution* concentrations can be prepared as needed.

## Calibration

The osmometer should be calibrated as per the manufacturer's instructions using either purchased or prepared *Standard Solutions* (as described in *Table 1*).

### PROCEDURE FOR CALIBRATION CHECK

The calibration check should be performed in the same manner that measurements will be performed. If individual measurements will be reported, the calibration check should be performed with a single measurement of a standard solution. If the mean of three measurements will be reported, the calibration check should be performed with the mean of three measurements of a standard solution. Unless a different solution is specified as part of the manufacturer's instructions, select at least one solution from *Table 1* that lies near the center of the expected range of osmolality for the test solution. Two *Standard Solutions* bracketing the test sample within 300 mOsmol/kg are also acceptable. The instrument reading should be within ±4 mOsmol/kg from the stated value for solutions ≤400 mOsmol/kg and within ±1% from the stated value for solutions >400 mOsmol/kg. If the instrument fails to meet the acceptance criteria for the calibration check, then calibrate the instrument as per the manufacturer's instructions using either purchased or prepared *Standard Solutions* (as described in *Table 1*), and then repeat the calibration check of the instrument. After a successful check of the calibration, the instrument is ready for use.

## Test Solutions

For a solid for injection, reconstitute with the appropriate diluent as specified in the instructions on the labeling. For solutions, use the sample as is. [NOTE—A solution can be diluted to bring it within the range of measurement of the osmometer, if necessary, but the results must be expressed as those of the diluted solution and must NOT be multiplied by a dilution factor to calculate the osmolality of the original solution unless otherwise indicated in the monograph. The molal osmotic coefficient is a function of concentration and changes nonlinearly with dilution.] Unless otherwise directed in the monograph, use *Method 1*.

## Method 1: Freezing-Point Osmometry

### PROCEDURE

Verify that the instrument has been turned on for an appropriate amount of time (NLT 30 min unless the instrument contains an internal sensor) to enable the cooling bath to equilibrate to its normal operating temperature. Verify that the calibration of the instrument brackets the expected osmolality of the test solution. If not, perform a new calibration of the instrument such that the lower and upper calibration standards bracket the expected osmolality of the samples to be evaluated. At least each day of use, confirm the instrument calibration as described in *Procedure for Calibration Check*. Before each measurement, rinse the measurement cell with the solution to be tested, and verify that the thermocouple is clean and dry before immersing it into the test solution.

### TROUBLESHOOTING

Samples may sometimes fail to freeze if the sample viscosity is too high, if the sample is precooled too much or not enough, or if the mixing speed or the amplitude of the instrument is not optimally set. If test solutions occasionally fail to freeze, the osmolality measurements may not be accurate. The settings of the instrument should be optimized to reliably freeze the test solution, and then the instrument should be recalibrated with the optimized settings prior to re-evaluation of the test solutions.

Insoluble particles, emulsified droplets that are insoluble and entrained air, will not significantly affect the osmolality of the aqueous vehicle; however, these may affect the ability of the sample to freeze. If accurate measurement of the osmolality is affected by the presence of the insoluble phase, the insoluble phase should be removed by centrifugation and the osmolality of the clarified aqueous phase should be evaluated and reported.

## Method 2: Vapor Pressure Osmometry

### STANDARD SOLUTIONS

The osmolality reference standards in *Table 1* are based on freezing-point depression measurements (*8,9*) and represent the osmolality of the solution at the freezing point. However, manufacturers of dew point osmometers often typically design their instruments to be calibrated with the same standard solutions used for freezing-point depression instruments. Unless otherwise directed by the instrument manufacturer, it is permitted to use the same *Standard Solutions* that were defined above for use with the freezing-point depression instruments. When performing an instrument calibration and calibration check with these *Standard Solutions*, the stated value for the standard solution is considered to be the same as indicated for the freezing-point depression instruments.

### PROCEDURE

Ensure that the sample and instrument are located in a laboratory with good temperature control and that the sample is equilibrated to the temperature of the laboratory before performing the measurement. Verify that the instrument has been turned on for NLT 30 min to completely equilibrate to the lab temperature while operating. Verify that the calibration of the

instrument brackets the expected osmolality of the test solution. If not, perform a new calibration of the instrument such that the lower and upper calibration standards bracket the expected osmolality of the samples to be evaluated. At least each day of use, confirm the instrument calibration as described in *Procedure for Calibration Check*. If the sample is dispensed for the measurement by a pipette, use a calibrated pipette to deliver the specified volume of liquid to the sample chamber. Consistent timing during sample loading is important for consistent repeatability. The procedure and timing for sample loading need to be equivalent to those used for the instrument calibration.

TROUBLESHOOTING

Volatile ingredients (e.g., ethanol) may evaporate rapidly during the sample loading and measurement resulting in inaccurate and variable results.▲ (USP 1-Dec-2020)

***Change to read:***

## ▲REPORTING OF RESULTS

### Units

The units of osmolality are osmole per kilogram of water (Osmol/kg) or milliosmole per kilogram of water (mOsmol/kg). The units of osmolarity are osmole per liter of solution (Osmol/L) or milliosmole per liter of solution (mOsmol/L). It is not necessary to state "of water" or "of solution" when using these units. The use of "Osmol" alone must be avoided because it is not clear whether it refers to the number (osmoles of solute) or the osmolality or the osmolarity.

### Measurement Result

If a single measurement result is reported, it should be reported with the precision given by the repeatability of the instrument. Preferably, the mean of three or more measurements on the same solution should be reported with a precision represented by the standard deviation of the averaged measurements. Most osmometers report results to the nearest whole number, therefore, the mean result should also be rounded to the nearest whole number and reported in units of mOsmol/kg.

### Conversion to Osmolarity

Freezing-point depression and vapor pressure measurements directly result in an assessment of the osmolality. However, it may be desirable to report the results in units of osmolarity. The measured osmolality $(\xi_m)$ can be converted to osmolarity $(\xi_c)$ using:

$$\xi_c = \xi_m(\rho - C)$$

where $\rho$ is the density of the solution and C is the total solute concentration, both expressed in grams per milliliter.

Example of conversion to osmolarity:

A 3% (w/v) solution of sodium bicarbonate contains 0.030 g/mL of anhydrous sodium bicarbonate. The density of this solution was found to be 1.0192 g/mL at 20°, and its measured osmolality $(\xi_m)$ was 615 mOsmol/kg.

[NOTE—1 g/mL = 1 kg/L.]

$$(p - C) = \left(1.0192\frac{\text{kg solution}}{\text{L solution}} - 0.030\frac{\text{kg solution}}{\text{L solution}}\right) = 0.9892\frac{\text{kg water}}{\text{L solution}}$$

$$\text{Osmolarity}\,(\xi_C) = (615\ \ \text{mOsmol/kg}\ \ H_2O) \times (0.9892\ \text{kg}\ \ H_2O/\text{L solution}) = 608\ \text{mOsmol/L solution}$$

### Tonicity

Tonicity is a medical term that relates to the osmotic pressure difference between the internal and external sides of a cell membrane. In many cases tonicity and osmolality are not the same because some solutes are able to rapidly pass through the cell membrane. Red blood cells, erythrocytes, are typically considered the standard for defining what is considered an isotonic solution. If red blood cells are immersed in a solution and the cells swell and become turgid or burst, the solution is hypotonic. If the red blood cells shrink and desiccate, the solution is hypertonic. An isotonic solution produces no change in the size of the red blood cells and the cell wall remains flaccid. Measurements of osmolality or osmolarity alone are not sufficient to characterize the tonicity of a liquid. It is preferable to use the terms hypoosmotic, hyperosmotic, and isoosmotic when discussing the relative osmolality of solutions. The standard for an isoosmotic solution is 0.9% sodium chloride (NaCl) solution, which has an osmolality of 285 mOsmol/kg and an osmolarity of 284 mOsmol/L.▲ (USP 1-Dec-2020)

## ▲OSMOLARITY

Osmolarity of a solution is a theoretical quantity expressed in osmoles/L (Osmol/L) of a solution and is widely used in clinical practice because it expresses osmoles as a function of volume. Osmolarity cannot be measured but is calculated theoretically from the experimentally measured value of osmolality.

Sometimes, osmolarity ($\xi_c$) is calculated theoretically from the molar concentrations:

$$\xi_c = \Sigma \nu_i c_i$$

$\nu_i$ = number of particles formed by the dissociation of one molecule of the $i^{th}$ solute
$c_i$ = molar concentration of the $i^{th}$ solute in solution

For example, the osmolarity of a solution prepared by dissolving 1 g of vancomycin in 100 mL of 0.9% sodium chloride solution can be calculated as follows:

[3 × 10 g/L/1449.25(molecular weight of vancomycin) + 2 × 9 g/L/58.44(molecular weight of sodium chloride)] × 1000 = 329 mOsmol/L

The results suggest that the solution is slightly hyperosmotic because the osmolality of blood ranges between 285 and 310 mOsmol/kg. However, the solution is found to be hypoosmotic and has an experimentally determined osmolality of 255 mOsmol/kg.[1] The example illustrates that osmolarity values calculated theoretically from the concentration of a solution should be interpreted cautiously and may not represent the osmotic properties of infusion solutions.

The discrepancy between theoretical (osmolarity) and experimental (osmolality) results is, in part, due to the fact that the osmotic pressure of a real solution is less than that of an ideal solution because of interactions between solute molecules or between solute and solvent molecules in a solution. Such interactions reduce the pressure exerted by solute molecules on a semipermeable membrane, reducing experimental values of osmolality compared to theoretical values. This difference is related to the molal osmotic coefficient ($\Phi_{m,i}$). The example also illustrates the importance of determining the osmolality of a solution experimentally, rather than calculating the value theoretically.

To convert to osmolality, it is necessary to know the kilogram of water per liter of solution as the conversion factor. The density of the solution should be measured and the amount of (anhydrous) solute per unit of volume should be known based on the preparation of the solution. If working with an unknown solution, the value of a loss on drying measurement could also be used (assuming water is the only volatile component in the solution).

**Example 1:** A 3% (w/v) solution of sodium bicarbonate contains 0.030 g/mL of anhydrous sodium bicarbonate. The density of this solution was found to be 1.0192 g/mL at 20°, and its measured osmolality was 615 mOsmol/kg.

[NOTE—1 g/mL = 1 kg/L.]

$$\left(p - c\right) = \left(1.0192\ \frac{kg\ \ solution}{L\ \ solution} - 0.030\frac{kg\ \ solute}{L\ \ solution}\right)$$

$$\left(p - c\right) = 0.9892\frac{kg\ \ solution}{L\ \ solution}$$

$$Osmolarity\left(\xi_c\right) = \left(615\ mOsmol/kg\ H_2O\right) \times \left(0.9892\ \ kg\ H_2O/L\ \ solution\right)$$

$$Osmolarity\ \left(\xi_c\right) = 608\ \ \ mOsmol/L$$

**Example 2:** An aqueous solution sodium lauryl sulfate (SLS) as raw material has a content of 30% (on a w/v basis) and has a specific gravity of 1.08 g/mL at 20°. It also contains 0.5% of sodium sulfate ($Na_2SO_4$). Calculate the predicted osmolarity and convert this into expected osmolality, if it is evaluated (assume an ideal solute, $\Phi_m = 1.0$). The molecular weight of SLS is 288.37 g/mol. The molecular weight of sodium sulfate ($Na_2SO_4$) is 142.04 g/mol. The density of the material at 20° is 1.08/0.997 = 1.083 g/mL.

$$\left(p - c\right) = \left(1.083\frac{kg\ \ solution}{L\ \ solution} - 0.305\frac{kg\ \ solute}{L\ \ solution}\right)$$

$$\left(p - c\right) = 0.778\frac{kg\ \ water}{L\ \ solution}$$

$$Osmolarity\ \left(\xi_c\right) = 608\ \ mOsmol/L$$

The osmolarity contributions would be:

***Delete the following:***

## ▲MEASUREMENT OF OSMOLALITY

The osmolality of a solution is commonly determined by the measurement of the freezing point depression of the solution.

### Apparatus

The apparatus, an osmometer for freezing point depression measurement, consists of the following: a means of cooling the container used for the measurement; a temperature measuring device with an appropriate current- or potential-difference measurement device that may be graduated in temperature change or in osmolality; and a means of mixing the sample.

Osmometers that measure the vapor pressures of solutions are less frequently employed. They require a smaller volume of specimen (generally about 5 µL), but the accuracy and precision of the resulting osmolality determination are comparable to those obtained by the use of osmometers that depend upon the observed freezing points of solutions.

### Standard Solutions

Prepare *Standard Solutions* as specified in *Table 1*, as necessary.[2]

Once prepared, the *Standard Solutions* may be stored in nonpermeable container–closure systems. They should be prepared fresh every week as they are nonsterile, unpreserved solutions. If using purchased solutions, follow the manufacturer's expiration date.

**Table 1. Standard Solutions for Osmometer Calibration[a]**

| Standard Solutions (Weight in g of sodium chloride per kg of water) | Osmolality (mOsmol/kg) ($\xi_m$) | Molal Osmotic Coefficient ($\Phi_{m,\,NaCl}$) | Freezing Point Depression (°) $\Delta T_f$ |
|---|---|---|---|
| 3.087 | 100 | 0.9463 | 0.186 |
| 6.260 | 200 | 0.9337 | 0.372 |
| 9.463 | 300 | 0.9264 | 0.558 |
| 12.684 | 400 | 0.9215 | 0.744 |
| 15.916 | 500 | 0.9180 | 0.930 |
| 19.147 | 600 | 0.9157 | 1.116 |
| 22.380 | 700 | 0.9140 | 1.302 |

[a] Adapted from the *European Pharmacopoeia,* 4th Edition, 2002, p. 50

### Test Solution

For a solid for injection, constitute with the appropriate diluent as specified in the instructions on the labeling. For solutions, use the sample as is.

[NOTE—A solution can be diluted to bring it within the range of measurement of the osmometer, if necessary, but the results must be expressed as that of the diluted solution and must NOT be multiplied by a dilution factor to calculate the osmolality of the original solution, unless otherwise indicated in the monograph. The molal osmotic coefficient is a function of concentration. Therefore, it changes with dilution.]

### Procedure

First, calibrate the instrument by the manufacturer's instructions. Confirm the instrument calibration with at least one solution from *Table 1* such that the osmolality of the *Standard Solution* lies within 50 mOsmol/kg of the expected value of the *Test Solution* or the center of the expected range of osmolality of the *Test Solution*. The instrument reading should be within ±4

[2] Commercially available solutions for osmometer calibration, with osmolalities equal to or different from those listed in *Table 1* and standardized by methods traceable to National Institute of Standards and Technology (NIST) (www.nist.gov), may be used.

@2024 USPC

mOsmol per kg from the *Standard Solution.* Introduce an appropriate volume of each *Standard Solution* into the measurement cell as in the manufacturer's instructions, and start the cooling system. Usually, the mixing device is programmed to operate at a temperature below the lowest temperature expected from the freezing point depression. The apparatus indicates when the equilibrium is attained. If necessary, calibrate the osmometer, using an appropriate adjustment device such that the reading corresponds to either the osmolality or freezing point depression value of the *Standard Solution* shown in *Table 1*.

[NOTE—If the instrument reading indicates the freezing point depression, the osmolality can be derived by using the appropriate formula under *Osmolality*.]

Repeat the procedure with each *Test Solution*. Read the osmolality of the *Test Solution* directly, or calculate it from the measured freezing point depression.

Assuming that the value of the osmotic coefficient is essentially the same whether the concentration is expressed in molality or molarity, the experimentally determined osmolality of a solution can be converted to osmolarity in the same manner in which the concentration of a solution is converted from molality to molarity. Unless a solution is very concentrated, the osmolarity of a solution ($\xi_c$) can be calculated as follows:

$$\xi_c = 1000\xi_m/(1000/\rho + \Sigma w_i v_i)$$

$\xi_m$ = experimentally determined osmolality
$\rho$ = density of the solution
$w_i$ = weight (g)
$v_i$ = partial specific volume of the $i^{th}$ solute (mL/g)

The partial specific volume of a solute is the change in volume of a solution when an additional 1 g of solute is dissolved in the solution. This volume can be determined by the measurement of densities of the solution before and after the addition of the solute. The partial specific volumes of salts are generally very small, around 0.1 mL/g. However, those of other solutes are generally higher. For example, the partial specific volumes of amino acids are in the range of 0.6–0.9 mL/g. It can be shown from the above equation correlating osmolarity with osmolality that:

$$\xi_c = \xi_m (\rho - c)$$

$\xi_m$ = experimentally determined osmolality
$\rho$ = density of the solution (g/mL)
$c$ = total solute concentration (g/mL)

Thus, alternatively, the osmolarity can also be calculated from experimentally determined osmolality from the measurement of density of the solution by a suitable method and the total weight of the solute, after correction for water content, dissolved per milliliter of the solution. ▲ (USP 1-Dec-2020)

# ⟨786⟩ PARTICLE SIZE DISTRIBUTION ESTIMATION BY ANALYTICAL SIEVING

***Change to read:***

▲•Portions of the chapter text that are national *USP* text, and are not part of the harmonized text, are marked with symbols (• •) to specify this fact.•▲ (USP 1-May-2023)

Sieving is one of the oldest methods of classifying powders and granules by particle size distribution. When using a woven sieve cloth, the sieving will essentially sort the particles by their intermediate size dimension (i.e., breadth or width). Mechanical sieving is most suitable where the majority of the particles are larger than about 75 µm. For smaller particles, the light weight provides insufficient force during sieving to overcome the surface forces of cohesion and adhesion that cause the particles to stick to each other and to the sieve, and thus cause particles that would be expected to pass through the sieve to be retained. For such materials, other means of agitation such as air-jet sieving or sonic sifting may be more appropriate. Nevertheless, sieving can sometimes be used for some powders or granules having median particle sizes smaller than 75 µm where the method can be validated. In pharmaceutical terms, sieving is usually the method of choice for classification of the coarser grades of single powders or granules. It is a particularly attractive method in that powders and granules are classified only on the basis of particle size, and in most cases the analysis can be carried out in the dry state.

Among the limitations of the sieving method are the need for an appreciable amount of sample (normally at least 25 g, depending on the density of the powder or granule, and the diameter of test sieves) and difficulty in sieving oily or other cohesive powders or granules that tend to clog the sieve openings. The method is essentially a two-dimensional estimate of size because passage through the sieve aperture is frequently more dependent on maximum width and thickness than on length.

This method is intended for estimation of the total particle size distribution of a single material. It is not intended for determination of the proportion of particles passing or retained on one or two sieves.

Estimate the particle size distribution as described under *Dry Sieving Method,* unless otherwise specified in the individual monograph. Where difficulty is experienced in reaching the endpoint (i.e., material does not readily pass through the sieves) or when it is necessary to use the finer end of the sieving range (below 75 µm), serious consideration should be given to the use of an alternative particle-sizing method.

Sieving should be carried out under conditions that do not cause the test sample to gain or lose moisture. The relative humidity of the environment in which the sieving is carried out should be controlled to prevent moisture uptake or loss by the sample. In the absence of evidence to the contrary, analytical test sieving is normally carried out at ambient humidity. Any special conditions that apply to a particular material should be detailed in the individual monograph.

## PRINCIPLES OF ANALYTICAL SIEVING

Analytical test sieves are constructed from a woven-wire mesh, which is of simple weave that is assumed to give nearly square apertures and is sealed into the base of an open cylindrical container. The basic analytical method involves stacking the sieves on top of one another in ascending degrees of coarseness, and then placing the test powder on the top sieve.

The nest of sieves is subjected to a standardized period of agitation, and then the weight of material retained on each sieve is accurately determined. The test gives the weight percentage of powder in each sieve size range.

This sieving process for estimating the particle size distribution of a single pharmaceutical powder is generally intended for use where at least 80% of the particles are larger than 75 µm. The size parameter involved in determining particle size distribution by analytical sieving is the length of the side of the minimum square aperture through which the particle will pass.

Sieves are selected to cover the entire range of particle sizes present in the test specimen. A nest of sieves having a $\sqrt{2}$ progression of the area of the sieve openings is recommended. The nest of sieves is assembled with the coarsest screen at the top and the finest at the bottom. Use micrometers or millimeters in denoting test sieve openings. [NOTE—▲Sieve▲ (USP 1-May-2023) numbers are provided in the table for conversion purposes only.] Test sieves are made from stainless steel or, less preferably, from brass or other suitable nonreactive wire.

Calibration and recalibration of test sieves is in accordance with the most current edition of ISO 3310-1. Sieves should be carefully examined for gross distortions and fractures, especially at their screen frame joints, before use. Sieves may be calibrated optically to estimate the average opening size, and opening variability, of the sieve mesh. Alternatively, for the evaluation of the effective opening of test sieves in the size range of 212 to 850 µm, Standard Glass Spheres are available. Unless otherwise specified in the individual monograph, perform the sieve analysis at controlled room temperature and at ambient relative humidity.

## Cleaning Test Sieves

Ideally, test sieves should be cleaned using only an air jet or a liquid stream. If some apertures remain blocked by test particles, careful gentle brushing may be used as a last resort.

***Change to read:***

## Test Specimen

If the test specimen weight is not given in the monograph for a particular material, use a test specimen having a weight between 25 and 100 g, depending on the bulk density of the material, and test sieves having a ▲diameter of ▲ (USP 1-May-2023) 200-mm ▲or 203-mm (8-inch)▲ (USP 1-May-2023). For ▲sieves of 75-mm or▲ (USP 1-May-2023) 76-mm ▲(3-inch) diameter▲ (USP 1-May-2023), the amount of material that can be accommodated is approximately 1/7th▲ of ▲ (USP 1-May-2023) which can be accommodated on a 200-mm ▲or 203-mm ▲ (USP 1-May-2023)sieve. ▲♦ [NOTE—The 203-mm (8-inch) frame diameter sieve is equivalent to the 200-mm frame diameter sieve. The 76-mm (3-inch) frame diameter sieve is equivalent to the 75-mm frame diameter sieve.] ♦▲ (USP 1-May-2023) Determine the most appropriate weight for a given material by test sieving accurately weighed specimens of different weights, such as 25, 50, and 100 g, for the same time period on a mechanical shaker. [NOTE—If the test results are similar for the 25-g and 50-g specimens, but the 100-g specimen shows a lower percentage through the finest sieve, the 100-g specimen size is too large.] Where only a specimen of 10 to 25 g is available, smaller diameter test sieves conforming to the same mesh specifications may be substituted, but the endpoint must be redetermined. The use of test samples having a smaller mass (e.g., down to 5 g) may be needed. For materials with low apparent particle density, or for materials mainly comprising particles with a highly isodiametrical shape, specimen weights below 5 g for a 200-mm ▲or 203-mm sieve▲ (USP 1-May-2023) may

Official

https://pharmacopeia.cn/v-download/

be necessary to avoid excessive blocking of the sieve. During validation of a particular sieve analysis method, it is expected that the problem of sieve blocking will have been addressed.

If the test material is prone to picking up or losing significant amounts of water with varying humidity, the test must be carried out in an appropriately controlled environment. Similarly, if the test material is known to develop an electrostatic charge, careful observation must be made to ensure that such charging is not influencing the analysis. An antistatic agent, such as colloidal silicon dioxide and/or aluminum oxide, may be added at a 0.5 percent (m/m) level to minimize this effect. If both of the above effects cannot be eliminated, an alternative particle-sizing technique must be selected.

## Agitation Method

Several different sieve and powder agitation devices are commercially available, all of which may be used to perform sieve analyses. However, the different methods of agitation may give different results for sieve analyses and endpoint determinations because of the different types and magnitude of the forces acting on the individual particles under test. Methods using mechanical agitation or electromagnetic agitation, and that can induce either a vertical oscillation or a horizontal circular motion, or tapping or a combination of both tapping and horizontal circular motion are available. Entrainment of the particles in an air stream may also be used. The results must indicate which agitation method was used and the agitation parameters used (if they can be varied), because changes in the agitation conditions will give different results for the sieve analysis and endpoint determinations, and may be sufficiently different to give a failing result under some circumstances.

***Change to read:***

## Endpoint Determination

The test sieving analysis is complete when the weight on any of the test sieves does not change by more than 5% or 0.1 g (10% in the case of ▲75-mm or▲ (USP 1-May-2023) 76-mm sieves) of the previous weight on that sieve. If less than 5% of the total specimen weight is present on a given sieve, the endpoint for that sieve is increased to a weight change of not more than 20% of the previous weight on that sieve.

If more than 50% of the total specimen weight is found on any one sieve, unless this is indicated in the monograph, the test should be repeated, but with the addition to the sieve nest of a more coarse sieve, intermediate between that carrying the excessive weight and the next coarsest sieve in the original nest, i.e., addition of the ISO series sieve omitted from the nest of sieves.

# SIEVING METHODS

## Mechanical Agitation

### DRY SIEVING METHOD

Tare each test sieve to the nearest 0.1 g. Place an accurately weighed quantity of test specimen on the top (coarsest) sieve, and replace the lid. Agitate the nest of sieves for 5 minutes. Then carefully remove each from the nest without loss of material. Reweigh each sieve, and determine the weight of material on each sieve. Determine the weight of material in the collecting pan in a similar manner. Reassemble the nest of sieves, and agitate for 5 minutes. Remove and weigh each sieve as previously described. Repeat these steps until the endpoint criteria are met (see *Endpoint Determination* under *Test Sieves*). Upon completion of the analysis, reconcile the weights of material. Total losses must not exceed 5% of the weight of the original test specimen.

Repeat the analysis with a fresh specimen, but using a single sieving time equal to that of the combined times used above. Confirm that this sieving time conforms to the requirements for endpoint determination. When this endpoint has been validated for a specific material, then a single fixed time of sieving may be used for future analyses, providing the particle size distribution falls within normal variation.

If there is evidence that the particles retained on any sieve are aggregates rather than single particles, the use of mechanical dry sieving is unlikely to give good reproducibility, and a different particle size analysis method should be used.

## Air Entrainment Methods

### AIR JET AND SONIC SIFTER SIEVING

Different types of commercial equipment that use a moving air current are available for sieving. A system that uses a single sieve at a time is referred to as air jet sieving. It uses the same general sieving methodology as that described under the *Dry Sieving Method,* but with a standardized air jet replacing the normal agitation mechanism. It requires sequential analyses on individual sieves starting with the finest sieve to obtain a particle size distribution. Air jet sieving often includes the use of finer test sieves than those used in ordinary dry sieving. This technique is more suitable where only oversize or undersize fractions are needed.

In the sonic sifting method, a nest of sieves is used, and the test specimen is carried in a vertically oscillating column of air that lifts the specimen and then carries it back against the mesh openings at a given number of pulses per minute. It may be necessary to lower the sample amount to 5 g, when sonic sifting is employed.

The air jet sieving and sonic sieving methods may be useful for powders or granules when mechanical sieving techniques are incapable of giving a meaningful analysis.

Official

https://pharmacopeia.cn/

These methods are highly dependent upon proper dispersion of the powder in the air current. This requirement may be hard to achieve if the method is used at the lower end of the sieving range (i.e., below 75 µm), when the particles tend to be more cohesive, and especially if there is any tendency for the material to develop an electrostatic charge. For the above reasons endpoint determination is particularly critical, and it is very important to confirm that the oversize material comprises single particles and is not composed of aggregates.

## INTERPRETATION

The raw data must include the weight of test specimen, the total sieving time, and the precise sieving methodology and the set values for any variable parameters, in addition to the weights retained on the individual sieves and in the pan. It may be convenient to convert the raw data into a cumulative weight distribution, and if it is desired to express the distribution in terms of a cumulative weight undersize, the range of sieves used should include a sieve through which all the material passes. If there is evidence on any of the test sieves that the material remaining on it is composed of aggregates formed during the sieving process, the analysis is invalid.

# ⟨787⟩ SUBVISIBLE PARTICULATE MATTER IN THERAPEUTIC PROTEIN INJECTIONS

This chapter can be used as an alternative to *USP* general chapter *Particulate Matter in Injections* ⟨788⟩. It specifically addresses therapeutic protein injections and related preparations, allowing use of smaller test product volumes and smaller test aliquots to determine particulate matter content, with sample-handling instructions that take into account the issues associated with the analysis of these materials. Although the methodology and limits presented in this chapter are preferred for therapeutic protein injections, the use of regulatory-acceptable alternative analytical methods with adequately developed subvisible particulate limits is acceptable.

Therapeutic protein injections are biotechnology-derived products of protein or peptides and other therapeutic protein injections such as naturally sourced therapeutic proteins, including their final infusion preparations. Certain preparations that are not amenable to these tests, such as prophylactic vaccines, are not included in this guidance.

Particulate matter in therapeutic protein injections consists of mobile undissolved substances that may originate from various sources. The particles may be (a) truly foreign, or "extrinsic", e.g., unexpected foreign material, such as cellulose; (b) "intrinsic" resulting from addition or by insufficient cleaning during manufacturing, such as tank metals or gaskets, lubricants, filling hardware, or resulting from instability, e.g., changes over time, such as insoluble drug salt forms or package degradation; and (c) "inherent", such as particles of the protein or formulation components. All of these particle types may be detected and counted in the test method described in this chapter. In addition, for light obscuration (LO) methods, gas bubbles are commonly counted during particulate matter testing and are counting artifacts. For the determination of subvisible particles in therapeutic protein injections, the *Light Obscuration Particle Count Test* is the preferred method. The *Microscopic Particle Count Test* similar to that described in ⟨788⟩ may be useful in cases where the particles being analyzed are primarily nonproteinaceous, or in cases where examination of particle characteristics may be important. The results from this test are not equivalent to those from the LO test.

Not all therapeutic protein injections can be examined directly for subvisible particles by the LO method. When the test method is not directly applicable to specific test samples, as indicated by issues with method verification (reproducibility, linearity), a quantitative dilution with an appropriate diluent can be made to allow analysis by light obscuration. Method verification may be required to ensure the appropriateness of the sample handling procedures and the performance of the method for each drug product.

In the tests described below, the results obtained by examining a discrete unit or group of units for particulate matter cannot be extrapolated with certainty to other units that remain untested. Thus, sampling plans based on known operational factors must be developed to support valid inferences from observed data in order to characterize the level of particulate matter in a large group of units. Sampling plans should be based on considerations of product volume, particle numbers historically found in comparison to limits, particle size distribution, and variability of particle counts between units. Products that are used with a final filter during administration (in-line) are exempt from these requirements, providing that scientific data are available to justify the exemption.

***Change to read:***

## LIGHT OBSCURATION PARTICLE COUNT TEST

Analysts should use a suitable instrument that is based on the principle of light blockage and that allows an automatic determination of particle size and number.

The sensor selected must be appropriate for the intended particle size range and anticipated particle count. Several standardization steps such as sample volume accuracy, sample flow rate, sensor resolution, calibration, and particle count accuracy are important for the proper operation of the apparatus and are further reviewed in general information chapter ▲*Methods for the Determination of Subvisible Particulate Matter* ⟨1788⟩▲ (CN 1-May-2021).[1]

For equipment calibration purposes, use of NIST-traceable particle size standards or equivalent traceable standards, see ⟨1788⟩. These standards generally are between 2 and 100 µm. Analysts should verify the performance of the apparatus using the USP Particle Count RS dispersed in particle-free water at an appropriate volume. Care must be taken to avoid agglomeration of particles during dispersion in the calibration process. The definition for *Particle-Free Water* is provided in the introductory section of *Reagents, Indicators, and Solutions*.

### General Precautions

Carry out the test under conditions that limit ingress of particulate matter, preferably in a laminar-flow cabinet. The glassware and equipment used should be properly cleaned and handled to remain particle free. Care should be taken to minimize shaking and other stresses to the preparations (for liquids or reconstituted powders) and to prevent introduction of air bubbles into the preparation under examination. This is particularly important when preparations are combined or transferred to the container in which the determination will be carried out.

[1] For informational purposes only, analysts can refer to ⟨1788⟩, which may be a helpful but not mandatory resource.

https://pharmacopeia.cn/v29240/

## Preparatory Steps

Glassware selected for the method should accommodate the volume of blank and sample aliquots, allow easy mixing, and be amenable to repeated cleaning used to prevent any significant contribution to particle counts. Typically, separate vessels are utilized and retained specifically for this test only. Cleaning and rinsing of the method glassware should be in close proximity to the counting area.

The work area and equipment should be separated from general lab traffic. A good supply of filtered water (to comply with *Particle-Free Water*) and support equipment should be maintained and available for the routine work. Refer to general information chapter ⟨1788⟩.[1]

Two types of system controls are recommended: a *Blank Test* and *System Suitability Verification*.

1. The *Blank Test* involves the following:
    A. Run at the start of the day or analysis to ensure that proper care has been used in preparing the site and apparatus for use (*Environmental Blank*).
    B. Any additional blanks run throughout the day (such as between product families) should also comply with the *Blank Test* requirements (*Procedural Blank*).
2. The *System Suitability Verification* is run to verify proper count/mL and ratio for the current USP Particle Count RS or equivalent commerical standard. See general information chapter ⟨1788⟩.[1]

## Blank Test

In order to check that (a) the environment is suitable for the test, (b) the glassware is properly cleaned, and (c) the water or suitable solvent that will be used is particle free (b and c constitute the "blank"), the following test is carried out. Determine the count in five aliquots of degassed particle-free water or suitable solvent, representative of the product test volume (but NLT 1 mL). If the number of particles 10 µm or greater in size exceeds 1 particle per mL for the combined aliquot volume, the precautions taken for the test are not sufficient. Repeat the preparatory steps until the environment, glassware, and water are suitable for the test determination. The *Blank Test* must be run initially each day (environment) and is recommended throughout the daily routine, especially between product families (procedural).

## System Suitability Verification

To verify system suitability, *Particle-Free Water* and the USP Particle Count RS or equivalent commercial standard aqueous suspension are tested from the same or similar type of container as product samples, are degassed in the same manner, and generally are handled like the test article. Ensure that the system can meet the *Blank Test* requirement. Determine the particulate matter in a sample of the USP Particle Count RS that corresponds to the product test volume, according to the method described below. Results from the Standard preparation should fall within the stated specifications of the Reference Standard.

## Method

Product samples are tested in the manner that most suitably represents delivery (e.g., expelled syringe contents). For parenterals that have a sufficient volume (i.e., volume large enough to facilitate testing), testing of individual units is often diagnostic. For parenteral products that do not have a sufficient volume, carefully and thoroughly mix each unit, then combine the contents of a suitable number of units in a separate container to obtain the volume required for a single test (generally 0.2–5.0 mL). If a dilution is performed, ensure that the blank container has sufficient volume for product and diluents and that few, if any, particles are introduced in the process. Open each unit cautiously, remove the sealing closure, and avoid contamination of the contents before sampling, diluting, or, if necessary, pooling.

When a product solvent is specified, e.g., for lyophilized solids or powders for parenteral use, the reconstitution or dilution must be performed with the appropriate amount of specified solvent. In this case, the solvent itself may be tested to ensure that it is not a significant source of particles. Subtraction of the solvent particle count from the total count is not allowed.

Eliminating gas bubbles is a key step, especially for proteinaceous products that readily entrain gas. Two methods are recommended: either allowing the product fluid to stand under ambient pressure or applying a gentle (e.g., 75 Torr) vacuum. Other methods may be used when demonstrated to be suitable. Sonication should be avoided.

Once the samples have been degassed, they must be remixed gently to suspend all particles by mixing the contents of the sample gently but thoroughly by an appropriate means, e.g., slow swirling of the container by hand. Inversion to mix the product fluid is not recommended at any time.

Immediately after mixing, withdraw NLT four aliquots, each of a volume appropriate for the instrument's capacity (generally 0.2–5.0 mL). Count the number of particles over the selected size range, including particles equal to or greater than 10 and 25 µm. Disregard the result obtained for the first aliquot, and calculate the mean number of particles at each size range for the remaining aliquots of the preparation being tested. A tare volume also can be applied to control sampling that should be representative of the sensor dynamic range and needle volume.

## General Considerations

Dilution is allowed as long as the diluent and methods are demonstrated to be appropriate and the smallest level of dilution that allows for reproducible testing is used. Under certain circumstances dilution of samples may be required to obtain reliable results. This may be the case with high-concentration products and/or high-viscosity products that cannot be drawn into the instrument properly; products that cause saturation of the instrument sensor due to high counts, especially in the smaller than 10-µm size ranges; and cases where the high concentration results in very small differences in refractive index between the

Official

https://pharmacopeia.cn/

solution and the protein aggregates, etc. In situations where sample dilution is conducted, the underlying rationale for the dilution as well as the suitability of the selected dilution scheme including choice of diluent must be demonstrated. Suitability of the dilution scheme and of the diluent may be assessed by demonstrating consistency of results over a dilution range. Bridging studies with and without dilution at size ranges intended for particle counting should be considered. Studies exploring the ability of dilution to decrease the number of aggregates, or to increase particles due to changes in the ratio of protein to excipients, should also be performed. An orthogonal technique may be used to justify the suitability of the method by verifying the impact of dilution.

## Evaluation

The values below are derived historically from general chapters ⟨788⟩ and ⟨789⟩. If specifications are different from those stated below, they will be indicated in an individual monograph where available.

For parenteral products that are therapeutic protein injections for infusion or injection supplied in containers with a nominal content of less than or equal to 100 mL:

> The average number of particles present in the units tested should not exceed 6000 per container equal to or greater than 10 µm and should not exceed 600 per container equal to or greater than 25 µm.

For therapeutic protein injections supplied in containers with a nominal content of more than 100 mL, and parenteral infusion preparations or injections with a nominal content of more than 100 mL:

> The average number of particles present in the units tested should not exceed 25/mL equal to or greater than 10 µm and should not exceed 3/mL equal to or greater than 25 µm. Also, total particle load should not exceed 6000 per container equal to or greater than 10 µm and should not exceed 600 per container equal to or greater than 25 µm.

Products that are used with a final filter during administration (in-line) are exempt from these requirements, providing that scientific data are available to justify the exemption. However, filtrates are expected to comply with the guideline. For products supplied or first reconstituted in <100 mL, and then diluted for infusion in a volume >100 mL, particle content should be assessed both before and after dilution and evaluated based on their final volume.

## MICROSCOPIC PARTICLE COUNT TEST

As noted, the LO method is the preferred method for therapeutic protein injections and parenteral infusions. However, the microscopic method may be used when appropriate, such as determination of extrinsic and intrinsic particle types only. It should be demonstrated, however, that particular classes of particles (e.g., inherent) are also being counted when using this method. For the determination of product acceptability, apply the limits for the membrane microscopic test in general chapter ⟨788⟩. Because of the interference of some protein particles and their physical characteristics (fragile or translucent), the results of the *Microscopic Particle Count Test* are not equivalent to those of the *Light Obscuration Particle Count Test*, and the two methods cannot be considered interchangeable.

# ⟨788⟩ PARTICULATE MATTER IN INJECTIONS

This general chapter is harmonized with the corresponding texts of the *European Pharmacopoeia* and/or the *Japanese Pharmacopoeia*. These pharmacopeias have undertaken not to make any unilateral change to this harmonized chapter. Portions of the present general chapter text that are national USP text, and therefore not part of the harmonized text, are marked with symbols (⬥⬥) to specify this fact.

Particulate matter in injections and parenteral infusions consists of extraneous mobile undissolved particles, other than gas bubbles, unintentionally present in the solutions.

⬥As stated in *Injections and Implanted Drug Products* ⟨1⟩, solutions for injection administered by the intramuscular or subcutaneous route must meet the requirements of *Particulate Matter in Injections* ⟨788⟩. This requirement has been indefinitely postponed for products for veterinary use. Parenterals packaged and labeled exclusively for use as irrigating solutions are exempt from the requirements of *Particulate Matter in Injections* ⟨788⟩. Radiopharmaceutical preparations are exempt from the requirements of *Particulate Matter in Injections* ⟨788⟩. Parenteral products for which the labeling specifies use of a final filter prior to administration are exempt from the requirements of *Particulate Matter in Injections* ⟨788⟩, provided that scientific data are available to justify this exemption.⬥

For the determination of particulate matter, two procedures, *Method 1 (Light Obscuration Particle Count Test)* and *Method 2 (Microscopic Particle Count Test)*, are specified hereinafter. When examining injections and parenteral infusions for subvisible particles, *Method 1* is preferably applied. However, it may be necessary to test some preparations by the *Light Obscuration Particle Count Test* followed by the *Microscopic Particle Count Test* to reach a conclusion on conformance to the requirements.

Not all parenteral preparations can be examined for subvisible particles by one or both of these methods. When *Method 1* is not applicable, e.g., in the case of preparations having reduced clarity or increased viscosity, the test should be carried out according to *Method 2*. Emulsions, colloids, and liposomal preparations are examples. Similarly, products that produce air or gas bubbles when drawn into the sensor may also require microscopic particle count testing. If the viscosity of the preparation to be tested is sufficiently high so as to preclude its examination by either test method, a quantitative dilution with an appropriate diluent may be made to decrease viscosity, as necessary, to allow the analysis to be performed.

The results obtained in examining a discrete unit or group of units for particulate matter cannot be extrapolated with certainty to other units that remain untested. Thus, statistically sound sampling plans must be developed if valid inferences are to be drawn from observed data to characterize the level of particulate matter in a large group of units.

⬥For the purpose of this chapter, small-volume parenteral is synonymous with small-volume injection, and large-volume parenteral is synonymous with large-volume injection.⬥

## METHOD 1 LIGHT OBSCURATION PARTICLE COUNT TEST

Use a suitable apparatus based on the principle of light blockage that allows for an automatic determination of the size of particles and the number of particles according to size. The definition for *particle-free water* is provided in *Reagents, Indicators, and Solutions—Reagent Specifications*.

The apparatus is calibrated using dispersions of spherical particles of known sizes between 10 µm and 25 µm. These standard particles are dispersed in *particle-free water*. Care must be taken to avoid aggregation of particles during dispersion. ⬥System suitability can be verified by using the USP Particle Count RS.⬥

### General Precautions

The test is carried out under conditions limiting particulate matter, preferably in a laminar flow cabinet.

Very carefully wash the glassware and filtration equipment used, except for the membrane filters, with a warm detergent solution, and rinse with abundant amounts of water to remove all traces of detergent. Immediately before use, rinse the equipment from top to bottom, outside and then inside, with *particle-free water*.

Take care not to introduce air bubbles into the preparation to be examined, especially when fractions of the preparation are being transferred to the container in which the determination is to be carried out.

In order to check that the environment is suitable for the test, that the glassware is properly cleaned, and that the water to be used is particle-free, the following test is carried out. Determine the particulate matter in five samples of *particle-free water*, each of 5 mL, according to the method described below. If the number of particles of 10 µm or greater size exceeds 25 for the combined 25 mL, the precautions taken for the test are not sufficient. The preparatory steps must be repeated until the environment, glassware, and water are suitable for the test.

### Method

Mix the contents of the sample by slowly inverting the container 20 times successively. If necessary, cautiously remove the sealing closure. Clean the outer surfaces of the container opening using a jet of *particle-free water*, and remove the closure, avoiding any contamination of the contents. Eliminate gas bubbles by appropriate measures such as allowing to stand for 2 min or sonicating.

For large-volume parenterals, single units are tested. For small-volume parenterals less than 25 mL in volume, the contents of 10 or more units are combined in a cleaned container to obtain a volume of NLT 25 mL; the test solution may be prepared by mixing the contents of a suitable number of vials and diluting to 25 mL with *particle-free water* or with an appropriate particle-free solvent when *particle-free water* is not suitable. Small-volume parenterals having a volume of 25 mL or more may be tested individually.

Official

https://nhathuocngocanh.com/

Powders for parenteral use are reconstituted with *particle-free water* or with an appropriate particle-free solvent when *particle-free water* is not suitable.

For pharmacy bulk packages for parenteral use labeled "Not for Direct Infusion", proceed as directed for small-volume parenterals when the volume is 25 mL or more. Calculate the test result on a portion that is equivalent to the maximum dose given in the labeling. For example, if the total bulk package volume is 100 mL and the maximum dose volume is 10 mL, then the average particle count per mL would be multiplied by 10 to obtain the test result based on the 10-mL maximum dose. [NOTE—For the calculation of test results, consider this maximum dose portion to be equivalent to the contents of one full container.]

Products packaged with dual compartments meant to hold a drug product and a solvent should be prepared and tested as directed for large-volume parenterals or small-volume parenterals, depending on container volume. Mix each unit as directed in the labeling, activating and agitating to ensure thorough mixing of the separate components and drug dissolution.

The number of test specimens must be adequate to provide a statistically sound assessment. For large-volume parenterals or for small-volume parenterals having a volume of 25 mL or more, fewer than 10 units may be tested, using an appropriate sampling plan.

Remove four portions, NLT 5 mL each, and count the number of particles equal to or greater than 10 µm and 25 µm. Disregard the result obtained for the first portion, and calculate the mean number of particles for the preparation to be examined.

### Evaluation

For preparations supplied in containers with a nominal volume of more than 100 mL, apply the criteria of *Test 1.A*.
For preparations supplied in containers with a nominal volume of less than 100 mL, apply the criteria of *Test 1.B*.
For preparations supplied in containers with a nominal volume of 100 mL, apply the criteria of *Test 1.B*.
[NOTE—*Test 1.A* is used in the *Japanese Pharmacopoeia*.]
If the average number of particles exceeds the limits, test the preparation by the *Microscopic Particle Count Test*.

TEST 1.A

**Solutions for parenteral infusion or solutions for injection supplied in containers with a nominal content of more than 100 mL:** The preparation complies with the test if the average number of particles present in the units tested does not exceed 25 per mL equal to or greater than 10 µm and does not exceed 3 per mL equal to or greater than 25 µm.

TEST 1.B

**Solutions for parenteral infusion or solutions for injection supplied in containers with a nominal content of less than 100 mL:** The preparation complies with the test if the average number of particles present in the units tested does not exceed 6000 per container equal to or greater than 10 µm and does not exceed 600 per container equal to or greater than 25 µm.

## METHOD 2 MICROSCOPIC PARTICLE COUNT TEST

Use a suitable binocular microscope, a filter assembly for retaining particulate matter, and a membrane filter for examination.

The microscope is adjusted to 100 ± 10 magnifications and is equipped with an ocular micrometer calibrated with an objective micrometer, a mechanical stage capable of holding and traversing the entire filtration area of the membrane filter, and two suitable illuminators to provide episcopic illumination in addition to oblique illumination.

The ocular micrometer is a circular diameter graticule (see *Figure 1*) and consists of a large circle divided by crosshairs into quadrants, transparent and black reference circles 10 µm and 25 µm in diameter at 100 magnifications, and a linear scale graduated in 10-µm increments. It is calibrated using a stage micrometer that is certified by either a domestic or international standard institution. A relative error of the linear scale of the graticule within ±2% is acceptable. The large circle is designated the graticule field of view (GFOV).

Official

Official

Figure 1. Circular diameter graticule. The large circle divided by crosshairs into quadrants is designated the graticule field of view (GFOV). Transparent and black circles having 10-µm and 25-µm diameters at 100× are provided as comparison scales for particle sizing.

Two illuminators are required. One is an episcopic brightfield illuminator internal to the microscope, the other is an external, focusable auxiliary illuminator that can be adjusted to give reflected oblique illumination at an angle of 10°–20°.

The filter assembly for retaining particulate matter consists of a filter holder made of glass or other suitable material, and is equipped with a vacuum source and a suitable membrane filter.

The membrane filter is of suitable size, black or dark gray in color, nongridded or gridded, and 1.0 µm or finer in nominal pore size.

## General Precautions

The test is carried out under conditions limiting particulate matter, preferably in a laminar flow cabinet.

Very carefully wash the glassware and filter assembly used, except for the membrane filter, with a warm detergent solution, and rinse with abundant amounts of water to remove all traces of detergent. Immediately before use, rinse both sides of the membrane filter and the equipment from top to bottom, outside and then inside, with *particle-free water*.

In order to check that the environment is suitable for the test, that the glassware and the membrane filter are properly cleaned, and that the water to be used is particle-free, the following test is carried out. Determine the particulate matter of a 50-mL volume of *particle-free water* according to the method described below. If more than 20 particles 10 µm or larger in size or if more than five particles 25 µm or larger in size are present within the filtration area, the precautions taken for the test are not sufficient. The preparatory steps must be repeated until the environment, glassware, membrane filter, and water are suitable for the test.

https://nhathuoclongdan.com/

## Method

Mix the contents of the samples by slowly inverting the container 20 times successively. If necessary, cautiously remove the sealing closure. Clean the outer surfaces of the container opening using a jet of *particle-free water*, and remove the closure, avoiding any contamination of the contents.

For large-volume parenterals, single units are tested. For small-volume parenterals less than 25 mL in volume, the contents of 10 or more units are combined in a cleaned container; the test solution may be prepared by mixing the contents of a suitable number of vials and diluting to 25 mL with *particle-free water* or with an appropriate particle-free solvent when *particle-free water* is not suitable. Small-volume parenterals having a volume of 25 mL or more may be tested individually.

Powders for parenteral use are constituted with *particle-free water* or with an appropriate particle-free solvent when *particle-free water* is not suitable.

The number of test specimens must be adequate to provide a statistically sound assessment. For large-volume parenterals or for small-volume parenterals having a volume of 25 mL or more, fewer than 10 units may be tested, using an appropriate sampling plan.

Wet the inside of the filter holder fitted with the membrane filter with several mL of *particle-free water*. Transfer to the filtration funnel the total volume of a solution pool or of a single unit, and apply a vacuum. If needed, add stepwise a portion of the solution until the entire volume is filtered. After the last addition of solution, begin rinsing the inner walls of the filter holder by using a jet of *particle-free water*. Maintain the vacuum until the surface of the membrane filter is free from liquid. Place the membrane filter in a Petri dish, and allow the membrane filter to air-dry with the cover slightly ajar. After the membrane filter has been dried, place the Petri dish on the stage of the microscope, scan the entire membrane filter under the reflected light from the illuminating device, and count the number of particles that are equal to or greater than 10 µm and the number of particles that are equal to or greater than 25 µm. Alternatively, partial membrane filter count and determination of the total filter count by calculation is allowed. Calculate the mean number of particles for the preparation to be examined.

The particle sizing process with the use of the circular diameter graticule is carried out by estimating the equivalent diameter of the particle in comparison with the 10 µm and 25 µm reference circles on the graticule. Thereby the particles are not moved from their initial locations within the graticule field of view and are not superimposed on the reference circles for comparison. The inner diameter of the transparent graticule reference circles is used to size white and transparent particles, while dark particles are sized by using the outer diameter of the black opaque graticule reference circles.

In performing the *Microscopic Particle Count Test*, do not attempt to size or enumerate amorphous, semiliquid, or otherwise morphologically indistinct materials that have the appearance of a stain or discoloration on the membrane filter. These materials show little or no surface relief and present a gelatinous or film-like appearance. In such cases, the interpretation of enumeration may be aided by testing a sample of the solution by the *Light Obscuration Particle Count Test*.

## Evaluation

For preparations supplied in containers with a nominal volume of more than 100 mL, apply the criteria of *Test 2.A*.
For preparations supplied in containers with a nominal volume of less than 100 mL, apply the criteria of *Test 2.B*.
For preparations supplied in containers with a nominal volume of 100 mL, apply the criteria of *Test 2.B*.
[NOTE—*Test 2.A* is used in the *Japanese Pharmacopoeia*.]

TEST 2.A

**Solutions for parenteral infusion or solutions for injection supplied in containers with a nominal content of more than 100 mL:** The preparation complies with the test if the average number of particles present in the units tested does not exceed 12 per mL equal to or greater than 10 µm and does not exceed 2 per mL equal to or greater than 25 µm.

TEST 2.B

**Solutions for parenteral infusion or solutions for injection supplied in containers with a nominal content of less than 100 mL:** The preparation complies with the test if the average number of particles present in the units tested does not exceed 3000 per container equal to or greater than 10 µm and does not exceed 300 per container equal to or greater than 25 µm.

# ⟨789⟩ PARTICULATE MATTER IN OPHTHALMIC SOLUTIONS

Particulate matter consists of mobile, randomly sourced, extraneous substances, other than gas bubbles, that cannot be quantitated by chemical analysis because of the small amount of material they represent and because of their heterogeneous composition. Ophthalmic solutions should be essentially free from particles that can be observed on visual inspection. The tests described herein are physical tests performed for the purpose of enumerating extraneous particles within specific size ranges.

Every ophthalmic solution is subject to the particulate matter limits set forth for the test being applied, unless otherwise specified in the individual monograph. When higher limits are appropriate, they will be specified in the individual monograph. Ophthalmic preparations that are suspensions, emulsions, or gels are exempt from these requirements, as are medical devices. Refer to the specific monograph when a question of test applicability occurs.

Light obscuration and microscopic procedures for the determination of particulate matter in ophthalmic solutions are identical to those for injections; therefore, where appropriate, *USP* general test chapter *Particulate Matter in Injections* ⟨788⟩ is cross-referenced. This chapter provides a test approach in two stages. The ophthalmic solution is first tested by the light obscuration procedure (stage 1). If it fails to meet the prescribed limits, it must pass the microscopic procedure (stage 2) with its own set of test limits. Where for technical reasons the ophthalmic solution cannot be tested by light obscuration, microscopic testing may be used exclusively. Documentation is required, demonstrating that the light obscuration procedure is incapable of testing the ophthalmic solution or that it produces invalid results.

It is expected that most articles will meet the requirements on the basis of the light obscuration test alone; however, it may be necessary to test some articles by the light obscuration test followed by the microscopic test to reach a conclusion on conformance to requirements. Any product that is not a pure solution having a clarity and a viscosity approximating those of water may provide erroneous data when analyzed by the light obscuration counting method. Such materials may be analyzed by the microscopic counting method. In some instances, the viscosity of a material to be tested may be sufficiently high so as to preclude its analysis by either test method. In this event, a quantitative dilution with an appropriate diluent may be made to decrease viscosity, as necessary, to allow the analysis to be performed.

In the tests described below, the results obtained by examining a discrete unit or group of units for particulate matter cannot be extrapolated with certainty to other units that remain untested. Thus, sampling plans based on known operational factors must be developed if valid inferences are to be drawn from observed data to characterize the level of particulate matter in a large group of units. Sampling plans need to be based on consideration of product volume, particle numbers historically found to be present in comparison to limits, size distribution of particles present, and variability of particle counts between units.

Official

## LIGHT OBSCURATION PARTICLE COUNT TEST

This test applies to ophthalmic solutions, including solutions constituted from sterile solids, for which a test for *Particulate matter* is specified in the individual monograph. The test counts suspended particles that are solid or liquid.

### Test Apparatus, Instrument Standardization, Test Environment, Test Procedure, and Calculations

Proceed as directed in *Particulate Matter in Injections* ⟨788⟩, *Method 1 Light Obscuration Particle Count Test*.

### Interpretation

The ophthalmic solution meets the requirements of the test if the average number of particles present in the units tested does not exceed the appropriate value listed in *Table 1*. If the average number of particles exceeds the limit, test the article by the *Microscopic Particle Count Test*.

**Table 1. Light Obscuration Particle Test Limits**

| | Diameter | | |
|---|---|---|---|
| | ≥10 µm | ≥25 µm | ≥50 µm |
| Number of particles | 50/mL | 5/mL | 2/mL |

## MICROSCOPIC PARTICLE COUNT TEST

Some articles cannot be tested meaningfully by light obscuration. In such cases, individual monographs clearly specify that only a microscopic particle count is to be performed. The microscopic particle count test enumerates subvisible, essentially solid, particulate matter in ophthalmic solutions after collection on a microporous membrane filter. Some ophthalmic solutions, such as solutions that do not filter readily because of their high viscosity, may be exempted from analysis using the microscopic test.

When performing the microscopic test, do not attempt to size or enumerate amorphous, semiliquid, or otherwise morphologically indistinct materials that have the appearance of a stain or discoloration on the membrane surface. These materials show little or no surface relief and present a gelatinous or film-like appearance. Because in solution this material consists of units on the order of 1 µm or less, which may be counted only after aggregation or deformation on an analytical membrane, interpretation of enumeration may be aided by testing a sample of the solution by the light obscuration particle count method.

# ⟨790⟩ VISIBLE PARTICULATES IN INJECTIONS

## INTRODUCTION

All products intended for parenteral administration must be visually inspected for the presence of particulate matter as specified in *Injections and Implanted Drug Products* ⟨1⟩. Dry solids, from which constituted solutions are prepared for injection, meet the requirements for *Completeness and clarity of solutions* in *Injections and Implanted Drug Products* ⟨1⟩ when they are prepared just before use. Where used in this chapter, the term *essentially free* means that when injectable drug products are inspected as described herein, no more than the specified number of units may be observed to contain visible particulates. Particulate matter is defined in *Particulate Matter in Injections* ⟨788⟩ as extraneous mobile undissolved particles, other than gas bubbles, unintentionally present in solutions. See *Subvisible Particulate Matter in Therapeutic Protein Injections* ⟨787⟩ for additional information on inherent, intrinsic, and extrinsic particulates. Examples of such particulate matter include, but are not limited to, fibers, glass, metal, elastomeric materials, and precipitates. However, some products may contain inherent particles or agglomerates; in such cases, requirements for these particular visible particulates are specified in the individual monograph or in the approved regulatory application but the control and acceptance criteria for extraneous particles described in this chapter apply.

Where the nature of the contents or the container–closure system permits only limited capability for inspection of the total contents, the 100% inspection of a batch shall be supplemented with the inspection of constituted (e.g., dried) or withdrawn (e.g., dark amber container, suspensions, highly colored liquids) contents of a sample of containers from the batch. The destructive nature of these tests requires the use of a sample smaller[1] than those traditionally used for non-destructive acceptance sampling after 100% inspection. Although the tests described in this chapter may be useful during studies to examine product stability, this chapter is not intended to establish any new testing requirements for stability studies.

## INSPECTION PROCEDURE

Used along with 100% inspection during the manufacturing process, this procedure is sufficient to demonstrate that the batch is essentially free of visible particulates. A complete program for the control and monitoring of particulate matter remains an essential prerequisite.

Inspected units must be free of visible particulates when examined without magnification (except for optical correction as may be required to establish normal vision) against a black background and against a white background. Illumination at the inspection point is maintained at a minimum intensity between 2000 and 3750 lux. This can be achieved through the use of two 13-W or 15-W fluorescent lamps (e.g., F13/T5 or F15/T8). The use of a high-frequency ballast to reduce flicker from the fluorescent lamps is recommended. Alternative light sources (e.g., incandescent, LED) that provide illumination at the point of inspection within the specified minimum intensity range are acceptable. Higher illumination intensity is recommended for examination of colored solutions or product in containers other than clear glass.

Before performing the inspection, remove any adherent labels from the container, and wash and dry the outside. The unit under inspection should be gently swirled and/or inverted, ensuring that no air bubbles are produced, and inspected for approximately 5 s against each of the backgrounds. The presence of any particles should be recorded.

### Sampling at Batch Release (After 100% Manufacturing Inspection)

Sample and inspect the batch using ANSI/ASQ Z1.4 (or ISO 2859-1). General Inspection Level II, single sampling plans for normal inspection with an AQL of 0.65%. Alternative sampling plans with equivalent or better protection are acceptable. NMT the specified number of units contains visible particulates.

### Product in Distribution[2]

If it becomes necessary to evaluate product that has been shipped to customers (e.g., because of a complaint or regulatory concern), sample and inspect 20 units. If no particles are observed in the sample, the batch is considered essentially free of visible particulates. If available, additional units may be inspected to gain further information on the risk of particulates in the batch.

[1] The special level sampling plans described in ANSI/ASQ Z1.4–2008 or ISO 2859 are appropriate to guide the selection of sample size and acceptance criteria for this purpose.

[2] Testing outlined in *Product in Distribution* is permissible only if *Sampling at Batch Release (after 100% Manufacturing Inspection)* has been successfully completed.

# ⟨791⟩ pH

## INTRODUCTION

For compendial purposes, pH is defined as the value given by a suitable, properly calibrated, potentiometric sensor and measuring system. [NOTE—The measuring system has traditionally been referred to as the "pH meter." While the pH meter is still in common use, the measuring system can also be embedded inside the pH sensor, and the pH signal can be transmitted digitally to an external device such as a computer, Programmable Logic Controller (PLC), Distributed Control System (DCS), data acquisition system, terminal, or other microprocessor-controlled device.] By definition, pH is equal to $-\log_{10}[a_{H^+}]$ where $a_{H^+}$ is the activity of the hydrogen ($H^+$) or hydronium ion ($H_3O^+$), and the hydrogen ion activity very closely approximates the hydrogen ion concentration.

The practical pH scale is defined:

$$pH = pH_S + [(E - E_S)/k]$$

$E$ = measured potential where the galvanic cell contains the solution under test (pH)
$E_S$ = measured potential where the galvanic cell contains the appropriate buffer solution for calibration ($pH_S$)
$k$ = change in potential/unit change in pH and is derived from the Nernst equation (as follows)

$$k = \log_e(10) \times (RT/nF)$$

$R$ = 8.314 *J*/mole/°K
$T$ = temperature (°K)
$n$ = moles/half-reaction
$F$ = Faraday constant, *96485 C*/mole

The resulting equation is [0.05916 + 0.0001984($T$ – 25°)] volts at temperature $T$. Values of $k$ from 15°–35° are provided in *Table 1*.

**Table 1. Values of *k* for Various Temperatures**

| Temperature (°C) | *k* (V) |
|---|---|
| 15.00 | 0.05718 |
| 20.00 | 0.05817 |
| 25.00 | 0.05916 |
| 30.00 | 0.06016 |
| 35.00 | 0.06115 |

Values of $k$ at other temperatures can be determined from the equation above. For practical purposes, values of $k$ are determined from pH sensor calibration.

## pH MEASUREMENT SYSTEM

The measurement system consists of 1) a measuring electrode sensitive to hydrogen-ion activity, typically a glass electrode, though other electrode types are possible; 2) a suitable reference electrode, for example, a silver–silver chloride electrode; and 3) a voltage measurement system with an input resistance capable of measuring at a high input impedance of the pH sensor. The measuring and reference electrode may be separated or combined. The voltage measurement system may be separated from the pH sensor or integrated into the sensor. For most applications, a temperature measurement will be necessary for compensation of the Nernst temperature influence described above. A temperature device may be embedded into the pH sensor, or an external temperature device may be used.

## INSTRUMENT REQUIREMENTS

The measurement system shall be capable of performing a two-point (or more) pH calibration (see below). The accuracy of the pH measurement system is described in the *Calibration* section. The resolution of the pH measurement system shall be at least 0.01 pH. The instrument shall be capable of temperature-compensating the pH sensor measurement to convert the millivolt signal to pH units at any temperature, either automatically using a temperature device built into the sensor system or by manual entry of the sample temperature into the measurement system. The accuracy of the temperature measurement system shall be ±1°. The resolution of the temperature measurement system shall be at least 0.1°. Lab-based pH measurements are typically performed at 25 ± 2° unless otherwise specified in the individual monograph or herein. However, temperatures outside this range are acceptable if samples are more conveniently prepared at alternative temperatures. Examples of non-lab-based measurements include test samples inside process pipes, vessels, tanks, and other non-standard processing conditions. [NOTE—The definitions of pH, the pH scale, and the values assigned to the buffer solutions for calibration are for the purpose

Official

https://nhathuocngocanh.com/

of establishing a practical, operational system so that results may be compared between laboratories. The measured pH values do not necessarily correspond exactly to those obtained by the definition, $pH = -\log_{10} [a_{H^+}]$, rather the values obtained are closely related to the activity of the hydrogen-ion in aqueous solutions.] [NOTE—Where a pH measurement system is calibrated by use of an aqueous buffer and then used to measure the pH of nonaqueous systems, the ionization constant of the acid or base, the dielectric constant of the medium, the liquid-junction potential (which may give rise to errors of approximately 1 pH unit), and the hydrogen-ion response of the glass electrode are all changed. For these reasons, the values so obtained with solutions that are only partially aqueous in character can be regarded only as apparent pH values.]

## BUFFER SOLUTIONS FOR CALIBRATION OF THE pH MEASUREMENT SYSTEM

Buffer solutions for calibration are prepared as directed in *Table 2*.[1] Buffer salts of requisite purity can be obtained from the National Institute of Standards and Technology (NIST), other national authorities, or other suppliers. Buffer solutions should be stored in appropriate containers that ensure stability of the pH through the expiry date, and fitted with a tight closure. For buffer solutions greater than 11, the storage should be in containers that are resistant to or reduce carbon dioxide intrusion, which would lower the pH of the buffer. For buffer solutions lower than 11, they should typically be prepared at intervals not to exceed 3 months. For buffer solutions greater than 11, they should typically be prepared and used fresh unless carbon dioxide ingress is restricted. All buffer solutions should be prepared using *Purified Water*. *Table 2* indicates the pH of the buffer solutions as a function of temperature. The instructions presented here are intended for the preparation of solutions having the designated molal (m) concentrations. However, in order to facilitate their preparation, the instructions are given in molarity. The difference in concentration between molality and molarity preparations for these buffer solutions is less than 1%, and the pH difference is negligible. Calibration using buffer solutions shall be done in the temperature range of the buffers listed in *Table 2*. [NOTE—The Nernst temperature compensation corrects only for the electrode millivolt output change with temperature, not the actual pH change of the buffer solution with temperature, which is unique for each buffer.] Features such as automatic buffer recognition or buffer pH–temperature correction are available for convenience in accommodating the temperature influence on buffer solutions. The pH–temperature response can be determined from the values in *Table 2*.

**Table 2. pH Values of Buffer Solutions for Calibration**

Preparation of alternative volumes at the same concentrations to those indicated below is acceptable.

**Potassium tetraoxalate, 0.05 m:** Dissolve 12.61 g of $KH_3(C_2O_4)_2 \cdot 2H_2O$, and dilute with water to make 1000.0 mL.

**Potassium hydrogen tartrate, saturated at 25°:** Add $C_4H_5KO_6$ to water until saturation is exceeded at 25°. Then filter or decant.

**Potassium dihydrogen citrate, 0.05 M:** Dissolve 11.41 g of $C_6H_7KO_4$, and dilute with water to make 1000.0 mL.

**Potassium biphthalate, 0.05 m:** Dissolve 10.12 g of $KHC_8H_4O_4$, previously dried at 110° for 1 h, and dilute with water to make 1000.0 mL.

[1] Commercially available buffer solutions for pH measurement system, calibrated by methods traceable to NIST or other national authorities, labeled with a pH value accurate to 0.02 pH units may be used. Solutions prepared from ACS reagent-grade materials or other suitable materials, may be used provided the pH of the resultant solution is the same as that of the solution prepared from the NIST (or other national authorities)-certified material. Buffer solutions that are greater than 12 should be used immediately or should be prepared using freshly boiled water, and they should be stored under conditions to minimize carbon dioxide absorption and ingress.

Official

https://pharmacopeia.com/

**Equimolal phosphate, 0.05 m:** Dissolve 3.53 g of disodium hydrogen phosphate ($Na_2HPO_4$) and 3.39 g of potassium dihydrogen phosphate ($KH_2PO_4$), each previously dried at 120° for 2 h, and dilute with water to make 1000.0 mL.

**Potassium dihydrogen phosphate, 0.0087 M** and **disodium hydrogen phosphate, 0.0303 M:** Dissolve 1.18 g of $KH_2PO_4$ and 4.30 g of $Na_2HPO_4$, both dried for 2 h at 120 ± 2°, and dilute with water to make 1000.0 mL.

**Sodium tetraborate, 0.01 m:** Dissolve 3.80 g of $Na_2B_4O_7 \cdot 10H_2O$, and dilute with water to make 1000.0 mL. Protect from absorption of carbon dioxide.

**Sodium carbonate, 0.025 M** and **sodium bicarbonate, 0.025 M:** Dissolve 2.64 g of sodium carbonate ($Na_2CO_3$) and 2.09 g of sodium bicarbonate ($NaHCO_3$), and dilute with water to make 1000.0 mL.

**Calcium hydroxide, saturated at 25°:** Add $Ca(OH)_2$ to water until saturation is exceeded at 25°. Use water that has been recently boiled and protected from the atmosphere to limit carbon dioxide absorption. Then filter or decant.

***Change to read:***

## CALIBRATION

Because of variations in the nature and operation of the available pH measurement systems, it is not practical to provide universal directions for the calibration of the measurement system. However, the general principles to be followed are set forth in the following paragraphs. Examine the electrodes, especially the reference electrode and electrolyte level, if a liquid electrolyte is used. If necessary, replenish electrolyte supply, and observe other precautions indicated by the instrument and electrode manufacturers.

The calibration or verification of the pH measurement system should be periodically executed. The historical performance of the measurement system, the criticality of the pH measurement, the maintenance of the pH sensor, and the frequency of measurement operation are used to determine the frequency of the calibration/verification. ▲The procedure below allows for several calibration methodologies (two-point calibration, multiple-point calibration, and multiple-segment calibration).▲ (USP 1-Aug-2020)

If the pH of the buffer is sensitive to ambient carbon dioxide, then use *Purified Water* that has been recently boiled, and subsequently stored in a container designed to minimize ingress of carbon dioxide.

1. To calibrate the pH measurement system, select three buffer solutions for calibration, preferably from those given in *Table 2*, such that the expected pH of the material under test falls within their range. Two of the buffers are used for the calibration process, and the third buffer is used for verification. The value of the verification buffer shall be between two of the calibration buffers. If the operational range of the pH sensor is beyond the pH range of the buffer solutions in *Table 2*, then either 1) select two nearby pH buffers from *Table 2* or 2) select one from *Table 2* and another documented prepared buffer that is outside the range.
2. Rinse the pH sensor several times with water, then with the first buffer solution.
3. Immerse the pH sensor in the first buffer solution at a temperature within the range of *Table 2*.
4. If automatic temperature measurement and compensation are not included in the measuring system, manually enter the temperature of the buffer and pH value of the buffer solution at that temperature into the instrument. For temperatures not listed in *Table 2*, use linear interpolation to determine the pH value as a function of temperature.
5. Initiate the two-point calibration sequence with the first buffer according to the manufacturer's instructions.
6. Remove the pH sensor from the first buffer and rinse the electrode(s) with water, and then with the second buffer solution.
7. Immerse the pH sensor in the second buffer at a temperature within the range of *Table 2*.
8. If automatic temperature measurement and compensation are not included in the measuring system, manually enter the temperature of the buffer and pH value of the buffer solution at that temperature into the instrument.
9. Continue the two-point calibration sequence with the second buffer according to the manufacturer's instructions.
10. After completion of the two-point calibration process, verify that the pH slope and offset are within acceptable parameters. Typical acceptable parameters are a slope of 90%–105% and an offset of 0 ± 30 mV (0.5 pH units at 25°). Depending on the pH instrumentation, the pH slope and offset may be determined in software or by manual methods. If using manual methods, follow supplier instructions to calculate the pH sensor slope/offset. If these parameters are not within acceptable parameters, the sensor should be properly cleaned, replenished, serviced, or replaced, and the two-point calibration process shall be repeated.
11. Remove the pH sensor from the second buffer, and rinse thoroughly with water, and then the verification buffer.
12. Immerse the pH sensor in the verification buffer at a temperature within the range of *Table 2*.
13. If automatic temperature measurement and compensation are not included in the measuring system, manually enter the temperature of the buffer and pH value of the buffer solution at that temperature into the instrument.
14. The pH reading shall be within ±0.05 pH of the value in *Table 2* at the buffer solution temperature.

▲NOTE—If a multiple-point calibration process (three or more calibration buffers) plus at least one verification buffer are used, then repeat steps 9–14, assuring that the pH sensor slope and offset criteria (see step 10) and the calibration accuracy (see step 14) of this range are met. The value of the verification buffers shall be between the highest and lowest calibration buffers of the range.

NOTE—If a multiple-segment calibration process (three or more calibration buffers with at least two slopes and offsets) plus at least one verification buffer for each segment are used, then repeat steps 9–14 for each segment, assuring that the pH sensor slope and offset criteria (see step 10) and the calibration accuracy (see step 14) of each segment are met. The value of each verification buffer shall be between the highest and lowest calibration buffers for each segment.▲ (USP 1-Aug-2020)

https://pharmacopeia.com/

## OPERATION

All test samples should be prepared using *Purified Water*, unless otherwise specified in the monograph. All test measurements should use manual or automated Nernst temperature compensation.

1. Prepare the test material according to requirements in the monograph or according to specific procedures. If the pH of the test sample is sensitive to ambient carbon dioxide, then use *Purified Water* that has been recently boiled, and subsequently stored in a container designed to minimize ingress of carbon dioxide.
2. Rinse the pH sensor with water, then with a few portions of the test material.
3. Immerse the pH sensor into the test material and record the pH value and temperature.

In all pH measurements, allow sufficient time for stabilization of the temperature and pH measurement.

Diagnostic functions such as glass or reference electrode resistance measurement may be available to determine equipment deficiencies. Refer to the electrode supplier for diagnostic tools to assure proper electrode function.

Where approximate pH values suffice, indicators and test papers (see *Reagents, Indicators, and Solutions—Indicators and Indicator Test Papers, Indicators* and *Indicator and Test Papers*) may be suitable.

For a discussion of buffers, and for the composition of standard buffer solutions called for in compendial tests and assays, see *Reagents, Indicators, and Solutions—Solutions, Buffer Solutions*. This referenced section is not intended to replace the use of the pH calibration buffers in *Table 2*.

# ⟨795⟩ PHARMACEUTICAL COMPOUNDING—NONSTERILE PREPARATIONS

***Change to read:***

## ▲1. INTRODUCTION AND SCOPE

This chapter describes the minimum standards to be followed for the preparation of compounded nonsterile preparations (CNSPs) for humans and animals. For purposes of this chapter, nonsterile compounding is defined as combining, admixing, diluting, pooling, reconstituting other than as provided in the manufacturer's labeling, or otherwise altering a drug product or bulk drug substance to create a nonsterile preparation.

The requirements in this chapter must be followed to minimize harm, including death, to human and animal patients that could result from 1) excessive microbial contamination, 2) variability from the intended strength of correct ingredients (e.g., ±10% of the labeled strength), 3) physical and chemical incompatibilities, 4) chemical and physical contaminants, and/or 5) use of ingredients of inappropriate quality.

Handling of nonsterile hazardous drugs (HDs) must additionally comply with *Hazardous Drugs—Handling in Healthcare Settings* ⟨800⟩.

### 1.1 Scope

**1.1.1 CNSPs subject to the requirements in this chapter:** CNSPs that must comply with this chapter include but are not limited to the following dosage forms:

- Solid oral preparations
- Liquid oral preparations
- Rectal preparations
- Vaginal preparations
- Topical preparations (i.e., creams, gels, and ointments)
- Nasal and sinus preparations intended for local application (i.e., nasal sprays and nasal irrigation)
- Otic preparations (excluding use in perforated eardrums)

**1.1.2 Practices not subject to the requirements in this chapter:** The following practices are not considered compounding and are not required to meet the requirements of this chapter. Handling of nonsterile HDs should additionally comply with ⟨800⟩. Refer to facility SOPs for additional safe practices (e.g., labeling).

- *Nonsterile radiopharmaceuticals:* Compounding of nonsterile radiopharmaceuticals is subject to the requirements in *Radiopharmaceuticals—Preparation, Compounding, Dispensing, and Repackaging* ⟨825⟩.
- *Reconstitution:* Reconstitution of a conventionally manufactured nonsterile product in accordance with the directions contained in the manufacturer approved labeling
- *Repackaging:* Repackaging of conventionally manufactured drug products (see *Good Repackaging Practices* ⟨1178⟩ for recommendations)
- *Splitting tablets:* Breaking or cutting a tablet into smaller portions
- *Administration:* Preparation of a single dose for a single patient when administration will begin within 4 h. This includes crushing a tablet(s) or opening a capsule(s) to mix with food or liquids to facilitate patient dosing.

**1.1.3 Personnel and settings affected:** This chapter applies to all persons who prepare CNSPs and all places where CNSPs are prepared. This includes but is not limited to pharmacists, technicians, nurses, physicians, veterinarians, dentists, naturopaths, and chiropractors in all places including but not limited to pharmacies, hospitals and other healthcare institutions, patient treatment sites, and physicians' or veterinarians' practice sites.

The compounding facility's leadership and all personnel involved in preparing, storing, packaging, dispensing, and transporting CNSPs are responsible for 1) ensuring that the applicable practices and quality standards in this chapter are continually and consistently applied to their operations, and 2) proactively identifying and remedying potential problems within their operations. Personnel engaged in the compounding and dispensing of CNSPs must also comply with laws and regulations of the applicable regulatory jurisdiction.

**1.1.4 Oversight by designated person(s):** The compounding facility must designate one or more individuals to be responsible and accountable for the performance and operation of the facility and personnel for the preparation of CNSPs. The responsibilities of the designated person(s) include but are not limited to:

- Overseeing a training program to ensure competency of personnel involved in compounding, handling, and preparing CNSPs
- Selecting components
- Monitoring and observing compounding activities and taking immediate corrective action if deficient practices are observed
- Ensuring that standard operating procedures (SOPs) are fully implemented. The designated person(s) must ensure that follow-up is carried out if problems, deviations, or errors are identified
- Establishing, monitoring, and documenting procedures for the handling and storage of CNSPs and/or components of CNSPs

The designated person(s) must be identified in the facility's SOPs. If the compounding facility has only one person responsible for all compounding in the facility, then that person is the designated person.

## 2. PERSONNEL TRAINING AND EVALUATION

All personnel who compound or have direct oversight of compounding CNSPs must be initially trained and qualified by demonstrating knowledge and competency according to the requirements in this section (*2. Personnel Training and Evaluation*) before being allowed to perform their job functions independently.

Designated person(s) are responsible for creating and implementing a training program that describes the required training, the frequency of training, and the process for evaluating the competency of personnel. This program must equip personnel with knowledge and training in the required skills necessary to perform their assigned tasks. Personnel who compound or have direct oversight of compounding personnel must complete training initially and at least every 12 months in appropriate compounding principles and practices as described in this section. Other personnel, who do not compound and only perform functions such as in-process checks, final verification, or dispensing of CNSPs, must undergo training as required by the facility's SOPs.

Training and competency of personnel must be documented as described in *14. Documentation*.

Before beginning to compound CNSPs independently or have direct oversight of compounding personnel, personnel must complete training and be able to demonstrate knowledge of principles and competency of skills for performing nonsterile manipulations as applicable to their assigned tasks. Knowledge and competency must be demonstrated initially and at least every 12 months in at least the following core competencies:

- Hand hygiene
- Garbing
- Cleaning and sanitizing
- Handling and transporting components and CNSPs
- Measuring and mixing
- Proper use of equipment and devices selected to compound CNSPs
- Documentation of the compounding process (e.g., *7. Master Formulation and Compounding Records*)

Steps in the training procedure must include the following:

- Understand the requirements in this chapter
- Understand and interpret safety data sheets (SDSs) and, if applicable, certificates of analysis (COA)
- Read and understand procedures related to their compounding duties

Training and observation may be performed by the designated person(s) or an assigned trainer. Personnel must be observed and guided throughout the training process. The personnel will then be expected to repeat the procedures independently while under the direct supervision of the designated person(s) and/or assigned trainer. Personnel will be permitted to perform the procedure without direct supervision only after independently demonstrating understanding and competency. Upon completion of the training program, the designated person(s) and/or assigned trainer must document that personnel have been trained and successfully completed competency assessments (see *14. Documentation*).

In addition to the initial and annual competency training and evaluation described in this section, the designated person(s) should monitor and observe compounding activities and must take immediate corrective action if deficient practices are observed. Facility SOPs must describe procedures for monitoring and observing compounding activities and personnel.

If the facility has only one person in the compounding operation, that person must document that they have obtained training and demonstrated competency, and they must comply with the other requirements of this chapter.

## 3. PERSONAL HYGIENE AND GARBING

Individuals entering the compounding area must maintain appropriate personal hygiene. Individuals must evaluate whether they have a personal risk of potentially contaminating the compounding environment and CNSP (e.g., personnel with rashes, recent tattoos, oozing sores, conjunctivitis, or active respiratory infection). Individuals must report these conditions to the designated person(s). Because of the risk of contaminating the CNSP and the environment, the designated person(s) is responsible for evaluating whether these individuals should be excluded from working in compounding areas until their conditions have resolved.

### 3.1 Personnel Preparation

Personnel engaged in compounding must maintain appropriate hand hygiene and maintain appropriate cleanliness required for the type of compounding performed.

Before entering the compounding area, compounding personnel must remove any items that are not easily cleanable and that might interfere with garbing. At a minimum, personnel must:

- Remove personal outer garments (e.g., bandanas, coats, hats, and jackets)
- Remove all hand, wrist, and other exposed jewelry, including piercings that could interfere with the effectiveness of garbing or hand hygiene (e.g., watches or rings that may tear gloves)
- Remove earbuds or headphones

The designated person(s) may permit accommodations provided that the quality of the environment and CNSP will not be affected. All accommodations should be documented.

### 3.2 Hand Hygiene

Personnel must perform procedures necessary for appropriate hand hygiene when entering the compounding area to compound as described in *Box 1*.

The use of alcohol-based hand rub alone is not sufficient.

**Box 1. Hand Hygiene Procedures**

- Wash hands with soap and water for at least 30 s
- Dry hands completely with disposable towels or wipers
- Don gloves

Official

https://pharmacopeia.com/

To minimize the risk of cross contaminating other CNSPs and contaminating other objects (e.g., pens and keyboards), gloves should be wiped or replaced before beginning a CNSP that has different components.

All gloves must be inspected for holes, punctures, or tears and must be replaced immediately if such defects are detected.

### 3.3 Garb and Glove Requirements

Gloves must be worn for all compounding activities. Other garb (e.g., shoe covers, head or hair covers, facial hair covers, face masks, and gowns) must be appropriate for the type of compounding performed and should be worn as needed for the protection of personnel from chemical exposures and for prevention of CNSP contamination. Garbing requirements and frequency of changing garb must be determined by the facility and documented in the facility's SOPs.

Garb must be replaced immediately if it becomes visibly soiled or if its integrity is compromised. All gloves must be inspected for holes, punctures, or tears and must be replaced immediately if such defects are detected. Garb must be stored in a manner that minimizes contamination (e.g., away from sinks to avoid splashing).

Garb should be removed when leaving the compounding area. When personnel exit the compounding area, garb, except for gowns, should be discarded. Disposable garb must not be laundered. If gowns are worn, they may be reused if not damaged or soiled. If gowns are to be reused, they must remain in the compounding area, and should only be reused during the same shift. The facility's SOPs must describe cleaning and sanitization procedures for reusing goggles, respirators, and other reusable equipment.

If compounding an HD, appropriate personal protective equipment (PPE) must be worn and disposed of in accordance with ⟨800⟩.

## 4. BUILDINGS AND FACILITIES

### 4.1 Compounding Area

An area must be designated for nonsterile compounding. The method of designation must be described in the facility's SOPs. Other activities must not be occurring in the compounding area at the same time as compounding. The compounding area must be well lit and must be maintained in a clean, orderly, sanitary condition and in a good state of repair. There should not be carpet in the compounding area.

The compounding area must provide for the orderly placement of equipment and materials to prevent mix-ups among components, containers, labels, in-process materials, and finished CNSPs. The area should be designed, arranged, and used in a way that minimizes cross contamination from noncompounding areas.

### 4.2 Storage Area

Compounding personnel must monitor temperatures in the storage area(s) either manually at least once daily on days that the facility is open, or continuously with a temperature recording device to ensure the temperature remains within the appropriate range for the CNSPs and components. The results of the temperature readings must be documented on a temperature log or stored in the continuous temperature recording device and must be retrievable. All temperature monitoring equipment must be calibrated or verified for accuracy as recommended by the manufacturer or every 12 months if not specified by the manufacturer.

The compounding facility must adhere to SOPs to detect and reduce the risk of temperature excursions within the storage area(s).

When it is known that a CNSP or component has been exposed to temperatures either below or above the storage temperature limits for the CNSP or component, personnel must determine whether the CNSP or component integrity or quality has been compromised, and, if so, the CNSP or component must be discarded.

All CNSPs, components, equipment, and containers must be stored off the floor in a manner that prevents contamination and permits inspection and cleaning of the storage area(s).

### 4.3 Water Sources

A source of hot and cold water and an easily accessible sink must be available. The sink must be emptied of all items unrelated to compounding and must be cleaned if visibly soiled before being used to clean any equipment used in nonsterile compounding. The plumbing system must be free of defects that may contribute to the contamination of any CNSP. *Purified Water* (see *Water for Pharmaceutical Purposes* ⟨1231⟩*, 3.1.1 Purified Water*), distilled water, or reverse osmosis water should be used for rinsing equipment and utensils.

## 5. CLEANING AND SANITIZING

Cleaning and sanitizing the surfaces in the nonsterile compounding area(s) must occur on a regular basis at the minimum frequencies specified in *Table 1* or, if compounding is not performed daily, cleaning and sanitizing must be completed before initiating compounding. Cleaning and sanitizing must be repeated when spills occur and when surfaces are visibly soiled. Applicable cleaning and sanitizing must be documented daily on days when compounding occurs.

Surfaces should be resistant to damage by cleaning and sanitizing agents. Floors in the compounding area should be easily cleanable and should not be porous or particle generating.

Cleaning and sanitizing agents must be selected and used with consideration of compatibilities, effectiveness, and minimal potential to leave residues.

If cleaning and sanitizing are performed as separate steps, cleaning must be performed first.

**Table 1. Minimum Frequency for Cleaning and Sanitizing in Nonsterile Compounding Area(s)—Surfaces**

| Site | Minimum Frequency |
|---|---|
| Work surfaces | • At the beginning and end of each shift on days when compounding occurs, after spills, and when surface contamination (e.g., from splashes) is known or suspected<br>• Between compounding CNSPs with different components |
| Floors | • Daily on days when compounding occurs, after spills, and when surface contamination (e.g., from splashes) is known or suspected |
| Walls | • When visibly soiled, after spills, and when surface contamination (e.g., from splashes) is known or suspected |
| Ceilings | • When visibly soiled and when surface contamination (e.g., from splashes) is known or suspected |

Official

https://nhathuocngocanh.com/

**Table 1. Minimum Frequency for Cleaning and Sanitizing in Nonsterile Compounding Area(s)—Surfaces** *(continued)*

| | |
|---|---|
| Storage shelving | • Every 3 months, after spills, and when surface contamination (e.g., from splashes) is known or suspected |

## 6. EQUIPMENT AND COMPONENTS

### 6.1 Equipment

The equipment and components used for compounding a CNSP must be suitable for the specific compounding process.

Equipment surfaces that contact components must not be reactive, additive, or sorptive, and must not alter the quality of the CNSP. Disposable or dedicated equipment may be used to reduce the chance of bioburden and cross contamination.

Equipment must be stored in a manner that minimizes the risk of contamination and must be located to facilitate equipment use, maintenance, and cleaning. Equipment and devices used in the compounding or testing of compounded preparations must be inspected prior to use and, if appropriate, verified for accuracy as recommended by the manufacturer at the frequency recommended by the manufacturer or at least every 12 months, whichever is more frequent. After compounding, the equipment must be cleaned to prevent cross contamination of the next preparation.

Weighing, measuring, or otherwise manipulating components that could generate airborne chemical particles (e.g., active pharmaceutical ingredients [APIs], added substances, and conventionally manufactured products) must be evaluated to determine if these activities must be performed in a closed-system processing device to reduce the potential exposure to personnel or contamination of the facility or CNSPs. Examples of closed-system processing devices include containment ventilated enclosures (CVEs), biological safety cabinets (BSCs), and single-use containment glove bags. The process evaluation must be carried out in accordance with the facility's SOPs, and the assessment must be documented.

If a CVE or BSC is used, it must be certified at least every 12 months according to manufacturer specifications or other laws and regulations of the applicable regulatory jurisdiction.

If a BSC, CVE, or other nondisposable device is used, it must be cleaned as described in *Table 2*.

**Table 2. Minimum Frequency for Cleaning and Sanitizing in Nonsterile Compounding Area(s)—Equipment**

| Site | Minimum Frequency |
|---|---|
| CVE | • At the beginning and end of each shift on days when compounding occurs, after spills, and when surface contamination (e.g., from splashes) is known or suspected<br>• Clean and sanitize the horizontal work surface of the CVE between compounding CNSPs with different components |
| BSC | • At the beginning and end of each shift on days when compounding occurs, after spills, and when surface contamination (e.g., from splashes) is known or suspected<br>• Clean and sanitize the horizontal work surface of the BSC between compounding CNSPs with different components<br>• Clean and sanitize under the work surface at least monthly |
| Other devices and equipment used in compounding operations | • Before first use and thereafter in accordance with the manufacturer's recommendations<br>• If no recommendation is available, between compounding CNSPs with different components |

### 6.2 Components

The compounding facility must have written SOPs for the selection and inventory control of all components from receipt to use in a CNSP.

SDSs must be readily accessible to all personnel working with components located in the compounding facility. Personnel must be instructed on how to retrieve and interpret needed information.

**6.2.1 Component selection:** Designated person(s) must be responsible for selecting components to be used in compounding.

APIs:

- Must comply with the criteria in the *USP–NF* monograph, if one exists
- Must have a COA that includes specifications (e.g., compendial requirements for quality) and test results for the component that show the API meets expected quality
- In the United States, must be manufactured by an FDA-registered facility
- Outside of the United States, must comply with the laws and regulations of the applicable regulatory jurisdiction

All components other than APIs:

- Should be accompanied by a COA that verifies that the component meets the criteria in the *USP–NF* monograph, if one exists, and any additional specifications for the component
- In the United States, should be manufactured by an FDA-registered facility (If a component cannot be obtained from an FDA-registered facility, the designated person(s) must select a component that is suitable for the intended use.)
- Outside of the United States, must comply with the laws and regulations of the applicable regulatory jurisdiction

Water:

- *Purified Water* or better quality, e.g., *Sterile Water for Irrigation*, must be used for compounding nonsterile drug preparations when formulations indicate the inclusion of water

**6.2.2 Component receipt:** Upon receipt of components other than conventionally manufactured products, the COA must be reviewed to ensure that the component has met the acceptance criteria in an appropriate *USP–NF* monograph, if one exists. The following information must be documented (see *14. Documentation*) according to the facility's SOPs:

Official

https://pharmacopeia.com/

receipt date, quantity received, supplier name, lot number, expiration date, and results of any in-house or third-party testing performed.

For all components that lack a vendor expiration date, the date of receipt by the compounding facility must be clearly and indelibly marked on each packaging system. Packaging systems of components (i.e., API and added substances) that lack a vendor's expiration date must not be used by the compounding facility after 3 years from the date of receipt. A shorter expiration date must be assigned according to *Pharmaceutical Compounding—Sterile Preparations* ⟨*797*⟩*, 9.3.2 Component receipt* if the same component container is also used in sterile compounding or if the ingredient is known to be susceptible to degradation.

Any component found to be of unacceptable quality must be promptly rejected, clearly labeled as rejected, and segregated from active stock to prevent use before appropriate disposal. Any other lots of that component from the same vendor must be examined to determine whether the other lots have the same defect.

**6.2.3 Component evaluation before use:** Before use, compounding personnel must visually re-inspect all components. Each packaging system must be inspected to detect any container breakage, looseness of the cap or closure, or deviation from the expected appearance or texture of the contents that might have occurred during storage.

Compounding personnel must ascertain before use that components are of the correct identity based on the labeling and have been stored under required conditions in the facility.

If the identity, strength, purity, and quality of components intended for preparation of CNSPs cannot be verified (e.g., containers with damaged or incomplete labeling), the components must be immediately rejected. Any component found to be of unacceptable quality must be promptly rejected, clearly labeled as rejected, and segregated from active stock to prevent use before appropriate disposal.

**6.2.4 Component handling:** All components must be handled in accordance with the manufacturer's instructions or per laws and regulations of the applicable regulatory jurisdiction. The handling must minimize the risk of contamination, mix-ups, and deterioration (e.g., loss of identity, strength, purity, or quality). For each use, the lot must be examined for evidence of deterioration and other aspects of unacceptable quality. Once removed from the original container, any component not used in compounding (e.g., excess after weighing) should be discarded and not returned to the original container to minimize the risk of contaminating the original container.

**6.2.5 Component spill and disposal:** The facility must maintain current chemical hazard and disposal information (e.g., SDSs). Such information must be made accessible to compounding personnel.

The management and documentation of nonhazardous component spills and disposal must be described in the facility's SOPs.

The facility must have a readily accessible spill kit in the compounding area.

All personnel who may be required to remediate a spill must receive training in spill management of chemicals used and stored at the compounding facility. Training must be conducted at least every 12 months and documented for all personnel who may be required to clean up a spill.

Waste of any component must be disposed of in accordance with laws and regulations of the applicable regulatory jurisdiction. For information on the handling of HDs, see ⟨800⟩.

## 7. MASTER FORMULATION AND COMPOUNDING RECORDS

### 7.1 Creating Master Formulation Records

A master formulation record (MFR) is a detailed record of procedures that describes how the CNSP is to be prepared. An MFR must be created for each unique formulation of a CNSP. CNSPs are prepared according to the MFR, and the details of each preparation are documented on a compounding record (see *7.2 Creating Compounding Records*). Any changes or alterations to the MFR must be approved and documented according to the facility's SOP. See *Box 2* for information that must be included in an MFR.

**Box 2. Master Formulation Record**

An MFR must include at least the following information:

- Name, strength or activity, and dosage form of the CNSP
- Identities and amounts of all components; if applicable, relevant characteristics of components (e.g., particle size, salt form, purity grade, solubility)
- Container closure system(s)
- Complete instructions for preparing the CNSP including equipment, supplies, and description of compounding steps
- Physical description of the final CNSP
- Beyond-use date (BUD) and storage requirements
- Reference source to support the assigned BUD
- If applicable, calculations to determine and verify quantities and/or concentrations of components and strength or activity of the API(s)
- Labeling requirements (e.g., shake well)
- Quality control (QC) procedures (e.g., pH testing, visual inspection) and expected results
- Other information needed to describe the compounding process and ensure repeatability (e.g., adjusting pH, temperature)

### 7.2 Creating Compounding Records

A compounding record (CR) documents the compounding of each CNSP. A CR must be created for all CNSPs. Each CR must be reviewed for completeness before the CNSP is released. The name or other unique identifier of the person completing the review and the date of the review must be documented on the CR. The CR must permit traceability of all components in the case of a recall or known quality issue. The MFR can be used as the basis for preparing the CR. For example, a duplicate can be made of the MFR with blank fields for recording the information necessary to complete the CR. See *Box 3* for information that must be included in a CR.

**Box 3. Compounding Record**

A CR must include at least the following information:

- Name, strength or activity, and dosage form of the CNSP
- Date—or date and time—of preparation of the CNSP
- Assigned internal identification number (e.g., prescription, order, or lot number)
- A method to identify the individuals involved in the compounding process and individuals verifying the final CNSP
- Name, vendor or manufacturer, lot number, and expiration date of each component
- Weight or measurement of each component
- Total quantity of the CNSP compounded
- Assigned beyond-use date (BUD) and storage requirements
- If applicable, calculations to determine and verify quantities and/or concentrations of components and strength or activity of the API(s)
- Physical description of the final CNSP
- Results of quality control procedures (e.g., pH testing and visual inspection)
- MFR reference for the CNSP

## 8. RELEASE INSPECTIONS AND TESTING

All release inspections must be included in the facility's documentation (see *7. Master Formulation and Compounding Records* and *11. SOPs*). All checks, inspections, and any other required tests to ensure the quality of the CNSP must be detailed in the facility's MFR.

### 8.1 Visual Inspection

At the completion of compounding, before releasing and dispensing, the CNSP must be visually inspected to determine whether the physical appearance of the CNSP is as expected (e.g., color, texture, physical uniformity). Some CNSPs, as noted in their MFR, also must be visually checked for certain characteristics (e.g., emulsions must be checked for phase separation). The CNSP must be visually inspected to confirm that the CNSP and its labeling match the CR and the prescription or medication order. The inspection also must include a visual inspection of container closure integrity (e.g., checking for leakage, cracks in the container, or improper seals).

When a CNSP will not be released or dispensed on the day of preparation, a visual inspection must be conducted immediately before it is released or dispensed to make sure that the CNSP does not exhibit any defects (e.g., leakage) that could develop during storage. Any CNSP found to be of unacceptable quality (e.g., observed defects) must be promptly rejected, clearly labeled as rejected, and segregated from active stock to prevent use before appropriate disposal.

## 9. LABELING

Every CNSP must be labeled with appropriate, legible identifying information to prevent errors during storage, dispensing, and use. The term *labeling* designates all labels and other written, printed, or graphic matter on the immediate container or on or inside any packaging system or wrapper in which the article is enclosed, except any outer shipping container. The term *label* designates the part of the labeling on the immediate container. (See *Labeling* ⟨*7*⟩.)

All labeling must be in compliance with laws and regulations of the applicable regulatory jurisdiction.

The label on each container of the prepared CNSP must, at a minimum, display prominently and legibly the following information:

- Assigned internal identification number (e.g., barcode, prescription, order, or lot number)
- Active ingredient(s), and their amount(s), activity(ies), or concentration(s)
- Storage conditions if other than controlled room temperature
- BUD
- Dosage form
- Total amount or volume if it is not obvious from the container

The labeling on the dispensed CNSP should display the following information:

- Route of administration
- Indication that the preparation is compounded
- Any applicable special handling instructions
- Any applicable warning statements
- Compounding facility name, and contact information if the CNSP is to be sent outside of the facility or healthcare system in which it was compounded

Labeling procedures must be followed as described in the facility's SOPs to prevent labeling errors and CNSP mix-ups.

The label of the CNSP must be verified to ensure that it conforms with the following:

1. Prescription or medication order;
2. MFR (see *7.1 Creating Master Formulation Records*); and
3. CR (see *7.2 Creating Compounding Records*).

## 10. ESTABLISHING BEYOND-USE DATES

### 10.1 Terminology

Each CNSP label must state the date, or the hour and date, beyond which the preparation cannot be used and must be discarded (i.e., the BUD). BUDs for CNSPs are calculated in terms of hours, days, or months.

BUDs and expiration dates are not the same. An expiration date identifies the time during which a conventionally manufactured product, API, or added substance can be expected to meet the requirements of a compendial monograph, if one exists, or maintain expected quality, provided it is kept under the prescribed storage conditions. The expiration date limits the time during which a conventionally manufactured product, API, or added substance may be dispensed or used (see ⟨*7*⟩, *Labels and Labeling for Products in Other Categories, Expiration Date and Beyond-Use Date*).

### 10.2 Parameters to Consider in Establishing a BUD

BUDs for CNSPs should be established conservatively to ensure that the preparation maintains its required characteristics to minimize the risk of contamination or degradation.

When establishing a BUD for a CNSP, compounders must consider parameters that may affect quality, including but not limited to the following:

- Chemical and physical stability properties of the API and any added substances in the preparation (e.g., if the API and added substances in the preparation are known to rapidly degrade over time and/or under certain storage conditions, reduce the strength of the preparation, or produce harmful impurities)
- Compatibility of the container closure system with the finished preparation (e.g., leachables, interactions, adsorption, and storage conditions)
- Degradation of the container closure system, which can lead to a reduction in integrity of the CNSP
- Potential for microbial proliferation in the CNSP
- Significant deviations from essential compounding steps and procedures; changes to essential compounding steps may have an impact on the stability of the formulation

### 10.3 Establishing a BUD for a CNSP

The BUDs in *Table 4* are based on the ability of the CNSP to maintain chemical and physical stability and to suppress microbial growth. These BUDs represent the limit for CNSPs that are packaged in tight, light-resistant containers unless conditions in *10.4 CNSPs Requiring Shorter BUDs* or *10.5 Extending BUDs for CNSPs* apply.

The aqueous and nonaqueous dosage forms in *Table 4* are defined based on the water activity ($a_w$) of the most similar drug preparations described in *Table 3* or *Application of Water Activity Determination to Nonsterile Pharmaceutical Products* ⟨1112⟩. In general, the use of $a_w$ aids in assessing the susceptibility of CNSPs to microbial contamination and the potential for API degradation due to hydrolysis. The $a_w$ is different from the water content and may be considered as the available water to support microbial growth and hydrolytic reactions. Nonaqueous dosage forms will not support spore germination or microbial growth due to their low $a_w$. Reduced $a_w$ greatly assists in the prevention of microbial proliferation in conventionally manufactured products and is expected to convey the same benefit to CNSPs.

Compounders are not required to measure $a_w$ for CNSPs. While the manufactured products in ⟨1112⟩, *Table 2* and compounded preparations in *Table 3* below are not exhaustive, they provide examples of dosage forms that have an $a_w < 0.6$ and those that have an $a_w \geq 0.6$ and can assist personnel in determining the BUD by dosage form using *Table 4*.

When preparing CNSPs, raw materials and equipment contribute a bioburden to the final preparation. CNSPs with an $a_w \geq 0.6$, and a BUD within the limits of *Table 4*, should contain suitable antimicrobial agents to protect against the proliferation of bacteria, yeast, and mold contamination that may be inadvertently introduced anytime during the compounding process or throughout the BUD under appropriate handling and storage conditions. All CNSPs with an extended BUD must follow *10.5 Extending BUDs for CNSPs*. Careful consideration should be taken when selecting a preservative to ensure microbiological effectiveness and stability. When antimicrobial preservatives are contraindicated in a CNSP, storage of the preparation in a refrigerator is required if such storage does not change the physical or chemical properties of the CNSP (i.e., precipitation).

**Table 3. Water Activity of Common Compounded Nonsterile Dosage Forms[a]**

| Nonaqueous Dosage Forms: $a_w < 0.6$ | | | Aqueous Dosage Forms: $a_w \geq 0.6$ | | |
|---|---|---|---|---|---|
| **Dosage Form** | **Description** | **$a_w$** | **Dosage Form** | **Description** | **$a_w$** |
| Animal treat | Animal treat (oil flavor) | 0.507 | Animal treat | Animal treat with 15%–18% aqueous flavor | 0.716 |
| Capsule (oil filled) | Olive oil encapsulated | 0.468 | Cream | Cream vehicle (oil in water emulsion, petrolatum free) | 0.968 |
| Capsule (powder filled) | Powder base encapsulated | 0.435 | Cream | Emollient cream (petrolatum and mineral oil) | 0.984 |
| Gel (glycol based) | Propylene glycol, ethoxy diglycol, hydroxypropyl cellulose gel | 0.056 | Cream | Cream (oil in water emulsion with natural oils) | 0.989 |
| Lollipop (sorbitol based) | Sorbitol-based lollipop | 0.460 | Foam | Foaming surfactant solution | 0.983 |
| Ointment | Hydrophilic petrolatum | 0.396 | Gel (water based) | Alcohol-free aqueous gel | 0.990 |
| Ointment | Polyethylene and mineral oil gel base | 0.459 | Gel (water based) | Hydroxypropyl methylcellulose (HPMC) gel | 1.000 |
| Oral solution (glycol based) | 20% Polyethylene glycol and 80% propylene glycol | 0.009 | Lotion | Lotion (oil in water emulsion) | 0.986 |
| Oral solution (oil based) | Medium chain triglycerides oil | 0.338 | Nasal spray | Nasal spray | 0.991 |
| Oral suspension (fixed oil) | Fixed oil with thickener | 0.403 | Oral solution (water based) | Low-sucrose syrup vehicle | 0.906 |

**Table 3. Water Activity of Common Compounded Nonsterile Dosage Forms[a]** *(continued)*

| Nonaqueous Dosage Forms: $a_w < 0.6$ | | | Aqueous Dosage Forms: $a_w \geq 0.6$ | | |
|---|---|---|---|---|---|
| **Dosage Form** | **Description** | $a_w$ | **Dosage Form** | **Description** | $a_w$ |
| Powder for inhalation | Encapsulated powder for inhalation | 0.402 | Oral solution (water based) | 90% Water and 10% glycerin | 0.958 |
| Stick | Lip balm | 0.181 | Oral suspension (water based) | Oral suspension base | 0.992 |
| Suppository | Polyethylene glycol base | 0.374 | Rinse | Polymer gel with 30% water | 0.960 |
| Suppository | Fatty acid base | 0.385 | Shampoo | Shampoo | 0.976 |
| Tablet (compressed) | Compressed tablet | 0.465 | Simple syrup | Simple syrup | 0.831 |
| Tablet (triturate) | Tablet triturate (lactose and/or sucrose) | 0.427 | — | — | — |
| Troche or lozenge (gelatin based) | Gelatin troche or lozenge with NMT 3% aqueous flavor | 0.332 | — | — | — |
| Troche or lozenge (glycol based) | Polyethylene glycol troche or lozenge with NMT 3% aqueous flavor | 0.571 | — | — | — |

[a] The measured $a_w$ values in *Table 3* for the different dosage forms are intended to be representative examples. The descriptions listed are details about the tested formulation and are provided to assist personnel in determining whether their CNSPs are aqueous or nonaqueous.

**Table 4. BUD Limit by Type of Preparation in the Absence of a *USP–NF* Compounded Preparation Monograph or CNSP-Specific Stability Information[a]**

| Type of Preparation | BUD (days) | Storage Temperature[b] |
|---|---|---|
| **Aqueous Dosage Forms ($a_w \geq 0.60$)** | | |
| Nonpreserved aqueous dosage forms[c] | 14 | Refrigerator |
| Preserved aqueous dosage forms[c] | 35 | Controlled room temperature or refrigerator |
| **Nonaqueous Dosage Forms ($a_w < 0.60$)** | | |
| Oral liquids (nonaqueous)[d] | 90 | Controlled room temperature or refrigerator |
| Other nonaqueous dosage forms[e] | 180 | Controlled room temperature or refrigerator |

[a] A shorter BUD must be assigned when the physical and chemical stability of the CNSP is less than the BUD limit stated in the table (see *10.4 CNSPs Requiring Shorter BUDs*).
[b] See *Packaging and Storage Requirements* ⟨659⟩.
[c] An aqueous preparation is one that has an $a_w \geq 0.6$ (e.g., emulsions, gels, creams, solutions, sprays, or suspensions).
[d] A nonaqueous oral liquid is one that has an $a_w < 0.6$.
[e] Other nonaqueous dosage forms that have an $a_w < 0.6$ (e.g., capsules, tablets, granules, powders, nonaqueous topicals, suppositories, and troches or lozenges).

### 10.4 CNSPs Requiring Shorter BUDs

The BUDs in *Table 4* are the BUD limits for CNSPs in the absence of specific stability information. This does not absolve the designated person(s) from performing due diligence to determine if there is existing stability data that would require a shorter BUD.

Additionally,

- The BUD of the CNSP must not exceed the shortest remaining expiration date of any of the commercially available starting components.
- For CNSPs prepared from one or more compounded components, the BUD should generally not exceed the shortest BUD of any of the individual compounded components. However, there may be acceptable instances when the BUD of the final CNSP exceeds the BUD assigned to compounded components (e.g., pH-altering solutions). If the assigned BUD of the final CNSP exceeds the BUD of the compounded components, the physical, chemical, and microbiological quality of the final CNSP must not be negatively impacted.

### 10.5 Extending BUDs for CNSPs

- *CNSPs with a USP–NF monograph:* When compounding from a *USP–NF* compounded preparation monograph for the CNSP, the BUD must not exceed the BUD specified in the monograph.
- *CNSPs with stability information:* If there is a stability study using a stability-indicating analytical method for the API(s), CNSP formulation, and material of composition of the container closure that will be used, then the BUD indicated by the study may be used in lieu of the BUDs specified in *Table 4* for aqueous and nonaqueous dosage forms, up to a maximum of 180 days.

If the BUD of the CNSP is extended beyond the BUDs in *Table 4*, an aqueous CNSP must be tested for antimicrobial effectiveness (see *Antimicrobial Effectiveness Testing* ⟨51⟩). The designated person(s) may rely on antimicrobial effectiveness testing that is conducted (or contracted for) once for each formulation in the particular container closure system—including materials of composition of the container closure system—in which it will be packaged. Alternatively,

Official

DocId: GUID-98DCB48D-DC23-4A63-AD2E-01CA8979FB7E_6_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99595_06_01
@2024 USPC

the designated person(s) may rely on antimicrobial effectiveness testing results provided by an FDA-registered facility or published in peer-reviewed literature as long as the CNSP formulation (including any preservative) and container closure materials of composition are the same as those tested (unless a bracketing study is performed). When a bracketing study is performed, antimicrobial effectiveness testing may be performed on a low concentration and on a high concentration of the active ingredient in the formulation to establish preservative effectiveness across various strengths of the same formulation (e.g., bracketing). The concentration of all other ingredients (including preservatives) must fall within the bracketed range.

## 11. SOPS

Facilities preparing CNSPs must develop SOPs on all aspects of the compounding operation. All personnel who conduct or oversee compounding activities must be trained in the facility's SOPs and be responsible for ensuring that they are followed.

One or more person(s) must be designated to ensure that the facility's SOPs are fully implemented. The designated person(s) must ensure that follow-up occurs if problems, deviations, or errors are identified.

## 12. QUALITY ASSURANCE AND QUALITY CONTROL

Quality assurance (QA) is a system of procedures, activities, and oversight that ensures that the compounding process consistently meets quality standards. Quality control (QC) is the sampling, testing, and documentation of results that, taken together, ensure that specifications have been met before release of the CNSP. See *Quality Assurance in Pharmaceutical Compounding* ⟨1163⟩.

A facility's QA and QC programs must be formally established and documented in the facility's SOPs that ensure that all aspects of the preparation of CNSPs are conducted in accordance with the requirements in this chapter ( ⟨795⟩) and the laws and regulations of the applicable regulatory jurisdiction. Designated person(s) must ensure that the facility has formal, written QA and QC programs that establish a system of

1. Adherence to procedures,
2. Prevention and detection of errors and other quality problems,
3. Evaluation of complaints and adverse events, and
4. Appropriate investigations and corrective actions.

The facility's SOPs must describe the roles, duties, and training of the personnel responsible for each aspect of the QA program. Designated person(s) responsible for the QA program must have the training, experience, responsibility, and authority to perform these duties. The overall QA and QC program must be reviewed at least once every 12 months by the designated person(s). The results of the review must be documented, and appropriate action must be taken if needed.

### 12.1 Notification About and Recall of Dispensed CNSPs

The facility must have procedures in place to

- Determine when recalls must be initiated, which should include procedures to immediately notify the prescriber of a failure of specifications with the potential to cause patient harm (e.g., strength, purity, or other quality attributes)
- Recall any unused dispensed CNSPs and quarantine any stock remaining in the pharmacy
- Investigate if other lots are affected and recall if necessary

An SOP for recall of dispensed CNSPs must contain

- Procedures to determine the severity of the problem and the urgency for implementation and completion of the recall
- Procedures to determine the distribution of any affected CNSP, including the data and quantity of distribution
- Procedures to identify patients who have received the CNSP
- Procedures for disposal and documentation of the recalled CNSP
- Procedures to investigate and document the reason for recall

The nonsterile compounding facility must document the implementation of the recall procedures. The recall must be reported to appropriate regulatory bodies as required by the laws and regulations of the applicable regulatory jurisdiction.

### 12.2 Complaint Handling

Compounding facilities must develop and implement SOPs for handling complaints. Complaints may include but are not limited to concerns or reports on the quality, labeling, or possible adverse reactions related to a specific CNSP.

A designated person(s) must review all complaints to determine whether the complaint indicates a potential quality problem with the CNSP. If it does, a thorough investigation into the cause of the problem must be initiated and completed. The investigation must consider whether the quality problem extends to other CNSPs. Corrective action, if necessary, must be implemented for all potentially affected CNSPs.

Consider whether to initiate a recall of potentially affected CNSPs and whether to cease nonsterile compounding processes until all underlying problems have been identified and corrected.

A readily retrievable written or electronic record of each complaint must be kept by the facility, regardless of the source of the complaint (e.g., email, telephone, or mail). The record must contain the name of the complainant or other unique identifier, the date the complaint was received, the nature of the complaint, and the response to the complaint. In addition, to the extent that the information is known, the following should be recorded: the name and strength of the CNSP and the assigned internal identification number (e.g., prescription, order, or lot number).

The record must also include the findings of any investigation and any follow-up. Records of complaints must be easily retrievable for review and evaluation for possible trends and must be retained in accordance with the record-keeping requirements in *14. Documentation*. A CNSP that is returned in connection with a complaint must be quarantined until it is destroyed after completion of the investigation and in accordance with laws and regulations of the applicable regulatory jurisdiction.

@2024 USPC

### 12.3 Adverse Event Reporting

Adverse events potentially associated with the quality of CNSPs must be reported in accordance with the facility's SOPs and all laws and regulations of the applicable regulatory jurisdiction. If the investigation into an adverse event reveals a quality problem with a CNSP that is likely to affect other patients, those patients and prescribers potentially affected must be informed.

## 13. CNSP PACKAGING AND TRANSPORTING

### 13.1 Packaging of CNSPs

The facility's SOPs must describe packaging of CNSPs. Personnel should select and use packaging materials that will maintain the physical and chemical integrity and stability of the CNSPs. Packaging materials must protect CNSPs from damage, leakage, contamination, and degradation, while simultaneously protecting personnel from exposure.

### 13.2 Transporting of CNSPs

If transporting CNSPs, the facility must have written SOPs to describe the mode of transportation, any special handling instructions, and whether temperature monitoring devices are needed.

## 14. DOCUMENTATION

All facilities where CNSPs are prepared must have and maintain written or electronic documentation to demonstrate compliance with the requirements in this chapter. This documentation must include, but is not limited to, the following:

- Personnel training, competency assessments, and qualification records including corrective actions for any failures
- Equipment records (e.g., calibration, verification, and maintenance reports)
- COAs and all documentation required for components not conventionally manufactured
- Receipt of components
- SOPs, MFRs, and CRs
- Release inspection and testing records
- Information related to complaints and adverse events including corrective actions taken
- Results of investigations and corrective actions
- Records of cleaning and sanitizing the designated compounding area
- Temperature logs
- Accommodations to personnel compounding CNSPs
- Any required routine review (e.g., yearly review of QA and QC programs, yearly review of chemical hazard and disposal information)

Documentation must comply with all laws and regulations of the applicable regulatory jurisdiction. Records must be legible and stored in a manner that prevents their deterioration and/or loss. All required CRs for a particular CNSP (e.g., MFR, CR, and release inspection and testing results) must be readily retrievable for at least 2 years after preparation or as required by the laws and regulations of the applicable regulatory jurisdiction, whichever is longer.

## GLOSSARY

**Active pharmaceutical ingredient (API):** Any substance or mixture of substances intended to be used in the compounding of a preparation, thereby becoming the active ingredient in that preparation and furnishing pharmacological activity or other direct effect in the diagnosis, cure, mitigation, treatment, or prevention of disease in humans or animals or affecting the structure and function of the body. Also referred to as *Bulk drug substance*. A conventionally manufactured drug product is not an API but is typically manufactured from an API(s).

**Added substance:** An ingredient that is necessary to compound a preparation but is not intended or expected to cause a pharmacologic response if administered alone in the amount or concentration contained in a single dose of the compounded preparation. The term is used synonymously with inactive ingredient, excipient, and pharmaceutical ingredient.

**Administration:** The preparation of a nonsterile pharmacologic or other therapeutic agent for ingesting, inserting, applying, or otherwise providing a nonsterile medication in its final form to a single patient. This includes crushing a tablet(s) or opening a capsule(s) to mix with food or liquids to facilitate patient dosing.

**Alcohol-based hand rub:** An alcohol-containing preparation (liquid, gel, or foam) designed for application to the hands of healthcare personnel to inactivate microorganisms and/or temporarily suppress their growth. Such preparations may contain one or more types of alcohol, other active ingredients, excipients, and humectants.

**Assigned trainer:** One or more individuals assigned by the designated person(s) to be responsible and accountable for directly providing the training, observation, and/or evaluation of personnel for the preparation of CNSPs.

**Beyond-use date (BUD):** The date, or hour and date, after which a CNSP must not be used, stored, or transported. The date is determined from the date or time the preparation is compounded.

**Biological safety cabinet (BSC):** A ventilated cabinet that may be used for compounding. These cabinets are divided into three general classes (Class I, Class II, and Class III). Class II BSCs are further divided into types (Type A1, Type A2, Type B1, Type B2, and Type C1).

**Bulk drug substance:** See the entry for *Active pharmaceutical ingredient*.

**Certificate of analysis (COA):** A report from the supplier of a component, container, or closure that accompanies the supplier's material and contains the specifications and results of all analyses and a description of the material.

**Cleaning:** The process of removing substances (e.g., organic and inorganic material) from objects and surfaces, normally accomplished by manually or mechanically using water with detergents or enzymatic products.

**Cleaning agent:** An agent, usually containing a surfactant, used for the removal of substances (e.g., dirt, debris, microbes, and residual drugs or chemicals) from surfaces.

**Closed-system processing device:** A device designed to reduce the potential exposure to personnel or contamination of the facility or CNSPs. Examples include CVEs, BSCs, or single-use containment glove bags.

**Component:** Any ingredient used in the compounding of a preparation, including any API, added substance, or conventionally manufactured product.

**Compounded nonsterile preparation (CNSP):** A preparation not intended to be sterile that is created by combining, admixing, diluting, pooling, reconstituting other than as provided in the manufacturer's labeling, or otherwise altering a drug product or bulk drug substance.
**Compounding:** The process of combining, admixing, diluting, pooling, reconstituting other than as provided in the manufacturer's labeling, or otherwise altering a drug product or bulk drug substance to create a nonsterile preparation.
**Compounding area:** An area that is specifically designated for nonsterile compounding.
**Compounding personnel:** Personnel trained to compound or oversee compounding of preparations.
**Compounding record (CR):** Documents the compounding of each CNSP.
**Container closure system:** Packaging system components that together contain and protect the dosage form. This includes primary packaging system components and secondary packaging system components if the latter are intended to provide additional protection.
**Containment glove bag:** A single-use disposable glove bag that is capable of containing airborne chemical particles.
**Containment ventilated enclosure (CVE):** A full or partial enclosure that uses ventilation principles to capture, contain, and remove airborne contaminants through high-efficiency particulate air (HEPA) filtration and to prevent their release into the work environment.
**Conventionally manufactured product:** A pharmaceutical dosage form, usually the subject of an application approved by the applicable national regulatory agency, that is manufactured under current good manufacturing practice conditions.
**Designated person(s):** One or more individuals assigned to be responsible and accountable for the performance and operation of the facility and personnel as related to the preparation of CNSPs.
**FDA:** US Food and Drug Administration.
**Formulation:** The specific qualitative and quantitative composition of the final CNSP.
**Hazardous drug (HD):** Any drug identified by at least one of the following criteria: carcinogenicity, teratogenicity or developmental toxicity; reproductive toxicity in humans; organ toxicity at low dose in humans or animals; genotoxicity or new drugs that mimic existing HDs in structure or toxicity. See ⟨800⟩.
**Label:** The part of the labeling on the immediate container.
**Labeling:** All labels and other written, printed, or graphic matter on the immediate container or on or inside any packaging system or wrapper in which the article is enclosed, except for any outer shipping container.
**Master formulation record (MFR):** A detailed record of procedures that describes how the CNSP is to be prepared.
**Monograph:** A quality documentary standard within *USP–NF* that articulates the quality expectations for a medicine including for its identity, strength, purity, and performance. It also describes the tests to validate that a medicine and its ingredients meet these criteria.
**Oversight:** The review, monitoring, and supervision of actions taken by personnel; bearing responsibility for those actions; and being available if and when needed for consultation even if not physically present.
**Preservative:** A substance added to inhibit microbial growth.
**Purified water:** The minimal quality of source water for the production of *Purified Water* is drinking water whose attributes are prescribed by the US Environmental Protection Agency (EPA), the European Union, Japan, or the World Health Organization (WHO). This source water may be purified using unit operations that include deionization, distillation, ion exchange, reverse osmosis, filtration, or other suitable purification procedures. (See ⟨1231⟩*, 3.1.1 Purified Water*.)
**Quality assurance (QA):** A system of procedures, activities, and oversight that ensures that the compounding process consistently meets quality standards.
**Quality control (QC):** The sampling, testing, and documentation of results that, taken together, ensure that specifications have been met for the CNSP.
**Reconstitution:** The process of adding a diluent to a conventionally manufactured product to prepare a solution or suspension.
**Release inspection and testing:** Visual inspection and testing performed to ensure that a preparation meets appropriate quality characteristics.
**Sanitizing agent:** An agent for reducing, on inanimate surfaces, the number of microorganisms (e.g., 70% isopropyl alcohol).
**SDS:** Safety data sheet.
**SOP:** Standard operating procedure.
**Specification:** The tests, analytical methods, and acceptance criteria to which any components, CNSP, container closure system, equipment, or other material used in the compounding of CNSPs must conform to be considered acceptable for its intended use.
**Stability:** The extent to which a product or preparation retains physical and chemical properties and characteristics within specified limits throughout its expiration or BUD.
**Verify:** To confirm that a method, process, system, or equipment will perform as expected under the conditions of actual use.
**Water activity ($a_w$):** A measure of the fraction of total water that is unbound and freely available to participate in chemical, biochemical, or physicochemical reactions or provide an environment that can support microbial growth. Note that $a_w$ is not water content.▲ (Official 1-Nov-2023)

# ⟨797⟩ PHARMACEUTICAL COMPOUNDING—STERILE PREPARATIONS

***Change to read:***

## ▲1. INTRODUCTION AND SCOPE

This chapter describes the minimum standards to be followed for the preparation of compounded sterile preparations (CSPs) for human and animal drugs. Sterile compounding is defined as combining, admixing, diluting, pooling, reconstituting, repackaging, or otherwise altering a drug product or bulk drug substance to create a sterile preparation.

The requirements in this chapter must be followed to minimize harm, including death, to human and animal patients that could result from 1) microbial contamination [nonsterility], 2) excessive bacterial endotoxins, 3) variability from the intended strength of correct ingredients, 4) physical and chemical incompatibilities, 5) chemical and physical contaminants, and/or 6) use of ingredients of inappropriate quality.

Aseptic techniques, processes, and procedures must be followed for preparing any sterile medication. Processes and procedures must be in place to minimize the potential for contact with nonsterile surfaces, introduction of particulate matter or biological fluids, and mix-ups with other products or CSPs.

The use of technologies, techniques, materials, and procedures other than those described in this chapter is not prohibited as long as they are noninferior to those described herein and validated for the intended purpose (e.g., *Validation of Alternative Microbiological Methods* ⟨1223⟩ and *Validation of Compendial Procedures* ⟨1225⟩).

Unless otherwise specified in each section, the requirements of this chapter apply to compounding all categories of CSPs.

### 1.1 Scope

**1.1.1 CSPs affected:** The requirements in this chapter must be met to ensure the sterility of any CSP. Although the list below is not exhaustive, the following must be sterile:

- Injections, including infusions
- Irrigations for internal body cavities (i.e., any space that does not normally communicate with the environment outside of the body, such as the bladder cavity or peritoneal cavity). [NOTE—Irrigations for the mouth, rectal cavity, and sinus cavity are not required to be sterile.]
- Ophthalmic dosage forms
- Aqueous preparations for pulmonary inhalation. [NOTE—Nasal dosage forms intended for local application are not required to be sterile.]
- Baths and soaks for live organs and tissues
- Implants

**1.1.2 Specific practices**

**Allergenic extracts:** Licensed allergenic extracts are mixed and diluted to prepare prescription sets for administration to patients. A prescription set is a vial or set of vials of premixed licensed allergenic extracts for subcutaneous immunotherapy that have been diluted with an appropriate diluent for an individual patient. Because of certain characteristics of allergenic extracts and allergy practice, preparation of allergenic extract prescription sets is not subject to all of the requirements in this chapter that are applicable to other sterile CSPs. The standards for compounding allergenic extracts, which are described in *21. Compounding Allergenic Extracts*, are applicable only when

1. The compounding process involves transfer via sterile needles and syringes of conventionally manufactured sterile allergen products and appropriate conventionally manufactured sterile added substances; and
2. Manipulations are limited to penetrating stoppers on vials with sterile needles and syringes and transferring sterile liquids in sterile syringes to sterile vials.

**Blood-derived and other biological materials:** When compounding activities require the manipulation of a patient's blood-derived or other biological material (e.g., autologous serum), the manipulations must be clearly separated from other compounding activities and equipment used in CSP preparation activities, and they must be controlled by specific standard operating procedures (SOPs) to avoid any cross-contamination. Handling of blood components and other biological materials must additionally comply with laws and regulations of the applicable regulatory jurisdiction.

**Hazardous drugs:** Handling of sterile hazardous drugs (HDs) must additionally comply with *Hazardous Drugs—Handling in Healthcare Settings* ⟨800⟩.

**Repackaging:** Repackaging of a sterile product or preparation from its original container into another container must be performed in accordance with the requirements in this chapter.

**Sterile radiopharmaceuticals:** Compounding of radiopharmaceuticals is not required to meet the standards of this chapter as they are subject to the requirements in *Radiopharmaceuticals—Preparation, Compounding, Dispensing, and Repackaging* ⟨825⟩.

**1.1.3 Personnel and settings affected:** This chapter describes the minimum requirements that apply to all persons who prepare CSPs and all places where CSPs are prepared. This includes but is not limited to pharmacists, technicians, nurses, physicians, veterinarians, dentists, naturopaths, and chiropractors in all places including but not limited to hospitals and other healthcare institutions, medical and surgical patient treatment sites, infusion facilities, pharmacies, and physician or veterinarian practice sites. Any person entering a sterile compounding area, whether preparing a CSP or not, must meet the requirements in *3. Personal Hygiene and Garbing*.

The compounding facility must designate one or more individuals (i.e., the designated person(s)) to be responsible and accountable for the performance and operation of the facility and personnel in the preparation of CSPs and for performing other functions as described in this chapter.

@2024 USPC

**1.2 Administration**

For the purposes of this chapter, "administration" means the direct application of a sterile product or preparation to a single patient by injecting, infusing, or otherwise providing a sterile product or preparation in its final form.

Administration of medication is out of the scope of this chapter. Standard precautions such as the Centers for Disease Control and Prevention (CDC) safe injection practices apply to administration. See ⟨800⟩ for additional recommendations for the administration of hazardous drugs.

**1.3 Immediate-Use CSPs**

When all of the following conditions are met, compounding of CSPs for direct and immediate administration is not subject to the requirements for Category 1, Category 2, or Category 3 CSPs:

1. Aseptic techniques, processes, and procedures are followed, and written SOPs are in place to minimize the potential for contact with nonsterile surfaces, introduction of particulate matter or biological fluids, and mix-ups with other conventionally manufactured products or CSPs.
2. Personnel are trained and demonstrate competency in aseptic processes as they relate to assigned tasks and the facility's SOPs.
3. The preparation is performed in accordance with evidence-based information for physical and chemical compatibility of the drugs (e.g., approved labeling, stability and compatibility studies).
4. The preparation involves not more than 3 different sterile products.
5. Any unused starting component from a single-dose container must be discarded after preparation is complete. Single-dose containers must not be used for more than one patient.
6. Administration begins within 4 h following the start of preparation. If administration has not begun within 4 h following the start of preparation, it must be promptly, appropriately, and safely discarded.
7. Unless directly administered by the person who prepared it or administration is witnessed by the preparer, the CSP must be labeled with the names and amounts of all active ingredients, the name or initials of the person who prepared the preparation, and the 4-h time period within which administration must begin.

Handling of sterile hazardous drugs (HDs) must additionally comply with ⟨800⟩.

**1.4 Preparation Per Approved Labeling**

Compounding does not include mixing, reconstituting, or other such acts that are performed in accordance with directions contained in approved labeling or supplemental materials provided by the product's manufacturer.

Preparing a conventionally manufactured sterile product in accordance with the directions in the manufacturer's approved labeling is out of scope of this chapter only if

1. The product is prepared as a single dose for an individual patient; and
2. The approved labeling includes information for the diluent, the resultant strength, the container closure system, and storage time.

See ⟨800⟩ for additional recommendations for the preparation of hazardous drugs.

**Proprietary bag and vial systems:** Docking and activation of proprietary bag and vial systems in accordance with the manufacturer's labeling for *immediate* administration to an individual patient is not considered compounding and may be performed outside of an International Organization for Standardization (ISO) Class 5 environment.

Docking of the proprietary bag and vial systems for *future activation* and administration is considered compounding and must be performed in an ISO Class 5 environment in accordance with this chapter, with the exception of *14. Establishing Beyond-Use Dates*. Beyond-use dates (BUDs) for proprietary bag and vial systems must not be longer than those specified in the manufacturer's labeling.

**1.5 CSP Categories**

This chapter distinguishes three categories of CSPs: Category 1, Category 2, and Category 3, primarily based on the state of environmental control under which they are compounded, the probability for microbial growth during the time they will be stored, and the time period within which they must be used.

Category 1 CSPs are compounded under the least controlled environmental conditions and therefore are assigned a BUD of 12 h or less at controlled room temperature or 24 h or less when refrigerated, if compounded in accordance with all of the applicable requirements for Category 1 CSPs in this chapter.

Category 2 CSPs require more environmental controls and testing than Category 1 CSPs and may be assigned a BUD of greater than 12 h at controlled room temperature or more than 24 h if refrigerated, but not exceed the limits established in *Table 13* (see *14. Establishing Beyond-Use Dates*), if compounded in accordance with all of the applicable requirements for Category 2 CSPs in this chapter.

Category 3 CSPs undergo sterility testing, supplemented by endotoxin testing when applicable, and have more requirements than Category 2 CSPs for personnel qualification, use of sterile garb, use of sporicidal disinfectants, frequency of environmental monitoring, and stability determination. Category 3 CSPs may be assigned longer BUDs than those set for Category 2 CSPs but not exceeding the limits in *Table 14* (see *14. Establishing Beyond-Use Dates*), if compounded in accordance with all applicable requirements for Category 3 CSPs in this chapter (see *14.4 Additional Requirements for Category 3 CSPs*).

The requirements that are not specifically described as applicable to Category 1, Category 2, or Category 3, are applicable to the compounding of all CSPs unless the CSP is otherwise described in *1.1 Scope*.

Category 1, Category 2, and Category 3 CSPs can be compounded by using only sterile starting ingredients, or by using some or all nonsterile starting ingredients. If all components used to compound are sterile from the start, the sterility of the components must be maintained during compounding to produce a CSP.

If one or more of the starting components being used to compound is not sterile, the sterility of the compounded preparation must be achieved through a sterilization process (e.g., terminal sterilization in the final sealed container) or sterilizing filtration, and then sterility must be maintained if the CSP is subsequently manipulated. When compounding with nonsterile starting components, supplies, or equipment, the quality of the components, the

Official

https://pharmacopeia.com/

effectiveness of the sterilization step, and bacterial endotoxin mitigation strategies are critical to achieving a sterile preparation that is free from excessive bacterial endotoxins.

## 2. PERSONNEL TRAINING AND EVALUATION

All personnel who compound or have direct oversight of compounding personnel must be initially trained and qualified by demonstrating knowledge and competency in compounding CSPs according to the requirements in this section before being allowed to perform their job functions independently. Designated person(s) are responsible for creating and implementing a training program for personnel and for ensuring that compounders, personnel who have direct oversight of compounders, and personnel who perform restocking or cleaning and disinfection duties are initially trained and qualified by demonstrating knowledge and competency in maintaining the quality of the sterile compounding environment before being allowed to perform their job functions independently. Training and observation may be performed by the designated person(s) or an assigned trainer. Personnel who compound or have direct oversight of compounding personnel must complete training initially and at least every 12 months in appropriate sterile compounding principles and practices as described below (see *2.1 Demonstrating Knowledge and Competency of Core Skills*). Personnel who only perform restocking or cleaning and disinfecting duties outside of the primary engineering control (PEC) must complete ongoing training as required by the facility's SOPs. Personnel compounding only immediate-use CSPs must complete training as required by the facility's SOPs (see *1.3 Immediate-Use CSPs*).

Each compounding facility must develop a written training program that describes the required training, the frequency of training, and the process for evaluating the performance of individuals who compound, have direct oversight of compounding personnel, perform in-process checks, final verification, and dispensing of CSPs. This program must equip personnel with the appropriate knowledge and train them in the required skills necessary to perform their assigned tasks, and SOPs should specify the training required for such tasks.

Training and evaluation of personnel must be documented (see *20. Documentation*).

### 2.1 Demonstrating Knowledge and Competency of Core Skills

Before beginning to compound CSPs independently or have direct oversight of compounding personnel, personnel must complete training and be able to demonstrate knowledge of principles and competency of skills for performing sterile manipulations and achieving and maintaining appropriate environmental conditions as applicable to their assigned job functions. This must be completed initially and at least every 12 months in at least the following:

- Hand hygiene
- Garbing
- Cleaning and disinfection
- Calculations, measuring, and mixing
- Aseptic technique
- Achieving and/or maintaining sterility (and apyrogenicity if compounding with nonsterile components)
- Use of equipment
- Documentation of the compounding process (e.g., master formulation and compounding records)
- Principles of high-efficiency particulate air (HEPA)-filtered unidirectional airflow within the ISO Class 5 area
- Proper use of PECs
- Principles of movement of materials and personnel within the compounding area

If the facility has only one person in the compounding operation, that person must document that they have obtained training and demonstrated competency, and they must comply with the other requirements of this chapter.

### 2.2 Demonstrating Competency in Garbing and Hand Hygiene

Before beginning to compound Category 1, Category 2, or Category 3 CSPs or have direct oversight of compounding personnel, personnel must successfully complete an initial garbing competency evaluation no fewer than 3 separate times. The 3 successful completions must be in succession—failure of any of the 3 initial garbing competency evaluations requires repeat testing until personnel successfully complete 3 evaluations in a row. The garbing competency evaluation consists of a visual observation and gloved fingertip and thumb sampling (GFT) of both hands (see *Box 1*). Each of the 3 initial competency evaluations must occur after performing a separate and complete hand hygiene and full garbing procedure. All garbing competencies must be completed with gloved fingertip and thumb sampling after garbing (see *Box 1*) and a documented visual audit while performing hand hygiene and garbing procedures (see *3. Personal Hygiene and Garbing*). Gloved fingertip and thumb sampling after garbing, but before applying sterile 70% IPA to gloves, must be performed on donned sterile gloves on both hands in a classified area or segregated compounding area (SCA).

Failure is indicated by visual observation of improper hand hygiene and garbing procedures and/or gloved fingertip and thumb sampling results that exceed the action levels in *Table 1*. Results of the evaluation and corrective actions, in the event of failure, must be documented and the documentation maintained to provide a record and long-term assessment of personnel competency. Documentation must at a minimum include the name of the person evaluated; evaluation date and time; media and components used including manufacturer, expiration date, and lot number; starting temperature for each interval of incubation; dates of incubation; results and identification of the observer and personnel reading and documenting the results. Microbial identification of the colony-forming units (cfu) is not required for gloved fingertip and thumb sampling.

After the initial garbing competency evaluations, compounding personnel must successfully complete the garbing competency (see *Table 1*) at least one time every 6 months for personnel compounding Category 1 and Category 2 CSPs, and at least one time every 3 months for personnel compounding Category 3 CSPs. Personnel who have direct oversight of compounding personnel, but do not compound, must complete a garbing competency evaluation every 12 months. The evaluation should correspond to the type of garbing activities of the personnel they oversee. Personnel who have direct oversight of compounding personnel must not compound unless they successfully complete the garbing competency evaluation at the same intervals required for compounding personnel.

Official

https://pharmacopeia.com/

**Box 1. Gloved Fingertip and Thumb Sampling Procedures**

- Use one sampling media device (e.g., plates, paddles, or slides) per hand, containing general microbial growth agar (e.g., trypticase soy agar [TSA]) supplemented with neutralizing additives (e.g., lecithin and polysorbate 80) as this agar supports both bacterial and fungal growth.
- Label each media device with a personnel identifier, right or left hand, and the date and time of sampling.
- Do not apply sterile 70% isopropyl alcohol (IPA) to gloves immediately before touching the media device because this could cause a false-negative result. Using a separate media device for each hand, collect samples from all gloved fingertips and thumbs from both hands by rolling fingertip pads and thumb pad over the agar surface.
- Incubate the media device at 30°–35° for no less than 48 h and then at 20°–25° for no less than 5 additional days. Samples must be incubated in an incubator. Handle and store media devices to avoid contamination and prevent condensate from dropping onto the agar during incubation and affecting the accuracy of the cfu reading (e.g., invert plates).
- Record the number of cfu per hand (left hand, right hand).
- Determine whether the cfu action level is exceeded by counting the total number of cfu from both hands.

### 2.3 Competency Testing in Aseptic Manipulation

Before beginning to compound Category 1, Category 2, or Category 3 CSPs independently or have direct oversight of compounding personnel, personnel must successfully complete an aseptic manipulation competency evaluation. The aseptic manipulation competency evaluation consists of a visual observation, media-fill testing, followed by a gloved fingertip and thumb sampling on both hands, and surface sampling of the direct compounding area to assess aseptic technique and related practices (see *Box 2*).

For personnel compounding Category 1 and Category 2 CSPs, the aseptic manipulation competency must occur initially and at least every 6 months thereafter. For personnel compounding Category 3 CSPs, the aseptic manipulation competency must occur initially and at least every 3 months thereafter. Personnel who have direct oversight of compounding personnel must complete an aseptic manipulation competency evaluation annually. The evaluation should correspond to the type of activities of the personnel they oversee but does not require the same quantities. Personnel who have direct oversight of compounding personnel must not compound unless they successfully complete the aseptic manipulation competency evaluation that simulates the most difficult and challenging aseptic compounding procedures encountered by the person at the same intervals required for compounding personnel.

When performing a media-fill test, simulate the most difficult and challenging aseptic compounding procedures encountered by the person replacing all the components used in the CSPs with soybean–casein digest media. The simulation must capture elements that could potentially affect the sterility of the CSP including but not limited to:

- Factors associated with the length of the process that can pose contamination risk (e.g., operator fatigue, quality of equipment)
- Number of aseptic additions or transfers
- Number, type, and complexity of manipulations
- Number of personnel in the buffer room or SCA

If using commercial sterile microbial growth media, a certificate of analysis (COA) must be obtained from the supplier stating that the lot of the growth media will support the growth of microorganisms. Store microbial growth media in accordance with manufacturer instructions and initiate the media-fill test by the expiration date of the media. If preparing sterile microbial growth media in-house for sterile-to-sterile media-fill testing, the growth promotion capability of the media must be demonstrated for each batch and documented as described in *Sterility Tests* ⟨71⟩, *Culture Media and Incubation Temperatures, Growth Promotion Test of Aerobes, Anaerobes, and Fungi*.

Failure is indicated by visible turbidity or other visual manifestations of growth in the media in one or more container closure unit(s) on or before the end of the incubation period. Microbial identification of the cfu is not required for media-fill testing.

Immediately following the media-fill test, gloved fingertip and thumb sampling must be performed on both hands and inside of an ISO Class 5 PEC. If conducting gloved fingertip and thumb sampling in a compounding aseptic isolator (CAI), compounding aseptic containment isolator (CACI), or a pharmaceutical isolator, samples must be taken from the sterile gloves placed over the gloves attached to the restricted-access barrier system (RABS) or pharmaceutical isolator sleeves.

Successful completion of the gloved fingertip and thumb sampling after media-fill testing is defined as ≤3 cfu as a total from both hands. See *Table 1* for action levels for gloved fingertip and thumb sampling results. Microbial identification of the cfu is not required for gloved fingertip and thumb sampling.

Surface sampling of the direct compounding area must occur in accordance with the requirements in *6.3 Monitoring Surfaces for Viable Particles*. A failure in the media fill, gloved fingertip and thumb sampling, or surface sample constitutes an overall failure of the aseptic manipulation competency.

Results of the evaluation and corrective actions must be documented and the documentation maintained to provide a record and long-term assessment of personnel competency. Documentation must at a minimum include 1) the name of the person evaluated, 2) evaluation date and time, 3) media and components used including their manufacturer or supplier, 4) expiration dates and lot numbers, 5) starting temperature for each interval of incubation, 6) dates of incubation, 7) the results, and 8) the names or other identification of the observer and the person who reads and documents the results.

**Box 2. Media-Fill Testing Procedures**

- If all of the starting components are sterile to begin with, manipulate them in a manner that simulates sterile-to-sterile compounding activities, and transfer the sterile soybean–casein digest media into the same types of container closure systems commonly used at the facility. Do not further dilute the media unless specified by the manufacturer.
- If some of the starting components are nonsterile to begin with, dissolve a commercially available nonsterile soybean–casein digest powder in nonbacteriostatic water to make a 3% nonsterile solution. Manipulate it in a manner that simulates nonsterile-to-sterile compounding activities. Prepare at least 1 container as the positive control to demonstrate growth promotion, which is indicated by visible turbidity upon incubation.
- Once the compounding simulation is completed and the final containers are filled with the test media, perform a gloved fingertip and thumb sample on each hand and surface sample of the direct compounding area inside the PEC. Take the samples prior to disinfecting gloves and PEC. Handle and store samples to avoid contamination and prevent condensate from dropping onto the agar during incubation and affecting the accuracy of the cfu reading (e.g., invert containers).
- Incubate the final containers at 20°–25° and 30°–35° for a minimum of 7 days at each temperature band to detect a broad spectrum of microorganisms. The order of the incubation temperatures must be described in the facility's SOPs. Final containers must be incubated in an incubator.
- Failure is indicated by visible turbidity or other visual manifestations of growth in the media in one or more container closure unit(s) on or before 14 days.

## 3. PERSONAL HYGIENE AND GARBING

Personal hygiene and garbing are essential to maintain microbial control of the environment. Most microorganisms detected in cleanrooms are transferred from individuals. Squamous cells are normally shed from the human body at a rate of $10^6$ or more per hour, and those skin particles are covered with microorganisms. Individuals entering a compounding area must be properly garbed and must maintain proper personal hygiene to minimize the risk of contamination to the environment and/or CSPs.

Individuals that may have a higher risk of contaminating the CSP and the environment (e.g., personnel with rashes, recent tattoos, oozing sores, conjunctivitis, or active respiratory infections) must report these conditions to the designated person(s). The designated person(s) is responsible for evaluating whether these individuals should be excluded from working in compounding areas before their conditions have resolved because of the risk of contaminating the CSPs and the environment.

### 3.1 Personnel Preparation

All personnel entering a compounding area where Category 1, Category 2, or Category 3 CSPs are prepared must take appropriate steps to minimize microbial contamination of the environment and of the CSPs, including hand hygiene (see *3.2 Hand Hygiene*), garbing (see *3.3 Garbing Requirements*), and consideration of needed materials to be brought into the compounding area.

Food (including mints, gum, etc.) and drinks must not enter anterooms, buffer rooms, or segregated compounding areas.

Before entering a compounding area, individuals must remove any items that are not easily cleanable or are not necessary for compounding. At a minimum, individuals must:

- Remove personal outer garments (e.g., bandanas, coats, hats, jackets, sweaters, vests)
- Remove all cosmetics because they shed flakes and particles
- Remove all hand, wrist, and other exposed jewelry, including piercings that could interfere with the effectiveness of garbing (e.g., the fit of gloves, cuffs of sleeves, and eye protection) or otherwise increase the risk of contamination of the CSP. Cover any jewelry that cannot be removed.
- Not wear earbuds or headphones
- Not bring electronic devices that are not necessary for compounding or other required tasks into the compounding area
- Keep nails clean and neatly trimmed to minimize particle shedding and avoid glove punctures. Nail products (e.g., polish, artificial nails, and extenders) must not be worn
- Wipe eyeglasses, if worn

The designated person(s) may permit accommodations to personnel preparation as long as the quality of the CSP and environment will not be affected. Accommodations must be documented.

### 3.2 Hand Hygiene

Any person entering a compounding area where Category 1, Category 2, or Category 3 CSPs are prepared must wash hands and forearms up to the elbows with soap and water before initiating compounding activities. Brushes must not be used for hand hygiene. Hand dryers must not be used. To minimize the risk of extrinsic contamination, disposable soap containers must not be refilled or topped off.

**Box 3. Hand Washing Procedures**

- Clean underneath fingernails under warm running water using a disposable nail cleaner.
- Wash hands and forearms up to the elbows with soap and water for at least 30 s.
- Dry hands and forearms up to the elbows completely with low-lint disposable towels or wipers.

The order of hand washing and garbing depends on the placement of the sink (see *4.4 Water Sources*). The order of garbing must be determined by the facility and documented in the facility's SOPs. Hands must be sanitized with alcohol-based hand rub before donning sterile gloves (see *Box 4*). Sterile gloves must be donned in a classified room or SCA.

Unofficial

**Box 4. Hand Sanitizing Procedures**

- Apply an alcohol-based hand rub to dry skin.
- Apply product to one hand and rub hands together, covering all surfaces of hands and fingers, until hands are dry.
- Allow hands to dry thoroughly before donning sterile gloves.

### 3.3 Garbing Requirements

Any person entering a compounding area where Category 1, Category 2, or Category 3 CSPs are prepared must be properly garbed. Garb must be donned and doffed in an order that reduces the risk of contamination. The required garb, manner of storage, and order of garbing must be determined by the facility and documented in the facility's SOPs. When preparing Category 2 or Category 3 CSPs, all garb should be donned in a classified area before entering the buffer room. If hand hygiene is completed outside of a classified area, alcohol-based hand rub must be used prior to donning garb. Skin must not be exposed inside the ISO Class 5 PEC (e.g., gloves must not be donned or doffed inside the ISO Class 5 PEC exposing bare hands). Donning and doffing garb should not occur in the same area at the same time. The minimum garbing requirements for preparing Category 1 and Category 2 CSPs include the following:

- Low-lint garment with sleeves that fit snugly around the wrists and an enclosed neck (e.g., gown or coverall)
- Low-lint covers for shoes
- Low-lint cover for head that covers the hair and ears, and if applicable, cover for facial hair
- Low-lint face mask
- Sterile powder-free gloves
- If using a RABS (i.e., a CAI or CACI), disposable gloves should be worn inside the gloves attached to the RABS sleeves. Sterile gloves must be worn over the gloves attached to the RABS sleeve

Garb must be replaced immediately if it becomes visibly soiled or if its integrity is compromised. Gowns and other garb must be stored in a manner that minimizes contamination (e.g., away from sinks to avoid splashing). If compounding Category 1 and Category 2 CSPs, gowns may be reused within the same shift by the same person if the gown is maintained in a classified area or adjacent to, or within, the SCA in a manner that prevents contamination. When personnel exit the compounding area, garb, except for gowns, cannot be reused and must be discarded or laundered before reuse. The facility's SOPs must describe disinfection procedures for reusing goggles, respirators, and other reusable equipment.

If the facility compounds Category 3 CSPs, additional garbing requirements must be continuously met in the buffer room in which Category 3 CSPs are prepared. The following additional garbing requirements must be followed in the buffer room where Category 3 CSPs are prepared for all personnel regardless of whether Category 3 CSPs are compounded on a given day:

1. Do not allow any exposed skin in the buffer room (i.e., face and neck must be covered).
2. All low-lint outer garb must be sterile, including the use of sterile sleeves over gauntlet sleeves when a RABS is used.
3. Disposable garbing items must not be reused, and laundered garb must not be reused without being laundered and resterilized with a validated cycle.
4. The facility's SOPs must describe disinfection procedures for reusing goggles, respirators, and other reusable equipment.

If compounding an HD, appropriate personal protective equipment (PPE) must be worn and disposed of in accordance with ⟨800⟩.

**Gloves:** Gloves must be sterile and powder free. Application of sterile 70% IPA to gloves must occur immediately before compounding and regularly throughout the compounding process.

All gloves must be inspected for holes, punctures, or tears and must be replaced immediately if such defects are detected.

The RABS sleeves and gloves and the pharmaceutical isolator sleeves and gloves should be changed per the manufacturer's recommendations and as defined in the facility's SOPs.

## 4. FACILITIES AND ENGINEERING CONTROLS

Sterile compounding facilities must be designed, outfitted, and maintained properly to minimize the risk of contamination of CSPs. The required air quality must be achieved and maintained through PECs and secondary engineering controls (SECs). The anteroom, buffer room, and SCA must be separated from areas not directly related to compounding. The anteroom and buffer room must be appropriately controlled to achieve and maintain the required air quality classifications. The design of the facility should take into account the number of personnel and their movements, and the impact the placement of equipment, supplies, and components could have on the maintenance of air quality. The number of operations being performed, the equipment (e.g., PECs, carts, computers), the personnel in the compounding area (and in adjacent areas), and the complexity of the compounding procedures are critical considerations for maintaining control of environmental conditions in the facility.

### 4.1 Protection from Airborne Contaminants

Sterile compounding facilities must be designed to minimize the risk of airborne contamination of the area in which sterile compounding occurs. Proper design and controls are required to minimize the risk of exposure of CSPs to airborne contaminants.

**4.1.1 Air quality standards:** The ISO standards for air quality in controlled environments are provided in *Table 4* and referenced throughout this chapter.

**Table 4. ISO Classification of Particulate Matter in Room Air[a]**

| ISO Class | Particle Count per Cubic Meter[b] |
|---|---|
| 3 | 35.2 |
| 4 | 352 |
| 5 | 3520 |
| 6 | 35,200 |
| 7 | 352,000 |
| 8 | 3,520,000 |

[a] Adapted from ISO 14644-1, Cleanrooms and associated controlled environments—Part 1: Classification of air cleanliness by particle concentration.
[b] Limits for number of particles ≥0.5 µm measured under dynamic operating conditions.

**4.1.2 Design requirements to maintain air quality:** Facilities used for compounding CSPs must be designed so that air quality improves with movement through separate operational areas to the PEC. Classified areas in which the air quality is controlled (see *Table 4*) include anterooms, buffer rooms, and PECs.

- Anterooms providing access only to positive-pressure buffer rooms must meet at least ISO Class 8 classification. Anterooms providing access to negative-pressure buffer rooms must meet at least ISO Class 7 classification (see ⟨800⟩). Typically, personnel hand hygiene and garbing procedures, staging of components, and other activities that potentially generate higher levels of particulates are performed in the anteroom. Anterooms are also transition areas to ensure that proper air classification and pressure relationships are maintained between classified and unclassified areas.
- A buffer room must meet at least ISO Class 7 air quality. Activities in the buffer room must be controlled to minimize any effects on air quality in the area where CSPs are prepared.
- Category 1, Category 2, and Category 3 CSPs must be compounded in an ISO Class 5 or better PEC. If compounding only Category 1 CSPs, the PEC may be placed in an unclassified SCA.

**4.2 Facility Design and Environmental Controls**

In addition to minimizing airborne contamination, sterile compounding facilities must be designed and controlled to provide a well-lighted and comfortable working environment (see *Physical Environments That Promote Safe Medication Use* ⟨1066⟩). The cleanroom suite should be maintained at a temperature of 20° or cooler and a relative humidity of 60% or below to minimize the risk of microbial proliferation and to provide comfortable conditions for compounding personnel attired in the required garb. The temperature and humidity must be monitored in each room of the cleanroom suite each day that compounding is performed, either manually or by a continuous recording device. The results of the temperature and humidity readings must be documented at least once daily or stored in the continuous recording device and must be retrievable. The temperature and humidity readings must be reviewed as described in the facility's SOPs. Temperature and humidity in the cleanroom suite must be controlled through a heating, ventilation, and air conditioning (HVAC) system. Free-standing air conditioners, humidifiers, and dehumidifiers must not be used within the classified area or the SCA. Temperature and humidity monitoring devices must be verified for accuracy at least every 12 months or as required by the manufacturer.

The designated person(s) is responsible for ensuring that each area related to CSP preparation meets the classified air quality standard appropriate for the activities to be conducted in that area. The designated person(s) must also ensure that the ISO Class 5 areas are located, operated, maintained, monitored, and certified to have appropriate air quality.

**4.2.1 Types of SECs and design:** The PEC must be located in the buffer room of the cleanroom suite or the SCA in a manner that minimizes conditions that could increase the risk of microbial contamination. For example, strong air currents from opened doors, personnel traffic, or air streams from the HVAC system(s) can disrupt the unidirectional airflow of an open-faced PEC such as a laminar airflow workbench (LAFW). Access to the SEC must be restricted to authorized personnel and required materials.

**Cleanroom suite:** The ISO-classified anteroom and buffer room must be separated from the surrounding unclassified areas of the facility by fixed walls and doors, and controls must be in place to minimize the flow of lower-quality air into the more controlled areas. The classified rooms must be equipped with a pressure-differential monitoring system. Air supplied to the cleanroom suite must be introduced through HEPA filters that are located in the ceiling of the buffer room and anteroom.

Air returns in the cleanroom suite must be low on the wall unless a visual smoke study demonstrates an absence of stagnant airflow. This smoke study along with environmental monitoring must be repeated whenever a change is made to the placement of equipment within the room or any other alteration is performed within the cleanroom suite that affects the quality of the air (e.g., HVAC alterations, change of HEPA filter units).

The anteroom must have a line of demarcation to separate the clean side from the dirty side. The anteroom is entered through the dirty side, and the clean side is the area closest to the buffer room. Alternatively, facilities may be designed with two separate anterooms—a dirty anteroom and a clean anteroom. The anteroom is entered through the dirty anteroom, and the clean anteroom is the area closest to the buffer room.

It is also critical to control materials (e.g., supplies and equipment) as they move from classified areas of lower quality to those of higher quality (e.g., from an ISO Class 8 anteroom to an ISO Class 7 buffer room to an ISO Class 5 PEC) to minimize the influx of contaminants. Airlocks and interlocking doors may be used to facilitate better control of air balance between areas of differing ISO classification (e.g., between the buffer room and anteroom) or between a classified area and an unclassified area (e.g., between the anteroom and a hallway). If a pass-through chamber is used, both doors must never be opened at the same time, and doors should be interlocking.

Due to the interdependence of the various rooms or areas that make up a sterile compounding facility, it is essential to carefully define and control the dynamic interactions permitted between areas and rooms. Consider the placement of door closures, door surfaces, and the movement of the doors, all of which can affect airflow. Seals and sweeps should not be installed at doors between buffer rooms and anterooms. Access doors should be hands-free. Tacky mats must not be placed within ISO-classified areas. If compounding both sterile and nonsterile preparations (e.g., presterilization procedures), the respective PECs must be placed in separate rooms unless those PECs are sufficiently effective that the room can continuously maintain ISO Class 7 classification. If the PECs used for sterile and nonsterile compounding are placed in the same room, they must be placed at least 1 m apart, and particle-generating activity must not be performed when sterile compounding is in process.

**Segregated compounding area (SCA):** A PEC may be located within an unclassified area without an anteroom or buffer room. This type of design is called an SCA. Only Category 1 CSPs may be compounded in an SCA. The SCA must be located away from unsealed windows, doors that connect to the outdoors, and traffic flow, all of which may adversely affect the air quality in the PEC. An SCA must not be located where environmental control challenges (e.g., restrooms, warehouses, or food preparation areas) could negatively affect the air quality of the PEC within the SCA. The impact of activities (e.g., patient care activities) that will be conducted around or adjacent to the SCA must be considered carefully when designing such an area. The area within 1 m of the PEC should be dedicated only for sterile compounding (e.g., not storage, hand hygiene, donning and doffing garb, or other highly particle-generating activities such as patient care).

**4.2.2 The CSP compounding environment:** The PEC must be certified to meet ISO Class 5 or better conditions (see *Table 4*) during dynamic operating conditions and must be designed to minimize the risk of contamination during compounding of CSPs.

Unidirectional airflow must be maintained in the PEC. HEPA-filtered air must be supplied by the PEC at a velocity sufficient to sweep particles away from critical sites and maintain unidirectional airflow during operations. Proper design, control, and use minimizes turbulence and creation of eddies or stagnant air in the PEC.

**4.2.3 Types of PECs and placement:** Proper placement of the PEC is critical to ensuring an ISO Class 5 environment for preparing CSPs. Placement of the PEC must allow for cleaning around the PEC. See *Table 5* for a summary of minimum requirements for the placement of PECs for preparing non-HD CSPs.

Types of PECs and their placement include the following:

**Laminar airflow system (LAFS):** An LAFS provides an ISO Class 5 or better environment for sterile compounding. The LAFS provides unidirectional HEPA-filtered airflow that is designed to minimize the risk of contamination of a sterile compounding environment. The unidirectional airflow within the LAFS helps protect the direct compounding area (DCA) from process-generated contamination (e.g., opening wrappings of sterile containers, compounder movement) as well as from outside sources.

Types of LAFS and their placement include the following:

**Laminar airflow workbench (LAFW):** An LAFW is a device that provides an ISO Class 5 or better environment for sterile compounding. The LAFW provides either horizontal or vertical unidirectional HEPA-filtered airflow. [NOTE—An LAFW must not be used for preparation of antineoplastic and/or active pharmaceutical ingredient (API) HDs (see ⟨800⟩).]

**Integrated vertical laminar flow zone (IVLFZ):** An IVLFZ is a designated ISO Class 5 area serving as the PEC within an ISO Class 7 or cleaner buffer room. In the IVLFZ, unidirectional airflow is created by placing HEPA filters over the entire surface of the worktables and by effective placement of air returns. The unidirectional HEPA-filtered zone must be separated from the ISO Class 7 area with a physical barrier to direct the airflow downward over the work area to separate the DCA from potential sources of contamination. Strategic location of air returns in addition to full coverage of HEPA filters above the work surface is required. Both static and dynamic smoke studies verifying a continuous flow of HEPA-filtered air void of turbulence, dead air zones, and refluxing from the HEPA filters to and across the entire work area and to the air returns must be documented (e.g., with video). [NOTE—Dynamic airflow smoke pattern tests have shown that it is difficult to achieve this type of design and also achieve and maintain unidirectional airflow under dynamic operating conditions.]

[NOTE—An IVLFZ must not be used for preparation of antineoplastic and/or API HDs (see ⟨800⟩).]

**Class II biological safety cabinet (BSC):** A Class II BSC is a ventilated cabinet with an open front and inward and downward unidirectional HEPA-filtered airflow and HEPA-filtered exhaust. The BSC is designed to provide worker protection from exposure to airborne drugs and to provide an ISO Class 5 or better environment for preparing CSPs. [NOTE—The exhaust air from the BSC must be externally vented for preparation of antineoplastic and/or API HDs (see ⟨800⟩).]

**Placement of LAFS:** The LAFS must be located out of traffic patterns and away from room air currents that could disrupt the intended airflow patterns inside the PEC. If used to prepare only Category 1 CSPs, the ISO Class 5 PEC may be located in an unclassified SCA. If used to prepare Category 2 or Category 3 CSPs, the LAFS must be located within a cleanroom suite with an ISO Class 7 or better buffer room with an ISO Class 8 or better anteroom. A dynamic airflow smoke pattern test must be performed in the PEC initially and at least every 6 months to ensure that 1) the LAFS is properly placed into the facility and 2) compounders understand how to utilize the unidirectional airflow to maintain first air in the DCA.

**Restricted-access barrier system (RABS):** A RABS is an enclosure that provides HEPA-filtered ISO Class 5 unidirectional air. It allows for the ingress and/or egress of materials through defined openings that have been designed and validated to preclude the transfer of environmental air contamination and are generally not to be opened during compounding operations. RABS include compounding aseptic isolators (CAIs) and compounding aseptic containment isolators (CACIs). In a CAI or CACI, glove ports are used to provide physical separation between the surrounding area and the aseptic manipulations.

**Compounding aseptic isolator:** A CAI is designed for compounding non-HD CSPs. It is designed to maintain an ISO Class 5 environment throughout the compounding and material transfer processes. Air exchange into the

@2024 USPC

CAI from the surrounding environment must not occur unless the air has first passed through a HEPA filter. [NOTE—A CAI must not be used for preparation of antineoplastic and/or API HDs (see ⟨800⟩).]

**Compounding aseptic containment isolator:** A CACI is designed to provide worker protection from exposure to undesirable levels of airborne drug throughout the compounding and material transfer processes and to maintain an ISO Class 5 environment for compounding sterile HD preparations (see ⟨800⟩).

**Placement of RABS:** If used to prepare only Category 1 CSPs, the ISO Class 5 environment may be achieved by placing the RABS in an unclassified SCA. If used to prepare Category 2 or Category 3 CSPs, the RABS must be located within a cleanroom suite with an ISO Class 7 or better buffer room with an ISO Class 8 or better anteroom. For placement of a CACI used for the preparation of antineoplastic and/or API HDs, see ⟨800⟩.

When a RABS is used, the recovery time after opening the transfer chamber to achieve ISO Class 5 air quality must be documented (e.g., by the manufacturer), and internal procedures must be developed to ensure that adequate recovery time is allowed after opening and closing the RABS, both before and during compounding operations. A dynamic airflow smoke pattern test must be performed in the PEC under dynamic operating conditions initially and at least every 6 months to ensure that 1) the RABS is properly integrated into the facility and 2) compounders understand how to utilize the unidirectional airflow to maintain first air in the DCA.

**Pharmaceutical isolator:** A pharmaceutical isolator provides isolation from the surrounding area and maintains ISO Class 5 air quality during dynamic operating conditions. [NOTE—A CAI or CACI is not a pharmaceutical isolator.] A pharmaceutical isolator comprises four elements:

1. Controlled workspace
2. Transfer device(s)
3. Access device(s)
4. Integral decontamination system

**Placement of pharmaceutical isolators:** A pharmaceutical isolator used to prepare only Category 1 CSPs can be placed in an unclassified SCA. If the pharmaceutical isolator is used to prepare Category 2 or Category 3 CSPs, the pharmaceutical isolator must be placed in an ISO Class 8 or better room. [NOTE—An anteroom is not required when using a pharmaceutical isolator.] A dynamic airflow smoke pattern test must be performed in the PEC initially and at least every 6 months to ensure that 1) the pharmaceutical isolator is properly placed in the facility and 2) compounders understand how to utilize the unidirectional airflow to maintain first air in the work zone.

**Table 5. Summary of Minimum Requirements for Placement of PECs for Compounding Non-HD CSPs[a]**

| PEC Type | Device Type | Placement for Compounding Only Category 1 CSPs | Placement for Compounding Category 2 and 3 CSPs |
|---|---|---|---|
| LAFS | LAFW | Unclassified SCA | ISO Class 7 positive-pressure buffer room with an ISO Class 8 positive-pressure anteroom |
| | IVLFZ | N/A[b] | ISO Class 7 positive-pressure buffer room with an ISO Class 8 positive-pressure anteroom |
| | BSC | Unclassified SCA | ISO Class 7 positive-pressure buffer room with an ISO Class 8 positive-pressure anteroom |
| RABS | CAI or CACI | Unclassified SCA | ISO Class 7 positive-pressure buffer room with an ISO Class 8 positive-pressure anteroom |
| Pharmaceutical isolator | Pharmaceutical isolator | Unclassified SCA | ISO Class 8 positive-pressure room |

[a] For compounding HDs, see ⟨800⟩.
[b] An IVLFZ must not be used in an unclassified area.

If a robotic enclosure is used as the PEC, or placed within the PEC, a dynamic airflow smoke pattern test must be performed initially and at least every 6 months thereafter to ensure that 1) it is properly integrated into the facility, 2) there is no turbulence or refluxing at any critical site(s), 3) room air does not enter the PEC where sterile products and/or preparations may be exposed, and 4) all processes can be performed without introducing contamination to the DCA(s).

**4.2.4 Air exchange requirements:** For cleanroom suites, adequate HEPA-filtered airflow to the buffer room(s) and anteroom(s) is required to maintain the appropriate ISO classification during compounding activities. Airflow is measured in terms of the number of air changes per hour (ACPH). The ACPH may need to be higher to maintain the required ISO classification and microbial state of control depending on the following factors:

- Number of personnel permitted to work in the area
- Number of particles that may be generated from activities and processes in the area
- Equipment located in the room
- Room pressure

See *Table 6* for a summary of ACPH requirements for non-HD sterile compounding areas. Additional ACPH requirements include:

A minimum of 30 total HEPA-filtered ACPH must be supplied to ISO Class 7 rooms:

- The total HEPA-filtered air change rate must be adequate to maintain ISO Class 7 during dynamic operating conditions considering the factors listed above

Official

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:39:43 AM(EST)
Printed by: USP NF
Do Not Distribute

- At least 15 ACPH of the total air change rate in a room must come from the HVAC through HEPA filters located in the ceiling
- The HEPA-filtered air from the PEC, when added to the HVAC-supplied HEPA-filtered air, must increase the total HEPA-filtered ACPH to at least 30 ACPH
- If the PEC is used to meet the minimum total ACPH requirements, the PEC must not be turned off except for maintenance
- Rooms where activity levels are high may require more HEPA-filtered ACPH to maintain ISO Class 7 air quality under dynamic operating conditions
- The ACPH from HVAC, ACPH contributed from the PEC, and the total ACPH must be documented on the certification report

A minimum of 20 total HEPA-filtered ACPH must be supplied to ISO Class 8 rooms:

- The total HEPA-filtered air change rate must be adequate to maintain ISO Class 8 under dynamic operating conditions considering the factors listed above
- At least 15 ACPH of the total air change rate in a room must come from the HVAC through HEPA filters located in the ceiling
- Rooms where activity levels are high may require more HEPA-filtered ACPH to maintain ISO Class 8 air quality under dynamic operating conditions
- The total ACPH must be documented on the certification report

**Table 6. Summary of ACPH Requirements for Non-HD Sterile Compounding Areas**

| Compounding Area | ACPH Requirement |
|---|---|
| Unclassified SCA | No requirement |
| ISO Class 7 room(s) | ≥30 ACPH |
| ISO Class 8 room(s) | ≥20 ACPH |

**4.2.5 Establishing and maintaining pressure differentials:** Continuous differential positive pressure is required to minimize airflow from an area with lower air-quality classification to an area of higher air-quality classification. In a cleanroom suite, a minimum differential positive pressure of 0.020-inch water column is required between adjacent ISO-classified areas (e.g., between the buffer room and anteroom). The pressure differential between the anteroom and the unclassified area must not be less than 0.020-inch water column. No pressure differential is required between the SCA and the surrounding area. See ⟨800⟩ for pressure requirements for compounding HD CSPs.

Where pressure differentials are required, a pressure differential monitoring device must be used to continuously monitor the pressure differentials. The quantitative results from the pressure monitoring device must be reviewed and documented at least daily on the days when compounding is occurring.

**4.2.6 Facilities preparing Category 2 or Category 3 CSPs from nonsterile starting components:** Weighing, measuring, or otherwise manipulating components could generate airborne chemical particles (e.g., API or added substances). If preparing Category 2 or Category 3 CSP from nonsterile component(s), presterilization procedures, such as weighing and mixing, must be completed in an ISO Class 8 or better environment (e.g., anteroom or buffer room). Presterilization procedures must be performed in single-use containment glove bags, containment ventilated enclosures (CVEs), BSCs, or CACIs to minimize the risk of airborne contamination. CVEs, BSCs, or CACIs used for presterilization procedures must be certified at least every 6 months.

Presterilization procedures must not adversely affect the required air quality of the SEC as demonstrated during certification under dynamic operating conditions. Personnel must follow the hygiene and garbing requirements as described in *3. Personal Hygiene and Garbing* during presterilization procedures.

**4.3 Creating Areas to Achieve Easily Cleanable Conditions**

**4.3.1 Cleanroom suite:** The surfaces of ceilings, walls, floors, doors, door frames, fixtures, shelving, work surfaces, counters, and cabinets in the classified area must be smooth, impervious, free from cracks and crevices, and nonshedding so they can be cleaned and disinfected and to minimize spaces in which microorganisms and other contaminants can accumulate. Surfaces should be resistant to damage (e.g., rust) by cleaning agents, sporicidal and other types of disinfectants, and tools used to clean. Junctures between the ceiling and the walls and between the walls and the floor must be sealed to eliminate cracks and crevices where dirt can accumulate. If ceilings consist of inlaid panels, the panels must be caulked around each panel to seal them to the support frame.

Walls must be constructed of, or may be covered with, durable material (e.g., epoxy painted walls or heavy-gauge polymer) and the integrity of the surface must be maintained. Panels must be joined together and sealed to each other and the support structure. Floors must include coving to the sidewall, or the juncture between the floor and the wall must be caulked. Classified areas should minimize dust-collecting overhangs, such as utility pipes, and ledges, such as windowsills. If overhangs or ledges are present, they must be easily cleanable. The exterior lens surface of ceiling light fixtures must be smooth, mounted flush, and sealed. Any other penetrations through the ceiling or walls must be sealed.

**4.3.2 SCA:** The SCA and all surfaces (e.g., walls, floors, counters, and equipment) in the SCA must be clean, uncluttered, and dedicated to compounding. Surfaces in the SCA should be smooth, impervious, free from cracks and crevices, and non-shedding so they can be easily cleaned and disinfected and to minimize spaces in which microorganisms and other contaminants can accumulate. Surfaces should be resistant to damage (e.g., rust) by cleaning agents, sporicidal and other types of disinfectants, and tools used to clean. Dust-collecting overhangs, such as utility pipes, and ledges, such as windowsills, should be minimized. If overhangs or ledges are present, they must be easily cleanable.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99925_07_01
@2024 USPC

**4.4 Water Sources**

The facility where CSPs are prepared must be designed so that activities such as hand hygiene and garbing will not adversely affect the ability of the PEC to function as designed. Sinks should enable hands-free use. Surfaces of the sink(s) must be cleaned and disinfected each day of use, and a sporicidal disinfectant must be applied at least monthly (see *7.1 Agents and Supplies for Cleaning, Disinfecting, and Applying Sporicidal Disinfectants*).

In facilities with a cleanroom suite, the sink used for hand hygiene may be placed either inside or outside of the anteroom. If the sink is located outside of the anteroom, it must be located in a clean space to minimize the risk of bringing contaminants into the anteroom. If the sink is located inside the anteroom, it may be placed on either the clean side or the dirty side of the anteroom. [NOTE—The order of hand washing and garbing depends on the placement of the sink (see *3.2 Hand Hygiene* and *3.3 Garbing Requirements*)] . The buffer room must not contain plumbed water sources [e.g., sink(s), eyewash(es), shower(s), or floor drain(s)]. The anteroom must not contain floor drain(s). If installed, sprinkler systems should be recessed and covered, and the covers should be easily cleanable.

In a facility with an SCA design, a hand-washing sink must be placed not closer than 1 m to the PEC and may be either inside the SCA or in close proximity to the SCA.

**4.5 Placement and Movement of Materials**

Only furniture, equipment, and other materials necessary for performing compounding activities are permitted in a classified area or SCA, and they should be low-shedding and easily cleaned and disinfected. Their number, design, location, and manner of installation must not impact environmental air quality and must promote effective cleaning and disinfecting. No shipping carton(s) or other corrugated or uncoated cardboard are allowed in a classified area or SCA.

Carts used to transport components or equipment into classified areas must be constructed from nonporous materials with cleanable casters and wheels to promote mobility and ensure ease of cleaning and disinfection. In a cleanroom suite, carts must not be moved from the dirty side to the clean side of the anteroom unless the entire cart, including casters, is cleaned and disinfected.

Only equipment necessary for performing compounding activities is permitted in the PEC. Proper placement of equipment in a PEC must be initially verified by a dynamic airflow smoke pattern test to demonstrate minimal disruption in airflow. The dynamic airflow smoke pattern test must be repeated if equipment is placed in a different location. Equipment and other items used in a classified area or SCA should not be removed except for calibration, servicing, cleaning, or other activities associated with maintenance. If removed, these items must be cleaned and wiped with sterile 70% IPA or a suitable disinfectant before they are returned to the classified area or the SCA.

Materials necessary for performing compounding activities that have been exposed in patient care and treatment areas must not enter anterooms, buffer rooms, or segregated compounding areas unless thoroughly cleaned and disinfected. The designated person(s) is responsible for addressing other areas of risk in the facility's SOPs. The designated person(s) may permit accommodations as long as the quality of the CSP and environment will not be affected. Accommodations must be documented.

## 5. CERTIFICATION AND RECERTIFICATION

Before a compounding area is used to compound either Category 1, Category 2, or Category 3 CSPs, it must be independently certified using the requirements in this chapter and when applicable, manufacturer specifications. Certification indicates that the compounding area is meeting its design and air quality specifications (see *Table 4*).

Certification of the classified areas including the PEC must be performed initially, and recertification must be performed at least every 6 months and must include:

- *Airflow testing:* Airflow testing is performed to determine acceptability of the air velocity, the room air exchange rate, and the room pressure differential in doorways between adjacent rooms to ensure consistent airflow and that the appropriate quality of air is maintained under dynamic operating conditions. The ACPH from HVAC, ACPH contributed from the PEC, and the total ACPH must be documented on the certification report.
- *HEPA filter integrity testing:* HEPA filters must be leak tested at the factory and then leak tested again after installation and as part of recertification.
- *Total particle count testing:* (See *5.1 Total Airborne Particle Sampling*.) Total particle count testing must be performed under dynamic operating conditions using calibrated electronic equipment.
- *Dynamic airflow smoke pattern test:* Smoke pattern tests must be performed for each PEC during dynamic operating conditions to demonstrate unidirectional airflow and sweeping action over and away from the preparation(s).

Classified areas additionally must be recertified if there are changes to the area such as redesign, construction, replacement or relocation of any PEC, or alteration in the configuration of the room that could affect airflow or air quality.

All certification and recertification records must be reviewed by the designated person(s) to ensure that the classified environments meet the minimum requirements in this chapter. The number of personnel present in each PEC and SEC during total particle-count tests and dynamic airflow smoke-pattern tests must be documented. Records must be maintained in accordance with the requirements in *20. Documentation*.

A corrective action plan must be implemented and documented in response to any out-of-range results. Data collected in response to corrective actions must be reviewed to confirm that the actions taken have been effective.

**5.1 Total Airborne Particle Sampling**

The engineering control equipment function must function as designed to ensure that the levels of total airborne particles remain within acceptable limits during compounding (see *Table 4*). Total airborne particle count testing must be conducted in all classified areas during dynamic operating conditions at least every 6 months to measure the performance of the engineering controls that are being used to provide the specified levels of air cleanliness (e.g., in the ISO Class 5 PEC and ISO Class 7 and 8 rooms).

Total airborne particle sampling sites must be selected in all classified areas. Measurements of total airborne particles must be taken in each PEC at locations where there is greatest risk to the exposed CSPs, containers, and closures. When conducting sampling of the PEC, care should be taken to avoid disturbing the unidirectional airflow within the PEC. All sampling sites and procedures must be described in the facility's SOPs. Measurements of total airborne particles in other

Official

https://pharmacopeia.com/

classified areas, including the buffer room(s) and anteroom(s), should be taken at representative locations that reflect the quality of air in the room(s).

**Data evaluation and action levels:** If levels measured during the total air sampling program exceed the criteria in *Table 4* for the ISO classification of the area sampled, the cause must be investigated and corrective action taken and documented. Data collected in response to corrective actions must be reviewed to confirm that the actions taken have been effective. Some examples of corrective action include process or facility improvements or HEPA filter replacement or repair. The extent of the investigation should be consistent with the deviation and should include an evaluation of trends.

## 6. MICROBIOLOGICAL AIR AND SURFACE MONITORING

An effective microbiological air and surface monitoring program provides information on the environmental quality of the compounding area. In addition, an effective microbiological air and surface monitoring program identifies environmental quality trends over time, identifies potential routes of contamination, and allows for implementation of corrective actions to minimize the risk of CSP contamination. Sterile compounding facilities must develop and implement written procedures for microbiological air and surface monitoring (see *17. SOPs*). All microbiological air and surface monitoring procedures, the test results, and the corrective actions must be documented, and the records must be maintained in accordance with the requirements in *20. Documentation*. Data collected in response to corrective actions must be reviewed to confirm that the actions taken have been effective.

### 6.1 General Monitoring Requirements

The microbiological air and surface monitoring program must include 1) viable impact volumetric airborne particulate sampling and 2) surface sampling. The goals of a microbiological air and surface monitoring program are to determine whether contamination is present at unacceptable levels and to assess whether proper personnel practices are being followed, cleaning and disinfecting agents are effective, and environmental quality is maintained.

The microbiological air and surface monitoring program involves the collection and evaluation of samples from various air and surface locations to detect airborne and surface contaminants. The data from microbiological airborne and surface sampling are then used to assess risks for contamination, potential routes of contamination, and the adequacy of cleaning and disinfecting agents and procedures. Regular review of the sampling data must be performed to detect trends and the results of the review must be documented.

In addition, results from microbiological air and surface sampling must be reviewed in conjunction with personnel data (i.e., training records, visual observations, competency assessments) to assess the state of control and to identify potential risks of contamination. Corrective action in response to any adverse findings is required to maintain the necessary environmental quality for preparation of CSPs. Data must also be reviewed following corrective actions to confirm that the actions taken have been effective in achieving the required microbiological air and surface quality levels (see *Table 4*, *Table 7*, and *Table 8*).

Microbiological air and surface monitoring must be performed initially for sterile compounding facilities to establish a baseline level of environmental quality. After initial sampling, the environment in which sterile compounding activities are performed must be monitored according to the minimum frequencies described in this section to ensure that the environment remains suitable for sterile compounding.

Evaluating results collected over a period of time can be useful in identifying trends or determining that a significant change has occurred, even when the results fall within the specified levels.

Microbiological air and/or surface monitoring must be conducted in all classified areas during dynamic operating conditions to confirm that the required environmental quality is maintained. In addition to the specific sampling frequencies described in this section, sampling must be performed in the following circumstances:

- In conjunction with the certification of new facilities and equipment
- After any servicing of facilities or equipment (see *4. Facilities and Engineering Controls*)
- In response to identified problems (e.g., positive growth in sterility tests of CSPs)
- In response to identified trends (e.g., repeated positive gloved fingertip and thumb sampling results, failed media fill testing, or repeated observations of air or surface contamination)
- In response to changes that could impact the sterile compounding environment (e.g., change in cleaning agents)

The microbiological air and surface monitoring program must be clearly described in the facility's SOPs, which must include a diagram of the sampling locations, procedures for collecting samples, frequency of sampling, size of samples (e.g., surface area, volume of air), time of day of sampling in relation to activities in the compounding area, and action levels that will trigger corrective action.

The times and locations of sampling should be carefully selected based on their relationship to the activities performed in the area. It is important to obtain samples from locations that pose the highest possible risk of contamination to the CSP and that are likely to be representative of the conditions throughout the area. To obtain air and surface samples that are representative of the typical compounding conditions at the facility, in all PECs and classified rooms, air sampling must be conducted during dynamic operating conditions and surface sampling should be performed at the end of a compounding activity or shift but before the area has been cleaned and disinfected. The monitoring program must be designed and conducted in a manner that minimizes the chance that the sampling itself will contribute to contamination of the CSP or the environment.

It is important that personnel are trained and competent in air and surface sampling procedures to ensure accurate and reproducible sampling. All impaction air samplers must be serviced and calibrated as recommended by the manufacturer.

### 6.2 Monitoring Air Quality for Viable Airborne Particles

A monitoring program for viable airborne particles must be developed and implemented to assess microbiological air quality in all classified areas.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99925_07_01
@2024 USPC

**6.2.1 Viable air sampling—timing and locations:** Volumetric active air sampling of all classified areas using an impaction air sampler must be conducted in each classified area [e.g., ISO Class 5 PEC and ISO Class 7 and 8 room(s)] during dynamic operating conditions. For entities compounding Category 1 and Category 2 CSPs, this must be completed at least every 6 months. For entities compounding any Category 3 CSPs, this must be completed within 30 days prior to the commencement of any Category 3 compounding and at least monthly thereafter regardless of the frequency of compounding Category 3 CSPs. Air sampling sites must be selected in all classified areas.

**6.2.2 Viable air sampling procedures:** When conducting sampling of the PEC, care should be taken to avoid disturbing unidirectional airflow. See *Box 5* for active air sampling procedures. A general microbiological growth media that supports the growth of bacteria and fungi must be used (e.g., TSA). COAs from the manufacturer must verify that the sampling media devices meet the expected growth promotion, pH, and sterilization requirements. Samples must be incubated in an incubator at the temperatures listed in *Box 5*. The incubator temperature must be monitored during incubation, either manually or by a continuous recording device, and the results must be reviewed and documented as described in the facility's SOPs. The incubator must be placed in a location outside of the sterile compounding area.

**Box 5. Active Air Sampling Procedures for Viable Airborne Monitoring**

1. Follow the manufacturer's instructions for operation of the impaction air sampler, including placement of media device(s).
2. Using the impaction air sampler, test at least 1 cubic meter or 1000 L of air from each location sampled.
3. At the end of each sampling period, retrieve the media device and cover it. Handle and store media devices to avoid contamination and prevent condensate from dropping onto the agar during incubation and affecting the accuracy of the cfu reading (e.g., invert plates).
4. Incubate the media device at 30°–35° for no less than 48 h. Examine for growth. Record the total number of discrete colonies of microorganisms on each media device as cfu per cubic meter of air on an environmental sampling form based on sample type (i.e., viable air), sample location, and sample date.
5. Then incubate the media device at 20°–25° for no less than 5 additional days. Examine for growth. Record the total number of discrete colonies of microorganisms on each media device as cfu per cubic meter of air on an environmental sampling form based on sample type (i.e., viable air), sample location, and sample date.
6. Alternatively, to shorten the overall incubation period, two sampling media devices may be collected for each sample location and incubated concurrently.
   A. Both media devices could be TSA or one media device could be TSA and the other fungal media (e.g., malt extract agar [MEA] or Sabouraud dextrose agar [SDA]).
   B. Incubate each media device in a separate incubator. Incubate one media device at 30°–35° for no less than 48 h, and incubate the other media device at 20°–25° for no less than 5 days. If fungal media are used as one of the samples, incubate the fungal media sample at 20°–25° for no less than 5 days.
   C. Count the total number of discrete colonies of microorganisms on each media device, and record these results as cfu per cubic meter of air.
   D. Record the results of the sampling on an environmental sampling form based on sample type (i.e., viable air), and include the sample location and sample date.

**6.2.3 Viable air sampling data evaluation and action levels:** Evaluate cfu counts against the action levels in *Table 7* and examine counts in relation to previous data to identify adverse results or trends. If two sampling media devices are collected at a single location, all recovered growth on each must be documented and action levels applied to each sampling media device separately. If levels measured during the viable air monitoring program exceed the levels in *Table 7* for the ISO classification levels of the area sampled, the cause must be investigated and corrective action must be taken. Data collected in response to corrective actions must be reviewed to confirm that the actions taken have been effective. The corrective action plan must be dependent on the cfu count and the microorganism recovered. Some examples of corrective action include process or facility improvements, personnel training, cleaning and disinfecting, or HEPA filter repair and/or replacement. The extent of the investigation should be consistent with the deviation and should include an evaluation of trends. The corrective action plan must be documented and should include resampling of failed areas to confirm corrective action was successful. If levels measured during viable air sampling exceed the levels in *Table 7*, an attempt must be made to identify any microorganisms recovered to the genus level (see *Microbial Characterization, Identification, and Strain Typing* ⟨1113⟩) with the assistance of a microbiologist.

**Table 7. Action Levels for Viable Airborne Particle Air Sampling**

| ISO Class | Air Sampling Action Levels [cfu/cubic meter (1000 liters) of air/media device] |
|---|---|
| 5 | >1 |
| 7 | >10 |
| 8 | >100 |

### 6.3 Monitoring Surfaces for Viable Particles

Surface sampling is an important tool used to assist in maintenance of a suitably controlled environment for compounding CSPs. Surface sampling is useful for evaluating facility cleaning and material handling procedures, work surface cleaning and disinfecting procedures, and personnel competency in work practices such as cleaning and disinfecting. All sampling sites and procedures must be described in the facility's SOPs.

**6.3.1 Surface sampling—timing and locations:** Each classified area, including each room and the interior of each ISO Class 5 PEC and pass-through chambers connecting to classified areas, must be sampled for microbial contamination using a risk-based approach. Samples should be taken from the following classified areas:

- Equipment contained within the PEC
- Staging or work area(s) near the PEC
- Frequently touched surfaces

Surface sampling in the DCA must also be conducted in conjunction with media-fill testing to assess aseptic manipulation competency (see *2.3 Competency Testing in Aseptic Manipulation*)

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99925_07_01
@2024 USPC

When conducted, surface sampling should be performed at the end of a compounding activity or shift but before the area has been cleaned and disinfected.

For entities compounding Category 1 and Category 2 CSPs, surface sampling of all classified areas, and pass-through chambers connecting to classified areas, must be conducted at least monthly (see *Microbiological Control and Monitoring of Aseptic Processing Environments* ⟨1116⟩).

For entities compounding any Category 3 CSPs, surface sampling of all classified areas, and pass-through chambers connecting to classified areas, must be completed prior to assigning a BUD longer than the limits established in *Table 13*, and at least weekly (see ⟨1116⟩) on a regularly scheduled basis regardless of the frequency of compounding Category 3 CSPs. Additionally, surface sampling must be conducted within the PEC used to prepare Category 3 CSPs, at the end of each batch before cleaning and disinfection occurs, unless a self-enclosed robotic device is used. When a self-enclosed robotic device is used as the PEC to prepare Category 3 CSPs, surface sampling must be conducted at least once daily at the end of compounding operations, before cleaning and disinfection occurs.

**6.3.2 Surface sampling procedures:** See *Box 6* for the procedures for surface sampling on flat surfaces. Surface sampling media devices (e.g., plates, paddles, or slides) containing microbial growth media must be used for sampling flat surfaces. COAs from the manufacturer must verify that the sampling media devices meet the expected growth promotion, pH, and sterilization requirements. Surface sampling media devices must contain general microbial growth media (e.g., TSA) supplemented with neutralizing additives (e.g., lecithin and polysorbate 80) to neutralize the effects of any residual disinfecting agents. Surface sampling media devices must have a raised convex surface. Sterile swabs wetted with sterile water or a sterile neutralizing buffer may be used when sampling irregular surfaces and difficult-to-reach locations such as crevices, corners, and spaces between surfaces. After sampling, the sampled area must be thoroughly cleaned and disinfected (see *7. Cleaning, Disinfecting, and Applying Sporicidal Disinfectants and Sterile 70% IPA*).

Samples must be incubated in an incubator at the temperatures listed in *Box 6*. The incubator temperature must be monitored during incubation, either manually or by a continuous recording device, and the results must be reviewed and documented. The incubator must be placed in a location outside of the sterile compounding area.

**Box 6. Surface Sampling Procedures**

1. Remove the cover from the surface sampling media device. Using a rolling motion, firmly press the media surface onto the surface to be sampled. The media device will leave a residue of growth media on the sample site. After sampling, clean and disinfect the sampled area to remove the residue from the surface.
2. Cover each media device. Handle and store media devices to avoid contamination and prevent condensate from dropping onto the agar during incubation and affecting the accuracy of the cfu reading (e.g., invert plates).
3. Incubate media device(s) at 30°–35° for no less than 48 h. Examine for growth. Record the total number of discrete colonies of microorganisms on each media device as cfu per media device on an environmental sampling form based on sample type (i.e., surface), sample location, and sample date.
4. Incubate the media device at 20°–25° for no less than 5 additional days. Examine for growth. Record the total number of discrete colonies of microorganisms on each media device (cfu per sample) on the environmental sampling record based on sample type (i.e., surface), sample location, and sample date.
5. Alternatively, to shorten the overall incubation period, two surface sampling media devices may be collected for each sample location and incubated concurrently.
   A. Both media devices could be TSA or one media device could be TSA and the other fungal media (e.g., malt extract agar [MEA] or Sabouraud dextrose agar [SDA]). Media must be supplemented with neutralizing additives (e.g., lecithin and polysorbate 80).
   B. Incubate each media device in a separate incubator. Incubate one media device at 30°–35° for no less than 48 h, and incubate the other media device at 20°–25° for no less than 5 days. If fungal media are used, incubate the fungal media device at 20°–25° for no less than 5 days.
   C. Count the total number of discrete colonies of microorganisms on each media device, and record these results as cfu per media device.
   D. Record the results of the sampling on an environmental sampling form based on sample type (i.e., surface), and include the sample location and sample date.

**6.3.3 Surface sampling data evaluation and action levels:** Evaluate cfu counts against the action levels in *Table 8*, and examine counts in relation to previous data to identify adverse results or trends. If two sampling media devices are collected at a single location, all recovered growth on each must be documented and action levels applied to each sampling media device separately. If levels measured during surface sampling exceed the levels in *Table 8* for the ISO classification levels of the area sampled, the cause must be investigated and corrective action must be taken. Data collected in response to corrective actions must be reviewed to confirm that the actions taken have been effective. The corrective action plan must be dependent on the cfu count and the microorganism recovered. Some examples of corrective action include process or facility improvements, personnel training, cleaning and disinfecting, or HEPA filter replacement and/or repair. The extent of the investigation should be consistent with the deviation and should include an evaluation of trends. The corrective action plan must be documented. If levels measured during surface sampling exceed the levels in *Table 8*, an attempt must be made to identify any microorganism recovered to the genus level (see ⟨1113⟩) with the assistance of a microbiologist.

**Table 8. Action Levels for Surface Sampling**

| ISO Class | Surface Sampling Action Levels (cfu/media device) |
|---|---|
| 5 | >3 |
| 7 | >5 |
| 8 | >50 |

## 7. CLEANING, DISINFECTING, AND APPLYING SPORICIDAL DISINFECTANTS AND STERILE 70% IPA

Surfaces in classified areas used to prepare Category 1, Category 2, and Category 3 CSPs must be:

- Cleaned
- Disinfected

@2024 USPC

- Sporicidal disinfectants applied

according to the frequencies described in *Table 10* for each CSP category.

Additionally, in a PEC, sterile 70% IPA must be applied after cleaning and disinfecting, or after the application of a one-step disinfectant cleaner or sporicidal disinfectant, to remove any residue. Sterile 70% IPA must also be applied immediately before initiating compounding. During the compounding process sterile 70% IPA must be applied to the horizontal work surface, including any removable work trays, of the PEC at least every 30 min if the compounding process takes 30 min or less. If the compounding process takes more than 30 min, compounding must not be disrupted, and the work surface of the PEC must be disinfected immediately after compounding.

These activities are important because surfaces in classified areas and SCAs are a potential source of microbial contamination of CSPs.

The process of cleaning involves removing organic and inorganic materials from surfaces, usually with a manual or mechanical process and a cleaning agent. The process of disinfecting involves destruction of microorganisms, usually with a chemical agent. The process of applying a sporicidal disinfectant involves the destruction of bacterial and fungal spores. See *Table 9* for a summary of the purposes of the cleaning, disinfectant, and sporicidal disinfectants.

**Table 9. Purpose of Cleaning, Disinfecting, and Sporicidal Disinfectants**

| Type of Agent | Purpose |
|---|---|
| Cleaning | An agent, usually containing a surfactant, used for the removal of substances (e.g., dirt, debris, microbes, and residual drugs or chemicals) from surfaces. |
| Disinfectant | A chemical or physical agent used on inanimate surfaces and objects to destroy fungi, viruses, and bacteria. |
| Sporicidal | A chemical or physical agent that destroys bacterial and fungal spores when used at a sufficient concentration for a specified contact time. It is expected to kill all vegetative microorganisms. |

Surfaces must be cleaned prior to being disinfected with an EPA-registered disinfectant (or equivalent for entities outside the US) unless an EPA-registered (or equivalent for entities outside the US) one-step disinfectant cleaner is used to accomplish both the cleaning and disinfection in one step. A sporicidal disinfectant must also be applied. Some EPA-registered (or equivalent) one-step disinfectant cleaners may have sporicidal properties. Cleaning and disinfecting surfaces and applying a sporicidal disinfectant must occur at the minimum frequencies specified in *Table 10*.

All cleaning and disinfecting activities must be performed by trained and appropriately garbed personnel using facility-approved agents and procedures, which must be described in written SOPs. Personnel must be trained if there are any changes in the cleaning and disinfecting procedures. Cleaning must be performed in the direction of clean to dirty areas. The same floor mop may be used in both the buffer and anteroom, but only in that order. Mops used in areas where HDs are compounded must be dedicated for use only in those areas.

The frequency, method(s), and location(s) of cleaning, disinfecting, and applying sporicidal disinfectants must be established in written SOPs, in accordance with the manufacturer's instructions and must be followed by all cleaning personnel. The manufacturer's directions or published data for the minimum contact time must be followed for each of the cleaning, disinfecting, and sporicidal disinfectants used. When sterile 70% IPA is used, it must be allowed to dry. All cleaning, disinfecting, and application of sporicidal disinfectants must be documented according to the facility's SOPs.

**Table 10. Minimum Frequency for Cleaning and Disinfecting Surfaces and Applying Sporicidal Disinfectants in Classified Areas and in the SCA[a]**

| Site | Cleaning | Disinfecting[b] | Applying Sporicidal Disinfectant |
|---|---|---|---|
| PEC(s) and equipment inside the PEC(s) | • Equipment and all interior surfaces of the PEC daily on days when compounding occurs and when surface contamination is known or suspected | • Equipment and all interior surfaces of the PEC daily on days when compounding occurs and when surface contamination is known or suspected | • Monthly for entities compounding Category 1 and/or Category 2 CSPs<br>• Weekly for entities compounding Category 3 CSPs |

[b] Many disinfectants registered by the EPA are one-step cleaning and disinfecting agents, which means that the disinfectant has been formulated to be effective in the presence of light-to-moderate soiling without a separate cleaning step.
[c] Ceilings of the SCA are required to be cleaned, disinfected, and applied with sporicidal disinfectant only when visibly soiled and when surface contamination is known or suspected.

### 7.1 Agents and Supplies for Cleaning, Disinfecting, and Applying Sporicidal Disinfectants

**7.1.1 Agents:** Cleaning and disinfecting agents must be selected and used with careful consideration of compatibilities, effectiveness, and user safety. Considerations when selecting and using disinfectants include their antimicrobial activity, inactivation by organic matter, residue, shelf life, preparation requirements of the agent, and suitability for surfaces being disinfected. After the disinfectant or sporicidal disinfectant is applied to the surface, the agent must be allowed to dwell for the minimum contact time specified by the manufacturer.

Cleaning, disinfecting and sporicidal agents used within the PEC must be sterile. When diluting concentrated cleaning and disinfecting agents for use in the PEC, sterile water must be used. In classified areas outside of the PEC, sterile cleaning and disinfecting agents should be used. When diluting concentrated cleaning and disinfecting agents for use outside of the PEC, sterile water should be used.

**7.1.2 Supplies:** All cleaning and disinfecting supplies (e.g., wipers, sponges, pads, and mop heads) with the exception of tool handles and holders must be low lint. In addition, cleaning and disinfecting supplies used in the PEC must be sterile with the exception of tool handles and holders, which must be cleaned and disinfected prior to use in a PEC.

Wipers, sponges, pads, and mop heads should be disposable. If disposable cleaning supplies are used, they must be discarded after each cleaning activity. Reusable cleaning tools must be made of cleanable materials (e.g., handles should not be made of wood or any other porous material) and must be cleaned and disinfected before and after each use. Reusable cleaning tools must be dedicated for use in the classified areas or SCA and must not be removed from these areas except for disposal. They must be discarded as determined based on the condition of the tools. Cleaning supplies used in the classified areas and SCAs must be disposed of in a manner that minimizes the potential for dispersing contaminants into the air (e.g., with minimal agitation, away from work surfaces).

Once opened, sterile cleaning and disinfecting agents and supplies (e.g., closed containers of sterile wipers) and sterile 70% IPA may be reused for a time period specified as by the manufacturer and/or described in the facility written SOPs.

### 7.2 Procedures for Cleaning, Disinfecting, and Applying Sporicidal Disinfectants and Sterile 70% IPA in the PEC

Clean, disinfect, and apply a sporicidal disinfectant to equipment and all interior surfaces in the PEC at the minimum frequencies specified in *Table 10*. See *Box 7* and *Box 8* for procedures for cleaning, disinfecting, and applying a sporicidal disinfectant in the PEC.

**Box 7. Procedures for Cleaning and Disinfecting the PEC**

- If necessary, remove visible particles, debris, or residue with an appropriate solution (e.g., *Sterile Water for Injection* or *Sterile Water for Irrigation*) using sterile, low-lint wipers.
- Using a sterile low-lint wiper, apply a sterile cleaning agent followed by a sterile EPA-registered disinfectant or apply a sterile EPA-registered (or equivalent for entities outside the US) one-step disinfectant cleaner to equipment and all interior surfaces of the PEC.
- Ensure the contact time specified by the manufacturer is achieved.
- Using a sterile low-lint wiper, apply sterile 70% IPA to equipment and all interior surfaces in the PEC.
- Allow the surface to dry completely before beginning compounding.

**Box 8. Procedures for Applying a Sporicidal Disinfectant in the PEC**

- If necessary, remove visible particles, debris, or residue with an appropriate solution (e.g., *Sterile Water for Injection* or *Sterile Water for Irrigation*) using sterile, low-lint wipers.
- After cleaning and disinfecting (see *Box 7*), apply the sterile sporicidal disinfectant using a sterile low-lint wiper to all surfaces and the area underneath the work tray; if the sporicidal disinfectant is a sterile EPA-registered (or equivalent for entities outside the US) one-step disinfectant sporicidal cleaner, separate cleaning and disinfecting steps are not required.
- Ensure the contact time specified by the manufacturer is achieved.
- Using a sterile low-lint wiper, apply sterile 70% IPA to all interior surfaces, including underneath the work tray.
- Allow the surface to dry completely before beginning compounding.

## 8. INTRODUCING ITEMS INTO THE SEC AND PEC

### 8.1 Introducing Items into the SEC

Before any item is introduced into the clean side of anteroom(s), placed into pass-through chamber(s), or brought into the SCA, providing that packaging integrity will not be compromised, it must be wiped with a sporicidal disinfectant, EPA-registered disinfectant, or sterile 70% IPA using low-lint wipers by personnel wearing gloves. If an EPA-registered disinfectant or sporicidal disinfectant is used, the agent must be allowed to dwell for the minimum contact time specified by the manufacturer. If sterile 70% IPA is used, it must be allowed to dry. The wiping procedure should not compromise the packaging integrity or render the product label unreadable.

### 8.2 Introducing Items into the PEC

Just before any item is introduced into the PEC, it must be wiped with sterile 70% IPA using sterile low-lint wipers and allowed to dry before use. When sterile items are received in sealed containers designed to keep them sterile until opening, the sterile items may be removed from the covering as the supplies are introduced into the ISO Class 5 PEC without the need to wipe the individual sterile supply items with sterile 70% IPA. The wiping procedure must not render the product label unreadable.

### 8.3 Use of Sterile 70% IPA on Critical Sites within the PEC

Critical sites (e.g., vial stoppers, ampule necks, and intravenous bag septums) must be wiped with sterile 70% IPA in the PEC to provide both chemical and mechanical actions to remove contaminants. The sterile 70% IPA must be allowed to dry before personnel enter or puncture stoppers and septums or break the necks of ampules.

Official

## 9. EQUIPMENT, SUPPLIES, AND COMPONENTS

### 9.1 Equipment

PECs are described in *4.2.3 Types of PECs and placement*. Other equipment used in compounding CSPs (e.g., automated compounding devices [ACDs] and balances) should be of suitable composition such that the surfaces that contact components are not reactive or sorptive. Equipment that must be brought into classified areas must be wiped with a sporicidal disinfectant, EPA-registered disinfectant, or sterile 70% IPA using low-lint wipers.

Equipment must be placed in a manner that facilitates sterile compounding operations. The equipment must be capable of operating properly and within required performance parameters. Compounding personnel must follow established SOPs for the calibration, maintenance, cleaning, and use of the equipment based on the manufacturer's recommendations. Personnel must maintain records from equipment calibration, verification, and maintenance in accordance with the requirements in *20. Documentation*.

ACDs and other similar equipment are designed to assist in the compounding of preparations by delivering specific volumes of solution(s) automatically under computerized control.

Before using ACDs or other similar equipment, compounding personnel must conduct an accuracy assessment before the first use and again each day the equipment is used to compound CSPs. The precision of the equipment can be monitored based on an assessment of day-to-day variations in its accuracy measures. Compounding personnel must maintain a daily record of the accuracy measurements on the days the equipment is in use. Corrective actions must be implemented if accuracy measurements are outside the manufacturer's specification.

Weighing, measuring, or otherwise manipulating components that could generate airborne chemical particles (e.g., active pharmaceutical ingredients [APIs], added substances, conventionally manufactured products) must be evaluated to determine if these activities must be performed in a PEC or other closed system processing device (e.g., single use containment glove bag) to reduce the potential exposure to personnel or contamination of the facility or CSPs (See *4.2.6 Facilities preparing Category 2 or Category 3 CSPs from nonsterile starting component(s)*). The process evaluation must be carried out in accordance with the facility's SOPs and the assessment must be documented.

### 9.2 Supplies

Supplies (e.g., beakers, utensils, needles, syringes, filters, and tubing sets) should be of suitable composition such that the surfaces that contact components are not reactive or sorptive. Supplies in direct contact with the CSP must be sterile and depyrogenated.

### 9.3 Components

Compounding personnel must follow the facility's SOPs, which must address the selection, receipt, evaluation, handling, storage, and documentation of all CSP components, including all ingredients and container closures.

**9.3.1 Component selection:** Conventionally manufactured sterile products should be used when available and appropriate for the intended CSP.

When APIs are used:

- Must comply with the criteria in the *USP–NF* monograph, if one exists
- Must have a COA that includes the specifications (e.g., compendial requirements for quality) and that test results for the component show that the API meets expected quality
- In the United States, must be manufactured by an FDA-registered facility
- Outside of the United States, must comply with the laws and regulations of the applicable regulatory jurisdiction

For all components other than APIs:

- Must comply with the criteria in the *USP–NF* monograph, if one exists
- Must be accompanied by documentation (e.g., COA, labeling) that includes the specifications and test results and shows that the component meets the specifications
- In the US, should be manufactured by an FDA-registered facility
  - If a component cannot be obtained from an FDA-registered facility, the designated person(s) must select an acceptable and reliable source (see *Good Distribution Practices for Bulk Pharmaceutical Excipients* ⟨1197⟩). The compounding facility must establish the identity, strength, purity, and quality of the ingredients obtained from that supplier by reasonable means. Reasonable means may include but are not limited to visual inspections, evaluation of a COA supplied by the manufacturer, and/or verification by analytically testing a sample to determine conformance with the COA or other specifications.
- Outside of the US, must comply with the laws and regulations of the applicable regulatory jurisdiction

When CSPs are used as components, see *16. Use of CSPs as Components*. All APIs and other components used must be evaluated for suitability for use in sterile drug preparation. Components labeled with "not for pharmaceutical use", "not for injectable use", "not for human use" or an equivalent statement must not be used to compound for these purposes.

Each lot of commercially available sterile, depyrogenated containers and container closure systems must be accompanied by a COA or other documentation showing conformance with established specifications (i.e., sterility and depyrogenation requirements). If sterilization and depyrogenation of supplies or container closure systems are performed on site, the efficacy of each process must be established and documented (see *Sterilization of Compendial Articles* ⟨1229⟩).

**9.3.2 Component receipt:** Upon receipt of each lot of a component, the external packaging must be examined for evidence of deterioration and other aspects of unacceptable quality. Facility personnel must verify the labeling and condition of the component [e.g., whether the outer packaging is damaged and whether temperature-sensing indicators show that the component has been exposed to excessive temperature(s)].

Any component found to be of unacceptable quality must be promptly rejected, clearly labeled as rejected, and segregated from active stock to prevent use before appropriate disposal. Any other lots of that component from that vendor must be examined to determine whether other lots have the same defect.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99925_07_01

The date of receipt by the compounding facility must be clearly marked on each API or added substance package that lacks a vendor expiration date. Packages of components (i.e., API and added substances) that lack a vendor's expiration date must be assigned a conservative expiration date, not to exceed 1 year after receipt by the compounding facility.

**9.3.3 Component evaluation before use:** Compounding personnel must ascertain before use that components for CSPs are of the correct identity, appropriate quality, within expiry date and have been stored under appropriate conditions. The following information should be used to make this determination: prescription or medication order, compounding record (CR), master formulation record (if used), vendor label(s), COA(s) of API(s) and other component(s), product labeling of any conventionally manufactured sterile products, labeling of CSP(s), and documentation of the compounding facility's storage conditions and practices.

All components must be reinspected before use. All packages must be reinspected to detect container breaks, looseness of the cap or closure, and deviation from the expected appearance, aroma, and/or texture of the contents that might have occurred during storage. Sterile container closures must be visually reinspected to ensure that they are free from defects that could compromise sterility and that they are otherwise suitable for their intended use.

Any component found to be of unacceptable quality must be promptly rejected, clearly labeled as rejected, and segregated from active stock to prevent use before appropriate disposal. Any other lots of that component from that vendor must be examined to determine whether other lots have the same defect.

**9.3.4 Component handling and storage:** All components must be handled and stored in a manner that prevents contamination, mix-ups, and deterioration.

Components must be stored in closed containers under temperature, humidity, and lighting conditions consistent with those indicated in official monographs or specified by the suppliers and/or manufacturers.

Personnel must monitor temperature in the area(s) where components are stored either manually at least once daily on days that the facility is open or by a continuous temperature recording device to determine whether the temperature remains within the appropriate range. The results of the temperature readings must be documented on a temperature log or stored in the continuous recording device and must be retrievable. All monitoring equipment must be calibrated or verified for accuracy as recommended by the manufacturer or every 12 months if not specified by the manufacturer.

## 10. STERILIZATION AND DEPYROGENATION

When selecting the sterilization method for CSPs prepared from one or more nonsterile starting components or using nonsterile supplies or devices, personnel must take into consideration the nature of the component(s), their physical and chemical properties, and the intended container closure system.

The sterilization method used must sterilize the CSP without degrading its physical and chemical stability (e.g., affecting its strength, purity, or quality) or the packaging integrity. (See also the ⟨1229⟩ series of chapters.)

The following must be considered when selecting an appropriate sterilization method:

- Terminal sterilization (e.g., steam, dry heat, or irradiation) is the preferred method unless the specific CSP or container closure system cannot tolerate terminal sterilization
- Steam sterilization is not an option if moisture, pressure, or the temperatures used would degrade the CSP or if there is insufficient moisture to sterilize the CSP within the final, sealed, container closure system
- Filtration may not be an option for some compounded preparations, for example preparations with suspended drug particles or emulsions with a significant droplet size.

CSPs that are terminally sterilized (e.g., steam, dry heat, or irradiation) must use a process intended to achieve a probability of a nonsterile unit (PNSU) of $10^{-6}$. [NOTE—This is also called the sterility assurance level (SAL).] A PNSU of $10^{-6}$ is equivalent to a probability that 1 unit in a million is nonsterile. A PNSU value cannot be applied to CSPs that are aseptically filled into a sterile container following sterilization by filtration because sterilization by filtration is not terminal sterilization.

Injectable compounded preparations that contain nonsterile components or that come into contact with nonsterile devices (e.g., containers, tubing) during any phase of the compounding procedure must be sterilized within 6 h after completing the preparation to minimize the generation of bacterial endotoxins in CSPs.

A description of the terminal sterilization and depyrogenation process, including the temperature, pressure (if applicable), duration, permissible load conditions for each cycle, and the use of biological indicators and endotoxin challenge vials (ECVs) must be included in the facility's SOPs.

SOPs must include training and competency of personnel on all sterilization methods and equipment used by the facility. In addition, the SOPs must include a schedule and method for establishing and verifying the effectiveness of the terminal sterilization and depyrogenation methods selected, as well as the methods for maintaining and cleaning the sterilizing and depyrogenation equipment.

### 10.1 Depyrogenation

See *Dry Heat Depyrogenation* ⟨1228.1⟩. Dry heat depyrogenation must be used to render glassware, metal, and other thermostable containers and components pyrogen free. Depyrogenation processes typically operate at a range of temperatures, from approximately 170°–400°, depending on the exposure time (e.g., a cycle might hold the items at 250° for 30 min to achieve sterility and depyrogenation). The duration of the exposure period must include sufficient time for the items to reach the depyrogenation temperature. The items must remain at the depyrogenation temperature for the duration of the depyrogenation period.

The effectiveness of the dry heat depyrogenation cycle must be established initially and verified annually using ECVs to demonstrate that the cycle is capable of achieving a ≥3-log reduction in endotoxins (see *Bacterial Endotoxins Test* ⟨85⟩). The effectiveness of the depyrogenation cycle must be re-established if there are changes to the depyrogenation cycle described in SOPs (e.g., changes in load conditions, duration, or temperature). This verification must be documented.

Items that are not thermostable must be depyrogenated by multiple rinses with sterile, nonpyrogenic water (e.g., *Sterile Water for Injection* or *Sterile Water for Irrigation*) and then thoroughly drained or dried immediately before use in compounding See *Depyrogenation by Rinsing* ⟨1228.4⟩.

Printed by: USP NF
Do Not Distribute

**10.2 Sterilization by Filtration**

See *Sterilizing Filtration of Liquids* ⟨1229.4⟩. Sterilizing filters must be sterile, depyrogenated, have a nominal pore size of 0.22 µm or smaller, and be appropriate for pharmaceutical use. Sterilizing filters with labeling that states "for laboratory use only" or a similar statement must not be used for compounding CSPs. Sterilizing filters must be certified by the manufacturer to retain at least $10^7$ microorganisms of a strain of *Brevundimonas diminuta* per square centimeter of upstream filter surface area under conditions similar to those in which the CSPs will be filtered (i.e., pressure, flow rate, and volume filtered).

The designated person(s) must ensure—from available published information, from supplier documentation, or through direct challenge (e.g., filtering the CSP)—that the filters 1) are chemically and physically compatible with all ingredients in the CSP (e.g., water-miscible alcohols may damage filter integrity); 2) are chemically stable at the pressure and temperature conditions that will be used; and 3) have enough capacity to filter the required volumes. The filter dimensions and the CSP to be sterilized by filtration should permit the sterilization process to be completed without the need for replacement of the filter during the process. Filter units used to sterilize CSPs must be subjected to the manufacturers' recommended integrity testing, such as a post-use bubble point test. If multiple filters are required for the compounding process, each of the filters must pass a filter-integrity test.

When CSPs are known to contain excessive particulate matter, a prefiltration step must be performed using a filter of larger nominal pore size (e.g., 1.2 µm) or a separate filter of larger nominal pore size should be placed upstream of (i.e., prior to) the sterilizing filter to remove gross particulate contaminants before the CSP is passed through the sterilizing-grade filter. Excessive particulate matter requiring a prefiltration step could potentially be a signal of an inappropriate formulation, and therefore the formulation and the process should be assessed and modified if necessary. CSPs that were prepared using a filter that failed integrity tests must be discarded or, after investigating the cause of the failure and selection of an appropriate filter, refiltered for sterilization not more than one additional time.

**10.3 Sterilization by Steam Heat**

Temperatures used to achieve sterilization by steam heat are lower than those used to achieve depyrogenation. The process of thermal sterilization using saturated steam under pressure (i.e., autoclaving) is the preferred method for terminal sterilization of aqueous CSPs in their final, sealed container closure system (see *Steam Sterilization by Direct Contact* ⟨1229.1⟩). Steam sterilization is not an option if moisture, pressure, or the temperatures used would degrade the CSP.

To achieve sterility when steam sterilization is used, all materials must be directly exposed to steam under adequate pressure for the length of time necessary, as determined by use of appropriate biological indicators, to render the items sterile (e.g., 20–60 min at 121° saturated steam under a pressure of 15 psi, depending on the volume or size of the CSP being sterilized). The duration of the exposure period must include sufficient time for the entire contents of the CSP and other items to reach the sterilizing temperature. The CSP and other items must remain at the sterilizing temperature for the duration of the sterilization period.

CSPs must be placed in the autoclave to allow steam to reach the CSPs without entrapment of air. Flat, stainless-steel trays with low sides or ventilated bottoms will permit steam contact. When preparing items that must be wrapped for steam sterilization, wrap them in low-lint protective fabric or paper or seal in envelopes that will permit steam penetration and are designed to minimize the risk of post-sterilization microbial contamination. For CSPs, immediately before filling containers that will be steam sterilized, solutions must be passed through a filter with a nominal pore size of not larger than 1.2 µm for removal of particulate matter.

Sealed containers must be able to generate steam internally. Stoppered and crimped empty vials must contain a small amount of sterile water to generate steam.

The effectiveness of steam sterilization must be verified and documented with each sterilization run or load by using appropriate biological indicators, such as spores of *Geobacillus stearothermophilus* (ATCC 12980, ATCC 7953, or equivalent; see *Biological Indicators for Sterilization* ⟨1229.5⟩), and other confirmation methods such as physicochemical indicators (see *Physicochemical Integrators and Indicators for Sterilization* ⟨1229.9⟩).

The steam supplied must be generated using water per the manufacturer's recommendation. A calibrated data recorder or chart must be used to monitor each cycle and to examine for cycle irregularities (e.g., deviations in temperature or pressure). The date, run, and load numbers of the steam sterilizer used to sterilize a CSP must be documented in the CR.

**10.4 Sterilization by Dry Heat**

Dry heat may be used for those items that cannot be sterilized by steam or other means when the moisture would damage the material or the wrapping material is impermeable (see *Dry Heat Sterilization* ⟨1229.8⟩). Sterilization by dry heat requires higher temperatures and longer exposure times than sterilization by steam. The duration of the exposure period must include sufficient time for the entire contents of CSPs and other items to reach the sterilizing temperature. The CSP and other items must remain at the sterilizing temperature for the duration of the sterilization period. Immediately before filling ampules and vials that will be sterilized by dry heat, CSP solutions must be passed through a filter with a nominal pore size of not larger than 1.2 µm for removal of particulate matter.

Dry heat sterilization is usually performed in an oven designed for sterilization at 160° or higher. If lower temperatures are used, they must be shown to achieve effective sterilization (see ⟨1229.8⟩*, Validation of Dry Heat Sterilization, Biological Indicators*).

Heated air must be evenly distributed throughout the chamber, which is typically accomplished by an air blower. The calibrated oven must be equipped with temperature controls and a timer. During sterilization, sufficient space must be left between materials to allow for circulation of the hot air. A calibrated data recorder or chart must be used to monitor each cycle and the data must be reviewed to identify cycle irregularities (e.g., deviations in temperature or exposure time).

The effectiveness of the dry heat sterilization method must be verified and documented with each sterilization run or load using appropriate biological indicators such as spores of *Bacillus atrophaeus* (ATCC 9372; see ⟨1229.5⟩) and other confirmation methods (e.g., temperature-sensing devices). The date, run, and load numbers of the dry heat oven used to sterilize a CSP must be documented in the CR.

## 11. MASTER FORMULATION AND COMPOUNDING RECORDS

### 11.1 Creating Master Formulation Records

A master formulation record (MFR) is a detailed record of procedures that describes how the CSP is to be prepared. An MFR must be created for all CSPs prepared from nonsterile ingredient(s) or CSPs prepared for more than one patient. Any changes or alterations to the MFR must be approved and documented according to the facility's SOPs. *Box 9* lists the information that must be included in an MFR.

**Box 9. Master Formulation Records**

An MFR must include at least the following information:

- Name, strength or activity, and dosage form of the CSP
- Identities and amounts of all ingredients; if applicable, relevant characteristics of components (e.g., particle size, salt form, purity grade, solubility)
- Type and size of container closure system(s)
- Complete instructions for preparing the CSP, including equipment, supplies, a description of the compounding steps, and any special precautions
- Physical description of the final CSP
- BUD and storage requirements
- Reference source to support the stability of the CSP
- Quality control (QC) procedures (e.g., pH testing, filter integrity testing)
- Other information as needed to describe the compounding process and ensure repeatability (e.g., adjusting pH and tonicity; sterilization method, such as steam, dry heat, irradiation, or filter)

### 11.2 Creating Compounding Records

A CR documents the compounding of each CSP. A CR must be created for all Category 1, Category 2, and Category 3 CSPs. A CR must also be created for immediate-use CSPs prepared for more than one patient. The CR must be created to document the compounding process. A prescription or medication order or label may serve as the CR. If an ACD, workflow management system, or other similar equipment is used, the required information in the CR may be stored electronically as long as it is retrievable and contains the required information (see *Box 10*). An MFR can serve as the basis for preparing the CR. For example, a copy of the MFR can be made that contains spaces for recording the information needed to complete the CR. *Box 10* lists the information that must be included in a CR.

**Box 10. Compounding Records**

CRs must include at least the following information:

- Name, strength or activity, and dosage form of the CSP
- Date and time of preparation of the CSP
- Assigned internal identification number (e.g., prescription, order, or lot number)
- A method to identify the individuals involved in the compounding process and individuals verifying the final CSP
- Name of each component
- Vendor, lot number, and expiration date for each component for CSPs prepared for more than one patient and for CSPs prepared from nonsterile ingredient(s)
- Weight or volume of each component
- Strength or activity of each component
- Total quantity compounded
- Final yield (e.g., quantity, containers, number of units)
- Assigned BUD and storage requirements
- Results of QC procedures (e.g., visual inspection, filter integrity testing, pH testing)

If applicable, the CR must also include:

- MFR reference for the CSP
- Calculations made to determine and verify quantities and/or concentrations of components

## 12. RELEASE INSPECTIONS AND TESTING

All release testing procedures (e.g., visual inspections and testing) must be included in the facility's documentation (see *11. Master Formulation and Compounding Records* and *17. SOPs*). Any out-of-specification results must be investigated, and a corrective action plan must be implemented and documented as part of the quality assurance (QA) and QC program (see *18. Quality Assurance and Quality Control*).

### 12.1 Visual Inspection

At the completion of compounding, before release and dispensing, the CSP must be visually inspected to determine whether the physical appearance of the CSP is as expected (e.g., free of inappropriate visible particulates or other foreign matter, discoloration, or other defects). The CSP label must be visually inspected to confirm that the CSP and its labeling match the prescription or medication order. The inspection also must include a visual inspection of container closure integrity (e.g., checking for leakage, cracks in the container, or improper seals). Any CSP found to be of unacceptable quality (e.g., observed defects) must be promptly rejected, clearly labeled as rejected, and segregated from active stock to prevent use before appropriate disposal.

When a CSP will not be released or dispensed on the day of preparation, a visual inspection must be conducted immediately before it is released or dispensed to make sure that the CSP does not exhibit any defects such as precipitation, cloudiness, or leakage, which could develop during storage. Any CSP found to be of unacceptable quality (e.g., observed defects) must be promptly rejected, clearly labeled as rejected, and segregated from active stock to prevent use before appropriate disposal. Defects that indicate sterility or stability problems must be investigated to determine the cause according to the facility's SOPs (see *18. Quality Assurance and Quality Control*).

@2024 USPC

**12.2 Sterility Testing**

Sterility testing is not required for Category 1 CSPs (see *Table 12*). For Category 2 CSPs assigned a BUD that requires sterility testing (see *Table 13*) and all Category 3 CSPs, the testing must be performed according to ⟨71⟩ or a validated alternative method (see ⟨1223⟩) that is noninferior to ⟨71⟩ testing.

If sterility testing is performed, the minimum quantity of each container to be tested for each media is specified in ⟨71⟩, *Table 2*, and the number of containers required to be tested in relation to the batch size is specified in ⟨71⟩, *Table 3*, except as described below. The maximum batch size for all CSPs requiring sterility testing must be limited to 250 final yield units.

If the number of CSPs to be compounded in a single batch is less than the number of CSPs needed for testing as specified in ⟨71⟩, *Table 3*, additional units must be compounded to perform sterility testing as follows:

- If 1–39 CSPs are compounded in a single batch, the sterility testing must be performed on a number of units equal to 10% of the number of CSPs prepared, rounded up to the next whole number. For example:
  - If 1 CSP is compounded, 10% of 1 rounded up to the next whole number would indicate that 1 additional CSP must be prepared for sterility testing
  - If 39 CSPs are compounded, 10% of 39 rounded up to the next whole number would indicate that 4 additional CSPs must be prepared for sterility testing
- If more than 40 CSPs are prepared in a single batch, the sample sizes specified in ⟨71⟩, *Table 3* must be used.

If sterility testing is performed according to ⟨71⟩, the *Method Suitability Test* from that chapter must be performed to ensure that contamination can be recovered. If performing sterility testing according to ⟨71⟩, the *Membrane Filtration* method from that chapter is the method of choice when the CSP formulation permits. The preferred alternative is the ⟨71⟩, *Test for Sterility of the Product to Be Examined, Direct Inoculation of the Culture Medium* method. If an alternative method is used for sterility testing, the method must be validated (see ⟨1223⟩) and demonstrated to be suitable for that CSP formulation.

Sterility tests resulting in failures must prompt an investigation into the possible causes and must include identification of the microorganism, as well as an evaluation of the sterility testing procedure, compounding facility, process, and/or personnel that may have contributed to the failure. The source(s) of the contamination, if identified, must be corrected, and the facility must determine whether the conditions causing the sterility failure affect other CSPs. The investigation and resulting corrective actions must be documented.

**12.3 Bacterial Endotoxins Testing**

Category 1 injectable CSPs do not require testing for bacterial endotoxins. Category 2 injectable CSPs compounded from one or more nonsterile component(s) and assigned a BUD that requires sterility testing (see *Table 13*) and Category 3 injectable CSPs compounded from one or more nonsterile component(s) must be tested to ensure that they do not contain excessive bacterial endotoxins (see ⟨85⟩). Category 2 injectable CSPs compounded from one or more nonsterile component(s) and assigned a BUD that does not require sterility testing should be tested for bacterial endotoxins. In the absence of a bacterial endotoxin limit in an official *USP–NF* monograph or other CSP formula source, the CSP must not exceed the endotoxin limit calculated as described in ⟨85⟩ for the appropriate route of administration for humans. CSPs for nonhuman species must not exceed the endotoxin limit calculated as described in ⟨85⟩ based on the largest recommended dose and weight (or average weight for more than a single animal) of the target animal species unless a different limit is scientifically supported. CSPs administered epidurally should have the same endotoxin limit as that of intrathecally administered CSPs. See also *Guidelines on the Endotoxins Test* ⟨1085⟩.

## 13. LABELING

Category 1, Category 2, and Category 3 CSPs must be labeled with appropriate, legible identifying information to prevent errors during storage, dispensing, and use. The term *labeling* designates all labels and other written, printed, or graphic matter on the immediate container or on or inside any package or wrapper in which it is enclosed, except any outer shipping container. The term *label* designates that part of the labeling that is on the immediate container. See *Labeling* ⟨7⟩.

All labeling must be in compliance with laws and regulations of the applicable regulatory jurisdiction.

The label on each immediate container of the CSP must, at a minimum, display prominently and legibly the following information:

- Assigned internal identification number (e.g., barcode, prescription, order, or lot number)
- Active ingredient(s) and their amount(s), activity(ies), or concentration(s)
- Storage conditions if other than controlled room temperature
- BUD
- Dosage form
- Total amount or volume if it is not obvious from the container
- If it is a single-dose container, a statement stating such when space permits
- If it is a multiple-dose container, a statement stating such

The labeling on the CSP must display the following information, as applicable:

- Route(s) of administration
- Special handling instructions
- Warning statements
- Compounding facility name and contact information if the CSP is to be sent outside of the facility or healthcare system in which it was compounded

The labeling on the CSP should indicate that the preparation is compounded.

Labeling procedures must be followed as described in the facility's SOPs to prevent labeling errors and CSP mix-ups. The label of the CSP must be verified to ensure that it conforms with the

## 14. ESTABLISHING BEYOND-USE DATES

### 14.1 Terminology

Each CSP label must state the date, or the hour and date, beyond which the preparation must not be used and must be discarded (i.e., the BUD). The BUD is determined from the date and time that preparation of the CSP is initiated. The BUD is not intended to limit the time during which the CSP is administered (e.g., infused).

BUDs and expiration dates are not the same. An expiration date identifies the time during which a conventionally manufactured product, API, or added substance can be expected to meet the requirements of a *USP–NF* monograph, if one exists, or maintain expected quality provided it is kept under the specified storage conditions. The expiration date limits the time during which a conventionally manufactured product, API, or added substance may be dispensed or used (see ⟨7⟩, *Labels and Labeling for Products in Other Categories, Expiration Date and Beyond-Use Date*). Expiration dates are assigned by manufacturers based on analytical and performance testing of the sterility, chemical and physical stability, and packaging integrity of the product. Expiration dates are specific to a particular formulation in its container and at stated exposure conditions of illumination and temperature. See *Table 11* for a summary of terms.

**Table 11. Summary of Terms**

| Term | Definition | Applicability |
|---|---|---|
| BUD | Either the date, or hour and date, after which a CSP must not be used. The BUD is determined from the date and time that preparation of the CSP is initiated | Applies to all CSPs |
| Expiration date | The time during which a product can be expected to meet the requirements of the *USP–NF* monograph, if one exists, or maintain expected quality provided it is kept under the specified storage conditions. | Applies to all conventionally manufactured products, APIs, and added substances |

### 14.2 Parameters to Consider in Establishing a BUD

BUDs for CSPs should be established conservatively to ensure that the drug maintains its required characteristics (i.e., stability and sterility) until its BUD.

When establishing a BUD for a CSP, compounders must consider parameters that may affect quality, including but not limited to:

- Chemical and physical stability properties of the drug and/or its formulation
- Materials of composition of the container closure system and compatibility of the container closure system with the final preparation (e.g., leachables, interactions, adsorption, and storage conditions)

The BUDs for CSPs are based primarily on factors that affect the achievement and maintenance of sterility, which include but are not limited to the following:

- Conditions of the environment in which the CSP is prepared
- Aseptic processing and sterilization method
- Starting components (e.g., sterile or nonsterile ingredients)
- Whether or not sterility testing is performed
- Storage conditions (e.g., packaging and temperature)

**14.2.1 Terminal sterilization methods and aseptic processing:** A CSP may be prepared by the following methods (see *10. Sterilization and Depyrogenation*):

- Terminal sterilization, which includes compounding with sterile and/or nonsterile starting ingredient(s) and subsequent sterilization with a process intended to achieve a PNSU of $10^{-6}$ (e.g., steam, dry heat, irradiation).
- Aseptic processing, which includes 1) compounding with only sterile starting ingredient(s) or 2) compounding with nonsterile ingredient(s) followed by sterilization by filtration. [NOTE—Sterilization by filtration is not a form of terminal sterilization.]

Terminal sterilization is the preferred method of sterilization, unless the specific CSP or container closure system cannot tolerate terminal sterilization. *Table 13* allows for longer BUDs for terminally sterilized CSPs than for aseptically processed CSPs because terminal sterilization using a verified method provides reasonable assurance that a CSP will be sterile.

**14.2.2 Starting components:** The use of one or more nonsterile starting component(s) is a risk factor to be considered when preparing a CSP. A longer BUD is permitted for CSPs that are aseptically processed from conventionally manufactured sterile starting component(s) than from one or more nonsterile starting component(s).

**14.2.3 Sterility testing:** Sterility testing (see *12.2 Sterility Testing*) of a CSP can provide additional assurance of the absence of contamination, although passing a sterility test does not guarantee that all units of a batch of CSPs are sterile because contamination may not be uniformly distributed throughout the batch. A longer BUD is permitted if sterility testing results are within acceptable limits. The maximum batch size for all CSPs requiring sterility testing must be limited to 250 final yield units.

**14.2.4 Storage conditions:** Storage in colder conditions (i.e., in a refrigerator or freezer [see *Packaging and Storage Requirements* ⟨659⟩]) has been shown to slow the growth of most microorganisms. However, the chemical and physical stability of the CSP and its components must be considered when storing in colder conditions (e.g., some formulations may precipitate when stored in a refrigerator or freezer). A longer BUD is permitted in *Table 12* and *Table 13* for CSPs stored in colder conditions than for CSPs stored at controlled room temperature.

@2024 USPC

If the CSP will be stored in a frozen state, the container closure system must be able to withstand the physical stress (i.e., without breaking or cracking) during storage in a freezer. The CSP must be thawed in appropriate conditions to avoid compromising the physical and chemical stability of the preparation and its components (e.g., do not heat in a microwave). Once the CSP is thawed, the CSP must not be refrozen.

CSPs may be stored under different storage conditions before they are used (e.g., CSPs may first be frozen, then thawed in the refrigerator, and finally kept at controlled room temperature before administration). The storage time of a CSP must not exceed the original BUD placed on the CSP for its labeled storage condition, and BUDs must not be additive. For example, an aseptically processed CSP prepared from one or more nonsterile starting component(s) cannot be stored for 45 days in a freezer, then 4 days refrigerated, and then 24 h at controlled room temperature for a total of 50 days. Once a CSP has been stored under a condition that would require a shorter BUD (e.g., controlled room temperature), the CSP must be used within the time frame for that storage condition (in the previous example, 24 h).

### 14.3 Establishing a BUD for a CSP

BUDs for CSPs must be established in accordance with *Table 12* for Category 1 CSPs, *Table 13* for Category 2 CSPs and *Table 14* for Category 3 CSPs. One day is equivalent to 24 h.

The BUD limits in these tables are based on the risk of microbial contamination or not achieving and maintaining sterility despite implementation of the requirements in this chapter. The CSP formulation must remain chemically and physically stable, and its packaging must maintain its integrity for the duration of the BUD.

A shorter BUD must be assigned when the stability of the CSP or its components is less than the hours or days stated in the applicable table below. Additionally:

- The BUD must not exceed the shortest remaining expiration date of any of the commercially available starting components.
- For CSPs prepared from one or more compounded components, the BUD should generally not exceed the shortest BUD of any of the individual compounded components. However, there may be acceptable instances when the BUD of the final CSP exceeds the BUD assigned to compounded components (e.g., pH-altering solutions). If the assigned BUD of the final CSP exceeds the BUD of the compounded components, the physical, chemical, and microbiological quality of the final CSP must not be negatively impacted.

*Table 12* establishes the longest permitted BUDs for Category 1 CSPs. Category 1 CSPs may be prepared in an SCA or cleanroom suite (see *4.2 Facility Design and Environmental Controls*).

**Table 12. BUD Limits for Category 1 CSPs[a]**

| Storage Conditions | |
|---|---|
| **Controlled Room Temperature (20°–25°)** | **Refrigerator (2°–8°)** |
| ≤12 h | ≤24 h |

[a] A shorter BUD must be assigned when the physical and chemical stability of the CSP is less than the BUD limit stated in the table.

*Table 13* establishes the longest permitted BUDs for Category 2 CSPs. Category 2 CSPs must be prepared in a cleanroom suite (see *4.2 Facility Design and Environmental Controls*).

**Table 13. BUD Limits for Category 2 CSPs[a]**

| Preparation Characteristics | | Storage Conditions | | |
|---|---|---|---|---|
| **Compounding Method** | **Sterility Testing Performed and Passed** | **Controlled Room Temperature (20°–25°)** | **Refrigerator (2°–8°)** | **Freezer (–25° to –10°)** |
| Aseptically processed CSPs | No | Prepared from one or more nonsterile starting component(s): 1 day | Prepared from one or more nonsterile starting component(s): 4 days | Prepared from one or more nonsterile starting component(s): 45 days |
| | | Prepared from only sterile starting components: 4 days | Prepared from only sterile starting components: 10 days | Prepared from only sterile starting components: 45 days |
| | Yes | 30 days | 45 days | 60 days |
| Terminally sterilized CSPs | No | 14 days | 28 days | 45 days |
| | Yes | 45 days | 60 days | 90 days |

[a] A shorter BUD must be assigned when the physical and chemical stability of the CSP is less than the BUD limit stated in the table.

### 14.4 Additional Requirements for Category 3 CSPs

**14.4.1 Assigning Category 3 BUDs:** Increasing the storage time of a CSP introduces additional risk for chemical degradation, physical incompatibilities, the compromising of the container closure system, and microbial proliferation. To address these risks and maintain a higher state of environmental control, additional requirements must be met when assigning BUDs for Category 3 CSPs in accordance with *Table 14*. Category 3 CSPs must not be assigned a BUD longer than the limits in *Table 14*.

**14.4.2 Facility and Personnel Requirements for Category 3 CSPs:** In addition to the requirements in this section, other facility and personnel requirements related to compounding Category 3 CSPs are addressed throughout the chapter.

DocId: GUID-A4CAAA8B-6F02-4AB8-8628-09E102CBD703_7_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99925_07_01

- Category 3 personnel competency requirements apply to personnel who participate in or oversee the compounding of Category 3 CSPs (see *2.2 Demonstrating Competency in Garbing and Hand Hygiene* and *2.3 Competency Testing in Aseptic Manipulation*).
- Category 3 garbing requirements apply to all personnel entering the buffer room where Category 3 CSPs are compounded and apply at all times regardless of whether Category 3 CSPs are being compounded on a given day (see *3.3 Garbing Requirements*).
- Increased environmental monitoring requirements apply to all classified areas where Category 3 CSPs are compounded and apply at all times regardless of whether Category 3 CSPs are being compounded on a given day (see *6.2 Monitoring Air Quality for Viable Airborne Particles* and *6.3 Monitoring Surfaces for Viable Particles*).
- The frequency of application of sporicidal disinfectants applies to all classified areas where Category 3 CSPs are compounded and applies at all times regardless of whether Category 3 CSPs are being compounded on a given day (see *Table 10*).

**14.4.3 Stability Requirements for Category 3 CSPs:** The BUD assigned to a Category 3 CSP must be supported by stability data obtained using a stability-indicating analytical method that is able to distinguish the active ingredient from its degradants and impurities (e.g., by forced degradation studies) and quantify the amount of the active ingredient.

- The Category 3 CSP must be prepared according to the exact formulation (API and other ingredients of identical grade and procedures) from which the stability data are derived.
- The Category 3 CSP must be packaged and stored in a container closure of the same materials of composition as that used in the study.
- The analytical method must be validated based on characteristics such as those described in ⟨1225⟩.
- The compounding facility must have documentation of the stability study, including a description of the methodology (e.g., number of samples taken, storage conditions), validation of the method, the stability-indicating analytical method, and all of the results of the study.

If the Category 3 CSP is an injection (*Particulate Matter in Injections* ⟨788⟩) or if it is an ophthalmic solution (*Particulate Matter in Ophthalmic Solutions* ⟨789⟩), particulate-matter testing is conducted once per formulation with acceptable results.

Once for each formulation and for each container closure system in which it will be packaged, the container closure system used is evaluated for and conforms to container closure integrity to the end of the BUD (see *Package Integrity Evaluation—Sterile Products* ⟨1207⟩).

**14.4.4 Release testing for Category 3 CSPs**

- Each time the Category 3 CSP is prepared, it is sterility tested and meets the requirements of ⟨71⟩ or a validated alternative method (see *Table 14*) that is noninferior to ⟨71⟩ testing.
- Each time the Category 3 CSP is prepared, it is tested for endotoxins for acceptable results, if endotoxin testing is required under *12.3 Bacterial Endotoxins Testing*.

*Table 14* establishes the longest permitted BUDs for Category 3 CSPs. If all of the conditions described for Category 3 CSPs in this chapter are not met, the applicable BUD in *Table 13* must not be exceeded.

**Table 14: BUD Limits for Category 3 CSPs[a]**

| Preparation Characteristics | Storage Conditions | | |
|---|---|---|---|
| Compounding Method | Controlled Room Temperature (20°–25°) | Refrigerator (2°–8°) | Freezer (–25° to –10°) |
| Aseptically processed, sterility tested, and passing all applicable tests for Category 3 CSPs | 60 days | 90 days | 120 days |
| Terminally sterilized, sterility tested, and passing all applicable tests for Category 3 CSPs | 90 days | 120 days | 180 days |

[a] A shorter BUD must be assigned when the physical and chemical stability of the CSP is less than the BUD limit stated in the table.

### 14.5 Multiple-Dose CSPs

A compounded multiple-dose container is designed to contain more than one dose, intended to be entered or penetrated multiple times, and usually contains a preservative. A preservative is intended to inhibit the growth of microorganisms and minimize the risk of contamination. The use of preservatives must be appropriate for the CSP formulation and the route of administration. For example, the preservative must not be inactivated by any ingredients in the CSP, and some preservatives are not always appropriate for the patient (e.g., neonates) or route of administration (e.g., intrathecal or ophthalmic injection). The use of preservatives, however, must not be considered a substitute for aseptic technique.

A multiple-dose CSP must be prepared as a Category 2 or Category 3 CSP. An aqueous multiple-dose CSP must additionally pass antimicrobial effectiveness testing in accordance with *Antimicrobial Effectiveness Testing* ⟨51⟩. The compounder may rely on antimicrobial effectiveness testing 1) conducted (or contracted for) once for each formulation in the particular container closure system in which it will be packaged or 2) results from an FDA-registered facility or published in peer-reviewed literature sources, provided that the CSP formulation (including any preservative) and container closure system are exactly the same as those tested, unless a bracketing study is performed. Antimicrobial effectiveness testing may be performed on a low concentration and a high concentration of the active ingredient in the formulation to establish preservative effectiveness across various strengths of the same formulation (e.g., bracketing). The concentration of all other ingredients (including preservatives) must be the same throughout the bracketing study.

Official

https://pharmacopeia.com/

After a multiple-dose CSP container is initially entered or punctured, the multiple-dose container must not be used for longer than the assigned BUD or 28 days if supported by antimicrobial effectiveness testing results (see ⟨51⟩) on the CSP, whichever is shorter.

The container closure system used to package the multiple-dose CSP must be evaluated for and conform to container closure integrity (see ⟨1207⟩). The container closure integrity test needs to be conducted only once on each formulation and on fill volume in the particular container closure system in which the multiple-dose CSP will be packaged.

**Multiple-dose, nonpreserved, aqueous topical, and topical ophthalmic, CSPs:** The beyond-use date of a multiple-dose, aqueous, nonpreserved CSP intended for topical, including topical ophthalmic, administration may be assigned in accordance with *14.5 Multiple-Dose CSPs*. However, unpreserved aqueous, topical, including topical ophthalmic, formulations, are at high risk of microbial proliferation if contaminated during preparation or use.

To minimize the risk of patient harm, the requirement for passing antimicrobial effectiveness testing in accordance with ⟨51⟩ is not required only if the preparation is:

- Prepared as a Category 2 or Category 3 CSP
- For use by a single patient
- Labeled (in the label or labeling) to indicate that once opened, it must be discarded after 24 h when stored at controlled room temperature and/or that once opened, it must be discarded after 72 h when stored under refrigeration

## 15. USE OF CONVENTIONALLY MANUFACTURED PRODUCTS AS COMPONENTS

This section addresses the time within which an entered or punctured conventionally manufactured product must be used.

### 15.1 Use of Conventionally Manufactured Single-Dose Containers

A conventionally manufactured single-dose container is a container closure system that holds a sterile product for parenteral administration (injection or infusion) that is not required to meet the antimicrobial effectiveness testing requirements. If a single-dose vial is entered or punctured only in an ISO Class 5 or cleaner air, it may be used up to 12 h after initial entry or puncture as long as the labeled storage requirements during that 12-h period are maintained. Opened single-dose ampules must not be stored for any time period.

### 15.2 Use of Conventionally Manufactured Multiple-Dose Containers

A conventionally manufactured product in a multiple-dose container is intended to contain more than one dose of a drug product (see ⟨659⟩*, General Definitions, Injection Packaging Systems*). Once initially entering or puncturing the multiple-dose container, the multiple-dose container must not be used for more than 28 days (see ⟨51⟩) unless otherwise specified by the manufacturer on the labeling.

### 15.3 Use of Conventionally Manufactured Pharmacy Bulk Packages

A conventionally manufactured pharmacy bulk package is a container of a sterile product for parenteral use that contains many single doses. The contents are intended for use in a pharmacy admixture program and are restricted to the sterile preparation of admixtures for infusion or, through a sterile transfer device, for the filling of empty sterile containers. The pharmacy bulk package must be used according to the manufacturer's labeling (see ⟨659⟩*, General Definitions, Injection Packaging Systems*). The pharmacy bulk package must be entered or punctured only in an ISO Class 5 PEC.

## 16. USE OF CSPs AS COMPONENTS

This section addresses the use of CSPs (e.g., multiple-dose CSPs, single-dose CSPs, and compounded stock solutions) as components to prepare final CSPs.

When a CSP is used as a component, care must be taken to minimize the risk of contamination of both the starting component CSP and the final CSP(s).

- *Component CSP*: The component CSP must be assigned a BUD consistent with *14. Establishing Beyond-Use Dates* and must be stored under conditions for its assigned BUD when not in use.
- *Final CSP*: The final CSP must be assigned a BUD consistent with *14. Establishing Beyond-Use Dates*.

### 16.1 Use of Compounded Multiple-Dose CSPs

A multiple-dose CSP is designed to contain more than one dose of sterile preparation, intended to be entered or punctured multiple times, and usually contains a preservative. Multiple-dose CSPs are required to meet the criteria for antimicrobial effectiveness testing (see ⟨51⟩) and the requirements in *14.5 Multiple-Dose CSPs*. Multiple-dose CSPs must be stored under the conditions upon which its BUD is based (e.g., refrigerator or controlled room temperature). After a multiple-dose CSP is initially entered or punctured, the multiple-dose CSP must not be used for longer than the assigned BUD or 28 days, whichever is shorter. This time limit for entering or puncturing is not intended to restrict the BUD of the final CSP. See *14. Establishing Beyond-Use Dates*

### 16.2 Use of Compounded Single-Dose CSPs and CSP Stock Solutions

When a compounded single-dose CSP or CSP stock solution is used as a component to compound additional CSPs, the original compounded single-dose CSP or CSP stock solution must be entered or punctured in ISO Class 5 or cleaner air and must be stored under the conditions upon which its BUD is based (e.g., refrigerator or controlled room temperature). The component CSP may be used for sterile compounding for up to 12 h or its assigned BUD, whichever is shorter, and any remainder must be discarded. This time limit for entering or puncturing is not intended to restrict the BUD of the final CSP. See *14. Establishing Beyond-Use Dates*.

## 17. SOPs

Facilities that prepare CSPs must develop SOPs for the compounding process and other support activities. SOPs must include the types of CSPs that are prepared (i.e., Category 1, Category 2, Category 3). A designated person(s) must ensure that SOPs are appropriate and are implemented, which includes ensuring that personnel demonstrate competency in performing every procedure that relates to their job function. A designated person(s) must follow up to ensure that corrective actions are taken if problems, deviations, failures, or errors are identified. The corrective action must be documented.

All personnel who perform or oversee compounding or support activities must be trained in the SOPs. All compounding personnel must be trained to:

Official

https://pharmacopeia.com/

- Recognize potential problems, deviations, failures, or errors associated with preparing a CSP (e.g., those related to equipment, facilities, materials, personnel, the compounding process, or testing) that could potentially result in contamination or other adverse impact on CSP quality
- Report any problems, deviations, failures, or errors to the designated person(s)

SOPs must be reviewed initially and at least every 12 months by the designated person(s) to ensure that they reflect current practices, and the review must be documented. Any changes or alterations to an SOP must be made only by a designated person(s) and must be documented. Revisions to SOPs must be communicated to all personnel involved in these processes and procedures, and personnel should document acknowledgment of the communication.

## 18. QUALITY ASSURANCE AND QUALITY CONTROL

QA is a system of procedures, activities, and oversight that ensures that the compounding process consistently meets quality standards. QC is the sampling, testing, and documentation of results that, taken together, ensure that specifications have been met before release of the CSP. See *Quality Assurance in Pharmaceutical Compounding* ⟨1163⟩.

A facility's QA and QC programs must be formally established and documented in the facility's SOPs that ensure that all aspects of the preparation of CSPs are conducted in accordance with the requirements in this chapter ( ⟨797⟩) and the laws and regulations of the applicable regulatory jurisdiction. Designated person(s) must ensure that the facility has formal, written QA and QC programs that establish a system of:

1. Adherence to procedures
2. Prevention and detection of errors and other quality problems
3. Evaluation of complaints and adverse events
4. Appropriate investigations and corrective actions

The facility's SOPs must describe the roles, duties, and training of the personnel responsible for each aspect of the QA program. Designated person(s) responsible for the QA program must have the training, experience, responsibility, and authority to perform these duties. The overall QA and QC program must be reviewed at least once every 12 months by the designated person(s). The results of the review must be documented, and appropriate action must be taken if needed.

### 18.1 Notification About and Recall of Out-of-Specification Dispensed CSPs

If a CSP is dispensed or administered before the results of release testing are known, the facility must have procedures in place to:

- Immediately notify the prescriber of a failure of specifications with the potential to cause patient harm (e.g., sterility, strength, purity, bacterial endotoxin, or other quality attributes)
- Recall any unused dispensed CSPs and quarantine any stock remaining in the pharmacy
- Investigate if other lots are affected and recall if necessary

An SOP for recall of out-of-specification dispensed CSPs must contain:

- Procedures to determine the severity of the problem and the urgency for implementation and completion of the recall
- Procedures to determine the distribution of any affected CSP, including the date and quantity of distribution
- Procedures to identify patients who have received the CSP
- Procedures for disposal and documentation of the recalled CSP
- Procedures to investigate and document the reason for failure

The sterile compounding facility must document the implementation of the recall procedures. The recall must be reported to appropriate regulatory bodies as required by laws and regulations of the applicable regulatory jurisdiction.

### 18.2 Complaint Handling

Compounding facilities must develop and implement SOPs for handling complaints. Complaints may include but are not limited to concerns or reports on the quality, labeling, or possible adverse reactions related to a specific CSP.

A designated person(s) must review all complaints to determine whether the complaint indicates a potential quality problem with the CSP. If it does, a thorough investigation into the cause of the problem must be initiated and completed. The investigation must consider whether the quality problem extends to other CSPs. Corrective action, if necessary, must be implemented for all potentially affected CSPs.

Consider whether to initiate a recall of potentially affected CSPs and whether to cease sterile compounding processes until all underlying problems have been identified and corrected.

A readily retrievable written or electronic record of each complaint must be kept by the facility, regardless of the source of the complaint (e.g., email, telephone, or mail). The record must contain the name of the complainant or other unique identifier, the date the complaint was received, the nature of the complaint, and the response to the complaint. In addition, to the extent that the information is known, the following should be recorded: the name and strength of the CSP and the assigned internal identification number (e.g., prescription, order, or lot number).

The record must also include the findings of any investigation and any follow-up. Records of complaints must be easily retrievable for review and evaluation for possible trends and must be retained in accordance with the record-keeping requirements in *20. Documentation*. A CSP that is returned in connection with a complaint must be quarantined until it is destroyed after completion of the investigation and in accordance with laws and regulations of the applicable regulatory jurisdiction.

### 18.3 Adverse Event Reporting

Adverse events potentially associated with the quality of CSPs must be reported in accordance with the facility's SOPs and all laws and regulations of the applicable regulatory jurisdiction. If the investigation into an adverse event reveals a quality problem with a CSP that is likely to affect other patients, those patients and prescribers potentially affected must be informed.

## 19. CSP HANDLING, STORAGE, PACKAGING, SHIPPING, AND TRANSPORT

Processes and techniques for handling, storing, packaging, and transporting CSPs must be outlined in the facility's SOPs. Personnel who will be handling, storing, packaging, and transporting CSPs within the facility must be trained in accordance with the relevant SOPs, and the training must be documented.

### 19.1 Handling and Storing CSPs

CSPs must be handled in a manner that maintains CSP quality and packaging integrity. To help ensure that CSP quality is maintained during storage at the compounding facility, personnel must monitor conditions in the storage areas. A controlled temperature area (see ⟨659⟩) must be established and monitored to ensure that the temperature remains within the appropriate range for the CSP. The temperature must be monitored each day, either manually or by a continuous recording device. The results of the temperature readings must be documented in a temperature log per facility SOPs or stored in the continuous temperature recording device and must be retrievable. Temperature monitoring devices must be verified for accuracy at least every 12 months or as required by the manufacturer.

The compounding facility must detect and minimize temperature excursions that are outside the temperature limits within the controlled temperature areas. When it is known that a CSP has been exposed to temperatures either below or above the storage temperature limits for the CSP, a designated person(s) must determine (e.g., by consulting literature or analytical testing) whether the CSP is expected to retain its integrity or quality. If this cannot be determined, it must be discarded.

### 19.2 Packaging of CSPs

Packaging materials should protect CSPs from damage, leakage, contamination, degradation, and adsorption while preventing inadvertent exposure to transport personnel. The facility must select appropriate shipping containers and packaging materials based on the product specifications, information from vendors, and the mode of transport.

Alternative modes of transport and/or special packaging (e.g., tamper-evident closures) may be needed to protect the quality of CSPs. If the CSP is sensitive to light, light-resistant packaging materials must be used. In some cases, the CSP must be packaged in a special container (e.g., a cooler) to protect it from temperature fluctuations.

### 19.3 Shipping and Transporting CSPs

Compounding personnel must select modes of transport that are expected to deliver properly packed CSPs in an undamaged, sterile, and stable condition. Inappropriate transport can adversely affect the quality of CSPs. For example, preparation-specific considerations should be given to physical shaking that might occur during pneumatic tube transport or undue exposure to heat, cold, or light. When shipping or transporting CSPs that require special handling (e.g., CSPs with stability concerns), personnel must include specific handling instructions on the exterior of the container.

## 20. DOCUMENTATION

All facilities where CSPs are prepared must have and maintain written or electronic documentation to demonstrate compliance with the requirements in this chapter. This documentation must include, but is not limited to, the following:

- Personnel training, competency assessments, and qualification records including corrective actions for any failures
- Certification reports, including corrective actions for any failures
- Environmental air and surface monitoring procedures and results
- Equipment records (e.g., calibration, verification, and maintenance reports)
- Receipt of components
- SOPs, MFRs (if required), and CRs (if required)
- Release inspection and testing records
- Information related to complaints and adverse events including corrective actions taken
- Results of investigations and corrective actions

Documentation must comply with all laws and regulations of the applicable regulatory jurisdiction. Records must be legible and stored in a manner that prevents their deterioration and/or loss. All required documentation for a particular CSP (e.g., MFR, CR, and release inspection and testing results) must be readily retrievable for at least 2 years after preparation or as required by laws and regulations of the applicable regulatory jurisdiction or accrediting organization(s), whichever is longer.

## 21. COMPOUNDING ALLERGENIC EXTRACTS

Licensed allergenic extracts are mixed and diluted into prescription sets for an individual patient, even though these allergenic extract combinations are not specified in the approved licenses for the licensed biological products (e.g., Biological License Applications [BLA]).

Allergenic extract prescription sets must follow standards at least as stringent as those in this section as follows:

### 21.1 Personnel Qualifications for Compounding Allergenic Extract Prescription Sets

- A designated person(s) with training and expertise in allergen immunotherapy is responsible for ensuring that personnel who will be preparing allergenic extract prescription sets are trained, evaluated, and supervised.
- Before beginning to independently prepare allergenic extracts, all compounding personnel must complete training and be able to demonstrate knowledge of principles and skills for sterile compounding.
- Annual personnel training and competency must be documented. Personnel must demonstrate knowledge and competency in these procedures by passing written or electronic testing before they can be allowed to compound allergenic extract prescription sets.
- Before being allowed to independently compound, all compounders must successfully complete gloved fingertip and thumb sampling on both hands (see *Box 1* and *Table 1*) no fewer than 3 separate times. Each fingertip and thumb evaluation must occur after performing separate and complete hand hygiene and garbing procedures. After the initial competency evaluation, compounding personnel must successfully complete gloved fingertip and thumb sampling on both hands at least every 12 months thereafter.

Official

- Compounding personnel must have their sterile technique and related practices evaluated at least every 12 months as demonstrated by successful completion of a media-fill test (see *Box 2*). If compounding outside of a PEC, the post-media-fill surface sample is not required.
- Personnel who fail competency evaluations must successfully pass reevaluations in the deficient area(s) before they can resume compounding of allergenic extract prescription sets. The designated person(s) must identify the cause of failure and determine appropriate retraining requirements.
- Personnel who have not compounded an allergenic extract prescription set in more than 6 months must be evaluated in all core competencies before resuming compounding duties.

**21.2 Personnel Hygiene and Garbing for Compounding Allergenic Extract Prescription Sets**

- Before beginning compounding of allergenic extract prescription sets, personnel must perform hand hygiene (see *Box 3*) and garbing procedures according to the facility's SOPs.
- The minimum garb requirements include:
  - A low-lint garment with sleeves that fit snugly around the wrists and an enclosed neck (e.g., gowns)
  - A low-lint, disposable head cover that covers the hair and ears and, if applicable, a disposable cover for facial hair
  - Face mask
  - Sterile powder-free gloves
- Throughout the compounding process, personnel must apply sterile 70% IPA onto all surfaces of the gloves and allow them to dry thoroughly.

**21.3 Facilities for Compounding Allergenic Extract Prescription Sets**

- The compounding process must occur in an ISO Class 5 PEC or in a dedicated allergenic extract compounding area (AECA). The PEC or AECA used to compound allergenic extract prescription sets must be located away from unsealed windows, doors that connect to the outdoors, and traffic flow, all of which may adversely affect the air quality. Neither a PEC nor an AECA may be located where environmental control challenges (e.g., restrooms, warehouses, or food preparation areas) could negatively affect the air quality. The PEC or the work surfaces in the AECA must be located at least 1 m away from a sink. The impact of activities that will be conducted around or adjacent to the PEC or AECA must be considered carefully when designing such an area.
- If used, the PEC must be certified at least every 6 months (see *5. Certification and Recertification*).
- If used, a visible perimeter must define the AECA.
  - Access to the AECA during compounding must be restricted to authorized personnel.
  - During compounding activities, no other activity is permitted in the AECA.
  - The surfaces of walls, floors, fixtures, shelving, counters, and cabinets in the AECA must be cleanable.
  - Carpet is not allowed in the AECA.
  - Surfaces should be resistant to damage by cleaning and disinfecting agents.
  - The surfaces in the AECA upon which the allergenic extract prescription sets are prepared must be smooth, impervious, free from cracks and crevices, and non-shedding to allow for easy cleaning and disinfecting.
  - Dust-collecting overhangs such as utility pipes, ledges, and windowsills should be minimized. If overhangs or ledges are present, they must be easily cleanable.
  - The AECA must be designed and controlled to provide a well-lighted working environment, with temperature and humidity controls for the comfort of compounding personnel wearing the required garb.

**21.4 Cleaning and Disinfecting for Compounding Allergenic Extract Prescription Sets**

- In a PEC, all interior surfaces of the PEC must be cleaned and disinfected each day of use before compounding begins and when surface contamination is known or suspected. Apply sterile 70% IPA to the horizontal work surface between each prescription set.
- In an AECA, all work surfaces in the AECA where direct compounding is occurring must be cleaned and disinfected each day of use before compounding begins and when surface contamination is known or suspected. Apply sterile 70% IPA to the horizontal work surface between each prescription set.
  - If present, walls, doors, and door frames within the perimeter of the AECA must be cleaned and disinfected monthly and when surface contamination is known or suspected.
  - Ceilings within the perimeter of the AECA must be cleaned and disinfected when visibly soiled and when surface contamination is known or suspected.
- Vial stoppers on packages of conventionally manufactured sterile ingredients must be wiped with sterile 70% IPA to ensure that the critical sites are wet and allowed to dry before they are used to compound allergenic extract prescription sets.

**21.5 Establishing BUDs for Allergenic Extract Prescription Sets**

- The BUD for the prescription set must be no later than the earliest expiration date of any allergenic extract or any diluent that is part of the prescription set, and the BUD must not exceed 1 year from the date the prescription set is mixed or diluted.

**21.6 Labeling for Allergenic Extract Prescription Sets**

- The label of each vial of an allergenic extract prescription set must display the following prominently and understandably:
  - Patient name
  - Type and fractional dilution of each vial, with a corresponding vial number
  - BUD
  - Storage conditions

Unofficial

https://pharmacopeia.com/

**21.7 Shipping and Transporting Allergenic Extract Prescription Sets**

- If shipping or transporting allergenic extract prescription sets, compounding personnel must select modes of transport that are expected to deliver properly packed prescription sets in an undamaged, sterile, and stable condition. Inappropriate transport can adversely affect the quality of allergenic extract prescription sets.
- When shipping or transporting allergenic extract prescription sets that require special handling, personnel must include specific handling instructions on the exterior of the container.

**21.8 Documentation for Compounding Allergenic Extract Prescription Sets**

- All facilities where allergenic extract prescription sets are prepared must have and maintain written or electronic documentation to include, but not limited to, the following:
  - SOPs describing all aspects of the compounding process
  - Personnel training records, competency assessments, and qualification records including corrective actions for any failures
  - Certification reports of the PEC, if used, including corrective actions for any failures
  - Temperature logs for refrigerator(s)
  - CRs for individual allergenic extract prescription sets (see *Box 10*)
  - Information related to complaints and adverse events including corrective actions taken
  - Investigations and corrective actions

## GLOSSARY

**ACD:** Automated compounding device.
**ACPH:** Air changes per hour.
**Active pharmaceutical ingredient (API):** Any substance or mixture of substances intended to be used in the compounding of a preparation, thereby becoming the active ingredient in that preparation and furnishing pharmacological activity or other direct effect in the diagnosis, cure, mitigation, treatment, or prevention of disease in humans and animals or affecting the structure and function of the body. Also referred to as *Bulk drug substance*. A conventionally manufactured drug product is not an API but is typically manufactured from an API(s).
**Added substance:** An ingredient that is necessary to compound a preparation but is not intended or expected to cause a pharmacologic response if administered alone in the amount or concentration contained in a single dose of the compounded preparation. The term is used synonymously with the terms *inactive ingredient*, *excipient*, and *pharmaceutical ingredient*.
**Administration:** The direct application of a sterile product or preparation to a single patient by injecting, infusing, or otherwise providing a sterile product or preparation in its final form.
**Airlock:** A space with interlocked doors, constructed to maintain air pressure control when items move between two adjoining areas (generally with different air cleanliness standards). The intent of an airlock is to prevent ingress of particulate matter and microbial contamination from a lesser-controlled area.
**Alcohol-based hand rub:** An alcohol-containing preparation (liquid, gel, or foam) designed for application to the hands of healthcare personnel to inactivate microorganisms and/or temporarily suppress their growth. Such preparations may contain one or more types of alcohol, other active ingredients, excipients, and humectants.
**Allergenic extract:** A biological substance used for the diagnosis and/or treatment of allergic diseases such as allergic rhinitis, allergic sinusitis, allergic conjunctivitis, bee venom allergy, and food allergy.
**Allergenic extract compounding area (AECA):** A designated space, area, or room that is not required to be classified, with a visible perimeter that is suitable for preparation of allergenic extract prescription sets.
**Allergenic extract prescription set:** Combinations of licensed allergenic extracts that would be mixed and diluted to provide subcutaneous immunotherapy to an individual patient, even though these allergenic extract combinations are not specified in the approved BLAs for the licensed biological products.
**Anteroom:** An ISO Class 8 or cleaner room with fixed walls and doors where personnel hand hygiene, garbing procedures, and other activities that generate high particulate levels may be performed. The anteroom is the transition room between the unclassified area of the facility and the buffer room.
**Aseptic processing:** A method by which separate, sterile components (e.g., drugs, containers, or closures) are brought together under conditions that maintain their sterility. The components can either be purchased as sterile or, when starting with nonsterile components, can be separately sterilized prior to combining (e.g., by membrane filtration or by autoclave).
**Aseptic technique:** A set of methods used to keep objects and areas free of microorganisms and thereby minimize infection risk to the patient. It is accomplished through practices that maintain the microbe count at an irreducible minimum.
**Assigned trainer:** One or more individuals assigned by the designated person(s) to be responsible and accountable for directly providing the training, observation, and/or evaluation of personnel for the preparation of CSPs.
**Batch:** More than one CSP prepared as described in the MFR in a single, discrete process, and expected to have uniform character and quality, within specified limits.
**Beyond-use date (BUD):** The date, or hour and the date, after which a CSP must not be used, stored, or transported. The date is determined from the date and time the preparation is compounded.
**Biological safety cabinet (BSC):** A ventilated cabinet that may be used for compounding. These cabinets are divided into three general classes (Class I, Class II, and Class III). Class II BSCs are further divided into types (Type A1, Type A2, Type B1, Type B2, and Type C1).
**Biological safety cabinet (BSC), Class II:** A ventilated cabinet with an open front and inward and downward unidirectional HEPA-filtered airflow and HEPA-filtered exhaust. A BSC used to prepare a CSP must be capable of providing an ISO Class 5 or better environment for preparation of the CSPs.
**BLA:** Biological license application.

Official

**Blood components:** Any therapeutic constituent of blood separated by physical or mechanical means (e.g., white cells, red cells, platelets, plasma, serum). It is not intended to include plasma-derived products (e.g., albumin, coagulation factors, immunoglobulins) manufactured under an approved BLA or equivalent.
**BMBL:** Biosafety in Microbiological and Biomedical Laboratories.
**Buffer room:** An ISO Class 7 or cleaner room with fixed walls and doors where PEC(s) that generate and maintain an ISO Class 5 environment are physically located. The buffer room may only be accessed through the anteroom or another buffer room.
**Bulk drug substance:** See the entry for *Active pharmaceutical ingredient*.
**Category 1 CSP:** A CSP that is assigned a BUD of 12 h or less at controlled room temperature or 24 h or less refrigerated that is compounded in accordance with all applicable requirements for Category 1 CSPs in this chapter.
**Category 2 CSP:** A CSP that may be assigned a BUD of greater than 12 h at controlled room temperature or greater than 24 h refrigerated that is compounded in accordance with all applicable requirements for Category 2 CSPs in this chapter.
**Category 3 CSP:** A CSP that may be assigned a BUD exceeding the limits in *Table 13* for Category 2 CSPs and is compounded in accordance with all applicable requirements for Category 3 CSPs in this chapter.
**CDC:** Centers for Disease Control and Prevention.
**Certificate of analysis (COA):** A report from the supplier of a component, container, or closure that accompanies the supplier's material and contains the specifications and results of all analyses and a description of the material.
**CFU:** Colony-forming units.
**Classified area:** An area that maintains an air quality classification based on the ISO standards required in this chapter (see also the definition for *ISO class*).
**Cleaning:** The process of removing substances (e.g., organic and inorganic material) from objects and surfaces, normally accomplished by manually or mechanically using water with detergents or enzymatic products.
**Cleaning agent:** An agent, usually containing a surfactant, used for the removal of substances (e.g., dirt, debris, microbes, and residual drugs or chemicals) from surfaces.
**Cleanroom suite:** A classified area that consists of both an anteroom and buffer room.
**Component:** Any ingredient used in the compounding of a preparation, including any active ingredient, added substance, or conventionally manufactured product.
**Compounded sterile preparation (CSP):** A preparation intended to be sterile that is created by combining, admixing, diluting, pooling, reconstituting, repackaging, or otherwise altering a drug product or bulk drug substance.
**Compounded stock solution:** A sterile mixture of components that is used to compound additional CSPs.
**Compounding:** The process of combining, admixing, diluting, pooling, reconstituting, repackaging, or otherwise altering a drug product or bulk drug substance to create a sterile preparation.
**Compounding area:** The area where compounding is occurring (i.e., a cleanroom suite, inside the perimeter of the SCA, or AECA).
**Compounding aseptic containment isolator (CACI):** A type of RABS that uses HEPA filtration to provide an ISO Class 5 unidirectional air environment designed for the compounding of sterile HDs.
**Compounding aseptic isolator (CAI):** A type of RABS that uses HEPA filtration to provide an ISO Class 5 unidirectional air environment designed for compounding of sterile non-HDs.
**Compounding record (CR):** Documents the compounding of each CSP.
**Container closure system:** Packaging components that together contain and protect the dosage form. This includes primary packaging components and secondary packaging components, if the latter are intended to provide additional protection.
**Containment glove bag:** A single-use disposable glove bag that is capable of containing airborne chemical particles.
**Containment ventilated enclosure (CVE):** A non-ISO classified full or partial enclosure that uses ventilation principles to capture, contain, and remove airborne contaminants through HEPA filtration and prevent their release into the work environment.
**Conventionally manufactured product:** A pharmaceutical dosage form, usually the subject of an application approved by the applicable national regulatory agency, that is manufactured under current good manufacturing practice conditions.
**Critical site:** A location that includes any component or fluid pathway surfaces (e.g., vial septa, injection ports, and beakers) or openings (e.g., opened ampules and needle hubs) that are exposed and at risk of direct contact with air (e.g., ambient room or HEPA filtered), moisture (e.g., oral and mucosal secretions), or touch contamination.
**Designated person(s):** One or more individuals assigned to be responsible and accountable for the performance and operation of the facility and personnel as related to the preparation of CSPs.
**Direct compounding area (DCA):** A critical area within the ISO Class 5 PEC where critical sites are exposed to unidirectional HEPA-filtered air, also known as first air.
**Disinfectant:** A chemical or physical agent used on inanimate surfaces and objects to destroy fungi, viruses, and bacteria. Sporicidal disinfectants are considered a special class of disinfectants that also are effective against bacterial and fungal spores.
**Dynamic airflow smoke pattern test:** A PEC test in which a visible source of smoke, which is neutrally buoyant, is used to observe air patterns within the unidirectional space (i.e., the DCA) under dynamic operating conditions (see the entry for *Dynamic operating conditions*). This test is not appropriate for ISO Class 7 or ISO Class 8 cleanrooms that do not have unidirectional airflow (see the entry for *Visual smoke study*).
**Dynamic operating conditions:** Conditions in the compounding area in which operating personnel are present and simulating or performing compounding. The conditions should reflect the largest number of personnel and highest complexity of compounding expected during routine operations as determined by the designated person(s).
**ECV:** Endotoxin challenge vial.
**EPA:** US Environmental Protection Agency.
**Excipient:** See the entry for *Added substance*.
**FDA:** US Food and Drug Administration.
**Filter integrity test:** A test (e.g., bubble point test) of the integrity of a sterilizing grade filter performed after the filtration process to detect whether the integrity of the filter has been compromised.
**Final yield:** The total number of containers actually prepared at the end of the compounding process prior to release testing.

Official

https://pharmacopeia.com/

**First air:** The air exiting the HEPA filter in a unidirectional air stream.
**Formulation:** The specific qualitative and quantitative composition of the final CSP.
**Garb:** Items such as gloves, garments (e.g., gowns), shoe covers, head and facial hair covers, masks, and other items designed to reduce particle-shedding from personnel and minimize the risk of contamination of CSP(s).
**GFT:** Gloved fingertip and thumb sampling.
**Hazardous drug (HD):** Any drug identified by at least one of the following six criteria: carcinogenicity, teratogenicity or developmental toxicity, reproductive toxicity in humans, organ toxicity at low dose in humans or animals, genotoxicity, or new drugs that mimic existing HDs in structure or toxicity.
**High-efficiency particulate air (HEPA) filtration:** Being, using, or containing a filter designed to remove 99.97% of airborne particles measuring 0.3-micron or greater in diameter passing through it.
**HVAC:** Heating, ventilation, and air conditioning.
**Integrated vertical laminar flow zone (IVLFZ):** A designated ISO Class 5 area serving as the PEC within an ISO Class 7 or cleaner buffer room. In the IVLFZ, unidirectional airflow is created by placing HEPA filters over the entire surface of the worktables and by effective placement of air returns.
**IPA:** Isopropyl alcohol.
**ISO:** International Organization for Standardization.
**ISO class:** An air-quality classification from the International Organization for Standardization.
**Label:** The part of the labeling on the immediate container.
**Labeling:** All labels and other written, printed, or graphic matter on the immediate container or on or inside any packaging system or wrapper in which the article is enclosed, except any outer shipping container.
**Laminar airflow system (LAFS):** A device or zone within a buffer room that provides an ISO Class 5 or better air quality environment for sterile compounding. The system provides a unidirectional HEPA-filtered airflow.
**Laminar airflow workbench (LAFW):** A device that is a type of LAFS that provides an ISO Class 5 or better air quality environment for sterile compounding. The device provides a unidirectional HEPA-filtered airflow.
**Line of demarcation:** A visible line on the floor that separates the clean and dirty sides of the anteroom.
**Low-lint wiper:** A wiper exhibiting few, if any, fibers or other contamination, visible without magnification, which is separate from, or easily removed from, the wiper material in a dry condition.
**Master formulation record (MFR):** A detailed record of procedures that describes how the CSP is to be prepared.
**MEA:** Malt extract agar.
**Media-fill test:** A simulation used to qualify processes and personnel engaged in sterile compounding to ensure that the processes and personnel are able to prepare CSPs without contamination.
**Monograph:** A quality documentary standard within *USP–NF* that articulates the quality expectations for a medicine including for its identity, strength, purity, and performance. It also describes the tests to validate that a medicine and its ingredients meet these criteria.
**Multiple-dose container:** A container of sterile product for parenteral administration (e.g., injection or infusion) that is designed to contain more than one dose of the sterile product. A multiple-dose container is usually required to meet the antimicrobial effectiveness testing criteria. See ⟨659⟩, *Injection Packaging Systems, Multiple-dose container*.
**One-step disinfectant cleaner:** A product with an EPA-registered (or equivalent) claim that it can clean and disinfect a nonporous surface in the presence of light to moderate organic soiling without a separate cleaning step.
**Oversight:** The review, monitoring, and supervision of actions taken by personnel, bearing responsibility for those actions, and being available for consultation if and when needed even if not physically present.
**Pass-through chamber:** An enclosure with sealed doors on both sides that should be interlocked. The pass-through chamber is positioned between two spaces for the purpose of minimizing particulate transfer while moving materials from one space to another.
**Perimeter:** A visible demarcation (such as a door, walls, or visible marking on the floor) that defines the SCA or AECA.
**Pharmaceutical isolator:** An enclosure that provides HEPA-filtered ISO Class 5 unidirectional air operated at a continuously higher pressure than its surrounding environment and is decontaminated using an automated system. It uses only decontaminated interfaces or rapid transfer ports for materials transfer. [NOTE—A CAI or CACI is not a pharmaceutical isolator.]
**Pharmacy bulk package:** A conventionally manufactured sterile product for parenteral use that contains many single doses intended for use in a pharmacy admixture program. A pharmacy bulk package may either be used to prepare admixtures for infusion or, through a sterile transfer device, for filling sterile containers. See ⟨659⟩, *Injection Packaging Systems, Pharmacy bulk package*.
**Positive-pressure room:** A room that is maintained at higher pressure than the adjacent spaces, and therefore the net airflow is out of the room.
**PPE:** Personal protective equipment.
**Preservative:** A substance added to inhibit microbial growth.
**Primary engineering control (PEC):** A device or zone that provides an ISO Class 5 air quality environment for sterile compounding.
**Probability of a nonsterile unit (PNSU):** The probability of an item being nonsterile after it has been exposed to a verified sterilization process. A PNSU value can only be applied to terminal sterilization. [NOTE—This is also called the sterility assurance level (SAL).]
**Pyrogen:** A substance that induces a febrile reaction in a patient.
**Quality assurance (QA):** A system of procedures, activities, and oversight that ensures that the compounding process consistently meets quality standards.
**Quality control (QC):** The sampling, testing, and documentation of results that, taken together, ensure that specifications have been met before release of the CSP.
**Reconstitution:** The process of adding a diluent to a conventionally manufactured product to prepare a sterile solution or suspension.

@2024 USPC

**Release inspection and testing:** Visual inspection and testing performed to ensure that a preparation meets appropriate quality characteristics.

**Repackaging:** The act of removing a sterile product or preparation from its original primary container and placing it into another primary container, usually of smaller size without further manipulation.

**Restricted-access barrier system (RABS):** An enclosure that provides HEPA-filtered ISO Class 5 unidirectional air that allows for the ingress and/or egress of materials through defined openings that have been designed and validated to preclude the transfer of contamination, and that generally are not to be opened during operations. Examples of RABS include CAIs and CACIs.

**SDA:** Sabouraud dextrose agar.

**Secondary engineering control (SEC):** The area where the PEC is placed (e.g., a cleanroom suite or an SCA). It incorporates specific design and operational parameters required to minimize the risk of contamination within the compounding area.

**Segregated compounding area (SCA):** A designated space, area, or room that is not required to be classified and is defined with a visible perimeter. The SCA must contain a PEC and is suitable for preparation of Category 1 CSPs only.

**Single-dose containers:** A container of sterile product for parenteral administration (e.g., injection or infusion) that is designed for use with a single patient as a single injection/infusion. A single-dose container usually does not contain a preservative. See ⟨659⟩, *Injection Packaging Systems, Single-dose container*.

**SOP:** Standard operating procedure.

**Specification:** The tests, analytical methods, and acceptance criteria to which any component, CSP, container closure system, equipment, or other material used in compounding CSPs must conform to be considered acceptable for its intended use.

**Sporicidal disinfectant:** A chemical or physical agent that destroys bacterial and fungal spores when used in sufficient concentration for a specified contact time. It is expected to kill all vegetative microorganisms.

**Stability:** The extent to which a product or preparation retains physical and chemical properties and characteristics within specified limits throughout its expiration or BUD.

**Sterility:** The absence of viable microorganisms.

**Sterility assurance level (SAL):** See the entry for *Probability of a nonsterile unit* (PNSU).

**Sterilization by filtration:** Passage of a gas or liquid through a sterilizing-grade membrane to yield filtrates that are sterile.

**Sterilizing-grade filter:** Filter membranes that are documented to retain 100% of a culture of $10^7$ microorganisms of a strain of *Brevundimonas diminuta* per square centimeters of membrane surface under a pressure of not less than 30 psi. Such filter membranes are nominally 0.22- or 0.2-µm pore size.

**Terminal sterilization:** The application of a lethal process (e.g., steam, dry heat, irradiation) to sealed containers for the purpose of achieving a predetermined PNSU of greater than $10^{-6}$ or a probability of less than one in one million of a nonsterile unit.

**TSA:** Trypticase soy agar.

**Unclassified space:** A space not required to meet any air cleanliness classification based on the ISO.

**Unidirectional airflow:** Air within a PEC moving in a single direction in a uniform manner and at sufficient velocity to sweep particles away from the DCA.

**Verify:** To confirm that a method, process, system, or equipment will perform as expected under the conditions of actual use.

**Visual smoke study:** A test, used in ISO Class 7 and ISO Class 8 rooms that do not have unidirectional airflow, in which a visible source of smoke, which is neutrally buoyant, is used to verify an absence of stagnant airflow. This test does not need to be performed under dynamic operating conditions and is not appropriate for PECs (see the entry for *Dynamic airflow smoke pattern test*).

**Workflow management system:** Technology comprised of hardware and/or software that allows for automation to assist in the verification of components of, and preparation of, CSPs and to document components and processes.▲ (Official 1-Nov-2023)

# ⟨800⟩ HAZARDOUS DRUGS—HANDLING IN HEALTHCARE SETTINGS

## 1. INTRODUCTION AND SCOPE

This chapter describes practice and quality standards for handling hazardous drugs (HDs) to promote patient safety, worker safety, and environmental protection. Handling HDs includes, but is not limited to, the receipt, storage, compounding, dispensing, administration, and disposal of sterile and nonsterile products and preparations.

This chapter applies to all healthcare personnel who handle HD preparations and all entities that store, prepare, transport, or administer HDs (e.g., pharmacies, hospitals and other healthcare institutions, patient treatment clinics, physicians' practice facilities, or veterinarians' offices). Personnel who may potentially be exposed to HDs include, but are not limited to: pharmacists, pharmacy technicians, nurses, physicians, physician assistants, home healthcare workers, veterinarians, and veterinary technicians.

Entities that handle HDs must incorporate the standards in this chapter into their occupational safety plan. The entity's health and safety management system must, at a minimum, include:

- A list of HDs
- Facility and engineering controls
- Competent personnel
- Safe work practices
- Proper use of appropriate Personal Protective Equipment (PPE)
- Policies for HD waste segregation and disposal

The chapter is organized into the following main sections:

1. Introduction and Scope
2. List of Hazardous Drugs
3. Types of Exposure
4. Responsibilities of Personnel Handling Hazardous Drugs
5. Facilities and Engineering Controls
6. Environmental Quality and Control
7. Personal Protective Equipment
8. Hazard Communication Program
9. Personnel Training
10. Receiving
11. Labeling, Packaging, Transport, and Disposal
12. Dispensing Final Dosage Forms
13. Compounding
14. Administering
15. Deactivating, Decontaminating, Cleaning, and Disinfecting
16. Spill Control
17. Documentation and Standard Operating Procedures
18. Medical Surveillance

Glossary

Appendices

Appendix 1: Acronyms
Appendix 2: Examples of Designs for Hazardous Drug Compounding Areas
Appendix 3: Types of Biological Safety Cabinets

References

***Change to read:***

## 2. LIST OF HAZARDOUS DRUGS

The National Institute for Occupational Safety and Health (NIOSH) maintains a list of antineoplastic and other HDs used in healthcare. ▲For the purposes of this chapter, the term antineoplastic only refers to antineoplastic drugs included in Table 1 of the most current NIOSH List.▲ (RB 1-Jul-2020) An entity must maintain a list of HDs, which must include any items on the current NIOSH list that the entity handles. The entity's list must be reviewed at least every 12 months. Whenever a new agent or dosage form is used, it should be reviewed against the entity's list.

The NIOSH list of antineoplastic and other HDs provides the criteria used to identify HDs. These criteria must be used to identify HDs that enter the market after the most recent version of the NIOSH list, or that the entity handles as an investigational drug. If the information available on a drug is deemed insufficient to make an informed decision, consider the drug hazardous until more information is available.

DOI Ref: ifp62
DocId: GUID-5D76173F-5CB6-47B8-815E-7C275A916085_7_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M7808_07_01
@2024 USPC

**Box 1: Containment Requirements**

- Drugs on the NIOSH list that must follow the requirements in this chapter include:
  - Any HD API
  - Any antineoplastic requiring HD manipulation
- Drugs on the NIOSH list that do not have to follow all the containment requirements of this chapter if an assessment of risk is performed and implemented include:
  - Final dosage forms of compounded HD preparations and conventionally manufactured HD products, including antineoplastic dosage forms that do not require any further manipulation other than counting or repackaging (unless required by the manufacturer)
- For dosage forms of other HDs on the NIOSH list, the entity may perform an assessment of risk to determine alternative containment strategies and/work practices

Some dosage forms of drugs defined as hazardous may not pose a significant risk of direct occupational exposure because of their dosage formulation (e.g., tablets or capsules—solid, intact medications that are administered to patients without modifying the formulation). However, dust from tablets and capsules may present a risk of exposure by skin contact and/or inhalation. An assessment of risk may be performed for these dosage forms to determine alternative containment strategies and/or work practices. If an assessment of risk is not performed, all HDs must be handled with all containment strategies defined in this chapter.

The assessment of risk must, at a minimum, consider the following:

- Type of HD (e.g., antineoplastic, non-antineoplastic, reproductive risk only)
- Dosage form
- Risk of exposure
- Packaging
- Manipulation

If an assessment of risk approach is taken, the entity must document what alternative containment strategies and/or work practices are being employed for specific dosage forms to minimize occupational exposure. If used, the assessment of risk must be reviewed at least every 12 months and the review documented.

## 3. TYPES OF EXPOSURE

Routes of unintentional entry of HDs into the body include dermal and mucosal absorption, inhalation, injection, and ingestion (e.g., contaminated foodstuffs, spills, or mouth contact with contaminated hands). Containers of HDs have been shown to be contaminated upon receipt. Both clinical and nonclinical personnel may be exposed to HDs when they handle HDs or touch contaminated surfaces. *Table 1* lists examples of potential routes of exposure based on activity.

**Table 1. Examples of Potential Opportunities of Exposure Based on Activity**

| Activity | Potential Opportunity of Exposure |
|---|---|
| Receipt | • Contacting HD residues present on drug containers, individual dosage units, outer containers, work surfaces, or floors |
| Dispensing | • Counting or repackaging tablets and capsules |
| Compounding and other manipulations | • Crushing or splitting tablets or opening capsules<br>• Pouring oral or topical liquids from one container to another<br>• Weighing or mixing components<br>• Constituting or reconstituting powdered or lyophilized HDs<br>• Withdrawing or diluting injectable HDs from parenteral containers<br>• Expelling air or HDs from syringes<br>• Contacting HD residue present on PPE or other garments<br>• Deactivating, decontaminating, cleaning, and disinfecting areas contaminated with or suspected to be contaminated with HDs<br>• Maintenance activities for potentially contaminated equipment and devices |
| Administration | • Generating aerosols during administration of HDs by various routes (e.g., injection, irrigation, oral, inhalation, or topical application)<br>• Performing certain specialized procedures (e.g., intraoperative intraperitoneal injection or bladder instillation)<br>• Priming an IV administration set |
| Patient-care activities | • Handling body fluids (e.g., urine, feces, sweat, or vomit) or body-fluid-contaminated clothing, dressings, linens, and other materials |
| Spills | • Spill generation, management, and disposal |
| Transport | • Moving HDs within a healthcare setting |
| Waste | • Collection and disposal of hazardous waste and trace contaminated waste |

## 4. RESPONSIBILITIES OF PERSONNEL HANDLING HAZARDOUS DRUGS

Each entity must have a designated person who is qualified and trained to be responsible for developing and implementing appropriate procedures; overseeing entity compliance with this chapter and other applicable laws, regulations, and standards; ensuring competency of personnel; and ensuring environmental control of the storage and compounding areas. The designated

Official

https://pharmacopeia.com/

person must thoroughly understand the rationale for risk-prevention policies, risks to themselves and others, risks of non-compliance that may compromise safety, and the responsibility to report potentially hazardous situations to the management team. The designated person must also be responsible for the oversight of monitoring the facility and maintaining reports of testing/sampling performed in facilities, and acting on the results.

All personnel who handle HDs are responsible for understanding the fundamental practices and precautions and for continually evaluating these procedures and the quality of final HDs to prevent harm to patients, minimize exposure to personnel, and minimize contamination of the work and patient-care environment.

## 5. FACILITIES AND ENGINEERING CONTROLS

HDs must be handled under conditions that promote patient safety, worker safety, and environmental protection. Signs designating the hazard must be prominently displayed before the entrance to the HD handling areas. Access to areas where HDs are handled must be restricted to authorized personnel to protect persons not involved in HD handling. HD handling areas must be located away from breakrooms and refreshment areas for personnel, patients, or visitors to reduce risk of exposure.

Designated areas must be available for:

- Receipt and unpacking
- Storage of HDs
- Nonsterile HD compounding (if performed by the entity)
- Sterile HD compounding (if performed by the entity)

Certain areas are required to have negative pressure from surrounding areas to contain HDs and minimize risk of exposure. Consideration should be given to uninterrupted power sources (UPS) for the ventilation systems to maintain negative pressure in the event of power loss.

### 5.1 Receipt

Antineoplastic HDs and all HD APIs must be unpacked (i.e., removal from external shipping containers) in an area that is neutral/normal or negative pressure relative to the surrounding areas. HDs must not be unpacked from their external shipping containers in sterile compounding areas or in positive pressure areas.

### 5.2 Storage

HDs must be stored in a manner that prevents spillage or breakage if the container falls. Do not store HDs on the floor. In areas prone to specific types of natural disasters (e.g., earthquakes) the manner of storage must meet applicable safety precautions, such as secure shelves with raised front lips.

Antineoplastic HDs requiring manipulation other than counting or repackaging of final dosage forms and any HD API must be stored separately from non-HDs in a manner that prevents contamination and personnel exposure. These HDs must be stored in an externally ventilated, negative-pressure room with at least 12 air changes per hour (ACPH). Non-antineoplastic, reproductive risk only, and final dosage forms of antineoplastic HDs may be stored with other inventory if permitted by entity policy.

Sterile and nonsterile HDs may be stored together, but HDs used for nonsterile compounding should not be stored in areas designated for sterile compounding to minimize traffic into the sterile compounding area.

Refrigerated antineoplastic HDs must be stored in a dedicated refrigerator in a negative pressure area with at least 12 ACPH [e.g., storage room, buffer room, or containment segregated compounding area (C-SCA)]. If a refrigerator is placed in a negative pressure buffer room, an exhaust located adjacent to the refrigerator's compressor and behind the refrigerator should be considered.

### 5.3 Compounding

Engineering controls are required to protect the preparation from cross-contamination and microbial contamination (if preparation is intended to be sterile) during all phases of the compounding process. Engineering controls for containment are divided into three categories representing primary, secondary, and supplementary levels of control. A containment primary engineering control (C-PEC) is a ventilated device designed to minimize worker and environmental HD exposure when directly handling HDs. The containment secondary engineering control (C-SEC) is the room in which the C-PEC is placed. Supplemental engineering controls [e.g., closed-system drug-transfer device (CSTD)] are adjunct controls to offer additional levels of protection. *Appendix 2* provides examples for designs of HD compounding areas.

Sterile and nonsterile HDs must be compounded within a C-PEC located in a C-SEC. The C-SEC used for sterile and nonsterile compounding must:

- Be externally vented
- Be physically separated (i.e., a different room from other preparation areas)
- Have an appropriate air exchange (e.g., ACPH)
- Have a negative pressure between 0.01 and 0.03 inches of water column relative to all adjacent areas

The C-PEC must operate continuously if it supplies some or all of the negative pressure in the C-SEC or if it is used for sterile compounding. If there is any loss of power to the C-PEC, or if repair or moving occurs, all activities occurring in the C-PEC must be suspended immediately. If necessary, protect the unit by covering it appropriately per the manufacturer's recommendations. Once the C-PEC can be powered on, decontaminate, clean, and disinfect (if used for sterile compounding) all surfaces and wait the manufacturer-specified recovery time before resuming compounding.

@2024 USPC

A sink must be available for hand washing. An eyewash station and/or other emergency or safety precautions that meet applicable laws and regulations must be readily available. Care must be taken to locate water sources and drains in areas where their presence will not interfere with required ISO classifications. Water sources and drains must be located at least 1 meter away from the C-PEC.

For entities that compound both nonsterile and sterile HDs, the respective C-PECs must be placed in separate rooms, unless those C-PECs used for nonsterile compounding are sufficiently effective that the room can continuously maintain ISO 7 classification throughout the nonsterile compounding activity. If the C-PECs used for sterile and nonsterile compounding are placed in the same room, they must be placed at least 1 meter apart and particle-generating activity must not be performed when sterile compounding is in process.

### 5.3.1 NONSTERILE COMPOUNDING

In addition to this chapter, nonsterile compounding must follow standards in *Pharmaceutical Compounding—Nonsterile Preparations* ⟨795⟩. A C-PEC is not required if manipulations are limited to handling of final dosage forms (e.g., counting or repackaging of tablets and capsules) that do not produce particles, aerosols, or gasses.

The C-PECs used for manipulation of nonsterile HDs must be either externally vented (preferred) or have redundant–HEPA filters in series. Nonsterile HD compounding must be performed in a C-PEC that provides personnel and environmental protection, such as a Class I Biological Safety Cabinet (BSC) or Containment Ventilated Enclosure (CVE). A Class II BSC or a compounding aseptic containment isolator (CACI) may also be used. For occasional nonsterile HD compounding, a C-PEC used for sterile compounding (e.g., Class II BSC or CACI) may be used but must be decontaminated, cleaned, and disinfected before resuming sterile compounding in that C-PEC. A C-PEC used only for nonsterile compounding does not require unidirectional airflow because the critical environment does not need to be ISO classified.

The C-PEC must be placed in a C-SEC that has at least 12 ACPH. *Table 2* summarizes the engineering controls required for nonsterile HD compounding.

Due to the difficulty of cleaning HD contamination, surfaces of ceilings, walls, floors, fixtures, shelving, counters, and cabinets in the nonsterile compounding area must be smooth, impervious, free from cracks and crevices, and non-shedding.

**Table 2. Engineering Controls for Nonsterile HD Compounding**

| C-PEC | C-SEC Requirements |
|---|---|
| • Externally vented (preferred) or redundant–HEPA filtered in series<br>• Examples: CVE, Class I or II BSC, CACI | • Externally vented<br>• 12 ACPH<br>• Negative pressure between 0.01 and 0.03 inches of water column relative to adjacent areas |

### 5.3.2 STERILE COMPOUNDING

In addition to this chapter, sterile compounding must follow standards in ⟨797⟩.

All C-PECs used for manipulation of sterile HDs must be externally vented. Sterile HD compounding must be performed in a C-PEC that provides an ISO Class 5 or better air quality, such as a Class II or III BSC or CACI. Class II BSC types A2, B1, or B2 are acceptable. For most known HDs, type A2 cabinets offer a simple and reliable integration with the ventilation and pressurization requirements of the C-SEC. Class II type B2 BSCs are typically reserved for use with volatile components. *Appendix 3* describes the different types of BSCs.

A laminar airflow workbench (LAFW) or compounding aseptic isolator (CAI) must not be used for the compounding of an antineoplastic HD. A BSC or CACI used for the preparation of HDs must not be used for the preparation of a non-HD unless the non-HD preparation is placed into a protective outer wrapper during removal from the C-PEC and is labeled to require PPE handling precautions.

The C-PEC must be located in a C-SEC, which may either be an ISO Class 7 buffer room with an ISO Class 7 ante-room (preferred) or an unclassified containment segregated compounding area (C-SCA). If the C-PEC is placed in a C-SCA, the beyond-use date (BUD) of all compounded sterile preparations (CSPs) prepared must be limited as described in ⟨797⟩ for CSPs prepared in a segregated compounding area. *Table 3* summarizes the engineering controls required for sterile HD compounding.

**Table 3. Engineering Controls for Sterile HD Compounding**

| Configuration | C-PEC | C-SEC | Maximum BUD |
|---|---|---|---|
| ISO Class 7 buffer room with an ISO Class 7 ante-room | • Externally vented<br>• Examples: Class II BSC or CACI | • Externally vented<br>• 30 ACPH<br>• Negative pressure between 0.01 and 0.03 inches of water column relative to adjacent areas | As described in ⟨797⟩ |
| Unclassified C-SCA | • Externally vented<br>• Examples: Class II BSC or CACI | • Externally vented<br>• 12 ACPH<br>• Negative pressure between 0.01 and 0.03 inches of water column relative to adjacent areas | As described in ⟨797⟩ for CSPs prepared in a segregated compounding area |

**ISO Class 7 buffer room with an ISO class 7 ante-room:** The C-PEC is placed in an ISO Class 7 buffer room that has fixed walls, HEPA-filtered supply air, a negative pressure between 0.01 and 0.03 inches of water column relative to all adjacent areas and a minimum of 30 ACPH.

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Jul-2020
DOI Ref: ifp62
DocId: GUID-5D76173F-5CB6-47B8-815E-7C275A916085_7_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M7808_07_01

The buffer room must be externally vented. Because the room through which entry into the HD buffer room (e.g., ante-room or non-HD buffer room) plays an important role in terms of total contamination control, the following is required:

- Minimum of 30 ACPH of HEPA-filtered supply air
- Maintain a positive pressure of at least 0.02 inches of water column relative to all adjacent unclassified areas
- Maintain an air quality of ISO Class 7 or better

An ISO Class 7 ante-room with fixed walls is necessary to provide inward air migration of equal cleanliness classified air into the negative pressure buffer room to contain any airborne HD. A hand-washing sink must be placed in the ante-room at least 1 meter from the entrance to the HD buffer room to avoid contamination migration into the negative pressure HD buffer room.

Although not a recommended facility design, if the negative-pressure HD buffer room is entered though the positive-pressure non-HD buffer room, the following is also required:

- A line of demarcation must be defined within the negative-pressure buffer room for donning and doffing PPE
- A method to transport HDs, HD CSPs, and HD waste into and out of the negative pressure buffer room to minimize the spread of HD contamination. This may be accomplished by use of a pass-through chamber between the negative-pressure buffer area and adjacent space. The pass-through chamber must be included in the facility's certification to ensure that particles are not compromising the air quality of the negative-pressure buffer room. A refrigerator pass-through must not be used. Other methods of containment (such as sealed containers) may be used.

HD CSPs prepared in an ISO Class 7 buffer room with an ISO Class 7 ante-room may use the BUDs described in ⟨797⟩, based on the categories of CSP, sterility testing, and storage temperature.

**Containment segregated compounding area (C-SCA):** The C-PEC is placed in an unclassified C-SCA that has fixed walls, a negative pressure between 0.01 and 0.03 inches of water column relative to all adjacent areas, and a minimum of 12 ACPH. The C-SCA must be externally vented. A hand-washing sink must be placed at least 1 meter from C-PEC and may be either inside the C-SCA or directly outside the C-SCA.

Only low- and medium-risk HD CSPs may be prepared in a C-SCA. HD CSPs prepared in the C-SCA must not exceed the BUDs described in ⟨797⟩ for CSPs prepared in a segregated compounding area.

### 5.4 Containment Supplemental Engineering Controls

Containment supplemental engineering controls, such as CSTDs, provide adjunct controls to offer an additional level of protection during compounding or administration. Some CSTDs have been shown to limit the potential of generating aerosols during compounding. However, there is no certainty that all CSTDs will perform adequately. Until a published universal performance standard for evaluation of CSTD containment is available, users should carefully evaluate the performance claims associated with available CSTDs based on independent, peer-reviewed studies and demonstrated contamination reduction.

A CSTD must not be used as a substitute for a C-PEC when compounding. CSTDs should be used when compounding HDs when the dosage form allows. CSTDs must be used when administering antineoplastic HDs when the dosage form allows. CSTDs known to be physically or chemically incompatible with a specific HD must not be used for that HD.

## 6. ENVIRONMENTAL QUALITY AND CONTROL

Environmental wipe sampling for HD surface residue should be performed routinely (e.g., initially as a benchmark and at least every 6 months, or more often as needed, to verify containment). Surface wipe sampling should include:

- Interior of the C-PEC and equipment contained in it
- Pass-through chambers
- Surfaces in staging or work areas near the C-PEC
- Areas adjacent to C-PECs (e.g., floors directly under C-PEC, staging, and dispensing area)
- Areas immediately outside the HD buffer room or the C-SCA
- Patient administration areas

There are currently no studies demonstrating the effectiveness of a specific number or size of wipe samples in determining levels of HD contamination. Wipe sampling kits should be verified before use to ensure the method and reagent used have been tested to recover a specific percentage of known marker drugs from various surface types found in the sampled area. There are currently no certifying agencies for vendors of wipe sample kits.

There is currently no standard for acceptable limits for HD surface contamination. Common marker HDs that can be assayed include cyclophosphamide, ifosfamide, methotrexate, fluorouracil, and platinum-containing drugs. An example of measurable contamination would be cyclophosphamide levels >1.00 ng/cm$^2$, which were shown in some studies to result in uptake of the drug in exposed workers. If any measurable contamination is found, the designated person must identify, document, and contain the cause of contamination. Such action may include reevaluating work practices, re-training personnel, performing thorough deactivation, decontamination, cleaning, and improving engineering controls. Repeat the wipe sampling to validate that the deactivation/decontamination and cleaning steps have been effective.

## 7. PERSONAL PROTECTIVE EQUIPMENT

Personal Protective Equipment (PPE) provides worker protection to reduce exposure to HD aerosols and residues. Additional PPE may be required to handle the HDs outside of a C-PEC, such as treating a patient or cleaning a spill. The NIOSH list of antineoplastic and other HDs provides general guidance on PPE for possible scenarios that may be encountered in healthcare settings. Disposable PPE must not be re-used. Reusable PPE must be decontaminated and cleaned after use.

Official

https://pharmacopeia.cn/

Gowns, head, hair, shoe covers, and two pairs of chemotherapy gloves are required for compounding sterile and nonsterile HDs. Two pairs of chemotherapy gloves are required for administering injectable antineoplastic HDs. Gowns shown to resist permeability by HDs are required when administering injectable antineoplastic HDs. For all other activities, the entity's SOP must describe the appropriate PPE to be worn based on its occupational safety plan and assessment of risk (if used). The entity must develop SOPs for PPE based on the risk of exposure (see *Types of Exposure*) and activities performed.

Appropriate PPE must be worn when handling HDs including during:

- Receipt
- Storage
- Transport
- Compounding (sterile and nonsterile)
- Administration
- Deactivation/decontamination, cleaning, and disinfecting
- Spill control
- Waste disposal

## 7.1 Gloves

When chemotherapy gloves are required, they must meet American Society for Testing and Materials (ASTM) standard D6978 (or its successor). Chemotherapy gloves should be worn for handling all HDs including non-antineoplastics and for reproductive risk only HDs. Chemotherapy gloves must be powder-free because powder can contaminate the work area and can adsorb and retain HDs. Gloves must be inspected for physical defects before use. Do not use gloves with pin holes or weak spots.

When used for sterile compounding, the outer chemotherapy gloves must be sterile. Chemotherapy gloves should be changed every 30 minutes unless otherwise recommended by the manufacturer's documentation and must be changed when torn, punctured, or contaminated. Hands must be washed with soap and water after removing gloves.

## 7.2 Gowns

When gowns are required, they must be disposable and shown to resist permeability by HDs. Gowns must be selected based on the HDs handled. Disposable gowns made of polyethylene-coated polypropylene or other laminate materials offer better protection than those made of uncoated materials. Gowns must close in the back (i.e., no open front), be long sleeved, and have closed cuffs that are elastic or knit. Gowns must not have seams or closures that could allow HDs to pass through.

Cloth laboratory coats, surgical scrubs, isolation gowns, or other absorbent materials are not appropriate protective outerwear when handling HDs because they permit the permeation of HDs and can hold spilled drugs against the skin, thereby increasing exposure. Clothing may also retain HD residue from contact, and may transfer to other healthcare workers or various surfaces. Washing of non-disposable clothing contaminated with HD residue should only be done according to facility policy as drug residue may be transferred to other clothing. Potentially contaminated clothing must not be taken home under any circumstances.

Gowns must be changed per the manufacturer's information for permeation of the gown. If no permeation information is available for the gowns used, change them every 2–3 hours or immediately after a spill or splash. Gowns worn in HD handling areas must not be worn to other areas in order to avoid spreading HD contamination and exposing other healthcare workers.

## 7.3 Head, Hair, Shoe, and Sleeve Covers

Head and hair covers (including beard and moustache, if applicable), shoe covers, and sleeve covers provide protection from contact with HD residue. When compounding HDs, a second pair of shoe covers must be donned before entering the C-SEC and doffed when exiting the C-SEC. Shoe covers worn in HD handling areas must not be worn to other areas to avoid spreading HD contamination and exposing other healthcare workers.

Disposable sleeve covers may be used to protect areas of the arm that may come in contact with HDs. Disposable sleeve covers made of polyethylene-coated polypropylene or other laminate materials offer better protection than those made of uncoated materials.

## 7.4 Eye and Face Protection

Many HDs are irritating to the eyes and mucous membranes. Appropriate eye and face protection must be worn when there is a risk for spills or splashes of HDs or HD waste materials when working outside of a C-PEC (e.g., administration in the surgical suite, working at or above eye level, or cleaning a spill). A full-facepiece respirator provides eye and face protection. Goggles must be used when eye protection is needed. Eye glasses alone or safety glasses with side shields do not protect the eyes adequately from splashes. Face shields in combination with goggles provide a full range of protection against splashes to the face and eyes. Face shields alone do not provide full eye and face protection.

## 7.5 Respiratory Protection

Personnel who are unpacking HDs that are not contained in plastic should wear an elastomeric half-mask with a multi-gas cartridge and P100-filter until assessment of the packaging integrity can be made to ensure no breakage or spillage occurred during transport. If the type of drug can be better defined, a more targeted cartridge can be used.

https://pharmacopeia.cn/
Printed on: Fri Jan 05 2024 06:33:52 AM(EST)
Printed by: USP NF
Do Not Distribute

Surgical masks do not provide respiratory protection from drug exposure and must not be used when respiratory protection from HD exposure is required. A surgical N95 respirator provides the respiratory protection of an N95 respirator, and like a surgical mask, provides a barrier to splashes, droplets, and sprays around the nose and mouth.

For most activities requiring respiratory protection, a fit-tested NIOSH-certified N95 or more protective respirator is sufficient to protect against airborne particles. However, N95 respirators offer no protection against gases and vapors and little protection against direct liquid splashes (see the Centers for Disease Control and Prevention's (CDC's) Respirator Trusted-Source Information).

Fit test the respirator and train workers to use respiratory protection. Follow all requirements in the Occupational Safety and Health Administration (OSHA) respiratory protection standard (29 CFR 1910.134). An appropriate full-facepiece, chemical cartridge-type respirator or powered air-purifying respirator (PAPR) should be worn when there is a risk of respiratory exposure to HDs, including when:

- Attending to HD spills larger than what can be contained with a spill kit
- Deactivating, decontaminating, and cleaning underneath the work surface of a C-PEC
- There is a known or suspected airborne exposure to powders or vapors

### 7.6 Disposal of Used Personal Protective Equipment

Consider all PPE worn when handling HDs to be contaminated with, at minimum, trace quantities of HDs. PPE must be placed in an appropriate waste container and further disposed of per local, state, and federal regulations. PPE worn during compounding should be disposed of in the proper waste container before leaving the C-SEC. Chemotherapy gloves and sleeve covers (if used) worn during compounding must be carefully removed and discarded immediately into a waste container approved for trace contaminated waste inside the C-PEC or contained in a sealable bag for discarding outside the C-PEC.

## 8. HAZARD COMMUNICATION PROGRAM

Entities are required to establish policies and procedures that ensure worker safety during all aspects of HD handling. The entity must develop SOPs to ensure effective training regarding proper labeling, transport, storage, and disposal of the HDs and use of Safety Data Sheets (SDS), based on the Globally Harmonized System of Classification and Labeling of Chemicals (GHS).

Elements of the hazard communication program plan must include:

- A written plan that describes how the standard will be implemented
- All containers of hazardous chemicals must be labeled, tagged, or marked with the identity of the material and appropriate hazard warnings
- Entities must have an SDS for each hazardous chemical they use (29 CFR 1910.1200)
- Entities must ensure that the SDSs for each hazardous chemical used are readily accessible to personnel during each work shift and when they are in their work areas
- Personnel who may be exposed to hazardous chemicals when working must be provided information and training before the initial assignment to work with a hazardous chemical, and also whenever the hazard changes
- Personnel of reproductive capability must confirm in writing that they understand the risks of handling HDs

## 9. PERSONNEL TRAINING

All personnel who handle HDs must be trained based on their job functions (e.g., in the receipt, storage, compounding, repackaging, dispensing, administrating, and disposing of HDs). Training must occur before the employee independently handles HDs. The effectiveness of training for HD handling competencies must be demonstrated by each employee. Personnel competency must be reassessed at least every 12 months. Personnel must be trained prior to the introduction of a new HD or new equipment and prior to a new or significant change in process or SOP. All training and competency assessment must be documented.

The training must include at least the following:

- Overview of entity's list of HDs and their risks
- Review of the entity's SOPs related to handling of HDs
- Proper use of PPE
- Proper use of equipment and devices (e.g., engineering controls)
- Response to known or suspected HD exposure
- Spill management
- Proper disposal of HDs and trace-contaminated materials

## 10. RECEIVING

The entity must establish SOPs for receiving HDs. HDs should be received from the supplier in impervious plastic to segregate them from other drugs and to allow for safety in the receiving and internal transfer process. HDs must be delivered to the HD storage area immediately after unpacking.

PPE, including chemotherapy gloves, must be worn when unpacking HDs (see *Personal Protective Equipment*). A spill kit must be accessible in the receiving area.

Official

Do Not Distribute
Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Jul-2020
DOI Ref: ifp62
DocId: GUID-5D76173F-5CB6-47B8-815E-7C275A916085_7_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M7808_07_01
@2024 USPC

The entity must enforce policies that include a tiered approach, starting with visual examination of the shipping container for signs of damage or breakage (e.g., visible stains from leakage, sounds of broken glass). *Table 4* summarizes the steps for receiving and handling of damaged shipping containers.

**Table 4. Summary of Requirements for Receiving and Handling Damaged HD Shipping Containers**

| | |
|---|---|
| If the shipping container appears damaged | • Seal container without opening and contact the supplier<br>• If the unopened package is to be returned to the supplier, enclose the package in an impervious container and label the outer container "Hazardous"<br>• If the supplier declines return, dispose of as hazardous waste |
| If a damaged shipping container must be opened | • Seal the container in plastic or an impervious container<br>• Transport it to a C-PEC and place on a plastic-backed preparation mat<br>• Open the package and remove undamaged items<br>• Wipe the outside of the undamaged items with a disposable wipe<br>• Enclose the damaged item(s) in an impervious container and label the outer container "Hazardous"<br>• If the supplier declines return, dispose of as hazardous waste<br>• Deactivate, decontaminate, and clean the C-PEC (see *Deactivating, Decontaminating, Cleaning, and Disinfecting*) and discard the mat and cleaning disposables as hazardous waste |

When opening damaged shipping containers, they should preferably be transported to a C-PEC designated for nonsterile compounding. If a C-PEC designated for sterile compounding is the only one available, it must be disinfected after the decontamination, deactivation, and cleaning step before returning to any sterile compounding activity.

Damaged packages or shipping cartons must be considered spills that must be reported to the designated person and managed according to the entity's SOPs. Segregate HDs waiting to be returned to the supplier in a designated negative pressure area. Clean-up must comply with established SOPs.

## 11. LABELING, PACKAGING, TRANSPORT AND DISPOSAL

The entity must establish SOPs for the labeling, packaging, transport, and disposal of HDs. The SOPs must address prevention of accidental exposures or spills, personnel training on response to exposure, and use of a spill kit. Examples of special exposure-reducing strategies include small-bore connectors (such as Luer Lock) and syringes, syringe caps, CSTDs, the capping of container ports, sealed impervious plastic bags, impact-resistant and/or water-tight containers, and cautionary labeling.

### 11.1 Labeling

HDs identified by the entity as requiring special HD handling precautions must be clearly labeled at all times during their transport. Personnel must ensure that the labeling processes for compounded preparations do not introduce contamination into the non-HD handling areas.

### 11.2 Packaging

Personnel must select and use packaging containers and materials that will maintain physical integrity, stability, and sterility (if needed) of the HDs during transport. Packaging materials must protect the HD from damage, leakage, contamination, and degradation, while protecting healthcare workers who transport HDs. The entity must have written SOPs to describe appropriate shipping containers and insulating materials, based on information from product specifications, vendors, and mode of transport.

### 11.3 Transport

HDs that need to be transported must be labeled, stored, and handled in accordance with applicable federal, state, and local regulations. HDs must be transported in containers that minimize the risk of breakage or leakage. Pneumatic tubes must not be used to transport any liquid HDs or any antineoplastic HDs because of the potential for breakage and contamination.

When shipping HDs to locations outside the entity, the entity must consult the Transport Information on the SDS. The entity must ensure that labels and accessory labeling for the HDs include storage instructions, disposal instructions, and HD category information in a format that is consistent with the carrier's policies.

### 11.4 Disposal

All personnel who perform routine custodial waste removal and cleaning activities in HD handling areas must be trained in appropriate procedures to protect themselves and the environment to prevent HD contamination. Disposal of all HD waste, including, but not limited to, unused HDs and trace-contaminated PPE and other materials, must comply with all applicable federal, state, and local regulations.

## 12. DISPENSING FINAL DOSAGE FORMS

HDs that do not require any further manipulation, other than counting or repackaging of final dosage forms, may be prepared for dispensing without any further requirements for containment unless required by the manufacturer or if visual indicators of HD exposure hazards are present (e.g., HD dust or leakage).

Official

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:33:52 AM (EST)
Printed by: USP NF
Do Not Distribute
Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Jul-2020
DOI Ref: ifp62
DocId: GUID-5D76173F-5CB6-47B8-815E-7C275A916085_7_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M7808_07_01

Counting or repackaging of HDs must be done carefully. Clean equipment should be dedicated for use with HDs and should be decontaminated after every use. Tablet and capsule forms of antineoplastic HDs must not be placed in automated counting or packaging machines, which subject them to stress and may create powdered contaminants.

## 13. COMPOUNDING

Entities and personnel involved in compounding HDs must be compliant with the appropriate USP standards for compounding including ⟨795⟩ and ⟨797⟩. Compounding must be done in proper engineering controls as described in *Compounding*. When compounding HD preparations in a C-PEC, a plastic-backed preparation mat should be placed on the work surface of the C-PEC. The mat should be changed immediately if a spill occurs and regularly during use, and should be discarded at the end of the daily compounding activity. Disposable or clean equipment for compounding (such as mortars and pestles, and spatulas) must be dedicated for use with HDs.

Bulk containers of liquid and API HD must be handled carefully to avoid spills. If used, APIs or other powdered HDs must be handled in a C-PEC to protect against occupational exposure, especially during particle-generating activities (such as crushing tablets, opening capsules, and weighing powder).

## 14. ADMINISTERING

HDs must be administered safely using protective medical devices and techniques. Examples of protective medical devices include needleless and closed systems. Examples of protective techniques include spiking or priming of IV tubing with a non-HD solution in a C-PEC and crushing tablets in a plastic pouch.

Appropriate PPE must be worn when administering HDs. After use, PPE must be removed and disposed of in a waste container approved for trace-contaminated HD waste at the site of drug administration. Equipment (such as tubing and needles) and packaging materials must be disposed of properly, such as in HD waste containers, after administration.

CSTDs must be used for administration of antineoplastic HDs when the dosage form allows. Techniques and ancillary devices that minimize the risk posed by open systems must be used when administering HDs through certain routes. Administration into certain organs or body cavities (e.g., the bladder, eye, peritoneal cavity, or chest cavity) often requires equipment for which locking connections may not be readily available or possible.

Healthcare personnel should avoid manipulating HDs such as crushing tablets or opening capsules if possible. Liquid formulations are preferred if solid oral dosage forms are not appropriate for the patient. If HD dosage forms do require manipulation such as crushing tablet(s) or opening capsule(s) for a single dose, personnel must don appropriate PPE and use a plastic pouch to contain any dust or particles generated.

## 15. DEACTIVATING, DECONTAMINATING, CLEANING, AND DISINFECTING

All areas where HDs are handled and all reusable equipment and devices must be deactivated, decontaminated, and cleaned. Additionally, sterile compounding areas and devices must be subsequently disinfected.

The entity must establish written procedures for decontamination, deactivation, and cleaning, and for sterile compounding areas disinfection. Additionally, cleaning of nonsterile compounding areas must comply with ⟨795⟩ and cleaning of sterile compounding areas must comply with ⟨797⟩. Written procedures for cleaning must include procedures, agents used, dilutions (if used), frequency, and documentation requirements.

All personnel who perform deactivation, decontamination, cleaning, and disinfection activities in HD handling areas must be trained in appropriate procedures to protect themselves and the environment from contamination. All personnel performing these activities must wear appropriate PPE resistant to the cleaning agents used, including two pairs of chemotherapy gloves and impermeable disposable gowns (see *Personal Protective Equipment*). Additionally, eye protection and face shields must be used if splashing is likely. If warranted by the activity, respiratory protection must be used.

The deactivating, decontaminating, cleaning, and disinfecting agents selected must be appropriate for the type of HD contaminant(s), location, and surface materials. The products used must be compatible with the surface material. Consult manufacturer or supplier information for compatibility with cleaning agents used. Agents used for deactivation, decontamination, and cleaning should be applied through the use of wipes wetted with appropriate solution and not delivered by a spray bottle to avoid spreading HD residue. All disposable materials must be discarded to meet EPA regulations and the entity's policies. Perform cleaning in areas that are sufficiently ventilated. *Table 5* summarizes the purpose and example agents for each step.

**Table 5. Cleaning Steps**

| Cleaning Step | Purpose | Example Agents |
|---|---|---|
| Deactivation | Render compound inert or inactive | As listed in the HD labeling or other agents which may incorporate Environmental Protection Agency (EPA)-registered oxidizers (e.g., peroxide formulations, sodium hypochlorite, etc.) |
| Decontamination | Remove HD residue | Materials that have been validated to be effective for HD decontamination, or through other materials proven to be effective through testing, which may include alcohol, water, peroxide, or sodium hypochlorite |
| Cleaning | Remove organic and inorganic material | Germicidal detergent |

**Table 5. Cleaning Steps** *(continued)*

| Cleaning Step | Purpose | Example Agents |
|---|---|---|
| Disinfection (for sterile manipulations) | Destroy microorganisms | EPA-registered disinfectant and/or sterile alcohol as appropriate for use |

## 15.1 Deactivation

Deactivation renders a compound inert or inactive. Residue from deactivation must be removed by decontaminating the surface.

There is no one proven method for deactivating all compounds. The ultimate goal should be complete surface decontamination. Products that have known deactivation properties (EPA-registered oxidizing agents that are appropriate for the intended use) should be used when possible. Care should be taken when selecting materials for deactivation due to potential adverse effects (hazardous byproducts, respiratory effects, and caustic damage to surfaces). Damage to surfaces is exhibited by corrosion to stainless steel surfaces caused by sodium hypochlorite if left untreated. To prevent corrosion, sodium hypochlorite must be neutralized with sodium thiosulfate or by following with an agent to remove the sodium hypochlorite (e.g., sterile alcohol, sterile water, germicidal detergent, or sporicidal agent).

## 15.2 Decontamination

Decontamination occurs by inactivating, neutralizing, or physically removing HD residue from non-disposable surfaces and transferring it to absorbent, disposable materials (e.g., wipes, pads, or towels) appropriate to the area being cleaned. When choosing among various products available for decontaminating HDs, consideration should be given to surface compatibility and facility requirements. It is imperative to adhere to manufacturer's use instructions. Because of the growing number of assays available for HDs, additional surface wipe sampling is now possible and should be done to document the effectiveness of any agent used for decontamination of HD residue from work surfaces (see *Environmental Quality and Control*).

The amount of HD contamination introduced into the C-PEC may be reduced by wiping down HD containers. The solution used for wiping HD packaging must not alter the product label. The work surface of the C-PEC must be decontaminated between compounding of different HDs. The C-PEC must be decontaminated at least daily (when used), any time a spill occurs, before and after certification, any time voluntary interruption occurs, and if the ventilation tool is moved.

C-PECs may have areas under the work tray where contamination can build up. These areas must be deactivated, decontaminated, and cleaned at least monthly to reduce the contamination level in the C-PEC. Accessing this area may be difficult. Deactivate, decontaminate, and clean as much as possible of the C-PEC surfaces before accessing the area under the work tray. When deactivating, decontaminating, and cleaning the area under the work tray of a C-PEC, the containment airflows are compromised by opening the cabinets. To provide protection to the worker performing this task, respiratory protection may be required.

## 15.3 Cleaning

Cleaning is a process that results in the removal of contaminants (e.g., soil, microbial contamination, HD residue) from objects and surfaces using water, detergents, surfactants, solvents, and/or other chemicals. Cleaning agents used on compounding equipment should not introduce microbial contamination. No cleaning step may be performed when compounding activities are occurring.

## 15.4 Disinfection

Disinfection is a process of inhibiting or destroying microorganisms. Before disinfection can be adequately performed, surfaces must be cleaned. Disinfection must be done for areas intended to be sterile, including the sterile compounding areas.

# 16. SPILL CONTROL

All personnel who may be required to clean up a spill of HDs must receive proper training in spill management and the use of PPE and NIOSH-certified respirators (see *Personal Protective Equipment*). Spills must be contained and cleaned immediately only by qualified personnel with appropriate PPE. Qualified personnel must be available at all times while HDs are being handled. Signs must be available for restricting access to the spill area. Spill kits containing all of the materials needed to clean HD spills must be readily available in all areas where HDs are routinely handled. If HDs are being prepared or administered in a non-routine healthcare area, a spill kit and respirator must be available. All spill materials must be disposed of as hazardous waste.

The circumstances and management of spills must be documented. Personnel who are potentially exposed during the spill or spill clean up or who have direct skin or eye contact with HDs require immediate evaluation. Non-employees exposed to an HD spill should follow entity policy, which may include reporting to the designated emergency service for initial evaluation and completion of an incident report or exposure form.

SOPs must be developed to prevent spills and to direct the clean up of HD spills. SOPs must address the size and scope of the spill and specify who is responsible for spill management and the type of PPE required. The management of the spill (e.g., decontamination, deactivation, and cleaning) may be dependent on the size and type of spill. The SOP must address the location of spill kits and clean-up materials as well as the capacity of the spill kit. Written procedures should address use of appropriate full-facepiece, chemical cartridge-type respirators if the capacity of the spill kit is exceeded or if there is known or suspected airborne exposure to vapors or gases.

Official

https://pharmacopeia.com/

## 17. DOCUMENTATION AND STANDARD OPERATING PROCEDURES

The entity must maintain SOPs for the safe handling of HDs for all situations in which these HDs are used throughout a facility. The SOPs must be reviewed at least every 12 months by the designated person, and the review must be documented. Revisions in forms or records must be made as needed and communicated to all personnel handling HDs.

The SOPs for handling of HDs should include:

- Hazard communication program
- Occupational safety program
- Designation of HD areas
- Receipt
- Storage
- Compounding
- Use and maintenance of proper engineering controls (e.g., C-PECs, C-SECs, and CSTDs)
- Hand hygiene and use of PPE based on activity (e.g., receipt, transport, compounding, administration, spill, and disposal)
- Deactivation, decontamination, cleaning, and disinfection
- Dispensing
- Transport
- Administering
- Environmental monitoring (e.g., wipe sampling)
- Disposal
- Spill control
- Medical surveillance

Personnel who transport, compound, or administer HDs must document their training according to OSHA standards (see OSHA Standard 1910.120 Hazardous Waste Operations and Emergency Response) and other applicable laws and regulations.

## 18. MEDICAL SURVEILLANCE

Medical surveillance is part of a comprehensive exposure control program complementing engineering controls, safe work processes, and use of PPE. Healthcare workers who handle HDs as a regular part of their job assignment should be enrolled in a medical surveillance program. The general purpose of surveillance is to minimize adverse health effects in personnel potentially exposed to HDs. Medical surveillance programs involve assessment and documentation of symptom complaints, physical findings, and laboratory values (such as a blood count) to determine whether there is a deviation from the expected norms.

Medical surveillance can also be viewed as a secondary prevention tool that may provide a means of early detection if a health problem develops. Tracking personnel through medical surveillance allows the comparison of health variables over time in individual workers, which may facilitate early detection of a change in a laboratory value or health condition. Medical surveillance programs also look for trends in populations of workers. Examining grouped data compared with data from unexposed workers may reveal a small alteration or increase in the frequency of a health effect that would be obscured if individual workers' results alone were considered.

Medical surveillance evaluates the protection afforded by engineering controls, other administrative controls, safe work processes, PPE, and worker education about the hazards of the materials they work with in the course of their duties. The data-gathering elements of a medical surveillance program are used to establish a baseline of workers' health and then to monitor their future health for any changes that may result from exposure to HDs.

Elements of a medical surveillance program should be consistent with the entity's Human Resource policies and should include:

- Development of an organized approach to identify workers who are potentially exposed to HDs on the basis of their job duties
- Use of an entity-based or contracted employee health service to perform the medical surveillance while protecting the confidentiality of the employees' personal medical information
- Initial baseline assessment (pre-placement) of a worker's health status and medical history. Data elements collected include a medical (including reproductive) history and work history to assess exposure to HDs, physical examination, and laboratory testing. Methods used to assess exposure history include a review of:
  - Records of HDs handled, with quantities and dosage forms
  - Estimated number of HDs handled per week
  - Estimates of hours spent handling HDs per week and/or per month
  - Performance of a physical assessment and laboratory studies linked to target organs of commonly used HDs, such as a baseline complete blood count. Biological monitoring to determine blood or urine levels of specific HDs is not currently recommended in surveillance protocols, but may have a role in the follow-up of acute spills with a specific agent.
- Medical records of surveillance should be maintained according to OSHA regulation concerning access to employee exposure and medical records
- Monitoring workers' health prospectively through periodic surveillance using the elements of data gathering described above (updated health and exposure history, physical assessment, and laboratory measures, if appropriate)

Do Not Distribute

- Monitoring of the data to identify prevention failure leading to health effects; this monitoring may occur in collaboration with the employee health service
- Development of a follow-up plan for workers who have shown health changes suggesting toxicity or who have experienced an acute exposure. This follow-up should include evaluation of current engineering and administrative controls and equipment to ensure that all systems are appropriately and accurately implemented (see *Follow-Up Plan*)
- Completion of an exit examination when a worker's employment at the entity ends, to document the information on the employee's medical, reproductive, and exposure histories. Examination and laboratory evaluation should be guided by the individual's history of exposures and follow the outline of the periodic evaluation

## 18.1 Follow-Up Plan

The occurrence of exposure-related health changes should prompt immediate re-evaluation of primary preventive measures (e.g., administrative and engineering controls, PPE, and others). In this manner, medical surveillance acts as a check on the effectiveness of controls already in use.

The entity should take the following actions:

- Perform a post-exposure examination tailored to the type of exposure (e.g., spills or needle sticks from syringes containing HDs). An assessment of the extent of exposure should be conducted and included in a confidential database and in an incident report. The physical examination should focus on the involved area as well as other organ systems commonly affected (i.e., the skin and mucous membranes for direct contact or inhalation; the pulmonary system for aerosolized HDs). Treatment and laboratory studies will follow as indicated and be guided by emergency protocols
- Compare performance of controls with recommended standards; conduct environmental sampling when analytical methods are available
- Verify and document that all engineering controls are in proper operating condition
- Verify and document that the worker complied with existing policies. Review policies for the use of PPE and employee compliance with PPE use and policies. Review availability of appropriate PPE (see *Personal Protective Equipment*)
- Develop and document a plan of action that will prevent additional exposure of workers
- Ensure confidential, two-way communication between the worker and the employee health unit(s) regarding notification, discussions about a change in health condition, or detection of an adverse health effect
- Provide and document a follow-up medical survey to demonstrate that the plan implemented is effective
- Ensure that any exposed worker receives confidential notification of any adverse health effect. Offer alternative duty or temporary reassignment
- Provide ongoing medical surveillance of all workers at risk for exposure to HDs to determine whether the plan implemented is effective

Official

# GLOSSARY

**Active pharmaceutical ingredient (API):** Any substance or mixture of substances intended to be used in the compounding of a drug preparation, thereby becoming the active ingredient in that preparation and furnishing pharmacological activity or other direct effect in the diagnosis, cure, mitigation, treatment, or prevention of disease in humans and animals or affecting the structure and function of the body.

**Alternative duty:** Performance of other tasks that do not include the direct handling of HDs.

**Ante-room:** An ISO Class 7 or cleaner room where personnel hand hygiene, garbing procedures, and other activities that generate high particulate levels are performed. The ante-room is the transition room between the unclassified area of the facility and the buffer room.

**Assessment of risk:** Evaluation of risk to determine alternative containment strategies and/or work practices.

**Beyond-use date (BUD):** The date or time beyond which a compounded preparation cannot not be used and must be discarded (see ⟨795⟩ and ⟨797⟩). The date or time is determined from the date or time when the preparation was compounded.

**Biological safety cabinet (BSC):** A ventilated cabinet often used for preparation of hazardous drugs. These cabinets are divided into three general classes (Class I, Class II, and Class III). Class II BSCs are further divided into types (Type A1, Type A2, Type B1, and Type B2). See *Appendix 3* for details.

**Buffer room:** A type of C-SEC under negative pressure that meets ISO Class 7 or better air quality where the C-PEC that generates and maintains an ISO Class 5 environment is physically located. Activities that occur in this area are limited to the preparation and staging of components and supplies used when compounding HDs.

**Chemotherapy glove:** A medical glove that meets the ASTM Standard Practice for Assessment of Resistance of Medical Gloves to Permeation by Chemotherapy Drugs (D6978) or its successor.

**Classified space:** An area that maintains an air cleanliness classification based on the International Organization for Standardization (ISO).

**Cleaning:** The process of removing soil (e.g., organic and inorganic material) from objects and surfaces, normally accomplished by manually or mechanically using water with detergents or enzymatic products.

**Closed-system drug-transfer device (CSTD):** A drug-transfer device that mechanically prohibits the transfer of environmental contaminants into the system and the escape of HD or vapor concentrations outside the system.

**Compounded preparation:** A nonsterile or sterile drug or nutrient preparation that is compounded in a licensed pharmacy or other healthcare-related facility in response to or anticipation of a prescription or a medication order from a licensed prescriber.

**Compounding aseptic containment isolator (CACI):** A specific type of CAI that is designed for the compounding of sterile HDs. The CACI is designed to provide worker protection from exposure to undesirable levels of airborne drugs throughout the compounding and material transfer processes and to provide an aseptic environment with unidirectional airflow for compounding sterile preparations.

https://pharmacopeia.com/

**Compounding aseptic isolator (CAI):** An isolator specifically designed for compounding sterile, non-hazardous pharmaceutical ingredients or preparations. The CAI is designed to maintain an aseptic compounding environment throughout the compounding and material transfer processes.

**Compounding personnel:** Individuals who participate in the compounding process.

**Containment primary engineering control (C-PEC):** A ventilated device designed and operated to minimize worker and environmental exposures to HDs by controlling emissions of airborne contaminants through the following:

- The full or partial enclosure of a potential contaminant source
- The use of airflow capture velocities to trap and remove airborne contaminants near their point of generation
- The use of air pressure relationships that define the direction of airflow into the cabinet
- The use of HEPA filtration on all potentially contaminated exhaust streams

**Containment secondary engineering control (C-SEC):** The room with fixed walls in which the C-PEC is placed. It incorporates specific design and operational parameters required to contain the potential hazard within the compounding room.

**Containment segregated compounding area (C-SCA):** A type of C-SEC with nominal requirements for airflow and room pressurization as they pertain to HD compounding.

**Containment ventilated enclosure (CVE):** A full or partial enclosure that uses ventilation principles to capture, contain, and remove airborne contaminants through HEPA filtration and prevent their release into the work environment.

**Deactivation:** Treatment of an HD contaminant on surfaces with a chemical, heat, ultraviolet light, or another agent to transform the HD into a less hazardous agent.

**Decontamination:** Inactivation, neutralization, or removal of HD contaminants on surfaces, usually by chemical means.

**Doff:** To remove PPE.

**Don:** To put on PPE.

**Disinfection:** The process of inhibiting or destroying microorganisms.

**Engineering control:** Primary, secondary, and supplemental devices designed to eliminate or reduce worker exposure to HDs.

**EPA-registered disinfectant:** Antimicrobial products registered with the Environmental Protection Agency (EPA) for healthcare use against pathogens specified in the product labeling.

**Externally vented:** Exhausted to the outside.

**Final dosage form:** Any form of a medication that requires no further manipulation before administration.

**Globally Harmonized System of Classification and Labeling of Chemicals (GHS):** A system for standardizing and harmonizing the classification and labeling of chemicals.

**Goggles:** Tight-fitting eye protection that completely covers the eyes, eye sockets, and facial area that immediately surrounds the eyes. Goggles provide protection from impact, dust, and splashes. Some goggles fit over corrective lenses.

**Hazardous drug (HD):** Any drug identified by at least one of the following criteria:

- Carcinogenicity, teratogenicity, or developmental toxicity
- Reproductive toxicity in humans
- Organ toxicity at low dose in humans or animals
- Genotoxicity or new drugs that mimic existing HDs in structure or toxicity

**High-efficiency particulate air (HEPA) filtration:** An extended-medium, dry-type filter in a rigid frame, having a minimum particle collection efficiency of 99.97% for particles with a mass median diameter of 0.3 µm when tested at a rated airflow in accordance with MIL STD 282 using IEST Recommended Standard RP-CC001.5.

**Negative-pressure room:** A room that is maintained at a lower pressure than the adjacent areas; therefore the net flow of air is into the room.

**Pass-through:** An enclosure with interlocking doors that is positioned between two spaces for the purpose of reducing particulate transfer while moving materials from one space to another. A pass-through serving negative-pressure rooms needs to be equipped with sealed doors.

**Personal protective equipment (PPE):** Items such as gloves, gowns, respirators, goggles, faceshields, and others that protect individual workers from hazardous physical or chemical exposures.

**Positive-pressure room:** A room that is maintained at a higher pressure than the adjacent areas; therefore, the net flow of air is out of the room.

**Repackaging:** The act of removing a product from its original primary container and placing it into another primary container, usually of smaller size.

**Safety data sheet (SDS):** An informational document that provides written or printed material concerning a hazardous chemical. The SDS is prepared in accordance with the HCS [previously known as a Material Safety Data Sheet (MSDS)].

**Spill kit:** A container of supplies, warning signage, and related materials used to contain the spill of an HD.

**Standard operating procedure (SOP):** Written procedures describing operations, testing, sampling, interpretation of results, and corrective actions that relate to the operations that are taking place.

**Supplemental engineering control:** An adjunct control (e.g., CSTD) that may be used concurrently with primary and secondary engineering controls. Supplemental engineering controls offer additional levels of protection and may facilitate enhanced occupational protection, especially when handling HDs outside of primary and secondary engineering controls (e.g., during administering).

**Unclassified space:** A space not required to meet any air cleanliness classification based on the International Organization for Standardization (ISO).

## Appendix 3: Types of Biological Safety Cabinets

**Class I:** A BSC that protects personnel and the environment but does not protect the product/preparation. A minimum velocity of 75 linear feet/minute of unfiltered room air is drawn through the front opening and across the work surface, providing personnel protection. The air is then passed through a HEPA/ULPA (ultra-low particulate air) filter, either into the room or to the outside in the exhaust plenum, providing environmental protection.

**Class II:** Class II (Types A1, A2, B1, and B2) BSCs are partial barrier systems that rely on the movement of air to provide personnel, environmental, and product/preparation protection. Personnel and product/preparation protection are provided by the combination of inward and downward airflow captured by the front grille of the cabinet. Side-to-side cross-contamination of products/preparations is minimized by the internal downward flow of HEPA/ULPA filtered air moving toward the work surface and then drawn into the front and rear intake grilles. Environmental protection is provided when the cabinet exhaust air is passed through a HEPA/ULPA filter.

**Type A1 (formerly, Type A):** These Class II BSCs maintain a minimum inflow velocity of 75 feet/minute; have HEPA-filtered, down-flow air that is a portion of the mixed down-flow and inflow air from a common plenum; may exhaust HEPA-filtered air back into the laboratory or to the environment through an exhaust canopy; and may have positive-pressure contaminated ducts and plenums that are not surrounded by negative-pressure plenums. Type A1 BSCs are not suitable for use with volatile toxic chemicals and volatile radionuclides.

**Type A2 (formerly, Type B3):** These Class II BSCs maintain a minimum inflow velocity of 100 feet/minute; have HEPA-filtered, down-flow air that is a portion of the mixed down-flow and inflow air from a common exhaust plenum; may exhaust HEPA-filtered air back into the laboratory or to the environment through an exhaust canopy; and have all contaminated ducts and plenums under negative pressure or surrounded by negative-pressure ducts and plenums. If these cabinets are used for minute quantities of volatile toxic chemicals and trace amounts of radionuclides, they must be exhausted through properly functioning exhaust canopies.

**Type B1:** These Class II BSCs maintain a minimum inflow velocity of 100 feet/minute; have HEPA-filtered, down-flow air composed largely of uncontaminated, recirculated inflow air; exhaust most of the contaminated down-flow air through a dedicated duct exhausted to the atmosphere after passing it through a HEPA filter; and have all contaminated ducts and plenums under negative pressure or surrounded by negative-pressure ducts and plenums. If these cabinets are used for work involving minute quantities of volatile toxic chemicals and trace amounts of radionuclides, the work must be done in the directly exhausted portion of the cabinet.

**Type B2 (total exhaust):** These Class II BSCs maintain a minimum inflow velocity of 100 feet/minute; have HEPA-filtered, down-flow air drawn from the laboratory or the outside; exhaust all inflow and down-flow air to the atmosphere after filtration through a HEPA filter without recirculation inside the cabinet or return to the laboratory; and have all contaminated ducts and plenums under negative pressure or surrounded by directly exhausted negative-pressure ducts and plenums. These cabinets may be used with volatile toxic chemicals and radionuclides.

**Class III:** The Class III BSC is designed for work with highly infectious microbiological agents and other hazardous operations. It provides maximum protection for the environment and the worker. It is a gas-tight enclosure with a viewing window that is secured with locks and/or requires the use of tools to open. Both supply and exhaust air are HEPA/ULPA filtered. Exhaust air must pass through two HEPA/ULPA filters in series before discharge to the outdoors.

# ⟨801⟩ POLAROGRAPHY

Polarography is an electrochemical method of analysis based on the measurement of the current flow resulting from the electrolysis of a solution at a polarizable microelectrode, as a function of an applied voltage. The polarogram (see *Figure 1*) obtained by this measurement provides qualitative and quantitative information on electro-reducible and electro-oxidizable substances. The normal concentration range for substances being analyzed is from $10^{-2}$ molar to $10^{-5}$ molar.

In direct current (dc) polarography, the microelectrode is a dropping mercury electrode (DME) consisting of small reproducible drops of mercury flowing from the orifice of a capillary tube connected to a mercury reservoir. A saturated calomel electrode (SCE) with a large surface area is the most commonly employed reference electrode. As the voltage applied to the cell increases, only a very small residual current flows until the substance under assay undergoes reduction or oxidation. Then the current increases, at first gradually, then almost linearly with voltage, and it gradually reaches a limiting value as is shown in *Figure 1*.

@2024 USPC

On the initial rising portion of the polarographic wave, the increased flow of current results in a decrease in the concentration of the electro-active species at the electrode surface. As the voltage and current increase, the concentration of the reactive species decreases further to a minimal value at the electrode surface. The current is then limited by the rate at which the reacting species can diffuse from the bulk of the solution to the surface of the microelectrode. The final current rise is caused by the reaction of the supporting electrolyte. This large concentration of electrolyte is inert within the potential range used in the analysis, and it prevents the reactive species from reaching the electrode by electrical migration, thus assuring that the limiting current is diffusion-controlled.

Since, in the case of the DME, the electrode surface is being constantly renewed in a cyclic fashion, the current increases from a small value as the drop begins to form to a maximum value as the drop falls. By the use of a suitable recorder to measure the current, the characteristic saw-toothed record is obtained. The limiting current is the sum of the residual and the diffusion currents. The residual current is subtracted from the limiting current to give the wave height.

## ILKOVIC EQUATION

The linear relationship between the diffusion current ($i_d$) and the concentration of electro-active species is shown by the Ilkovic equation:

$$i_d = 708nD^{1/2}Cm^{2/3}t^{1/6}$$

in which $i_d$ is the maximum current in microamperes; n is the number of electrons required per molecule of electro-active substance; D is its diffusion coefficient, in square cm per second; C is the concentration, in millimoles per L; m is the rate of mercury flow from the DME, in mg per second; and t is the drop time, in seconds.

Modern polarographs are equipped with recorders capable of following the current during the latter portion of the drop life; consequently, the maximum of the oscillations is the measure of the current. When the current is measured only at the end of the drop life, the technique is termed sampled dc polarography. In this case, only the maximum currents are recorded and oscillations due to drop growth are not observed.

For instruments equipped with galvanometers to measure the current or recorders operated in a damped mode, the saw-toothed waves correspond to oscillations about the average current. In the latter case, the average of the oscillations is the measure of the current. For polarograms obtained in this manner, the $i_d$ given by the Ilkovic equation is the average current in microamperes observed during the life of the drop, when the coefficient 708 is replaced by 607.

## CONTROL OF THE DIFFUSION CURRENT

The Ilkovic equation identifies the variables that must be controlled to ensure that the diffusion current is directly proportional to the concentration of electro-active material. At 25° the diffusion coefficients for aqueous solutions of many ions and organic molecules increase 1% to 2% per degree rise in temperature. Thus the temperature of the polarographic cell must be controlled to within ±0.5°. The quantities m and t depend upon the dimensions of the capillary and the height of the mercury column above the electrode. Although results obtained with different capillaries can be compared if the product $m^{2/3}t^{1/6}$ is known, it is advisable to use the same capillary with a constant head of mercury during a series of analyses. The diffusion current is proportional to the square root of the height of the mercury column. A mercury reservoir with a diameter greater than 4 cm prevents any significant drop in the mercury level during a series of runs.

The capillary for the DME has a bore of approximately 0.04 mm and a length of 6 cm to 15 cm. The height of the mercury column, measured from the tip of the capillary to the top of the mercury pool, ranges from 40 cm to 80 cm. The exact length of the capillary and the height of the mercury column are adjusted to give a drop-time of between 3 and 5 seconds at open circuit with the capillary immersed in the test solution.

Equipment is available that allows controlled drop-times of fractions of a second to several seconds. As detail within a polarogram is related to the number of drops delivered during a given potential change, such short drop-times allow more rapid recording of the polarogram.

The current flowing through the test solution during the recording of a polarogram is in the microampere range. Thus, the current flow produces negligible changes in the test solution and several polarograms can be run on the same test solution without significant differences.

## HALF-WAVE POTENTIAL

The half-wave potential ($E_{1/2}$) occurs at the point on the polarogram one-half the distance between the residual current and the limiting current plateau. This potential is characteristic of the electro-active species and is largely independent of its concentration or the capillary used to obtain the wave. It is dependent upon the solution composition and may change with variations in the pH or in the solvent system or with the addition of complexing agents. The half-wave potential thus serves as a criterion for the qualitative identification of a substance.

The potential of the DME is equal to the applied voltage versus the reference electrode after correction for the iR drop (that potential need to pass the current, i, through the solution with a resistance R). It is especially important to make this correction for nonaqueous solutions, which ordinarily possess high resistance, if an accurate potential for the DME is needed. Correction of the half-wave potential is not required for quantitative analysis. Unless otherwise indicated, it is to be understood that potentials represent measurements made against the SCE.

## REMOVAL OF DISSOLVED OXYGEN

Inasmuch as oxygen is reduced at the DME in two steps, first to hydrogen peroxide and then to water, it interferes where polarograms are to be made at potentials more negative than about 0 volt versus SCE, and must be removed. This may be accomplished by bubbling oxygen-free nitrogen through the solution for 10 to 15 minutes immediately before recording the wave, the nitrogen first having been "conditioned" to minimize changes due to evaporation, by being passed through a separate portion of the solution.

It is necessary that the solution be quiet and vibration-free during the time the wave is recorded, to ensure that the current is diffusion-controlled. Therefore, the nitrogen aeration should be stopped and the gas be directed to flow over the surface of the solution before a polarogram is recorded.

In alkaline media, sodium bisulfite may be added to remove oxygen, provided the reagent does not react with other components of the system.

## MEASUREMENT OF WAVE HEIGHT

To use a polarogram quantitatively, it is necessary to measure the height of the wave. Since this is a measure of the magnitude of the diffusion current, it is measured vertically. To compensate for the residual current, the segment of the curve preceding the wave is extrapolated beyond the rise in the wave. For a well-formed wave where this extrapolation parallels the limiting current plateau, the measurement is unambiguous. For less well-defined waves, the following procedure may be used unless otherwise directed in the individual monograph. Both the residual current and the limiting current are extrapolated with straight lines, as shown by the graph (*Figure 1*). The wave height is taken as the vertical distance between these lines measured at the half-wave potential.

## PROCEDURE

[**Caution**—Mercury vapor is poisonous, and metallic mercury has a significant vapor pressure at room temperature. The work area in which mercury is used should be constructed in such a way that any spilled or spattered droplets of mercury can be completely recovered with relative ease. Scrupulously clean up mercury after each use of the instrument. Work in a well-ventilated laboratory, taking care to clean up any spilled mercury.]

Transfer a portion of the final dilution of the substance being assayed to a suitable polarographic cell immersed in a water bath regulated to 25 ± 0.5°. Pass a stream of nitrogen through the solution for 10 to 15 minutes to remove dissolved oxygen. Start the mercury dropping from the capillary, insert the capillary into the test solution, and adjust the height of the mercury reservoir. Switch the flow of nitrogen to pass over the surface of the solution, and record the polarogram over the potential range indicated in the individual monograph, using the appropriate recorder or galvanometer sensitivity to give a suitable wave. Measure the height of the wave, and unless otherwise directed in the monograph, compare this with the wave height obtained with the appropriate USP Reference Standard, measured under the same conditions.

## PULSE POLAROGRAPHY

In conventional dc polarography, the current is measured continuously as potential is applied as a linear ramp (see *Figure 2)*.

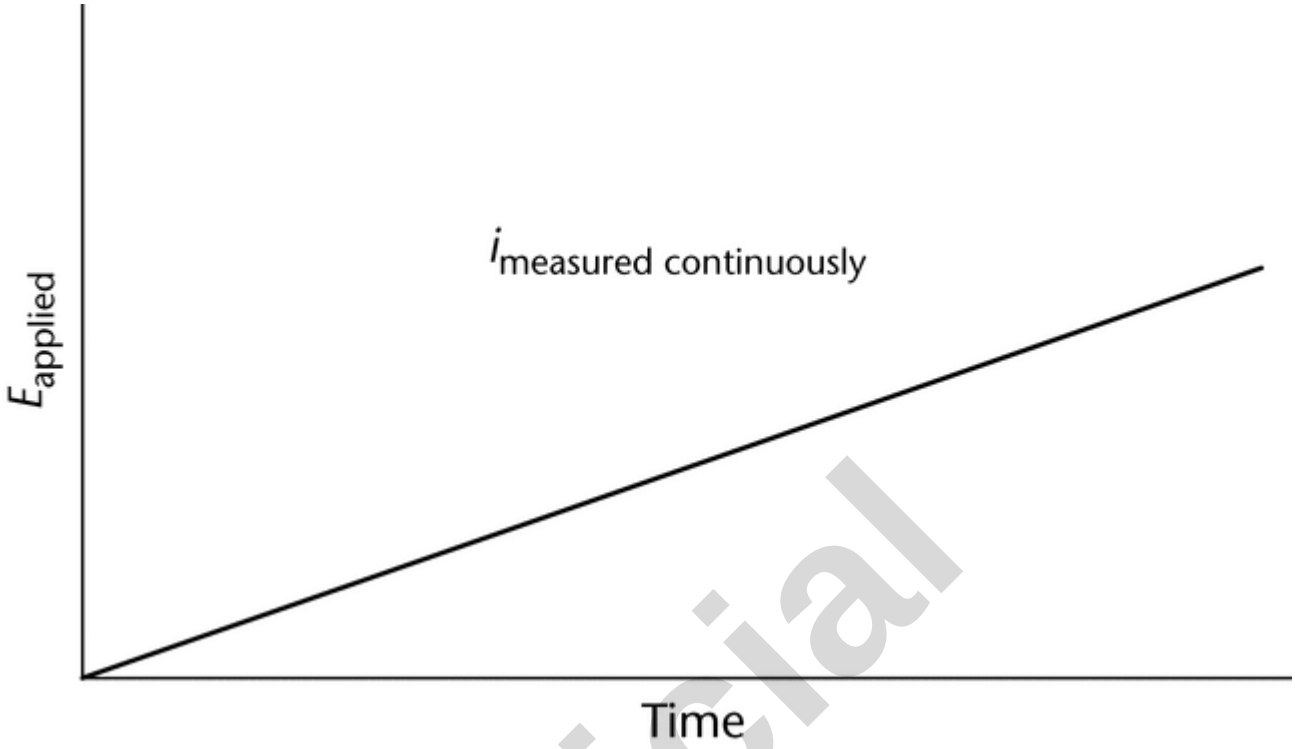

Fig. 2. Direct Current (dc) Polarography.

This current is composed of two elements. The first, the diffusion (faradaic) current, is produced by the substance undergoing reduction or oxidation at the working electrode, and is directly proportional to the concentration of this substance. The second element is the capacitative current (charging of the electrochemical double layer). The changes in these currents as the mercury drop varies in size produce the oscillations present in typical dc polarograms.

In normal pulse polarography, a potential pulse is applied to the mercury electrode near the end of the drop life, with the drop being held at the initial potential during growth period (see *Figure 3).*

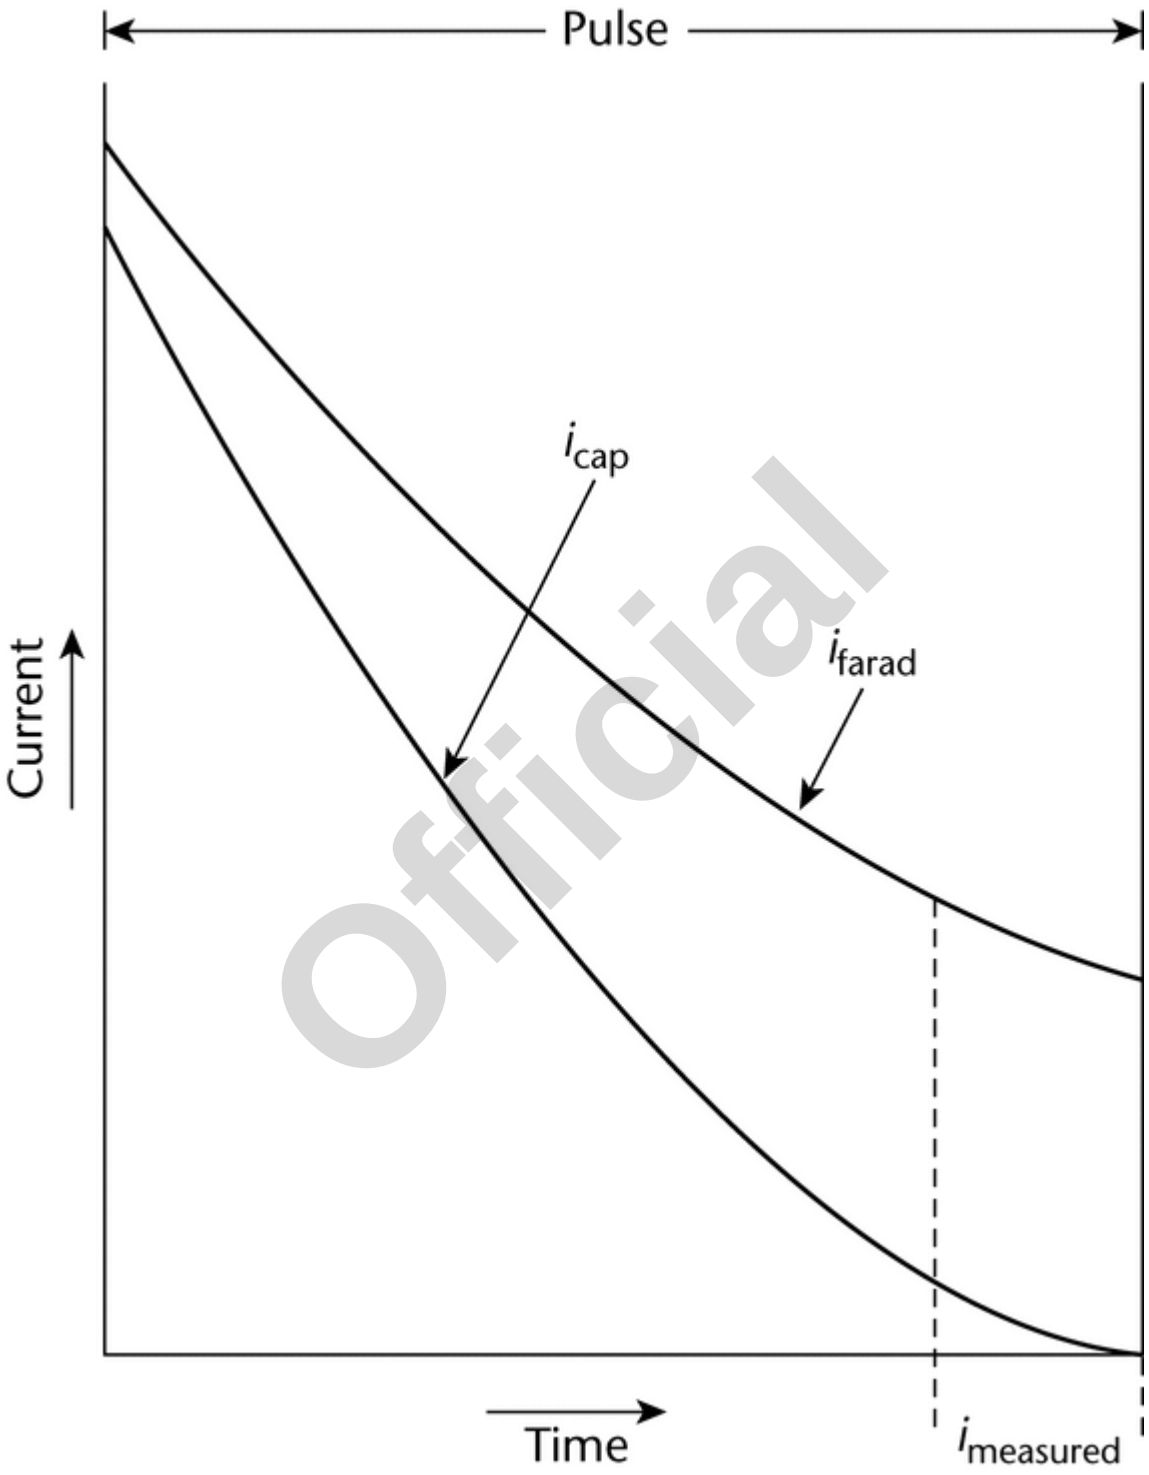

Fig. 4. Plot of Current Versus Time in Pulse Polarography.

In addition, since the pulse is applied for only a short duration, the diffusion layer is not depleted as extensively as in dc polarography and larger current levels are obtained for equivalent concentrations. Concentrations as low as $10^{-6}$ M can be measured, providing approximately a ten-fold increase in sensitivity over that with dc polarography. Limiting current values are more easily measured, since the waves are free from oscillations.

Differential pulse polarography is a technique whereby a fixed-height pulse applied at the end of the life of each drop is superimposed on a linear increasing dc ramp (see *Figure 5).*

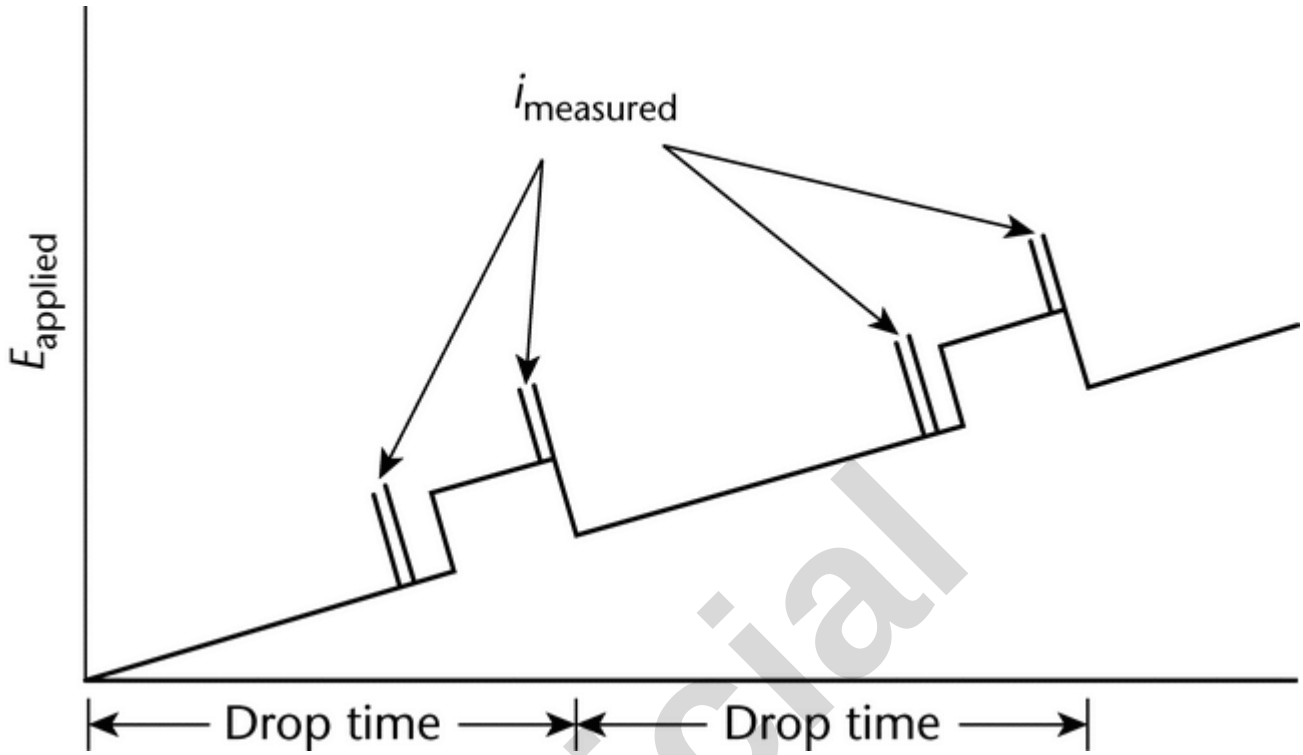

Fig. 5. Differential Pulse Polarography.

Current flow is measured just before application of the pulse and again at the end of the pulse. The difference between these two currents is measured and presented to the recorder. Such a differential signal provides a curve approximating the derivative of the polarographic wave, and gives a peak presentation. The peak potential is equivalent to:

$$E_{1/2} - \Delta E/2$$

where $\Delta E$ is the pulse height. The peak height is directly proportional to concentration at constant scan rates and constant pulse heights. This technique is especially sensitive (levels of $10^{-7}$M may be determined) and affords improved resolution between closely spaced waves.

## ANODIC STRIPPING VOLTAMMETRY

Anodic stripping voltammetry is an electrochemical technique whereby trace amounts of substances in solution are concentrated (reduced) onto an electrode and then stripped (oxidized) back into solution by scanning the applied voltage anodically. The measurement of the current flow as a function of this voltage and scanning rate provides qualitative and quantitative information on such substances. The concentration step permits analyses at $10^{-7}$M to $10^{-9}$M levels.

Basic instrumentation includes a voltage ramp generator; current-measuring circuitry; a cell with working, reference, and counter electrodes; and a recorder or other read-out device. Instruments having dc or pulse-polarographic capabilities are generally quite adequate for stripping application. The working electrode commonly used is the hanging mercury drop electrode (HMDE), although the mercury thin-film electrode (MTFE) has acquired acceptance. For analysis of metals such as silver, platinum, and gold, whose oxidation potentials are more positive than mercury, and mercury itself, the use of solid electrodes such as platinum, gold, or carbon is required. A saturated calomel electrode or a silver–silver chloride electrode serves as the reference except for the analysis of mercury or silver. A platinum wire is commonly employed as the counter electrode.

Test specimens containing suitable electrolyte are pipeted into the cell. Dissolved oxygen is removed by bubbling nitrogen through the cell for 5 to 10 minutes.

Generally, an electrolysis potential equivalent to 200 to 300 mV more negative than the half-wave potential of the material to be analyzed is applied (although this potential is to be determined experimentally), with stirring for 1 to 10 minutes. For reproducible results, maintain constant conditions (i.e., deposition time, stirring rate, temperature, specimen volume, and drop size if HMDE is used).

After deposition, the stirring is discontinued and the solution and electrode are allowed to equilibrate for a short period. The potential is then rapidly scanned anodically (10 mV/second or greater in dc polarography and 5 mV/second in differential pulse polarography). As in polarography, the limiting current is proportional to concentration of the species (wave height in dc and pulse; peak height in differential pulse), while the half-wave potential (dc, pulse) or peak potential (differential pulse) identifies the species. It is imperative that the choice of supporting electrolyte be made carefully in order to obtain satisfactory behavior. Quantitation is usually achieved by a standard addition or calibration method.

Official

https://pharmacopeia.cn/v-download/

This technique is appropriate for trace-metal analysis, but has limited use in organic determinations, since many of these reactions are irreversible. In analyzing substances such as chloride, cathodic stripping voltammetry may be used. The technique is the same as anodic stripping voltammetry, except that the substance is deposited anodically and then stripped by a cathodic voltage scan.

# ⟨811⟩ POWDER FINENESS

The particle size distribution should be estimated by *Particle Size Distribution Estimation by Analytical Sieving* ⟨786⟩ or by application of other methods where practical. A simple descriptive classification of powder fineness is provided in this chapter. For practical reasons, sieves are commonly used to measure powder fineness. Sieving is most suitable where a majority of the particles are larger than about 75 µm, although it can be used for some powders having smaller particle sizes where the method can be validated. Light diffraction is also a widely used technique for measuring the size of a wide range of particles.

## CLASSIFICATION OF POWDER FINENESS

Where the cumulative distribution has been determined by analytical sieving or by application of other methods, powder fineness may be classified in the following manner:

$x_{90}$ = particle dimension corresponding to 90% of the cumulative undersize distribution

$x_{50}$ = median particle dimension (i.e., 50% of the particles are smaller and 50% of the particles are larger)

$x_{10}$ = particle dimension corresponding to 10% of the cumulative undersize distribution

It is recognized that the symbol $d$ is also widely used to designate these values. Therefore, the symbols $d_{90}$, $d_{50}$, and $d_{10}$ may be used.

The following parameters may be defined based on the cumulative distribution. $Q_R(x)$ = cumulative distribution of particles with a dimension less than or equal to $x$ where the subscript $R$ reflects the distribution type.

| *R* | Distribution Type |
|---|---|
| 0 | Number |
| 1 | Length |
| 2 | Area |
| 3 | Volume |

Therefore, by definition:

1. $Q_R(x) = 0.90$ when $x = x_{90}$
2. $Q_R(x) = 0.50$ when $x = x_{50}$
3. $Q_R(x) = 0.10$ when $x = x_{10}$

An alternative but less informative method of classifying powder fineness is by use of the terms in the following table.

**Classification of Powders by Fineness**

| Descriptive Term | $X_{50}$ (µm) | Cumulative Distribution by Volume Basis, $Q_3(x)$ |
|---|---|---|
| Coarse | >355 | $Q_3(355) < 0.50$ |
| Moderately Fine | 180–355 | $Q_3(180) < 0.50$ and $Q_3(355) \geq 0.50$ |
| Fine | 125–180 | $Q_3(125) < 0.50$ and $Q_3(180) \geq 0.50$ |
| Very Fine | ≤125 | $Q_3(125) \geq 0.50$ |

## 1. INTRODUCTION

Radiopharmaceuticals and radioactive devices require specialized techniques in their production, testing, handling, dispensing, and administration in order to ensure optimal effectiveness and maintain safety for workers, patients, and the public. Hence, all operations involving these articles should be carried out by or under the supervision of personnel who have been appropriately trained in the handling of radioactive materials and appropriate instruments.

The facilities for the production, storage, and use of radioactive drugs and radioactive devices are generally subject to licensing by the U.S. Nuclear Regulatory Commission or Agreement State agency, or similar governmental agency outside the United States. Most radioactive drugs and radioactive devices are subject to other regulations relating to transportation, environmental release, and workplace safety.

*USP* monographs for radioactive articles include specifications for radionuclide identification and assay for radioactivity. Moreover, radioactivity counting assemblies or radiation detectors are required instruments for the determination of radionuclidic purity and radiochemical purity. The purpose of this general chapter is to provide standards for measurement of radioactivity, including instrument qualification, performance checks, identification of radionuclides and radionuclidic impurities, and assay of radionuclides.

Information regarding radioactivity is described in *Radioactivity—Theory and Practice* ⟨1821⟩, which includes definitions, types of decay, general considerations relating to radioactive decay, counting, radionuclide production, purity, labeling, and instrumentation for detection and measurement of radioactive emissions, as well as a glossary.

## 2. PERSONNEL TRAINING AND DOCUMENTATION

Personnel training should be completed in accordance with written policies and/or procedures. Documentation of the personnel training should be included in the Quality Assurance Program. The length of time to retain the documentation varies depending on the appropriate regulatory requirements.

## 3. QUALIFICATION OF INSTRUMENTS

Qualification of instruments should be completed in accordance with written policies and/or procedures. Documentation of the qualification of instruments should be included in the Quality Assurance Program. The length of time to retain the documentation varies depending on the applicable regulatory requirements.

### 3.1 Installation Qualification

Installation qualification (IQ) is to be performed upon installation of an instrument and after major repair. There are two categories in an IQ—visual inspection and operating environment. Visual inspection involves a check of the condition of the

@2024 USPC

instrument to determine if it is ready to use. The inspection confirms that all cables are intact, the instrument is intact with no broken pieces/parts, and all components of the equipment are in working order. The operating environment for the device is checked for proper temperature, humidity, and power requirements. The operating environment should also be checked to avoid high background radioactivity. Temperatures are typically 10°–30° C and relative humidity ranges are generally 20%–90%. Shielding may be necessary to ensure that the background radiation has no negative effect on the instrument performance.

### 3.2 Operational Qualification

Operational qualification (OQ) is a check of operational specifications for the equipment, including equipment set-up, functional testing of subsystems, and proper overall operation. OQ should describe operational procedures for the equipment and is performed after IQ and after major repairs. OQ should include all appropriate tests to show that the instrument is capable of functioning properly. Typical examples of OQ include clock accuracy, high voltage, zero adjust, background response, and contamination check.

### 3.3 Performance Qualification

Performance qualification (PQ) demonstrates that the equipment is capable of performing tasks required in the operating environment and provides the intended results. PQ should describe the required performance tasks for the equipment and include all appropriate tests to demonstrate that the instrument is performing within its operating parameters. These PQ tests are done following the OQ tests. Additionally, some or all the PQ tests are performed routinely (e.g., daily, quarterly, semiannually, annually) to demonstrate the instruments continual acceptance for use. Typical PQ tests include constancy and relative response, accuracy, reproducibility (precision), system linearity, determination of “quench” curves in liquid scintillation counters, and supplier equivalence.

### 3.4 Geometry Testing

The purpose of the geometry test is to demonstrate correct readings of the test sample, accounting for differences in the container, volume, or position of the test sample compared to the radioactive calibration standard. Geometry testing should be performed at installation of the dose calibrator and for each type of vial and syringe used to contain the test sample. Testing should include the test sample holder. Corrections factors may be developed as needed.

## 4. ONGOING PERFORMANCE TESTS OF INSTRUMENTS

Performance and operational tests are completed periodically to ensure the instrument is capable of meeting specified criteria for accurate assays and that no changes have occurred since initial testing. Tests include physical inspection, measurement of system parameters, and operational tests with radioactive calibration sources. These tests should also be completed after repair. Regulatory agencies may require specific tests at a regular frequency. The following sections describe the performance tests using a dose calibrator as an example. Ongoing performance tests for other instruments used for radiation measurements should be designed as appropriate to each instrument, testing the parameters that are pertinent to ensuring the performance of the instrument, considering its application and the level of precision of measurement required. The same principles will apply to other instruments used for radiation measurements.

### 4.1 Physical Inspections

Ensure that the dose calibrator and associated accessories, such as source holders and well liners, are undamaged and that foreign objects are not present in the chamber. Prior to use, repair or replace any damaged components as required and remove all foreign objects.

### 4.2 System Parameters

The system electronics should be tested according to the manufacturer’s diagnostic testing procedures. The results should meet the acceptance criteria detailed in the manufacturer’s manual. These parameters typically include the high voltage on the chamber, the zero adjustment on the electrometer, verification of communication between components of the system, and the accuracy of the system clock.

If the manufacturer’s diagnostic procedures are not available, then at a minimum the user should check, record, and trend the chamber high voltage and the measured value for the electrometer zero check. Small changes in the high voltage will identify system malfunctions that might not be apparent with the use of radioactive calibration sources, but will begin impacting higher activity readings. The system clock should be checked and should be accurate within one minute.

### 4.3 Operational Tests

#### BACKGROUND AND CONTAMINATION TEST

The purpose of this test is to determine the background radiation level and to ensure the absence of contamination that may affect measurements on the dose calibrator. Background radiation may fluctuate due to movement of sources near the chamber,

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99615_02_01
@2024 USPC

as well as by contamination in or near the chamber, the liner, or the source holder. For this reason, this test should be performed with the liner and the source holder in the chamber. All radioactive sources should be well shielded or at a sufficient distance from the chamber. The background radiation level should be determined and recorded at initial installation, and periodically verified. The background should be recorded at least once on each day of use, or more frequently if necessary, using the most common radionuclide setting. It is especially important to verify if the minimum assayed quantity of radioactivity decreases.

## CONSTANCY TEST

The purpose of this test is to ensure the constancy of the dose calibrator over time. This test should be performed on each day of use, and completed after the system tests outlined above. Typical radioactive calibration sources used in this test are Cesium–137 or Cobalt–60 contained within a solid matrix. Cobalt–57 might not be suitable because of its nominal half-life of less than one year. The radioactive calibration source is not required to have the same geometry as routine test samples. A single radioactive calibration source is sufficient for this check. The source is placed in the source holder and the reading recorded for the dedicated radionuclide setting, as well as for all other commonly used radionuclide settings. This ensures no drift in response for any setting. Results should be recorded and be within the appropriate range of the decay corrected value recorded during IQ. Control charts or other data representations should be used to identify and document trends.

## ACCURACY TEST

The purpose of this test is to demonstrate the stability of the dose calibrator over the energy range used. This test should be performed annually or after the dose calibrator is repaired or moved. If the dose calibrator is used to measure the quantity of multiple radionuclides, two or three different radioactive calibration sources with different energies should be included to cover the expected energy range of the radionuclides. These calibration sources are typically contained in a solid matrix and do not necessarily match the geometry of routine test samples. If the dose calibrator is only used for a single radionuclide, or only for positron emission tomography (PET) radionuclides, a single calibration source may be adequate. The quantity of radioactivity in the calibration source should be greater than 100 µCi ($3.7 \times 10^6$ Bq). Sources used for this test should be traceable to a National Metrology Institute (NMI). Measurements of the calibration source activity are recorded and the average measured value is compared to the expected value. The measured value should be within the appropriate range of the expected value.

## REPRODUCIBILITY TEST

The purpose of this test is to measure the precision of the dose calibrator and should be performed at least annually. The radioactive calibration source should have a half-life such that decay corrections are not required over the period of the test. The quantity of radioactivity in the calibration source should be greater than 100 µCi ($3.7 \times 10^6$ Bq). An appropriate number of consecutive readings are recorded using the same geometry. Each of the measurements taken should be within an appropriate range of the mean of all the measurements.

## LINEARITY TEST

The purpose of this test is to show that the response of the dose calibrator is linear across the range of radioactivity levels to be measured. This is especially critical at high levels of radioactivity where the measured radioactivity may differ from the true radioactivity due to saturation effects, and at low levels of radioactivity due to variations on the background radiation and changes in the source positioning. This test should be performed annually or after the dose calibrator has been repaired or moved.

The test is considered successful if the ratio of the measured radioactivity to the expected activity is within the appropriate range of the expected values. Three techniques may be employed for this test: decay, graded shield, and graded source. Use of graded shields is acceptable once an initial linearity test using the decay method is successfully completed. Refer to the manufacturer's recommendations on the use of the graded shields. The graded source method requires accurate measurements of volume or mass, and is not generally recommended.

*Table 1* is an example of ongoing performance checks for dose calibrators.

**Table 1. List of Performance Tests**

| Parameter | Daily[a] | Annually (at a minimum) |
|---|---|---|
| Physical inspection | Yes | N/A |
| System electronics | Yes | N/A |
| Clock accuracy | Yes | N/A |
| High voltage | Yes | N/A |
| Zero adjust | Yes | N/A |
| Background response/contamination check | Yes | N/A |
| Radioactive calibration source (constancy and relative response) | Yes | N/A |
| Accuracy | See footnote[b] | Yes |
| Reproducibility (precision) | See footnote[b] | Yes |
| System linearity | See footnote[b] | Yes |

# 5. IDENTIFICATION OF RADIONUCLIDES

## 5.1 Half-Life Determination

The half-life is an identifying characteristic of a radionuclide. The half-life is determined by measuring the quantity of radioactivity in the test sample as a function of time. The approximate half-life may be used to confirm the radionuclidic identity. Perform the measurements using an appropriately calibrated instrument, such as a quantitative radioactivity detector, provided the quantity of radioactivity is within the linear range of the instrument throughout the measurements and the geometry of the test sample is not changed during the measurements.

The test sample may be used directly, or diluted and/or dried in a capsule as needed. The test sample is prepared in a manner that avoids losses during handling. If the test sample is a liquid or solution, the sample is held in a closed container. If the test sample is a residue from drying in a capsule, the sample is protected by a cover consisting of a sheet of adhesive cellulose acetate or other material. The quantity of radioactivity in the test sample should be sufficient to allow measurements over the time frame of the test. If necessary, correction for dead-time losses may be applied. The measured half-life should be within the range of the expected half-life as defined in each particular application of this test.

## 5.2 Gamma-Ray Spectrometry

The gamma-ray emission spectrum may be used to identify and quantify gamma-emitting radionuclides. The detector should be calibrated with a radioactive calibration source traceable to a NMI. The calibration source used to determine the efficiency of the detector should have a sufficient quantity of radioactivity to produce an adequate number of counts for each photopeak used in the calibration. The calibration source and the test sample should be measured with the same geometry and distance from the detector. It is critical that the geometry, including vial type and volume, be the same because these factors affect the amount of incident radiation on the detector. Photopeaks in the test sample should be comparable to those in the calibration source, both in terms of energy and intensity. The presence of unknown peaks or changes in peak abundance is indicative of impurities. Ensure that background radiation levels remain constant during the measurement, as changes may result in unknown peaks. Counting time or shielding should be optimized to achieve the necessary required minimum detectable activity to meet test specifications. It may be necessary to allow the radioactivity in the test sample to decay before it is possible to detect impurities at the required levels. There may also be short-lived impurities present, so an analysis should be completed to identify impurities and their half-lives to ensure the sample is assayed prior to their decay. Positron-emitting radionuclides typically cannot be differentiated because their emitted energy (511 keV) is the same for each radionuclide; thus, gamma-ray spectrometry is not a recommended prerelease test for radionuclidic identity for PET radionuclides. Some positron-emitting radionuclides have characteristic gamma-ray emissions in addition to 511 keV, which may be used for purposes of identification (e.g., Ge-69 and Na-22). Performance tests of the gamma-spectroscopy system should be completed on each day of use to ensure the functionality of the system.

## 5.3 Beta-Emitter Analysis and Identification

The purpose of the beta-emitter analysis and identification is to determine the maximum energy of the beta particle, which is unique and can be used for identification. Beta-emitting radionuclides can be identified either by evaluation of their spectrum or by measuring their mass attenuation coefficients in a series of absorption foils and constructing an attenuation curve. Performance tests of the beta counting system should be completed on each day of use to ensure the functionality of the system.

## 5.4 Alpha Spectrometry

The alpha emission spectrum may be used to identify and quantify alpha-emitting radionuclides. Pure alpha emitters present unique challenges due to their low penetration distance and their toxicity, especially if they are volatile compounds that could create airborne radioactivity and therefore internal radiation exposure to the experimenter or operator. Alpha particles can be detected either by the use of proportional counters, scintillation detection using a silver-activated zinc sulfide phosphor, or by the techniques of liquid scintillation counting (LSC). Performance tests of the alpha spectroscopy system should be completed on each day of use to ensure the functionality of the system.

# 6. ASSAY OF RADIONUCLIDES

## 6.1 Measurement of Radioactivity Using a Dose Calibrator

Using a holder, the test sample is placed in the chamber of the dose calibrator at a given position. Once the response is stable, the radioactivity reading is taken. Performing measurements on the test sample with the same geometry as the calibration source provides the most accurate results; however, geometry correction factors may be developed and used as necessary. Refer to the manufacturer's recommendations for the maximum radioactivity that can be determined in the dose calibrator.

## 6.2 Measurement of Radioactivity Using a Solid-State Detector

The test sample is positioned in front of the detector or into the well of a well-type detector. The detector must be adequately shielded and calibrated using a radioactive calibration source traceable to an NMI.

## 6.3 Measurement of Radioactivity Using Chromatographic Systems

A scintillation detector can be used for dynamic radioactivity measurements (e.g., the eluate of a liquid chromatograph is directed over or through a detector). The quantity of radioactivity in the test sample should provide a count rate that is within the linear range of the detector.

## 6.4 Measurement of Radioactivity Using a Liquid Scintillation Counter

LSC is the standard laboratory method to quantify radioactivity of particle-emitting radionuclides, mostly beta- and alpha-emitting radionuclides. The sample to be analyzed may require a liquid scintillation fluid (cocktail) depending on the energy of the beta particle. The LSC detection method uses liquid scintillation cocktails to transform emitted radiation into detectable light photons. The sample to be analyzed is placed into a liquid scintillation vial and the cocktail is added in the required amount. While a sample that can be dissolved into the fluid is preferred, other samples can be assayed if the impact on the light output is quantified. The detector should be calibrated using an appropriate radioactive calibration source traceable to an NMI. The absorption of scintillation photons is called quench, and it is necessary to develop a "quench curve" during PQ and additional quench curves may be necessary for different types of samples to correct the counting efficiency. Performance tests of the LSC should be completed on each day of use to ensure the functionality of the system.

## GLOSSARY

The following definitions apply to commonly encountered words and phrases when dealing with radioactivity.

**Alpha particles** ($\alpha$)**:** Positively charged particles emitted from nuclei during radioactive decay. Alpha particles are Helium-4 nuclei, consisting of two protons and two neutrons, but no electrons.

**Beta particles ($\beta^-$):** Negatively charged particles that are emitted from nuclei during radioactive decay. Beta particles are electrons.

**Calibration factor:** The coefficient used to convert the measured ionization chamber current to a nominal radioactivity. This term is often referred to as the "calibration coefficient".

**Calibration time:** Arbitrary time and date, if appropriate at which the specified amount of radioactivity is present.

**Counting assembly:** Consists of a sensing unit and an electronic scaling device. The sensing unit may be a Geiger-Müller tube, a proportional counter, a scintillation detector in which a photomultiplier tube is employed in conjunction with a scintillator, or a solid-state semiconductor.

**Dose calibrator:** A well-type ionization chamber commonly used to assay radiopharmaceuticals. Display units are typically in curies (μCi/mCi/Ci) or becquerels (kBq/MBq/GBq).

**Gamma rays** ($\gamma$-rays)**:** Electromagnetic radiation emitted from nuclei during radioactive decay. Gamma rays have a wide range of energies. The gamma rays emitted from a given radionuclide are always at the same energy(ies) providing a unique signature that enables the identification of a gamma-emitting radionuclide.

**Geiger-Müller counter:** Often referred to as "G-M counter" or "Geiger counter". An instrument in which a high voltage potential is applied across a volume of inert gas for the purpose of collecting ions produced by a radiation field. The negative electrons are internally multiplied to produce a readily detectable current pulse. Display units are typically counts per minute (cpm) or milliroentgen per hour (mR/hr).

**Geometry:** The characteristics of a radioactive source (i.e., container type, container wall thickness, volume, and position of the container in the well chamber) that, along with the physical characteristics of the ionization chamber, affect the magnitude of the calibration coefficient for a specific radionuclide. The principal geometry considerations that may affect the accuracy of a source measurement in a dose calibrator are container configuration, source volume, position of the source in the chamber well, and the radionuclide itself.

[NOTE—It is customary to compare a standardized preparation and radiopharmaceutical drug or preparation using identical geometry conditions for assay, identification, and other parameters. The validity of the result is critically dependent upon the reproducibility of the spatial relationships of the source to the detector and its surroundings and upon the accuracy of the standardized preparation.]

**Ionization chamber:** An instrument in which an electric field is applied across a volume of inert gas for the purpose of collecting ions produced by a radiation field. The positive ions and negative electrons drift along the lines of force of the electric field, and are collected on electrodes, producing an ionization current. The most commonly used form of ionization chambers for measurement of the activities of radiopharmaceuticals is a well-type ionization chamber known as a dose calibrator.

**Isobars:** Nuclides with the same mass number (protons + neutrons).

**Isomers:** Atoms with the same number of protons and neutrons, but a different nuclear energy configuration. Short-lived radioactive isomers are generally referred to as metastable. Different isomers are different nuclides based on their nuclear energy configurations.

**Isotones:** Nuclides with the same number of neutrons and a different number of protons. Isotones are different elements with different atomic masses.

**Isotopes:** Nuclides with the same number of protons and a different number of neutrons. Isotopes are the same element with a different atomic mass.

**Isotopic carrier** (also referred to as carrier)**:** A stable isotope of the element concerned either present in or added to the radioactive preparation in the same chemical form as the radionuclide.

Official

https://pharmacopeia.com/

**Liquid scintillation counter (LSC):** An instrument which detects scintillation light from the absorption of radiation energy in a scintillation liquid. This instrument is used primarily for beta-emitting radionuclides that do not also emit gamma photons. For best results, the radioactive sample should be soluble in the scintillation liquid.

**Minimum detectable activity:** Smallest quantity of radioactivity that can be detected above the background with a specified level of confidence.

**National Metrology Institute** (NMI)**:** A measurement standards body, which is a laboratory of metrology that establishes standards for a country or organization. For example, National Institute of Standards and Technology (NIST) is the NMI for the United States.

**Nuclide:** An atom with a specific number of protons and neutrons in a given nuclear energy state.

**Positrons** ($\beta^+$)**:** Positively charged particles emitted from a nucleus during radioactive decay. Positrons are anti-electrons.

**Radioactivity:** (1) The spontaneous transformation of nuclei characterized by the emission of particles or photons. Radioactivity is typically described as atoms undergoing radioactive decay per unit time (or disintegrations per unit time). (2) The quantity of radioactive material, as measured in units of curies (U.S. units) or becquerels (SI units). The quantity of radioactive material may also be referred to as activity.

**Radiochemical identity:** The molecular structure of the intended active radiopharmaceutical ingredient, which is present in the radiopharmaceutical preparation.

**Radiochemical purity:** The ratio, expressed as a percentage, of the radioactivity of the intended active radiopharmaceutical ingredient to the total radioactivity of all radioactive ingredients and impurities present in the radiopharmaceutical preparation.

**Radioisotope:** A radioactive atom, generally used in the context of an isotope of an element.

**Radionuclide:** An unstable nuclide that undergoes radioactive decay; a radioactive nucleus. The terms radionuclide and radioisotope are commonly used interchangeably.

**Radionuclidic identity:** The intended radionuclide in the radiopharmaceutical preparation.

**Radionuclidic purity:** The ratio, expressed as a percentage, of the radioactivity of the intended radionuclide to the total radioactivity of all radionuclides in the radiopharmaceutical preparation.

**Radiopharmaceutical** (radiopharmaceutical preparation/radioactive drug)**:** A finished dosage form that contains a radioactive substance in association with one or more other ingredients and that is intended to diagnose, stage a disease, monitor treatment, or provide therapy. A radiopharmaceutical includes any nonradioactive reagent kit or radionuclide generator that is intended to be used in the preparation of any such substance. The terms radiopharmaceutical and radioactive drug are commonly used interchangeably.

**Scintillation crystal counter:** An instrument consisting of a crystal scintillator, such as NaI (Tl), with attached photomultiplier tube and associated electronics. Scintillation light produced from the absorption of gamma and X-rays in the crystal is converted to electrons and amplified in the photomultiplier tube. The resultant current pulse may be further analyzed with regard to photon energy. A commonly used form of this instrument that has a hole in the crystal of sufficient size to allow placement of a test tube or similar container is known as a "well counter".

**Semiconductor detector:** An instrument consisting of a semiconductor material, such as silicon or germanium crystals, that detects ionizing radiation through generation of charge carriers (passage of electrons through holes). The current pulse produced by migration of these charge carriers, under the influence of a voltage potential across the material, can be further amplified and analyzed to determine the quantity and energy of the incident radiation.

**Solid-state detector:** A crystal-based detector, in contrast to a gas-based detector. Often is used as a synonym for a semiconductor detector.

**Strength:** The radioactivity concentration of the radiopharmaceutical at the calibration time. The unit of strength is the amount of radioactivity on a volume basis (e.g., mCi/mL or MBq/mL).

**Total radioactivity:** The radioactivity of the radionuclide, expressed per unit (e.g., vial, capsule, ampoule, generator, and others) at the calibration time.

**Validation:** Establishment of documented evidence that a method, process, or system meets its intended requirements.

**Verification:** Confirmation that an established method, process, or system meets predetermined acceptance criteria.

**X-rays:** A type of electromagnetic radiation emitted from the electron orbitals. While they do not arise from the nucleus they are often present immediately following a decay event if there are interactions between the emitted radiation and the orbital electrons.

## 1. INTRODUCTION

Radionuclides used in positron emission tomography (PET) typically possess short physical half-lives, $T_{1/2}$ (e.g., $T_{1/2}$ of $^{15}O$ = 2.03 min, $^{62}Cu$ = 9.67 min, $^{13}N$ = 9.96 min, $^{11}C$ = 20.4 min, $^{68}Ga$ = 67.7 min, $^{18}F$ = 109.8 min, $^{64}Cu$ = 12.7 h). As a result, these radionuclides usually are produced using particle acceleration techniques (e.g., cyclotrons) or from generators, and then are processed into the final PET drug product in close proximity to the site where the PET procedure will be conducted.

The short half-lives of PET radionuclides create unique constraints for the preparation and testing of PET drug products. This chapter describes guidelines for making and testing PET drug products based on the following constraints:

- It is not possible to complete all testing before the use of PET drug products.
- An entire batch or sub-batch of a PET drug product may be contained in a single vial. Samples withdrawn for quality control (QC) testing are representative of the entire batch or sub-batch.
- An entire batch or sub-batch may be administered to a single patient.
- The mass of the PET drug in a PET drug product usually ranges from nanogram to microgram quantities.
- PET drug products do not enter a traditional drug distribution chain. Instead, PET drug products are used in-house or are delivered to the point of use by dedicated couriers.
- Small-scale facilities for the preparation of PET drug products have limited personnel and resources, which require the following:
    - Allowance for multiple operations in one area with adequate controls;
    - Allowance for the making and testing of multiple PET drug products using shared equipment;
    - Appropriate requirements for aseptic operations;
    - Appropriate requirements for system suitability and other day-of-use activities;
    - QC requirements for components, materials, and supplies;
    - Self-verification of significant steps in radionuclide production, PET drug production, or compounding and testing; and
    - Single-person oversight of production and compounding, review of batch records, and release authorization.

The scope of this chapter includes the production and compounding of PET drug products for human administration as used (a) according to state-regulated practice of medicine and pharmacy, (b) according to an approved investigational new drug (IND) application (see 21 CFR 312), and (c) according to research uses under the supervision of a Radioactive Drug Research Committee (RDRC; see 21 CFR 361). The scope of this chapter does not include dispensing activities as defined in other USP general chapters.

## 2. PERSONNEL

Sufficient numbers of personnel with the appropriate education, training, and experience are needed for the preparation and testing of PET drug products. The number depends on the size and complexity of the operations executed at each facility.

### 2.1 Training Requirements

Personnel should be trained before they begin to make and test PET drug products. Training can be performed by various methods, including live instruction, audio-video instruction, and study of publications. Training should address but is not limited to radionuclide production techniques, synthetic and purification methods, materials, components, reagents, stock solutions, automated and manual apparatus used to make PET drug products, and QC methods, including equipment, software, and documentation. Training must be documented.

### 2.2 Aseptic Operations Training

Training should address aseptic manipulations as well as the techniques and equipment used to achieve and maintain International Organization for Standardization (ISO) Class 5 environmental conditions. Training also should address all aseptic operations, including the assembly of sterile components, compounding, and filtration. Manipulations of sterile solutions should be performed by operators who are qualified to use aseptic techniques (see *Facilities and Equipment* below).

Personnel involved in aseptic operations should be evaluated periodically by aseptic simulations in which a microbiological growth medium is used to assess the quality of the aseptic operation. Aseptic simulations should provide the following:

- Include all manipulations required for the aseptic assembly of the PET drug product vial assembly (e.g., vial, filter, and syringe assembly, etc.).
- Represent worst-case scenarios for aseptic operations.
- Be performed in triplicate to qualify a new operator. Each operator should be requalified annually by conducting at least one media fill.
- Be performed any time procedures are changed significantly.

After the simulation process, the media should show the absence of contamination after incubation at a suitable temperature for 14 days. An operator who fails written assessments or whose aseptic simulations result in microbial growth should be immediately re-instructed and re-evaluated to ensure correction of aseptic practice deficiencies.

## 3. QUALITY ASSURANCE

QA is a broad concept that covers all matters that influence identity, strength, quality, and purity of a PET drug product. QC is a subset of QA that deals with testing of materials and PET drug products to determine if they meet acceptance criteria. The QA function typically consists of oversight activities, and the QC function consists of execution activities.

QC functions include the following.

- Evaluate each lot of incoming material to ensure that it meets its established specifications before use in the preparation or testing of PET drug products.
- Evaluate each batch of a PET drug product to ensure the batch meets its established specifications before authorizing the final release of the batch.

The oversight functions associated with QA include the following:

- Review completed batch records for accuracy and completeness.
- Approve procedures, specifications, processes, and methods.
- Ensure that personnel are properly trained and qualified, as appropriate.
- Ensure that PET drug products have adequately defined identity, strength, quality, and purity.
- Ensure that changes to component quality, suppliers, changes to production procedures, and changes to testing procedures and specifications are appropriate and implemented properly.
- Investigate errors and ensure that appropriate corrective and preventive actions are taken to prevent their recurrence.
- Handle complaints.
- Ensure that the PET drug products are produced, tested, labeled, released, and distributed according to the facility's established procedures and practices for PET drug products.
- Conduct periodic audits to monitor compliance with established procedures and practices for PET drug products.

Personnel at the facility may perform both QA and QC functions.

## 4. FACILITIES AND EQUIPMENT

Facilities should be adequate for the production, compounding, and testing of PET drug products. Work areas should be organized to prevent cross-contamination, mix-ups, and errors, especially in areas used for making multiple PET drug products. Work areas should be periodically cleaned to prevent the contamination of equipment, materials, components, or PET drug products by personnel or environmental conditions that could reasonably be expected to adversely affect PET drug product quality. These requirements should be described in written procedures, and their routine execution should be documented.

DOI: https://doi.org/10.31003/USPNF_M99617_01_01

## 4.1 Environmental Controls for Parenteral PET Drug Products

Because the sterility test results for parenteral PET drug products are obtained after release, facilities and equipment should ensure a sterile PET drug product.

### ASEPTIC WORKSTATION

The primary environmental control for aseptic operations is a high-efficiency particulate air (HEPA) filter that is capable of producing air with a cleanliness rating of ISO Class 5. This can be achieved with a laminar airflow workstation, aseptic isolator, biological safety cabinet, or other suitable device (generically, aseptic workstations). The aseptic workstation should be protected from sources of microbial contamination and should be located in an area where personnel traffic is limited. The area around the aseptic workstation should not be used for storage of materials that shed large quantities of particulate matter (e.g., corrugated boxes).

The proper operation of the aseptic workstation must be certified by measurement of airborne particles, HEPA filter integrity testing, pressure differential testing, or other means. The specific tests depend on the type of aseptic workstation. Certification should be performed at the inception of operation and at least annually thereafter or after repair or replacement of the HEPA filter. These requirements supersede those in other USP general information chapters (e.g., *Microbiological Control and Monitoring of Aseptic Processing Environments* ⟨1116⟩).

The work area inside the aseptic workstation should be clean. The internal surfaces should allow easy cleaning and disinfection. The internal surfaces should be cleaned and disinfected with appropriate disinfectants that are sterile filtered or certified sterile with a manufacturer's certification.

### MICROBIOLOGICAL TESTING

Microbiological testing of the environment should be performed to assess air quality and surface disinfection of the aseptic areas. This can be achieved by either settling plates or active air-sampling plates. Surface disinfection of critical surfaces (e.g., the work surface of the aseptic workstation or operators' fingers) should be assessed with swab or contact plates. For microbiological testing of the aseptic workstation, the air should be tested as part of the workstation qualification (e.g., every six months) and the surface (using swab or contact plates) should be assessed after use, each day of use. Nonviable particle counts may be determined less frequently following certification of the *Aseptic workstation* (see above).

Alert and action limits should be established for samples obtained during microbiological testing. Typical alert levels are set at less than three colony-forming units (cfu) per plate. More than three cfu require corrective actions that may include operator retraining, recertification of the aseptic workstation, or other actions. The results of microbiological testing also should be used in the investigation of positive sterility tests.

## 4.2 Equipment

Equipment used to make and test PET drug products should be appropriate for its intended purpose and should be installed, cleaned, and maintained in an appropriate manner. Equipment should be capable of producing consistent results.

The following requirements should be described in written procedures, and performance of these procedures should be documented.

1. *Installation of New Equipment*—Newly installed equipment should be qualified before it is used to make or test PET drug products at an appropriate level of detail based on complexity. All qualification activities should be properly documented, including the date and the name of the person who performed the qualification. For more complex equipment, qualification consists of three phases:
    - Installation Qualification (IQ)—IQ is a check of items required for proper installation of the equipment, including physical location, required utilities and supplies, communications, and environmental conditions. IQ should describe the installation procedure for the equipment.
    - Operational Qualification (OQ)—OQ is a check of operational specifications for the equipment, including equipment set-up, functional testing of subsystems, and proper overall operation. OQ should describe operational procedures for the equipment.
    - Performance Qualification (PQ)—PQ demonstrates that the equipment is capable of performing tasks required to make and test PET drug products in the operating environment and that the equipment provides the intended results. PQ should describe the required performance tasks for the equipment.
2. *Calibration of Equipment*—Analytical equipment calibration should be performed before use, as appropriate. A schedule should be developed for recalibration and should have a sufficient frequency to ensure accurate results. Calibration activities should be properly documented, including the date and the name of the person who performed the calibration.
3. *Preventive Maintenance of Equipment*—A preventive maintenance schedule should be developed for major production and testing equipment, including automated chemistry modules, gas chromatographs, high-performance liquid chromatographs, and others. The schedule should have a sufficient frequency to minimize equipment downtime. Major repairs may require recalibration and requalification. Preventative maintenance activities should be properly documented, including the date of such performance and the name of the person who performed them.

## 4.3 Cleaning Equipment and Components

Equipment used in production or compounding of PET drug products includes automated, computer-controlled devices, as well as manually operated apparatus. Before it is used in making PET drug products, equipment should be properly cleaned to

Official

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99617_01_01
@2024 USPC

ensure that the resulting PET drug product meets established specifications for identity, strength, quality, and purity (see *Controls and Acceptance Criteria for Finished PET Drug Products* below). Once cleaned, equipment should be maintained in a state of cleanliness before use.

Equipment may be used to make multiple batches of one or more PET drug products. Documented studies should demonstrate the effectiveness of the cleaning process between batches. All impurities should be controlled at levels that conform to established specifications for identity, strength, quality, and purity. Written procedures for line clearance between batches of different PET drug products should describe routine execution of cleaning processes.

### 4.4 Day-of-Use Checks

Day-of-use checks are necessary for processing equipment to ensure proper function. Written procedures for the day-of-use checks should be established and followed. These procedures should be designed to check key parameters at the beginning of each operational cycle (e.g., temperature, pressure integrity, gas supply, vacuum supply, proper delivery line selection, reagent delivery volumes, gas flow rates, radiation monitors, and other process sensors). Some parameters may be periodically checked as part of the calibration and preventive maintenance schedules as described above.

### 4.5 System Suitability for QC Equipment

System suitability tests are necessary for QC equipment to ensure that the equipment, components, and personnel (i.e., the system) function as a whole to execute the desired analytical method. System suitability tests should be performed prior to using the equipment according to established procedures. Written procedures should be established and followed for system suitability tests, and the test results should be documented.

The system suitability tests required for chromatographic methods include tailing factor, replicate injections, and resolution. When the test chromatogram used for system suitability contains only a single peak, then tailing factor, replicate injections, and column efficiency (theoretical plates) are adequate. The use of internal or external standards with a known concentration is necessary for these determinations. Standards should be prepared from well-characterized materials or from materials that have a manufacturer's certification. Two acceptable approaches that may be used for chromatographic methods are the following:

1. Create a calibration curve from a range of standards with known concentrations. The concentrations of the standards should bracket the conditions of use for the chromatographic method. The calibration curve should be used over a suitably specified period of time (e.g., six months), after which time a new one should be created. A new calibration curve should be created each time an alteration is made to the chromatographic system. Routine system suitability for replicate injections consists of a single injection of a known standard and a measurement of the concentration based on the calibration curve. If the measured concentration agrees with the known concentration within a predefined range (e.g., 10% for manual injections and 5% for automated injections), this demonstrates the suitability of the system for replicate injections and ensures that the calibration curve is appropriate for use in subsequent sample injections. The tailing factor and resolution (or column efficiency, as appropriate) should be determined from the same chromatogram.
2. At the beginning of each testing cycle, create a single-point calibration from two injections of a known standard. The measured area of the peaks for these injections should agree within a predefined range (e.g., 10% for manual injections and 5% for automated injections). Then the results are averaged and used with the standard concentration to provide a calibration factor that is used in subsequent sample injections for that day. The tailing factor and resolution (or column efficiency as appropriate) should be determined from one of the two chromatograms.

Other chromatographic parameters such as signal-to-noise ratio, limit of detection, and limit of quantitation can be determined as part of routine system suitability testing.

System suitability tests also may be appropriate for other QC equipment, including dose calibrators, scanners for radio–thin layer chromatography (radio–TLC), and multichannel analyzers. When used, these tests should be performed at installation, relocation, and appropriate intervals thereafter. These tests should use known standards to demonstrate the proper function of the equipment, for example:

1. *Dose Calibrator*—Accuracy, geometry, and linearity should be assessed at installation and at appropriate intervals thereafter. The instrument should be calibrated in accordance with nationally recognized standards or the manufacturer's instructions. Routine system suitability testing should include a constancy check with a suitable high-energy radionuclide source.
2. *Radio–TLC Scanner*—Uniformity, positional accuracy, detector linearity, and resolution should be assessed with a suitable radionuclide source. Routine system suitability testing should include checks for these parameters.
3. *Multichannel Analyzer*—Sensitivity and resolution should be assessed at installation and at appropriate intervals thereafter. Routine system suitability testing should include a constancy check with a suitable high-energy radionuclide source.

## 5. CONTROL OF COMPONENTS, MATERIALS, AND SUPPLIES

Components, materials, and supplies that are used in the preparation of PET drug products should be controlled to avoid contamination, mix-ups, and errors. A designated person should be responsible for ensuring that these activities are carried out and completed properly. Records of completed examinations and tests for components, materials, and supplies should be maintained for one year after their expiration or for one year after batch release, whichever is longer. The following activities should be established and performed:

1. Establish written specifications for the identity, strength, quality, and purity of ingredients, reagents, target materials, and gases.

https://pharmacopeia.cn/
Printed on: Fri Jan 05 2024 06:37:17 AM(EST)
Printed by: USP NF
Do Not Distribute
Status: Currently Official on 05-Jan-2024
Official Date: Official Prior to 2013
DOI Ref: 3152s
DocId: GUID-D4D78DB7-60F3-4CA7-A792-E1F012A9A81B_1_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99617_01_01

2. Establish written specifications for the identity and quality of sterile empty vials, transfer lines, sterile stopcocks, sterile needles, sterile membrane filters, and other components used in the PET drug product vial assembly.
3. Establish written specifications for the identity, strength, quality, and purity of analytical supplies (e.g., solvents, chromatography columns, and authentic standards), sterility test media, and endotoxin test reagents used in the testing of PET drug products.
4. Establish appropriate storage conditions (based on heat, light, humidity, and other factors) for components, materials, and supplies used to make and test PET drug products.
5. Store components, materials, and supplies in a controlled-access area according to established storage conditions. Segregate components, materials, and supplies as appropriate to avoid mix-ups and errors.
6. Log each lot of shipment of components, materials, and supplies, and record the date of receipt, quantity received, manufacturer, manufacturer's lot number, and expiration date. If no expiration date is designated by the manufacturer, assign one based on knowledge of its physical and chemical properties and previous experience with its use. For organic substrates and reagents that are potentially susceptible to degradation or to a change in composition, the expiration date should be based on the material's stability.
7. Determine that each lot of components, materials, and supplies complies with established written specifications. Compliance with specifications can be demonstrated by inspection of the labeling or inspection of the manufacturer's certification. The identity of each lot of components, materials, and supplies should be verified by defined procedures, tests, or documented manufacturer's certification, as appropriate. Perform an identity test for precursors (e.g., melting point determination or other appropriate tests). Alternatively, the manufacturer's certification can be used as the only acceptance criterion for a precursor if final testing of the PET drug product ensures that the correct precursor has been used. Reference standards used in chromatographic procedures should have suitable documentation of identity and purity. Other components can be accepted on the basis of a manufacturer's certification only.
8. Membrane filters used with parenteral PET drug products should have a manufacturer's certification. Examine the manufacturer's certification for each lot to ensure compliance with written specifications.
9. Media used in the sterility testing of PET drug products may be obtained from commercial sources. If the media is obtained from commercial sources, then growth-promotion testing that uses a suitable single species of organism should be performed on initial qualification of the supplier and periodically (e.g., quarterly) thereafter.

## 6. PROCESS AND OPERATIONAL CONTROLS

### 6.1 Process Controls

The following process controls should be established and summarized in a master formula for the PET drug product. A designated person should be responsible for ensuring that these activities are carried out and completed properly.

1. Written acceptance criteria for the identity, strength, quality, and purity of each PET drug product should be established. For PET drug products intended for parenteral administration, specifications should include sterility and bacterial endotoxins. If a *USP* monograph exists or if there are specifications that have been previously accepted by the appropriate regulatory agency (e.g., FDA), then these standards, if applicable, may be applied as the minimum acceptance criteria.
2. Written procedures for the preparation of each PET drug product should provide the following:
    - Incorporate, for each PET drug product intended for parenteral administration, sterile membrane filtration (0.22 µm) or steam sterilization;
    - Incorporate, for each PET drug product intended for inhalation, particulate filtration (0.45 µm);
    - Describe routine cleaning procedures for equipment and facilities;
    - Describe components, materials, and supplies used to make PET drug products, including precursors, standards, reagents, stock solutions, and related items;
    - Describe the process and the steps used to make the PET drug product;
    - Describe the formulation process, including the use of stabilizers, buffers, and other agents;
    - Describe calculations performed for quantitative parameters associated with making and QC testing the PET drug product (e.g., including radiochemical yield, radiochemical purity, specific activity, solvent amounts, etc.);
    - Describe QC tests for the final PET drug product (see *Controls and Acceptance Criteria for Finished PET Drug Products* below), including a schedule that defines whether or not each test should be performed on each batch and that states if the test results should be complete at the time of release.
3. The quality of each batch of a PET drug product should be verified by full finished product testing prior to use to ensure the product meets all specifications.
4. In cases where testing as described in the previous paragraph is not possible or impractical, the quality of a PET drug product may also be ensured by documented validation studies in lieu of prerelease tests. Such studies should provide the following:
    - Demonstrate a consistent process that is suitable for the intended preparation of the PET drug product;
    - Be completed on three batches made according to the master formula, and all three batches should meet all acceptance criteria;
    - Include evaluation of radiochemical identity and purity, radionuclidic identity and purity, specific activity, sterility (for parenteral PET drug products), bacterial endotoxins (for parenteral PET drug products), pH, appearance, stereochemical purity (for applicable compounds), residual solvents, other toxic chemicals that may have been used during the synthesis or purification procedure, effective concentration of a stabilizer (if any), chemical purity of the PET drug product, and equivalence of initial and final sub-batches (see *Definitions* above);

Official

https://pharmacopeia.cn/v3/

- Be repeated if the process and steps described in the master formula have been altered in a way that could change the identity, strength, quality, or purity of the PET drug product;

5. The processes and steps described in the master formula should be updated as needed and should be reviewed annually to ensure they are current. Prior to the implementation of updates, appropriate validation and/or verification should be approved and performed.

Appropriate controls of computer-controlled equipment should ensure that process changes are instituted only by authorized personnel and that such changes are documented and verified. Production, compounding, and test methods should be backed up and controlled to avoid accidental use of outdated methods. In the case of processes or test methods from a vendor that are used without alteration, it is acceptable to rely on vendor certification for software verification and proper operation.

## 6.2 Operational Controls

The following operational controls should be established and summarized in a batch record that is a subset of the master formula for the PET drug product. The batch record should adequately document the routine process for making the PET drug product. A designated person should be responsible for ensuring that these activities are carried out and completed properly. Completed batch records and associated documentation should be maintained for one year after batch release.

1. Execute suitable line clearance procedures to avoid mix-ups and cross-contamination, including the inspection of areas used to make and test PET drug products, and the inspection of all equipment for cleanliness and suitability before use. Remove extraneous materials and labels from these areas and equipment.
2. Ensure the correct identity, strength, quality, and purity of components, materials, and supplies used in the preparation of the PET drug product. Label components as appropriate for identity and traceability purposes.
3. Execute routine cleaning procedures for equipment and facilities.
4. Prepare the PET drug product according to the current master formula, and for each batch maintain a batch record. Batch records may consist of paper documents, electronic records, or combinations thereof. Spreadsheets and other electronic recordkeeping tools should be verified to ensure traceability, data integrity, accuracy of results for calculations, and so on. The batch record should include the following:
    - Lot numbers or other unique identifiers for all components, materials, and supplies used to make the PET drug product;
    - A description of the individual procedures that were followed;
    - The initials, signature, or other identifier of the responsible individual indicating that critical steps and processes used to make and test the PET drug product were completed;
    - The percent yield calculated on the basis of the known or expected amount of the starting radionuclide that is synthetically incorporated into the PET drug product;
    - Raw analytical data on each batch of the PET drug product;
    - Labeling for the PET drug product (see *Labeling* below);
    - Calculations for key parameters defined in the master formula;
    - Results obtained from QC tests of the PET drug product, including chromatograms, print-outs, and other test data;
    - The initials of the analyst who performed each QC test;
    - A notation of the result for each QC test and whether or not the result meets the acceptance criteria;
    - The date and time of release and the signature of the individual who assumes overall responsibility for, and adherence to, the procedures used to make the batch and authorizes the release of the batch for human administration; and
    - Documentation on the batch record of process deviations, when applicable.

Entries in batch records should be made immediately after the activity is performed and should include the initials, signature, or other identifier for the person making the entry. Corrections to paper entries should be dated and initialed, signed, or noted with an identifier of the person making the corrections but leaving the original entry still readable.

## 6.3 Aseptic Operations for Parenteral PET Drug Products

Because the sterility test results for parenteral PET drug products are obtained after release for human administration, aseptic operations and procedures should adequately ensure a sterile PET drug product. All aseptically prepared PET drug products for parenteral administration should be filtered through a sterile membrane filter of 0.22-µm or finer pore size into a closed sterile vial or container or sterilized by steam sterilization. Although the chemical synthesis of a parenteral PET drug product may take place in an open or closed apparatus, the membrane filtration of the PET drug product should be a closed system downstream of the membrane filter. This system should be aseptically assembled from presterilized, commercially available components.

### COMPONENTS

The sterile components used in the aseptically assembled apparatus typically consist of an empty vial, needles, membrane filters, vent needles, syringes, tubing, stopcocks, and perhaps others. All components should be single-use, commercially available, presterilized items. If components in the aseptically assembled apparatus are sterilized by the PET facility, the sterilization processes should be verified. The exact configuration of the PET drug product vial assembly is process dependent. A typical example is a sterile, empty vial with a membrane filter of 0.22-µm pore size attached to a needle that is inserted through the vial septum for filtration, a membrane filter of 0.22-µm pore size attached to a needle that is inserted through the vial septum for venting the vial during filtration, and a syringe with needle inserted through the vial septum for removal of the QC sample after filtration is complete.

DOI Ref: 3152s
DocId: GUID-D4D78DB7-60F3-4CA7-A792-E1F012A9A81B_1_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99617_01_01

PET DRUG PRODUCT VIAL ASSEMBLY

Aseptic techniques should be used in the preparation of the PET drug product vial assembly, especially the assembly of all components downstream from the membrane sterilizing filter. These operations should be performed in an ISO Class 5 environment (see *Facilities and Equipment* above).

Following the creation of the PET drug product vial assembly in the ISO Class 5 environment, the assembly can be removed to another location for filtration. The location can be a noncontrolled environment as long as the integrity of the PET drug product vial assembly is not compromised during the process. Any PET drug product vial assembly that is compromised during this process should be discarded.

ASEPTIC TECHNIQUES

Any sterile component downstream from the membrane filter that contacts the PET drug product should be handled using suitable aseptic techniques inside the aseptic workstation. During aseptic operations, operators should wear proper attire, including a clean laboratory jacket, forearm sleeves, hair cover, sanitized gloves that cover the wrist, and beard/moustache covers (as appropriate). Multiple PET drug product vial assemblies can be prepared in a single aseptic operational cycle. The storage conditions and time for assembled vials should be based on data from aseptic simulations.

STERILITY TEST INOCULATIONS

Sterility tests should be performed to assess the quality of PET drug products intended for parenteral administration. The inoculation of sterility test media should be performed in a manner that is consistent with personnel radiation exposure requirements but that also minimizes the risk of false positives caused by adventitious contamination during the inoculation process. For media tubes with a screw-cap opening, the inoculation should be performed in the aseptic workstation. Media tubes with a septum cap can be inoculated in a shielded area that does not contain a HEPA filter.

## 7. STABILITY

Written specifications for the expiration time and storage conditions should be established for each PET drug product. The expiration time should be based on the results of stability testing (and specific activity requirements, as appropriate). Stability testing of the PET drug product should be performed at the highest strength of the PET drug product and in the intended final vial or container. At least three batches of the PET drug product should be stored according to proposed conditions and should be examined after a time period equal to the proposed shelf life. In addition, the PET drug product should meet acceptance criteria for radiochemical purity, appearance (color and clarity), pH, and stabilizer effectiveness (as appropriate) and chemical purity at expiry. Analytical methods should be reliable, meaningful, and specific. Stability studies should be repeated if there is a change in strength, stabilizer (or preservative) content that has the potential to affect the stability, the final vial or container, storage conditions, or expiration time. The results of stability testing should be documented.

## 8. CONTROLS AND ACCEPTANCE CRITERIA FOR FINISHED PET DRUG PRODUCTS

Written specifications for identity, strength, quality, and purity should be established for each PET drug product. For PET drug products intended for parenteral administration, specifications should be included for sterility and bacterial endotoxins.

Written procedures should be developed for QC tests. QC and documentation requirements should be established for each batch or sub-batch of a PET drug product (see *Process and Operational Controls* above). All QC tests should be executed by qualified and trained personnel according to written procedures.

The short half-life of PET radionuclides frequently precludes the completion of all QC tests before shipment of the PET drug product. This effectively creates two levels of release, one for distribution and the other for human administration. This is acceptable as long as the QC tests required for release of the PET drug product for human administration (see below) are completed before administration. The controls used in the release for distribution should be previously established in writing and should be documented in routine practice. It is not necessary to retain reserve samples of PET drug products.

If a *USP* compendial test procedure is used, the procedure should be verified to demonstrate that the test works under the conditions of actual use. Noncompendial test procedures used in the testing of a PET drug product should be reliable and specific. Supporting data for use of all analytical methods should be documented. Data derived from process studies or from in-process controls can be used as a basis for the omission of some QC tests. An example of this approach is the chlorodeoxyglucose determination in the testing of [$^{18}$F]fludeoxyglucose. Supporting data from process studies or in-process controls should be documented.

### 8.1 Quality Control Tests

The following QC tests should be performed on each batch before release for administration:

1. Appearance by visual inspection for color and clarity (absence of particulate matter) for parenteral dosage forms.
2. Measurement of the pH for parenteral dosage forms.
3. Determination of the radiochemical purity and identity of all dosage forms.
4. Determination of the radionuclidic identity of all dosage forms by half-life measurement.
5. Determination of the strength.
6. Determination of the specific activity of PET drug products that have mass-dependent localization or toxicity concerns.

Official

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:37:17 AM(EST)
Printed by: USP NF
Do Not Distribute

7. Determination of residual solvents used in the synthesis or purification processes.
8. Determination of the chemical purity and residual compounds used in the synthesis or purification processes (e.g., cryptand [2.2.2]).
9. Determination of preservative or stabilizer, if present.

For PET drug products with very short-lived radionuclides, prepare an initial QC sub-batch that is representative of successive sub-batches prepared in a defined operational cycle. The QC tests described in the previous paragraph should be considered for the QC sub-batch before release of subsequent sub-batches for human administration. For subsequent sub-batches of parenteral and inhaled dosage forms, visual inspection should be performed before human administration. In certain cases, limited testing of each sub-batch before administration may be appropriate (e.g., for pH determination of [$^{13}$N]ammonia produced by Devarda's alloy).

## 8.2 Periodic Quality Indicating Tests

For all PET drug products, periodically measure the radionuclidic purity of decayed samples of the PET drug product to assess the presence of long-lived radionuclides that are produced in targetry associated with the particle accelerator. For PET drug products labeled with certain radionuclides (e.g., $^{94m}$Tc, $^{124}$I, $^{64}$Cu, $^{76}$Br, and others), consider the measurement of radionuclidic purity by gamma spectrometry. Periodic quality indicating tests for PET drug products also include low-level nontoxic impurities (e.g., Class 3 residual solvents). The periodic testing should be performed at predetermined intervals rather than on a batch-to-batch basis.

## 8.3 Microbiological Tests for Sterile PET Drug Products

For PET drug products intended for parenteral administration, perform the following QC tests in addition to those described previously:

1. Determine the integrity of the membrane filter. Filter units used to sterilize PET drug products should be subjected to manufacturers' recommended integrity tests such as the bubble point test. Perform the filter integrity test after completion of filtration and before release of the PET drug product for human administration. In the case of PET drug products with $T_{1/2} < 10$ min, the PET drug product can be released for human administration before completion of the filter integrity test. In this case, the test should be completed as soon as possible after release.
2. Perform a test for bacterial endotoxins on each batch or QC sub-batch of a PET drug product. The test can be performed using recognized procedures in *USP* (see *Bacterial Endotoxins Test* ⟨85⟩). Regardless of which test is used, it should be initiated before release of each batch for human administration. For PET drug products with very short-lived radionuclides, complete the test on the QC sub-batch before the release of subsequent sub-batches for human administration. After a record of successful bacterial endotoxin tests is established for a particular PET drug product, it is necessary only to test the first batch prepared each day for that PET drug product.
3. Perform a test for sterility on each batch or QC sub-batch. The sterility test consists of the inoculation and incubation of a sample into each of two media: tryptic soy broth and fluid thioglycollate. The inoculated volume may be adjusted to avoid excessive losses because of sterility testing (e.g., 0.1 mL inoculated into 10 mL of media). The incubation period for sterility tests should begin within 30 hours of the membrane filtration. The samples can be inoculated immediately after completion of the membrane filtration, or they can be allowed to decay in a shielded area for as long as 30 hours before inoculation. It is acceptable to exceed the 30-hour period because of weekends or holidays provided it is shown that the extended period does not significantly reduce the viability of a suitable indicator organism in the sample. The sterility test may be performed using other recognized procedures in *USP* (see *Sterility Tests* ⟨71⟩). Samples should be tested individually and may not be pooled. After a record of successful sterility tests is established for a particular PET drug product, it is only necessary to test the first batch prepared each day for that PET drug product.

## 8.4 Conditional Final Release Tests

When a required QC test for a PET drug product cannot be completed because of a malfunction of testing equipment, it may be appropriate to conditionally release the batch. PET drug products may not be released without determination of radiochemical identity and purity. The batch may be released if the following conditions are met:

1. Review historical QC data to assess the frequency of out-of-specification (OOS) results or failures associated with the QC test. A conditional release is appropriate only if the historical data reveal a record of successful completion of the QC test.
2. Confirm that the acceptance criteria are met for all other QC tests for the batch.
3. Retain a sample of the conditionally released batch.
4. Promptly correct the malfunction of the testing equipment.
5. Complete the omitted QC test on the sample as soon as possible after the malfunction has been corrected. This is not necessary if the omitted QC result is meaningless after decay of the PET drug product.
6. If the sample fails the omitted QC test, immediately notify the physician or receiving facility that ordered the PET drug product.
7. Document all actions regarding the conditional release of the PET drug product, including the justification for the release, results of completed testing, and any notifications and corrective and preventive actions resulting from the incident.

In addition to the finished QC testing, other appropriate laboratory determinations could involve in-process testing of an attribute that is equivalent to finished-product testing of that attribute; continuous statistical process monitoring; or some combination of these approaches with finished testing of each PET drug product.

## 9. IF A PET DRUG PRODUCT DOES NOT CONFORM TO SPECIFICATIONS

When the result of a QC test for a PET drug product does not meet established acceptance criteria, the result is OOS. An OOS result does not necessarily mean that the final PET drug product is a failure and should be rejected. Instead, an OOS investigation should be performed to determine if the OOS result indicates a true failure or an analytical error.

If an OOS investigation concludes that the OOS result was caused by an analytical error, invalidate the original test. If a printout is associated with this test, mark the printout *invalid*, retain it for the batch record, and repeat the test.

If an OOS investigation concludes that the OOS result was a true failure, the batch should be rejected and cannot be released for human administration. Segregate the batch to avoid its potential use. Investigate all failures and document the results according to written procedures. The investigation should include, but is not limited to, the examination of processes, operations, and records from previous batches, as well as complaints and other relevant sources of information. If possible, assign an actual or probable cause to the failure, and document corrective actions undertaken as a result of the investigation. Depending on the nature of the failure, the PET drug product may be reprocessed according to pre-established written procedures (see *Reprocessing* below).

When a sterility test for a PET drug product shows signs of microbial growth, the test result is OOS and should be investigated. Upon completion of the investigation, immediately notify all receiving facilities if the product fails to meet the criterion for sterility, including the microbiological findings from the investigation.

## 10. REPROCESSING

If a PET drug product is rejected as a true failure, the batch may be reprocessed according to established procedures. It is not possible to describe all possible reprocessing operations, but some examples could include the following:

- pH adjustment;
- A second passage through a membrane filter in the event of a failed filter integrity test; and
- A second passage through a purification column to remove an impurity.

If a PET drug product is reprocessed, the reprocessed batch should be tested to ensure it meets the established acceptance criteria for the PET drug product before release for human administration.

## 11. LABELING

The following information should appear on the label attached to the final PET drug container:

- The name of the PET drug product, including the dosage form;
- The assigned batch number; and
- Any required warning statements or symbols (e.g., investigational use, radioactive).

The following information should appear on the shielding for the PET drug product:

- The name of the PET drug product, including the dosage form;
- The assigned batch number;
- The date and time of calibration;
- Any required warning statements or symbols (e.g., investigational use, radioactive);
- As appropriate, the total radioactivity in MBq (or mCi) or the strength in MBq/mL (or mCi/mL) at time of calibration;
- Expiration time and date;
- Added substance(s) (e.g., stabilizer inactive ingredients);
- The name of the producer where the PET drug product was made or the name of the distributor;
- Other applicable warning statement(s) (e.g., “Do not use if cloudy or if it contains particulate matter” or investigational use labeling); and
- Other pertinent information (if required), such as storage condition(s), half-life.

## GLOSSARY

**Batch:** A quantity of PET drug product that is intended to have uniform character and quality, within specified limits, and that is made in a single operational cycle produced according to one or more production order(s).

**Conditional final release:** A final release for patient administration before completion of required tests because of a malfunction of analytical equipment.

**Lot:** A quantity of materials (e.g., reagents, solvents, gases, purification columns, and other auxiliary materials) that have uniform character and quality within specified limits and are used to make a PET drug product.

**PET drug:** A radioactive substance (active pharmaceutical ingredient) that exhibits spontaneous disintegration of unstable nuclei by the emission of positrons and is incorporated into a PET drug product to furnish direct effect in the diagnosis or monitoring of a disease or a manifestation of a disease in humans, or monitoring treatment of disease or therapeutic procedures (e.g., tumor therapy).

**PET drug product:** A finished dosage form that contains a PET drug, whether or not in association with one or more other ingredients.

**Compounding:** The practice as described in the Food, Drug and Cosmetic Act (1997) Chapter II, Section 121 (a) (ii) (1) (B) of synthesizing or formulating a PET drug product, by or on the order of a practitioner who is licensed by a State to compound or order compounding for a PET drug product, and is compounded in accordance with that State’s law, for a patient or for research, teaching, or quality control.

Official

https://pharmacopeia.com/

**Line clearance:** The segregation and cleaning of different processing and work areas to avoid cross-contamination and mix-ups between the production and/or compounding of different PET drug products.

**Manufacturer's certification:** Documentation, including, but not limited to, certificates of analysis, certificates of conformance, or certificates of quality obtained from the manufacturer, supplier, or vendor of a material or component that describes critical quality characteristics used to determine acceptability of use.

**Out of specification (OOS):** A quality control test result for a PET drug product that does not conform to established acceptance criteria.

**Production:** The process of synthesis or formulation of a PET drug product including processing, packaging, labeling, reprocessing, and testing for investigational or research use.

**Quality assurance (QA):** A planned system for ensuring that a PET drug product possesses defined identity, strength, quality, and purity required for its intended purpose by procedures, tests, and analytical methods.

**Quality control (QC):** A system for testing the quality of components, materials, supplies, and PET drug products by procedures, tests, analytical methods, and acceptance criteria.

**Specific Activity:** The radioactivity of a radionuclide per unit mass of the element or compound. The unit of specific activity is radioactivity per mass expressed on a gram or mole basis (e.g., mCi/µg [MBq/µg], Ci/mmol [GBq/mmol]).

**Strength:** The radioactivity concentration of the PET drug in the PET drug product on a volume basis at the time of calibration. The unit of strength is the amount of radioactivity per volume at the time of calibration (e.g., mCi/mL [MBq/mL]).

**Sub-batch:** A quantity of PET drug product having uniform character and quality, within specified limits, that is produced during one succession of multiple irradiations using a given synthesis or purification operation. A group of sub-batches collectively form a batch that is intended to have uniform character and quality, within specified limits. Sub-batches may be required for PET drug products with very short-lived radionuclides (e.g., $^{13}N$ and $^{15}O$) because QC tests cannot be completed before use.

**Validation:** Establishment of documented evidence that a method, process, or system meets its intended requirements.

**Verification:** Confirmation that an established method, process, or system meets predetermined acceptance criteria.

GLOSSARY
APPENDIX

# 1. INTRODUCTION

Radiopharmaceuticals, as defined in this chapter (see *Glossary*), are a subset of radioactive materials (RAMs) falling under the control of the US Nuclear Regulatory Commission (NRC) or NRC-contracted agreement state agency. Radiopharmaceuticals are also a subset of prescription drugs falling under the control of the US FDA for manufacturing and marketing. Other federal regulatory authorities (e.g., Department of Transportation) have control over certain activities related to radiopharmaceuticals. Compliance with these regulations, as applicable, must be ensured in addition to compliance with the standards described in this chapter. [NOTE—Users outside the US must comply with equivalent regulations, as applicable, pertaining to radiopharmaceuticals.]

This chapter is intended to provide uniform minimum standards for the preparation, compounding, dispensing, and repackaging of sterile and nonsterile radiopharmaceuticals for humans and animals that occur as part of state-licensed activities (e.g., the practice of pharmacy and the practice of medicine). These standards apply to all radiopharmaceutical processing activities, including those with radionuclides that emit a single photon, a positron, or a therapeutic particle. Furthermore, these standards apply to sterile intravascular radioactive devices (e.g., radioactive microspheres for intravascular brachytherapy).

This chapter does not apply to the following activities:

- Manufacturing of approved radiopharmaceuticals (e.g., NDA, ANDA, BLA) in FDA-registered manufacturing establishments
- Manufacturing of radiopharmaceuticals as investigational agents (e.g., IND, RDRC)
- Compounding of radiopharmaceuticals in a registered FDCA §503B outsourcing facility
- Preparation/compounding of positron emission tomography (PET) drugs that are not manufactured as approved drug products (e.g., NDA, ANDA, BLA) and conforms with *Positron Emission Tomography Drugs for Compounding, Investigational, and Research Uses* ⟨823⟩
- Administration of radiopharmaceuticals to patients

In each of these scenarios except for patient administration, the further processing and manipulation of the drug product after release falls within the scope of this chapter.

This chapter does not apply to the preparation of non-radioactive drugs, including those used as pharmacologic adjuncts for certain nuclear medicine procedures. These drugs must be prepared following standards described in *Pharmaceutical Compounding—Nonsterile Preparations* ⟨795⟩ and *Pharmaceutical Compounding—Sterile Preparations* ⟨797⟩.

This chapter applies to all practice settings where radiopharmaceuticals are prepared, compounded, dispensed, or repackaged. Practice settings consist of state-licensed nuclear pharmacies, federal nuclear pharmacy facilities, and other healthcare facilities, including, but not limited to: nuclear medicine departments in hospitals and clinics, nuclear cardiology clinics (fixed site or mobile), and other specialty clinics.

This chapter applies to all individuals who prepare, compound, dispense, or repackage radiopharmaceuticals. Applicable individuals consist of authorized nuclear pharmacists (ANPs) and authorized user (AU) physicians, as well as individuals working under their supervision. This includes, but is not limited to, student pharmacists, nuclear pharmacy technicians, nuclear medicine technologists and students, and physician residents and trainees.

US federal and state radiation regulatory authorities require limiting radiation exposure to personnel who handle radiopharmaceuticals, which necessitates special provisions for radiation protection. The principles of radiation safety involve time, distance, shielding, and radioactive contamination control. Moreover, the use of radiation detection and measuring devices is a necessary component of radiopharmaceutical handling procedures. Strict adherence to all typical aseptic handling practices is not possible in many scenarios where radiopharmaceuticals are handled. Thus, it is necessary to balance aseptic handling practices (patient safety) with radiation protection practices (worker safety). This chapter describes appropriate strategies that provide assurance of maintaining patient safety, while also ensuring the safety of individuals performing these activities. Because radiopharmaceuticals represent a unique class of prescription drugs, the use of technologies, techniques, materials, and procedures other than those described in this chapter are not prohibited so long as they are documented to be equivalent or superior to those described herein.

## 1.1 Nonsterile Radiopharmaceuticals

Examples of nonsterile radiopharmaceuticals include oral capsules and oral solutions. For conventionally manufactured products or compounded preparations obtained from 503B-registered outsourcing facilities, dispensing can proceed as described in *12. Dispensing*. For prepared or compounded preparations, such preparations must comply with applicable identity, quality, and purity standards, as described in manufacturer labeling, *USP* monographs, or other appropriate sources (e.g., documented, peer-reviewed materials). They can then be dispensed as described in this chapter.

### 1.2 Sterile Radiopharmaceuticals

Examples of sterile radiopharmaceuticals include injectables (e.g., intravenous, intrathecal, intraperitoneal, subcutaneous, and intradermal), inhalations, ophthalmics, and intra-organ instillations. For conventionally marketed products, see *12. Dispensing*. For prepared or compounded preparations, such preparations must comply with applicable identity, quality, and purity standards. For compounded preparations involving one or more nonsterile components, a sterilization procedure (e.g., filtration with bubble point testing) must be performed prior to dispensing. For injectable compounded preparations involving one or more components that are not certified to be pyrogen-free, bacterial endotoxin testing, as defined in *Bacterial Endotoxins Test* ⟨85⟩, must be performed prior to dispensing.

The most important factor for maintaining sterility is the avoidance of touch contamination. Wipe the vial septum with sterile 70% isopropyl alcohol (IPA) prior to initial needle puncture. If the vial shield top is then closed, the septum must be disinfected again with sterile 70% IPA prior to another needle puncture. Some vial shields are constructed such that the vial septum is recessed and difficult to access. One approach for disinfecting the vial septum in this type of vial shield is to use right-angle forceps to hold a sterile 70% IPA wipe and apply direct contact with the vial septum. It is also acknowledged that such vial shields disrupt first air contacting the vial septum during certain handling conditions. Wipe the septum with sterile 70% IPA frequently whenever multiple punctures are occurring (e.g., removing several individual doses from a multiple-dose container).

## 2. RADIATION SAFETY CONSIDERATIONS

The handling of radiopharmaceuticals necessitates meeting the radiation regulatory agency requirements for worker safety. This involves licensing commitments to keep all exposure levels for the workers involved as low as reasonably achievable (ALARA) practices. Principles of radiation safety involve time, distance, shielding, and contamination control. Moreover, radiation detection and measuring devices are necessary. Aseptic handling practices must be balanced with radiation safety considerations, based on the following:

- Knowledge, training, experience, and professional judgment related to the type, abundance, and energy of the radioactive emissions
- The quantity of radioactivity, volume, handling steps, and timing
- Other factors, which can vary on a case-by-case basis

### 2.1 Time

Radiation exposure to personnel is directly proportional to the quantity of radiation handled and the time handling the RAM; minimizing handling time will minimize radiation exposure. Personnel handling radiopharmaceuticals may work quickly in a controlled and safe manner, including multiple hand movements in and out of the ISO Class 5 primary engineering control (PEC) during aseptic processes.

### 2.2 Distance

Radiation exposure follows the inverse square law; increasing the distance between the operator and the RAM will decrease radiation exposure to personnel by the square of the distance. Handlers of radiopharmaceuticals may utilize techniques to increase distance, such as using remote handling tools, including within an ISO Class 5 PEC.

### 2.3 Shielding

Radiation exposure to personnel decreases with the use of shielding materials. Therefore, handlers of radiopharmaceuticals may use various shielding materials (e.g., lead, tungsten) in various configurations. The use of shielding, such as L-block, torso, vial, and syringe shields, is usually required throughout the radiopharmaceutical handling process, including within an ISO Class 5 PEC.

### 2.4 Radiation Contamination Control

RAM contamination (e.g., spills, drips, sprays, volatility) is an important concern for radiation protection. Therefore, various techniques and materials may be used by handlers of radiopharmaceuticals to minimize radioactive contaminations. For example, container contents are maintained at neutral or negative pressure, because positive pressure in a container is a common cause of radioactive contamination. Disposable absorbent pads are commonly used to contain such radioactive contamination and, when used in an ISO Class 5 PEC, the pads must be clean and low-lint. Vertical air flow, not horizontal, in a PEC is used to control contamination. When exposure to blood and other potentially infectious material is reasonably anticipated, some engineered needlestick prevention devices may pose a radiation hazard to employees. Policies must be implemented for handling biohazardous radioactive sharps while minimizing contamination.

#### RADIATION DETECTORS AND MEASURING DEVICES

Radiopharmaceuticals require measurement with a suitable radiation measuring device (e.g., dose calibrator). These and other necessary equipment, (e.g., monitors, bar code scanner, label printer) may be placed inside an ISO Class 5 PEC but should be placed in a manner that minimizes disruptions of airflow.

As per RAM license requirements, individuals must wear body and, as required, extremity dosimeters (e.g., a ring worn on a finger) for long-term monitoring of personnel radiation exposure. The body dosimeter should be worn underneath the gown. Any extremity dosimeter must be worn underneath gloves and must not interfere with proper fit of gloves.

## 3. IMMEDIATE USE OF STERILE RADIOPHARMACEUTICALS

The preparation and dispensing of sterile radiopharmaceuticals in a patient care setting may be handled as an immediate use practice. The information below describes the appropriate handling requirements for immediate use sterile radiopharmaceuticals in an ambient environment that lacks primary and secondary engineering controls (SEC) when intended for a single patient. Strict aseptic technique and limited beyond-use date (BUD) must be adhered to given the lack of engineering controls.

- Appropriate for preparation (including minor deviations) and/or dispensing that is limited to use for a single patient.
- Preparation (including preparations with minor deviations) components must be sterile, conventionally manufactured drug products (e.g., NDA, ANDA).
- Dispensing of drug products produced under an approved IND or RDRC protocol is allowed.
- Manipulations for any unit doses (e.g., decreasing the dosage, needle changes) or dispensing for one patient (e.g., withdrawing a dose) is allowed.
- Must be administered within 1 hour of the first container puncture or exposure of any critical site involved (e.g., syringe tip, needle hub or needle) to ambient air, whichever is first.
- All components involved (e.g., Tc-99m sodium pertechnetate syringe or vial, final prepared radiopharmaceutical kit vial, diluent vial) must be discarded within 1 hour of being punctured or after use for a single patient administration, whichever is first.
- Dose pooling (combining doses from two or more syringes to meet one patient's need) may be performed as immediate use. Any residual activity that remains must be immediately discarded and not utilized for any other patient.
- Follow hand hygiene and garbing in *4.4 Hand Hygiene and Garbing for Immediate Use Preparations*.
- Follow *10.4 Preparation of Radiolabeled Red Blood Cells for Immediate Use* for red blood cell labeling.
- Follow *12.2 Labeling* for labeling.
- Area for sterile preparation and/or dispensing must be functionally separate from nonsterile compounding area (e.g., radiolabeling food) during the time of use.
- Does not require a segregated radiopharmaceutical processing area (SRPA), classified area, or PEC.
- The number of steps or punctures is not limited.
- Does not require personnel to complete the aseptic qualifications as detailed in *4.1 Aseptic Qualifications* (e.g., aseptic technique training with documented assessment, media fill challenge, gloved fingertip testing).
- While adding a non-radioactive, sterile and commercially manufactured pharmaceutical (e.g., lidocaine) to a unit dose is otherwise considered compounding, it is allowed for immediate use purposes as long as all of the above are adhered to.
- Dose splitting (splitting a unit dose for administration to more than one patient) may not be performed as immediate use; if performed, dose splitting must be done in an ISO class 5 PEC in either an SRPA or in an ISO class 8 or better buffer area.

## 4. PERSONNEL QUALIFICATIONS, TRAINING, AND HYGIENE

Personnel must be trained to work with radiopharmaceuticals per the policies and standard operating procedures (SOPs) authorized by an ANP or AU physician. These individuals (e.g., nuclear medicine technologists or nuclear pharmacy technicians) must follow these policies and SOPs of the ANP or AU physician and work under their supervision. As appropriate, this should include blood-borne pathogens training.

Individuals entering a compounding area must be properly garbed and must maintain proper personal hygiene to minimize the risk of contamination to the environment and/or radiopharmaceuticals. Individuals who have a condition that may pose a higher potential of contaminating the radiopharmaceutical and the environment with microorganisms (e.g., rashes, sunburn, recent tattoos, oozing sores, conjunctivitis, or active respiratory infection) must report these conditions to their supervisor. The designated person is responsible for evaluating whether these individuals should be excluded from working in sterile processing areas before their conditions are resolved.

### 4.1 Aseptic Qualifications

Personnel must prove competency, as applicable to their job functions, prior to performing radiopharmaceutical aseptic tasks that are beyond immediate use. These qualifications may be conducted at a different site if all SOPs are identical for the applicable job function. These qualifications must be completed and documented initially, and then successfully repeated at intervals described below in *Timing of Reevaluation and Requalification* under the observation of a designated person and include the following:

- Aseptic technique training with a documented assessment (written or electronic)
- Garbing and hand hygiene, as defined by the policies and SOPs
- PEC cleaning and disinfecting
- Gloved fingertip and thumb sampling
- Media-fill testing

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M11915_05_01

GLOVED FINGERTIP AND THUMB SAMPLING

Appropriate garbing, including sterile gloves, is necessary for personnel who enter and perform tasks in an ISO Class 5 PEC (e.g., aseptic manipulations, cleaning the PEC). Personnel that perform such functions must prove their competency in this process. Gloved fingertip and thumb sampling must be performed initially on both hands, immediately following hand-hygiene and garbing. Successful completion of initial gloved fingertip and thumb sampling is defined as zero colony-forming unis (cfu) and subsequent gloved fingertip and thumb sampling after media-fill testing is defined as ≤3 cfu (total for both hands).

- The gloved fingertip and thumb sampling must be performed with touch plates or other devices (e.g., plates, paddles, or slides) that contain a general microbial growth agar [e.g., trypticase soy agar (TSA) soybean–casein digest media] supplemented with neutralizing additives (e.g., lecithin and polysorbate 80) as this supports both bacterial and fungal growth
- Gloves must not be disinfected immediately before touching the sampling device, as this could cause a false-negative result
- Using a separate sampling device for each hand, a gloved fingertip and thumb sample from both hands must be collected by rolling finger pads and thumb pad over the agar surface
- The plates must be incubated in an incubator at 30°–35° for no less than 48 h, and then at 20°–25° for no less than 5 additional days

MEDIA-FILL TESTING

Media-fill testing is necessary for all personnel who prepare, compound, dispense, and repackage sterile radiopharmaceuticals. This testing must be reflective of the actual manipulations to be carried out by the individual and must simulate the most challenging and stressful conditions to be encountered in the worker's duties.

- Media-fill tests must be documented as defined by the facility's policies and SOPs.
- Media-fill tests should be performed at the end of a work session in the PEC.
- Media-fill tests must be performed with a commercial source of soybean–casein digest medium. Those performing sterile-to-sterile processing activities must start with sterile media. Those performing nonsterile-to-sterile compounding must use a nonsterile soybean–casein digest powder to make a solution. Dissolve nonsterile commercially available soybean–casein digest medium in nonbacteriostatic water to make a 3% nonsterile solution. Manipulate it in a manner that simulates nonsterile-to-sterile compounding activities. Prepare at least 1 container as the positive control to demonstrate growth promotion, which is indicated by visible turbidity upon incubation.
- The certificate of analysis (CoA) must include documentation of growth promotion testing for each lot of media used.
- Once the media-fill simulation is completed and the final containers are filled with the test medium, incubate media-filled containers in an incubator for 7 days at 20°–25° followed by 7 days at 30°–35° to detect a broad spectrum of microorganisms. Failure is indicated by visible turbidity or other visual manifestations of growth in the medium in 1 or more container–closure unit(s) on or before 14 days.
- In the event of failure, results of the evaluation and corrective actions must be documented and the documentation maintained to provide a record and long-term assessment of personnel competency. Documentation must at a minimum include the name of the person evaluated, evaluation date/time, media and components used including manufacturer, expiration date and lot number, starting temperature for each interval of incubation, dates of incubation, and the results.

## 4.2 Reevaluation, Retraining, and Requalification

REQUALIFICATION AFTER FAILURE

Personnel who fail visual observation of hand hygiene, garbing, and aseptic technique, gloved fingertip and thumb sampling, or media-fill testing must successfully pass reevaluations in the deficient area(s) before they can resume processing of sterile preparations. All failures, retraining, and reevaluations must be documented.

REQUALIFICATION PROGRAM

Personnel must successfully complete requalification in the core competencies listed in *4.1 Aseptic Qualifications*. Successful completion must be demonstrated through observation, written testing, and hands-on demonstration of skills.

TIMING OF REEVALUATION AND REQUALIFICATION

**Visual observation:** Personnel must be visually observed while performing hand hygiene, garbing SOPs, and aseptic technique procedures initially, and then at least once every 12 months.
**Gloved fingertip and thumb sampling:** Personnel must perform fingertip and thumb sampling 3 times initially, and then every 12 months (in conjunction with media-fill testing).
**Media-fill testing:** After initial qualification, conduct a media-fill test of all personnel engaged in sterile radiopharmaceutical processing at least every 12 months (in conjunction with gloved fingertip and thumb sampling).
**Cleaning and disinfecting:** Retrain and requalify personnel in the cleaning and disinfecting of sterile processing areas every 12 months or in conjunction with any change(s) in cleaning and disinfecting SOPs, whichever is sooner.
**After a pause in sterile radiopharmaceutical processing:** Personnel that have not performed radiopharmaceutical processing in more than 6 months must be requalified in all core competencies before resuming duties.

**Sterile compounding using a nonsterile drug substance or components:** Personnel who perform sterile compounding using a nonsterile drug substance or components (see *11.3 Sterile Compounding Using a Nonsterile Drug Substance or Components*) must be requalified in all core competencies every 6 months.

### 4.3 Ancillary Personnel

Personnel who are authorized to be within the sterile processing area and do not handle sterile preparations are not required to complete training on media-fill testing but are required to complete all other training and testing. Other personnel or visitors (e.g., auditors, regulators, student observers) must comply with garbing and gloving SOPs but do not need to prove competency.

### 4.4 Hand Hygiene and Garbing for Immediate Use Preparations

Radiopharmaceuticals may be prepared and dispensed as immediate use, and the precautions related to personal hygiene to be followed must include the following:

- Hand hygiene: Wash hands and arms to the wrists with soap and water or use a suitable alcohol-based hand rub with a time based on institution policies to reduce bioburden on the hands.
- Garbing: Immediately after hand hygiene, don a clean coat/gown that has not been exposed to a patient or patient care area, and either don sterile gloves or don nonsterile disposable gloves and then disinfect the gloves with sterile 70% IPA. [NOTE—A different lab coat must be worn to care for a patient than the coat/gown used for radiopharmaceutical preparation.]

### 4.5 Hand Hygiene and Garbing for Buffer Areas and Segregated Radiopharmaceutical Processing Area

In situations involving repackaging, dispensing, preparation, preparation with minor deviations, or compounding of sterile radiopharmaceuticals in an ISO Class 5 PEC, the following precautions related to personal hygiene are to be followed:

- Before entering the SRPA or buffer area, personnel must remove outer garments (e.g., bandanas, coats, hats, jackets, sweaters, vests); all cosmetics; all hand, wrist, and other exposed jewelry including piercings that could interfere with the effectiveness of the garbing (e.g., the fit of gloves, cuffs of sleeves, and eye protection). Nail products (e.g., artificial nails, polish, extenders) are prohibited. Natural nails must be kept neat and trimmed. Remove ear buds and headphones. Radiation dosimetry devices are allowed, as required by the RAM license.
- Do not bring electronic devices that are not necessary for compounding or other required tasks.
- Immediately before entering the SRPA or buffer area, remove visible debris from underneath fingernails under warm running water using a disposable nail cleaner. Personnel must wash hands and arms up the elbows with soap and water for at least 30 s and then dry hands using low-lint towels. Alternatively, hand washing may be performed after donning shoe covers, head/hair covers, and face mask, as described below.
- Personnel must don the following garb—shoe covers, head/hair/facial hair covers, face mask—in an order that eliminates the greatest risk of contamination, as defined in facility SOPs.
- If not already performed, remove visible debris from underneath fingernails under warm running water using a disposable nail cleaner. Personnel must then wash hands and arms up to the elbows with soap and water for at least 30 s and then dry hands using low-lint towels. Electronic hand dryers are not permitted.
- Personnel must then perform hand antisepsis cleansing using a suitable alcohol-based hand rub.
- Personnel must then don a low-lint gown with sleeves that fit snugly around the wrists and enclosed at the neck. Disposable gowns are preferred. If reusable gowns are used, a clean gown must be donned daily.
- Personnel must then aseptically don sterile, powder-free gloves. Gloves must completely and snugly cover the ends of the gown cuffs so that skin on the wrists and upper hands is completely enveloped.
- Because gloves may not remain sterile due to touching or handling potentially nonsterile materials, personnel must periodically apply sterile 70% IPA to gloves while balancing the risk of radioactivity contamination.
- Personnel must also routinely inspect the gloves that they are wearing for holes, punctures, radioactivity contamination, or tears. If a defect, radioactivity contamination, or malfunction is detected, personnel must immediately remove the gloves, repeat antiseptic hand cleansing using an alcohol-based hand rub, and don new sterile gloves.
- Direct personnel touch contamination is the most common source of microorganisms, so personnel must avoid touch contamination of container septa, needles, syringe and needle hubs, and other critical sites.

When personnel exit the buffer area or SRPA, shoe covers, head/hair covers, face masks, and gloves must be properly disposed of and new ones donned for each reentry into the buffer area or SRPA. Gowns may be re-used within the same shift if the gown is maintained in a classified area or in (or immediately outside of) the SRPA that minimizes contamination (e.g., away from sinks).

## 5. FACILITIES AND ENGINEERING CONTROLS

### 5.1 Facility Design and Environmental Controls

In addition to minimizing airborne contamination, sterile radiopharmaceutical facilities must be designed and controlled to provide a well-lighted and comfortable working environment (see *Physical Environments That Promote Safe Medication Use* ⟨1066⟩). The classified areas and SRPA must be continuously maintained at a temperature of 25° or cooler and should be

@2024 USPC

continuously maintained at a relative humidity (RH) below 60% to minimize the risk for microbial proliferation and provide comfortable conditions for personnel attired in the required garb. The temperature and humidity must be monitored in the classified areas each day that it is used, either manually or by a continuous recording device. The results of the temperature and humidity readings must be documented at least once daily or stored in the continuous recording device, and must be retrievable. The temperature and humidity readings must be reviewed as described in the facility's SOPs. Free-standing humidifiers/dehumidifiers and air conditioners must not be used within the classified area or SRPA. Temperature and humidity monitoring devices must be verified for accuracy at least every 12 months or as required by the manufacturer.

The designated person is responsible for ensuring that each area related to sterile radiopharmaceutical processes meets the classified air quality standard appropriate for the activities to be conducted in that area. They must also ensure that the ISO Class 5 PECs are located, operated, maintained, monitored, and certified to have appropriate air quality.

## TYPES OF SECONDARY ENGINEERING CONTROLS AND DESIGN

Due to the interdependence of the various areas or areas that make up a sterile radiopharmaceutical processing facility, it is essential to define and control the dynamic interactions permitted between areas. When designing doors, consider the placement of door closures, door surfaces, and the movement of the door, all of which can affect airflow. Tacky surfaces must not be used in ISO-classified areas.

The PEC must be located in a SEC, which may be either an ISO-classified buffer room with ante-room or an SRPA, in a manner that minimizes conditions that could increase the risk of microbial contamination. For example, strong air currents from opened doors, personnel traffic, or air streams from the HVAC system(s) can disrupt the unidirectional airflow of an open-faced PEC such as a laminar airflow workbench (LAFW) or biological safety cabinet (BSC). The ISO-classified ante-room and buffer area must be separated from the surrounding unclassified areas of the facility with fixed walls and doors. Facility design and controls must be in place to minimize the flow of lower-quality air into the more controlled areas. Air supplied to the classified areas must be introduced through HEPA filters that are located in the ceiling. Returns must be low on the wall unless a visual smoke study demonstrates an absence of stagnant airflow where particulate will accumulate. A smoke study of the PEC must be repeated whenever a change to the placement of the PEC within the area is made. The classified areas must be equipped with a pressure-differential monitoring system. The ante-room must have a line of demarcation to separate the clean side from the less clean side. The ante-room is entered through the less clean side, and the clean side is the area closest to the buffer area. Required garb must be worn prior to crossing the line of demarcation (see *4. Personnel Qualifications, Training, and Hygiene*).

A PEC may be located within an unclassified area, without an ante-room or buffer area. This type of design is called an SRPA. Only sterile radiopharmaceutical preparation, preparation with minor deviations, dispensing, and repackaging may be performed in an SRPA. If the SRPA meets ISO Class 8 total airborne particle count specifications, it can also be used for storage and elution of non-direct infusion radionuclide generators (e.g., Tc-99m). The SRPA must be located away from unsealed windows, doors that connect to the outdoors, and traffic flow which may adversely affect the air quality in the PEC. The impact of activities that will be conducted around or adjacent to the SRPA must be considered carefully when designing such an area. A visible perimeter must establish the boundaries of the SRPA. Access to the SRPA must be restricted to authorized personnel and required materials. An SRPA must not be located adjacent to environmental control challenges.

It is also critical to control materials (e.g., supplies and equipment) as they move from classified areas of lower quality to those of higher quality (e.g., ISO Class 8 ante-room to ISO Class 7 buffer area to ISO Class 5 PEC) to prevent the influx of contaminants. Airlocks and interlocking doors can be used to facilitate better control of air flow between areas of differing ISO classification (e.g., between the buffer area and ante-room), or between a classified area and an unclassified area (e.g., between the ante-room and an unclassified area such as a hallway) See *5.7 Environmental Controls* for a description of air pressure differentials. If a pass-through is used, both doors must never be opened at the same time, which may be achieved using interlocking mechanisms.

## THE RADIOPHARMACEUTICAL PROCESSING ENVIRONMENT

The PEC must be certified to meet ISO Class 5 or better conditions (see *Table 1*) and must be designed to minimize microbial contamination during processing of radiopharmaceuticals under dynamic operating conditions.

The airflow in the PEC must be unidirectional (laminar flow), and because of the particle collection efficiency of the filter, the "first air" at the face of the filter is, for the purpose of aseptic processing, free from airborne particulate contamination. HEPA-filtered air must be supplied in the direct processing area (DPA) (ISO Class 5; see *Table 1*) at a velocity sufficient to sweep particles away from aseptic processing areas and maintain unidirectional airflow as much as possible during operations, given the limitations added from the radiation shielding in the DPA. Proper design and control prevents turbulence and stagnant air in the DPA. In situ air pattern analysis via smoke studies must be conducted at the critical area to demonstrate unidirectional airflow and sweeping action under dynamic conditions.

**Table 1. ISO Classification of Particulate Matter in Area Air[a]**

| ISO Class | Particle Count[b] /m³ |
|---|---|
| 3 | 35.2 |
| 4 | 352 |
| 5 | 3520 |
| 6 | 35,200 |
| 7 | 352,000 |
| 8 | 3,520,000 |

[b] Limits for number of particles ≥0.5 µm measured under dynamic operating conditions.

### TYPES OF PECS AND PLACEMENT

Proper placement of the PEC is critical to ensuring an ISO Class 5 environment for preparing radiopharmaceuticals. Placement of the PEC must allow for cleaning around the PEC.

A PEC provides an ISO Class 5 or better environment for sterile radiopharmaceuticals. The unidirectional airflow within the PEC helps protect the DPA from process-generated contamination of an aseptic processing environment. The unidirectional airflow within the PEC helps protect the DPA from process-generated contamination (e.g., opening wrappings of sterile containers, worker movement, etc.) as well as from outside sources.

**Laminar airflow workbench (LAFW):** An LAFW used for preparing radiopharmaceuticals must provide vertical unidirectional HEPA-filtered airflow. In cases where the LAFW is located within the segregated containment area of a hot-cell, it is acceptable for a horizontal unidirectional HEPA-filtered airflow pattern to be utilized.

**Biological safety cabinet (BSC) Class II:** A BSC Class II is a cabinet with an open front, inward airflow, downward unidirectional HEPA-filtered airflow, and HEPA-filtered exhaust. The BSC is designed to provide worker protection from exposure to biohazardous material and to provide an ISO Class 5 or better environment for preparing sterile radiopharmaceuticals.

**Placement of PEC:** The PEC must be located out of traffic patterns and away from area air currents that could disrupt the intended airflow patterns inside the PEC. If used only to prepare, prepare with minor deviations, dispense, or repackage sterile radiopharmaceuticals the ISO Class 5 PEC may be placed in an unclassified SRPA. If used to compound sterile radiopharmaceuticals, the PEC must be located within an ISO Class 7 or better buffer area with an ISO Class 8 or better ante-room. A dynamic airflow smoke pattern test must be performed initially and at least every 6 months to ensure that the PEC is properly placed into the facility and that workers understand how to utilize the unidirectional airflow to maintain first air as much as possible given the limitations added from the radiation shielding in the DPA.

### AIR-EXCHANGE REQUIREMENTS

For classified areas, adequate HEPA-filtered airflow to the buffer area(s) and ante-room(s) is required to maintain the appropriate ISO classification during processing activities. Airflow is measured in terms of the number of HEPA-filtered air changes per hour (ACPH). The ACPH may need to be higher to maintain the required ISO classification and microbial state of control depending on these factors: the number of personnel permitted to work in the area, the number of particulates that may be generated from activities and processes in the area, the equipment located in the area, the area pressure, and the effects of temperature. The summary of ACPH requirements is listed in *Table 2*.

A minimum of 30 total HEPA-filtered ACPH must be supplied to ISO Class 7 areas.

- The total HEPA-filtered air change rate must be adequate to maintain ISO Class 7 under dynamic operating conditions considering factors listed above
- At least 15 ACPH of the total air change rate in a room must come from the HVAC through HEPA filters located in the ceiling
- The HEPA-filtered air from the PEC, when added to the HVAC-supplied HEPA-filtered air, increases the total HEPA-filtered ACPH to at least 30 ACPH
- If the PEC is used to meet the minimum total ACPH requirements, the PEC must not be turned off except for maintenance
- The ACPH from HVAC, ACPH contributed from the PEC, and the total ACPH must be documented on certification reports

A minimum of 20 ACPH of HEPA-filtered air must be supplied to ISO Class 8 areas.

- The total HEPA-filtered air change rate must be adequate to maintain ISO Class 8 under dynamic operating conditions considering factors listed above
- At least 15 ACPH of the total air change rate in a room must come from the HVAC through HEPA filters located in the ceiling
- Ante-rooms where activity levels are high may require more HEPA-filtered ACPH to maintain ISO Class 8 under dynamic operating conditions
- The total ACPH must be documented on certification reports

**Table 2. Summary of ACPH Requirements for Sterile Radiopharmaceutical Processing**

| Processing Area | ACPH Requirement |
|---|---|
| Unclassified SRPA | No requirement |
| ISO Class 7 area | ≥30 ACPH |
| ISO Class 8 area | ≥20 ACPH |

## 5.2 Creating Areas to Achieve Easily Cleanable Conditions

### CLASSIFIED AREAS

The surfaces of ceilings, walls, floors, doors, door frames, fixtures, shelving, work surfaces, counters, and cabinets in the classified area must be smooth, impervious, free from cracks and crevices, and non-shedding, so they can be cleaned and disinfected, and to minimize spaces in which microorganisms and other contaminants can accumulate. Surfaces should be resistant to damage by cleaning agents, disinfectants, and tools used to clean. Junctures between the ceiling and the walls and between the wall and the floor must be sealed to eliminate cracks and crevices where dirt can accumulate. If ceilings consist of inlaid panels, each panel must be caulked or otherwise sealed and secured to seal them to the support frame.

Official

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M11915_05_01
@2024 USPC

Walls must be constructed of or covered with a durable material (e.g., epoxy-painted walls or heavy-gauge polymer) and the integrity of the surface must be maintained. Panels must be joined together and sealed to each other and the support structure. Floors must include coving to the sidewall or the juncture between the floor and wall must be caulked. Floors must include coving to the sidewall. Classified areas should minimize dust-collecting overhangs such as utility pipes and ledges such as windowsills. If overhangs or ledges are present, they must be easily cleanable. The exterior lens surface of ceiling light fixtures must be smooth, mounted flush, and sealed. Any other penetrations through the ceiling or walls must be sealed.

SRPA

The SRPA and all surfaces (e.g., walls, floors, counters, equipment) within the SRPA must be clean, uncluttered, and dedicated to sterile radiopharmaceutical processing activities. Surfaces in the SRPA should be smooth, impervious, free from cracks and crevices, and non-shedding, so they can be easily cleaned and disinfected, and to minimize spaces in which microorganisms and other contaminants can accumulate. Surfaces should be resistant to damage by cleaning agents, disinfectants, and tools used to clean. Dust-collecting overhangs such as utility pipes and ledges such as windowsills should be minimized. If overhangs or ledges are present, they must be easily cleanable.

## 5.3 Water Sources

The facility where sterile radiopharmaceuticals are prepared must be designed so that activities such as hand hygiene and garbing should not adversely affect the ability of the PEC to function as designed. Sinks should enable hands-free use with a closed system of soap (i.e., non-refillable) to minimize the risk of extrinsic contamination. In facilities with an ante-room and buffer area, the sink used for hand hygiene may be placed either inside or outside of the ante-room. If the sink is located outside of the ante-room, it must be located in a clean space to minimize the risk of bringing in contaminants into the ante-room. If the sink is located inside the ante-room, it may be placed on either the clean side or the less-clean side of the ante-room. [NOTE—The order of hand washing and garbing would depend on the placement of the sink (see *4.5 Hand Hygiene and Garbing for Buffer Areas and Segregated Radiopharmaceutical Processing Area*).] The buffer area must not contain plumbed water sources [e.g., sink(s), eyewash(es), shower(s), or floor drain(s)]. The ante-room must not contain floor drain(s). If installed, sprinkler systems in classified areas should be recessed and covered, and should be easily cleanable. In a facility with an SRPA design, the sink must be accessible but located at least 1 m from the PEC and generators, if present. The sink must not be located inside the perimeter of the SRPA.

## 5.4 Placement and Movement of Materials

Only furniture, equipment, and other materials necessary are permitted in the classified area or SRPA and they should be low-shedding and easily cleaned and disinfected. Their number, design, location, and manner of installation must not adversely impact environmental air quality and must promote effective cleaning and disinfecting. No shipping carton(s) or other corrugated or uncoated cardboard are allowed in the classified area or SRPA.

Carts used to transport components or equipment into classified areas must be constructed from nonporous materials with cleanable casters and wheels. All items must be wiped with low-lint wipers and an appropriate disinfectant by personnel wearing gloves before they are brought into the clean side of ante-room(s), pass-through(s), into an SRPA or into an ISO 5 PEC. However, constraints that would lead to excessive radiation exposure to radiation for workers and thereby be contradictory to following ALARA safety principles (e.g., the wiping of unshielded sources of radioactive material) might preclude this from occurring. In a classified area, carts must not be moved from the dirty side to the clean side of the ante-room unless the entire cart, including casters, is cleaned and disinfected.

## 5.5 Classified Areas

Activities and tasks carried out within the buffer area must be limited to only those necessary. Food, drinks, and materials exposed in patient care and treatment areas must not enter ante-rooms or buffer areas. When processing activities require the manipulation of blood-derived or other biological material (e.g., radiolabeling patient's or donor's blood cells), the manipulations must be clearly separated from routine material-handling procedures and equipment used in radiopharmaceutical preparation activities, and they must be controlled by specific SOPs to avoid any cross-contamination.

## 5.6 Remote Aseptic Processing Involving a Hot-Cell

A hot-cell device provides an inherent physical segregation for the ISO Class 5 aseptic processing area. If the hot-cell is located in an ISO-classified space, personnel must garb according to requirements listed in *4.5 Hand Hygiene and Garbing for Buffer Areas and Segregated Radiopharmaceutical Processing Area*. In settings where tasks are carried out within the hot-cell enclosure not within an ISO-classified space by remote means (i.e., no direct intervention by personnel into the ISO Class 5 space), it is not necessary for personnel to don the garbing described in *4.5 Hand Hygiene and Garbing for Buffer Areas and Segregated Radiopharmaceutical Processing Area* to carry out these aseptic manipulations or to perform other routine tasks in the general area where the hot-cell is located. If hand and arm incursions into the interior of the hot-cell might be necessary for personnel to stage the required materials and supplies, the personnel must garb in relation to the contamination risk associated with the individual hot-cell/ISO Class 5 relationship.

For situations where a PEC device is located within a hot-cell, dynamic airflow smoke pattern tests must show that the staging of supplies and materials in the demarcated PEC area does not allow the influx of unclassified air into the PEC. Personnel may be garbed in nonsterile gloves and a low-particulate lab coat for interventions that are outside of the PEC. A failure of the airflow

https://pharmacopeia.cn/
Printed on: Fri Jan 05 2024 06:40:28 AM(EST)
Printed by: USP NF
Do Not Distribute
Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Jan-2024
DOI Ref: 7yebr
DocId: GUID-4F561781-FBF6-4AF6-AF64-89A06583B7A1_5_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M11915_05_01
@2024 USPC

smoke pattern test requires personnel to garb in accordance with *4.5 Hand Hygiene and Garbing for Buffer Areas and Segregated Radiopharmaceutical Processing Area* for all incursions into the hot-cell.

For situations where the hot-cell is an integrated HEPA filtration system with a clear demarcated area that is a PEC, dynamic airflow smoke pattern tests must show that the staging of supplies and materials into the demarcated PEC area does not allow the influx of less than ISO Class 5 quality air into the PEC. Personnel may be garbed in nonsterile gloves and a low-particulate lab coat for interventions that are outside of the PEC. A failure of the airflow smoke pattern test requires personnel to garb in accordance with *4.5 Hand Hygiene and Garbing for Buffer Areas and Segregated Radiopharmaceutical Processing Area* for all incursions into the PEC.

Since other hot-cell/PEC configurations and technologies may exist, verification (either by airflow smoke pattern tests or other manufacturer specified methods) must ensure, upon each certification, that the staging of materials and supplies does not allow for the intrusion of less than ISO Class 5 air into the designated ISO Class 5 space. A failure of the airflow smoke pattern test requires personnel to garb in accordance with *4.5 Hand Hygiene and Garbing for Buffer Areas and Segregated Radiopharmaceutical Processing Area* for all incursions into the hot-cell.

## 5.7 Environmental Controls

All RAM users must comply with the conditions specified in their approved RAM license application and regulations, and RAM license conditions may supersede the following requirements for environmental controls described in this section. Pass-through enclosures for transferring radiopharmaceuticals from controlled handling areas (e.g., buffer area) should be designed to provide reasonable balance between maintenance of air quality and other worker safety concerns (e.g., radiation exposure, physical injury from lifting heavy shielded cases). At a minimum, there must be a mechanical system or SOP in place that ensures that both doors cannot be open at the same time. There may be both positive and negative air pressure within the facility; positive pressure to minimize the potential of microbial contamination in sterile drug preparation areas, and negative pressure to minimize potential radioactive contamination from volatile or airborne radiopharmaceuticals. Positive pressure environments must have a minimum differential positive pressure of 0.02-inch water column between each ISO-classified area (e.g., between the buffer area and ante-room). The pressure differential between the ante-room and the unclassified area must be no less than a positive 0.02-inch water column. Refer to the RAM license for negative pressure requirements. For preparation of sterile radiopharmaceuticals, consideration of both concerns could be addressed as follows:

1. Buffer area, if present, must be positive pressure compared to the ante-room
2. Ante-room, if present, must be positive pressure compared to unclassified portions of the restricted area
3. Restricted area, in the presence of volatile or airborne radiopharmaceuticals, must be negative pressure compared to the unrestricted area
4. SRPA must be negative pressure compared to unrestricted areas in the presence of volatile or airborne radiopharmaceuticals (e.g., I-131 sodium iodide and Xenon).

Various environmental controls for various preparation scenarios (see *Table 7* for maximum BUDs for differing environments) are described in the following sections. *Table 1* details the limits for particle counts for each specific ISO classification.

### ESTABLISHING AND MAINTAINING PRESSURE DIFFERENTIALS

Any time a pressure differential is required, a pressure monitoring device is required. In a classified area, a pressure differential monitoring system must be used to continuously monitor the pressure differential between the ante-room(s) and buffer area(s) and between the ante-room and the general environment outside the classified area(s) or area(s). The results from the pressure monitoring system must be reviewed and documented at least daily on days the area is used. All pressure monitoring devices must be tested for accuracy and required performance at least every 6 months.

### AMBIENT ATMOSPHERE FOR IMMEDIATE USE PREPARATIONS

The following requirements should be met in ambient atmosphere environments:

- Non-patient care space, functionally separate (not necessarily a different area) from the patient care area, such as a radiopharmaceutical handling space, or hot lab, in a hospital, clinic, or mobile coach
- A designated area for medication preparation that is clean and free from clutter
- Low traffic (i.e., limited number of people going in and out or moving around the area during times that radiopharmaceutical processing is being carried out)

### SRPA WITH VERTICAL FLOW ISO CLASS 5 PEC(S) FOR RADIOPHARMACEUTICAL PREPARATIONS

An SRPA with vertical ISO Class 5 PECs must meet the following requirements:

- Area surrounding the PEC may be ambient (unclassified) atmosphere
- Area must be clean, uncluttered, and dedicated to the processing of radiopharmaceuticals
- Appropriate for preparation, preparation with minor deviations, repackaging, and dispensing of radiopharmaceuticals

An area that meets ISO Class 8 total airborne particle-count specifications may be used to store and elute non-direct infusion radionuclide generators (e.g., Tc-99m).

### AN ISO CLASS 8 BUFFER AREA WITH VERTICAL FLOW ISO CLASS 5 PEC(S) WITH AN ADJACENT ISO CLASS 8 ANTE-ROOM

This environment is appropriate for all activities listed in *SRPA with Vertical Flow ISO Class 5 PEC(s) for Radiopharmaceutical Preparations*.

Official

https://nhathuocngocanh.com/

AN ISO CLASS 7 BUFFER AREA WITH VERTICAL FLOW ISO CLASS 5 PEC(S) WITH AN ADJACENT ISO CLASS 8 OR BETTER ANTE-ROOM

This environment is appropriate for all activities listed in *An ISO Class 8 Buffer Area with Vertical Flow ISO Class 5 PEC(s) with an Adjacent ISO Class 8 Ante-Room* and sterile compounding.

HOT-CELL

This environment is appropriate for all activities listed in *SRPA with Vertical Flow ISO Class 5 PEC(s) for Radiopharmaceutical Preparations*.

CERTIFICATION OF PECS AND ENVIRONMENT IN WHICH THE PEC IS LOCATED

Certification of the classified areas, including the PEC, must be performed initially and recertification must be performed at least every 6 months using procedures outlined in the current Controlled Environment Testing Association (CETA) certification guide for *Sterile Compounding Facilities*, or an equivalent guideline, and must include the following:

- Airflow testing: To determine acceptability of the air velocity, the air exchange rate, and area pressure cascade to ensure that air consistently flows from most to least clean areas, and that the appropriate quality of air is maintained under dynamic operating conditions.
- HEPA filter integrity testing: HEPA filters must be leak tested after installation and as part of recertification.
- Total particle counts testing: Conducted under dynamic operating conditions using calibrated electronic equipment.
- Smoke visualization studies: Performed under either simulated or dynamic operating conditions to demonstrate unidirectional airflow and sweeping action over and away from the preparation(s).

In cases where technologies exist for hot-cell and PEC configurations that are not consistent for certification by the current CETA standards, other equivalent means for certifying the PEC may be performed and documented per facility SOPs. In this case, the PEC must maintain the environmental equivalent for total particle counts and the protection of the ISO Class 5 area from intrusions of lesser controlled air.

DAILY MONITORING OF ENVIRONMENT

The temperature and humidity must be monitored in the SRPA or area containing a hot-cell, and if in a classified area the pressure must monitored, each day that preparations are made, either manually or by a continuous recording device. These include:

- Relative humidity should be kept at 60% or lower
- Temperature and relative humidity continuous readings must be confirmed daily to have remained within the acceptable range
- Excursions must be documented and, if applicable, appropriate corrective actions taken
- Temperature monitoring devices must be verified for accuracy every 12 months or as required by the manufacturer
- Monitoring of pressure differentials must be performed

See *Packaging and Storage Requirements* ⟨659⟩ for information on controlled area temperature and allowable excursions.

## 6. MICROBIOLOGICAL AIR AND SURFACE MONITORING

An effective air and surface monitoring program provides information on the environmental quality of the classified areas where sterile radiopharmaceuticals are processed. The program identifies environmental quality trends over time, potential routes of microbiological contamination, and allows for implementation of corrective actions to prevent microbiological contamination of the radiopharmaceuticals. Facilities must develop and implement written air and surface monitoring procedures for all sterile radiopharmaceutical classified areas. Air and surface monitoring results and the corrective actions must be documented, and records must be readily retrievable as required by jurisdictional laws and regulations.

### 6.1 General Monitoring Requirements

The goals of an air and surface monitoring program are to determine whether microbiological contamination is present at unacceptable levels and to assess whether proper personnel practices are being followed, cleaning and disinfecting agents are effective, and environmental quality is maintained. The microbiological air and surface monitoring program must include viable impact volumetric airborne particulate sampling and surface sampling.

Air and surface sampling must be performed initially for classified areas in a facility to establish a baseline level of environmental quality. After initial sampling, the classified areas must be monitored according to the minimum frequencies described in this section to ensure that the environment remains in a suitable state for aseptic processing tasks.

The air and surface monitoring program involves the collection and evaluation of samples from various air and surface locations to detect viable microbiological contaminants. The data are then used to assess risks for contamination, potential routes of contamination, and the adequacy of cleaning and disinfection techniques and agents specified in the facility SOPs. Regular review of the sampling data must be performed to detect trends such as elevated levels of microbial bioburden, elevated levels of nonviable particulates, or other adverse changes within the environment. Evaluating results collected over a period of time can be useful in identifying trends or determining that a significant change has occurred, even when the results fall within the specified limits.

In addition, results must be reviewed in conjunction with personnel data (i.e., training records, visual observations, competency assessments) to assess the state of control and to identify potential risks of contamination. Prompt corrective action in response to any adverse findings is required to maintain the necessary environmental quality for handling sterile radiopharmaceutical. Data must also be reviewed following corrective actions to confirm that the actions taken have been effective in achieving the required air and surface quality levels (see *Table 3* and *Table 4*).

Air and surface sampling must be conducted during actual or simulated dynamic operating conditions to confirm that the required environmental quality in classified areas is maintained. Due to radiation exposure concerns for the workers involved, it is permissible for sampling to be carried out at the conclusion of sterile radiopharmaceutical processing but prior to cleaning and disinfecting the surface area. In this case, simulated tasks that are reflective of the routine aseptic activities are performed. In addition to the specific sampling frequencies described in this section, sampling must be performed in any of the following circumstances:

- In conjunction with the certification of new facilities and equipment
- After any modification of facilities or equipment
- In response to identified problems (e.g., positive growth in sterility tests of compounded radiopharmaceuticals)
- In response to identified trends (e.g., repeated positive gloved fingertip sampling results or failed media-fill testing involving more than one operator where a review of the operator technique shows no reasonable flaws in process; repeated observations of air or surface contamination)
- In response to changes that could impact the controlled area environments (e.g., significant change in cleaning process or the agents involved)

To obtain an air and surface sample that is representative of the typical aseptic operating conditions at the facility, air and surface sampling must be conducted under dynamic or simulated dynamic operating conditions in all PECs and classified areas. If conducted during actual sterile processing, the monitoring program must be designed and conducted in a manner that minimizes the chance that the sampling itself will contribute to contamination of the sterile radiopharmaceutical(s) or the environment.

The air and surface monitoring program must be clearly described in the established SOPs of the facility and must include a diagram of the sampling locations, SOPs for collecting samples, frequency of sampling, size of samples (e.g., surface area, volume of air), time of day of sampling in relation to activities in the classified areas, and action levels that will trigger corrective action. The locations of sampling should be carefully selected based on their relationship to the activities performed in the area. It is important to obtain samples from locations that pose the highest possible contamination risk to the sterile radiopharmaceuticals involved with the operation's processes and that are likely to be representative of the conditions throughout the area.

Evaluating results collected over a period of time can be useful in identifying trends or determining that a significant change has occurred, even when the results fall within the specified limits.

It is important that personnel who operate the equipment be trained in the proper operation of the air and surface sampling equipment to ensure accurate and reproducible sampling. All air sampling devices must be serviced and calibrated as recommended by the manufacturer.

## 6.2 Monitoring Air Quality for Viable Airborne Particles

A monitoring program for viable airborne particles must be developed and implemented to assess microbiological air quality in all classified areas.

### VIABLE AIR SAMPLING: TIMING AND LOCATIONS

Volumetric active air sampling of all classified areas (e.g., ISO Class 5 PEC and ISO Class 7 and 8 areas) using an impaction device must be conducted during dynamic operating or simulated operating conditions at least every 6 months.

Air sampling sites must be selected in all classified areas. When conducting sampling of the PEC, care should be taken to avoid disturbing unidirectional airflow if taken during actual sterile processing activities. Viable air sampling must include:

1. Follow the manufacturer's instructions for operation of the air sampling device, including placement of media.
2. Using the sampling device, test at least 1 cubic meter or 1000 liters of air from each location sampled.
3. At the end of the sampling, retrieve the media plates/devices and cover.
4. Invert the media and incubate at 30°–35° for no less than 48 hours. Examine for growth. Record the total number of discrete colonies of microorganisms on each plate as cfu/$m^3$ of air on an environmental sampling form based on sample type (i.e., viable air). Include sample location and date.
5. Then incubate the inverted media at 20°–25° for no less than 5 additional days. Examine the media plates for growth. Record the total number of discrete colonies of microorganisms on each plate as cfu/$m^3$ of air on an environmental sampling form based on sample type (i.e., viable air). Include sample location and date.

Alternatively, to shorten the overall incubation period, two samples may be collected for each sample location and incubated concurrently. Both samples could be TSA or one sample could be TSA and the other fungal media [e.g., malt extract agar (MEA) or sabouraud dextrose agar (SDA)]. Incubate each sample in a separate incubator. Incubate one sample at 30°–35° for no less than 48 hours, and incubate the other sample at 20°–25° for no less than 5 days. Fungal media samples must be incubated at 20°–25° for no less than 5 days. Count the total number of discrete colonies of microorganisms on each sample, and record these results as cfu per sample.

Record the results of the sampling on an environmental sampling form based on sample type (i.e., viable air) and include the sample location, and sample date.

A general microbiological growth medium that supports the growth of bacteria and fungi must be used (e.g., TSA medium). CoA(s) from the manufacturer must verify that the medium meets the expected growth promotion, pH, and sterilization

@2024 USPC

requirements. Samples must be incubated in a temperature monitored incubator with a calibrated measuring device. The incubator temperature must be monitored during incubation, either manually or by a continuous recording device, and the results must be reviewed and documented. Incubators used for microbiological testing must be placed in a location outside of any classified area or SRPA and kept away from areas where compounding or sterile processing activities are carried out. All sampling activities must be performed by trained individuals.

### DATA EVALUATION AND ACTION LEVELS

Evaluate cfu counts against the action levels in *Table 3* and in relation to previous data to identify adverse results and/or trends. If two pieces of media were collected at a single location, all recovered growth on each must be documented and action levels are applied individually to each plate/device (i.e., results from each cubic meter of air sampled must be compared to the action level for that area). If levels measured during the viable air monitoring program exceed the levels in *Table 3* for the ISO classification levels of the area sampled, the cause must be investigated and corrective action must be taken. The corrective action plan must be dependent on the cfu count and the microorganism recovered. Some examples of corrective action include process or facility improvements, personnel training, cleaning and disinfecting, or HEPA filter replacement and/or repair, or reducing the BUD of the radiopharmaceutical during investigation and while carrying out the corrective action plan. The extent of the investigation should be consistent with the deviation and should include an evaluation of trends. The corrective action plan must be documented. If levels measured during viable air sampling exceed the levels in *Table 3*, an attempt must be made to identify any microorganism recovered to the genus level (see *Microbial Characterization, Identification, and Strain Typing* ⟨1113⟩) with the assistance of a qualified individual (e.g., microbiologist or industrial hygienist).

**Table 3. Action Levels for Viable Airborne Particle Air Sampling[a]**

| ISO Class | Air Sampling Action Levels [cfu/m$^3$ (1000 L) of air per plate] |
|---|---|
| 5 | >1 |
| 7 | >10 |
| 8 | >100 |

[a] Adapted from *Guidance for Industry: Sterile Drug Products Produced by Aseptic Processing—Current Good Manufacturing Practice*. US Department of Health and Human Services, Food and Drug Administration (FDA), September 2004.

## 6.3 Monitoring Surfaces for Viable Particles

Surface sampling is an important component of the maintenance of a suitably controlled environment for sterile radiopharmaceutical processing, especially because transfer of microbial contamination from improperly disinfected work surfaces (e.g., via inadvertent touch contact by personnel) is a potential source of contamination of the radiopharmaceutical(s). Surface sampling is useful for evaluating facility cleaning and material handling procedures, work surface cleaning and disinfecting procedures, and personnel competency in work practices such as proper cleaning and disinfection. All sampling sites and procedures must be described in the facility's SOP.

### SURFACE SAMPLING: TIMING AND LOCATIONS

Surface sampling of all classified areas and all PECs must be conducted at least monthly for the detection of microbial contamination. Each classified area must be sampled (see *Microbiological Control and Monitoring of Aseptic Processing Environments* ⟨1116⟩). The DPA of the PEC, and any equipment permanently contained in the PEC, must be sampled. Staging or work surfaces in classified areas near the PEC, frequently touched surfaces in classified areas, and pass-through enclosure(s) for all classified areas are to be evaluated to determine the locations that pose the greatest risk of harboring microbial contamination.

Surface sampling must be performed at the end of the radiopharmaceutical aseptic activities or shift, but before the area has been cleaned and disinfected. However, radiopharmaceutical personnel must also consider the appropriate exposure and contamination prevention measures prior to and while collecting samples. If the worker assesses that the risk for exposure is not in conformance with ALARA safety standards, measures must be taken to eliminate the risk (e.g., implementation of appropriate shielding, performing the sampling at a later time or alternate day).

### SAMPLING PROCEDURES

Surface sampling devices (e.g., plates, paddles, or slides) containing microbial growth media must be used for sampling flat surfaces. CoAs from the manufacturer must verify that the media meet the expected growth promotion, pH, and sterilization requirements. Surface sampling devices must contain general microbial growth media (e.g., TSA) supplemented with neutralizing additives (e.g., lecithin and polysorbate 80) to neutralize the effects of any residual disinfecting agents. If used, contact plates must have a raised convex surface. Sterile swabs wetted with sterile water or a sterile neutralizing buffer may be used when sampling irregular surfaces and difficult-to-reach locations, such as crevices, corners, and spaces between surfaces. After sampling, the sampled area must be thoroughly cleaned and disinfected.

Use the following procedures for surface sampling on flat surfaces:

1. Remove the cover from the surface sampling device. Firmly press, using a rolling motion, if possible, the media surface onto the surface to be sampled. The surface sampling device will leave a residue of growth medium on the sample site. After sampling, use sterile 70% IPA to remove residue. Cover each surface sampling device.
2. If using plates, invert the plates.

DOI: https://doi.org/10.31003/USPNF_M11915_05_01
@2024 USPC

3. Incubate the surface sampling devices at 30°–35° for no less than 48 hours. Examine for growth. Record the total number of discrete colonies of microorganisms on each media device as cfu/sample on an environmental sampling form based on sample type (i.e., surface). Include sample location and date.
4. Incubate the device at 20°–25° for no less than 5 additional days. Examine the media plates for growth. Record the total number of discrete colonies of microorganisms (cfu/sample) on the environmental sampling record based on sample type (i.e., surface). Include sample location and date.

Alternatively, to shorten the overall incubation period, two samples may be collected for each sample location.

1. Both samples could be TSA or one sample could be TSA and the other fungal media (e.g., MEA or SDA).
2. Incubate each sample in a separate incubator. Incubate one sample at 30°–35° for no less than 48 hours, and incubate the other sample at 20°–25° for no less than 5 days.
3. If fungal media are used as one of the samples, incubate the fungal media sample at 20°–25° for no less than 5 days.
4. Count the total number of discrete colonies of microorganisms on each sample, and record these results as cfu per sample. Record the results of the sampling.
5. Record the results of the sampling.

### DATA EVALUATION AND ACTION LEVELS

Evaluate cfu counts against the action levels in *Table 4* and examine counts in relation to previous data to identify adverse results or trends. If two devices were collected at a single location, all recovered growth on each must be documented and action levels are applied to each piece of media individually (i.e., results from each sampling device must be compared to the action level for the area). If levels measured during surface sampling exceed the levels in *Table 4* for the ISO classification levels of the area sampled, the cause must be investigated and corrective action must be taken. Data collected in response to corrective actions must be reviewed to confirm that the actions taken have been effective. The corrective action plan must be dependent on the cfu count and the microorganism recovered. Examples of corrective action include process or facility improvements, personnel training, cleaning and disinfecting, or HEPA filter replacement and/or repair, or reducing the BUD of the radiopharmaceutical(s) during investigation and while carrying out the corrective action plan. The extent of the investigation should be consistent with the deviation and should include an evaluation of trends. The corrective action plan must be documented. If levels measured during surface sampling exceed the levels in *Table 4*, an attempt must be made to identify any microorganism recovered to the genus level (see ⟨1113⟩) with the assistance of a qualified individual (e.g., microbiologist or industrial hygienist).

**Table 4. Action Levels for Surface Sampling**

| ISO Class | Surface Sampling Action Levels (cfu/device or swab) |
|---|---|
| 5 | >3 |
| 7 | >5 |
| 8 | >50 |

## 7. CLEANING AND DISINFECTING

Cleaning and disinfecting are important because surfaces in classified areas and SRPAs are a potential source of microbial contamination of sterile radiopharmaceuticals. The process of cleaning involves removing organic and inorganic residues from surfaces, usually with a manual or mechanical process and a cleaning agent. The process of disinfecting involves destruction of microorganisms, usually with a chemical or physical agent. Surfaces must be cleaned prior to being disinfected unless an Environmental Protection Agency (EPA)-registered (or equivalent) one-step disinfectant cleaner is used to accomplish both the cleaning and disinfection in one step. After cleaning and disinfecting or the application of a one-step disinfectant cleaner in a PEC, apply sterile 70% IPA to remove any residue.

Cleaning and disinfecting surfaces should occur at the minimum frequencies specified in *Table 5* or if activities are not performed daily, cleaning and disinfecting must be completed before initiating activities. The act of reducing or removing radioactivity (radioactive decontamination) from an object or surface must be balanced with the risk of spreading radioactive contamination. At times the best approach may be to shield the area until the radiation exposure levels are lower. This balance must be specified in SOPs (e.g., trigger levels for safe cleaning). The PEC should be checked for radioactive contamination prior to cleaning and disinfecting to prevent spreading radioactive contamination in the PEC.

All cleaning and disinfecting activities must be performed by trained and appropriately garbed personnel using facility-approved agents and procedures that must be described in written SOPs. Cleaning must be performed in the direction of most to least clean areas. The frequency, method(s), and location(s) of cleaning, disinfecting, and sporicidal agent use must be established in written SOPs, in accordance with the manufacturer's instructions when available, or based on sound microbiological cleaning techniques when unavailable, and must be followed by all cleaning personnel. The manufacturer's direction or published data for the minimum contact time must be followed for the cleaning, disinfecting, and sporicidal agents used. When sterile 70% IPA is used, it must be allowed to dry. All cleaning, disinfecting, and application of sporicidal agents must be documented according to facility SOPs.

| Floor(s) | Daily | Daily | Monthly |
| Storage shelving and storage bins | Monthly | Monthly | Monthly |

[a] Many disinfectants registered with the EPA are one-step cleaning and disinfecting agents, which means that the disinfectant has been formulated to be effective in the presence of light to moderate soiling without a separate cleaning step. Cleaning and disinfecting must be balanced with the risk of spreading radiation contamination. The best approach may be to shield the area until the radiation exposure levels are lower.

## 7.1 Cleaning, Disinfecting, and Sporicidal Agents

Cleaning and disinfecting agents must be selected and used with careful consideration of compatibilities, effectiveness, and user safety. Considerations when selecting and using disinfectants include their anti-microbial activity, inactivation by organic matter, residue, shelf life, preparation requirements of the agent, and suitability for surfaces being disinfected (see *Disinfectants and Antiseptics* ⟨1072⟩). After the disinfectant is applied on the surface to be disinfected, the disinfectant must be allowed to dwell for the minimum contact time specified by the manufacturer, during which time the surface cannot be disturbed. Only the 70% IPA used in the ISO Class 5 PEC must be sterile. Sporicidal agents must be used at least monthly on all surfaces in classified areas and SRPAs. Some EPA-registered (or equivalent) one-step disinfectant cleaners may have sporicidal properties. See *Table 6* for a summary of the purpose of the cleaning, disinfecting, and sporicidal agents.

**Table 6. Purpose of Cleaning, Disinfecting, and Sporicidal Agents**

| Type of Agent | Purpose |
|---|---|
| Cleaning agent | An agent for the removal of residues (e.g., dirt, debris, microbes, and residual drugs or chemicals) from surfaces. |
| Disinfecting agent | A chemical or physical agent used on inanimate surfaces and objects to destroy fungi, viruses, and bacteria. |
| Sporicidal agent | A chemical or physical agent that destroys bacterial and fungal spores when used in sufficient concentration for a specified contact time. It is expected to kill all vegetative microorganisms. |

## 7.2 Cleaning Supplies

All cleaning supplies (e.g., wipers and mop heads), with the exception of tool handles and holders, must be low-lint and should be disposable. If disposable cleaning supplies are used, they must be discarded after each cleaning activity. Reusable cleaning tools must be made of cleanable materials (e.g., no wooden handles) and must be cleaned and disinfected before and after each use. Reusable cleaning tools must be dedicated for use in the classified areas or SRPAs and must not be removed from these areas except for disposal. They must be discarded after an appropriate amount of time, to be determined based on the condition of the tools. Cleaning supplies and solutions used in the classified areas and SRPAs should be monitored for radioactive contamination after use and prior to disposal, as per facility SOPs. Dispose of cleaning supplies used in the classified areas and SRPAs in a manner that minimizes the potential for dispersing particulates into the air (e.g., with minimal agitation, away from work surfaces).

## 7.3 Cleaning and Disinfecting the PEC

Clean and disinfect the PEC at the minimum frequencies specified in *Table 5*. If the PEC contains a removable work tray, all sides of the work tray and the area underneath the work tray must be cleaned and disinfected at least monthly.

1. Survey all surfaces of the PEC for radioactive contamination and follow facility SOPs to decontaminate, if necessary.
2. Remove, if necessary, any particles, debris, or residue with an appropriate solution (e.g., *Sterile Water for Injection* or *Sterile Water for Irrigation*) using sterile, low-lint wipers.
3. Apply a cleaning agent followed by a disinfecting agent or apply an EPA-registered (or equivalent) one-step disinfectant cleaner and ensure that the contact time specified per manufacturer instructions is achieved.
4. Apply sterile 70% IPA
5. Allow the surface to dry completely before beginning activities.
6. The PEC must be wiped with a sporicidal agent at least monthly.

## 7.4 Disinfecting Supplies for Classified Areas and SRPAs

No shipping carton(s) or other corrugated or uncoated cardboard are allowed in the classified area (e.g., clean side of ante-room) or within the perimeter of the SRPA. Before items are introduced into a classified area or SRPA, they must be wiped with a sporicidal agent, EPA-registered (or equivalent) one-step disinfectant cleaner, or sterile 70% IPA using low-lint wipers. After the sporicidal or sterile disinfectant is applied onto the surface, the agent must be allowed to dwell on the surface for the minimum contact time specified by the manufacturer (see *6.1 General Monitoring Requirements*). The agent used for disinfecting the packaging must be compatible with the packaging and must not render the product label unreadable.

Any item to be transferred into the PEC from the classified area or SRPA must be disinfected with a sterile disinfectant (e.g., sterile 70% IPA).

In the case of radiopharmaceuticals being processed by remote means in a hot-cell, the opening of sterile packages (e.g., syringes, luer lock caps) may not be possible by remote means within the ISO Class 5 area. In this case, the syringes may be opened and appropriately labeled outside of the ISO Class 5 environment and placed in disinfected shielding, immediately prior to the forthcoming dispensing cycle.

## 7.5 Disinfecting Critical Sites

Critical sites (e.g., vial stoppers) must be wiped with sterile 70% IPA. The critical site must be wiped ensuring that both chemical and mechanical actions are used to remove contaminants. The sterile 70% IPA must be allowed to dry before piercing critical sites.

## 7.6 Cleaning and Disinfecting Items from Patient Care Area

Radiation shielding and equipment used in the classified area/SRPA or PEC that is exposed to patient care areas during the process of administration must be cleaned and disinfected before returning to any classified area (e.g., buffer or ante-room) or SRPA in accordance with the Centers for Disease Control and Prevention guidelines[1] as noncritical equipment requiring low-risk disinfection. Syringes that have been used in a patient care area must not be brought back into the classified area (e.g., buffer or ante-room) or SRPA for re-assaying or disposal unless the syringe is sealed inside an impervious container (e.g., sealed plastic bag) that is disinfected prior to entry into the classified area or SRPA. Equipment that has been exposed to needles and syringes contaminated with blood-borne pathogens and RAMs are considered mixed waste (e.g., syringe shields and syringe carrying containers). This equipment must be cleaned and disinfected through actions regulated by the facilities' SOPs. Equipment that contained or was in contact with mixed waste must be cleaned and disinfected with an appropriate agent(s) for blood.

# 8. ASSIGNING BUD

BUDs are based on the risk of microbial contamination with the assumption that the radiopharmaceutical(s) should remain chemically and physically stable, and its container–closure system should maintain its integrity for the duration of the BUD (*Table 7*). The time starts at the moment of the first sterile vial puncture or exposure of a critical site (e.g., syringe tip, needle hub, or needle) to ambient air, whichever is first. The BUDs stated in *Table 7* are maximum values in the absence of sterility

testing, and the assigned BUD may be shorter for a variety of reasons discussed below. The individual responsible for the manipulation assigns the BUD based on established testing data, either performed in-house or obtained from peer-reviewed literature.

**Table 7. Preparation Conditions for Sterile Radiopharmaceuticals**

| Preparation Conditions | | | |
|---|---|---|---|
| **Manipulation** | **PEC** | **SEC** | **BUD (hours)** |
| Immediate use | — | — | 1 |
| Direct infusion system, one puncture only (e.g., PET patient infusion system, Rb-82 generator) | — | — | 10 |
| Dispensing, repackaging, preparation, and preparation with minor deviations | ISO Class 5 | SRPA | 12 |
| Radionuclide generator storage/elution (e.g., non-direct infusion system; Tc-99m or Ga-68) | — | SRPA with ISO Class 8 total airborne particle count | 12 |
| Radionuclide generator storage/elution (e.g., non-direct infusion system; Tc-99m or Ga-68) | — | ISO Class 8 or better buffer area with ISO Class 8 or better ante-room | 24 |
| Dispensing, repackaging, preparation, and preparation with minor deviations | ISO Class 5 | ISO Class 8 or better buffer area with ISO Class 8 or better ante-room | 24 |
| Dispensing, repackaging, preparation, preparation with minor deviations, and compounding using sterile components | ISO Class 5 | ISO Class 7 or better buffer area with ISO Class 8 or better ante-room | 96 |
| Dispensing, repackaging, preparation, preparation with minor deviations, and compounding using a nonsterile component and performing sterilization procedure (e.g., filtration with bubble point testing) but without performing *Sterility Tests* ⟨71⟩ testing | ISO Class 5 | ISO Class 7 or better buffer area with ISO Class 8 or better ante-room | 24 |
| Radiolabeled blood components for immediate use [e.g., Tc 99m red blood cells (RBC)] | — | — | 1 |
| Radiolabeled blood components (e.g., radiolabeled leukocytes) | ISO Class 5 BSC | ISO Class 7 or better buffer area with ISO Class 8 or better ante-room | 6 h after the blood sample is obtained |

Official

For compounded preparations (sterile and nonsterile), the BUD is also dependent on maintenance of appropriate quality and purity, including radiochemical purity, radionuclidic purity, and other applicable parameters as specified in individual monographs or as clinically appropriate.

For preparations with minor deviations involving conventionally manufactured kits (sterile and nonsterile), the kit may state or suggest a use-by time in the package insert. For certain radiopharmaceuticals transportation time, radionuclide availability, and other factors may necessitate extending manufacturer-stated/suggested use-by time to meet patient needs. Assigning a BUD longer than the manufacturer-stated/suggested use-by time interval must be supported by evidence of the maintenance of appropriate quality and purity, including radiochemical purity and radionuclidic purity as specified in individual monographs, and other applicable parameters as clinically appropriate.

Assignment of a BUD for a radiopharmaceutical(s) must consider several factors, as applicable. Issues of concern include, but are not limited to, the following:

- Sterility: Maintenance of sterility is a major concern for any sterile preparation or product. Good aseptic handling practices in an appropriate environmentally-controlled area are the most critical factors in ensuring sterility. See *Table 7* for maximum BUD. The assigned BUD should not exceed the sterility-related times listed in *Table 7*, unless a longer time is justified by *Sterility Tests* ⟨71⟩.
- Radiochemical purity: Maintenance of radiochemical purity is affected by a variety of factors including, but not limited to, storage temperature, quantity of radioactivity, radioactivity concentration, presence or absence of antioxidants or other stabilizing agents, and container type (e.g., glass vial vs. plastic syringe). The assigned BUD must be based on stability studies in which these variables are controlled and are representative of the conditions of actual use. For factors that allow a range of values (e.g., storage temperature, quantity of radioactivity, radioactivity concentration), studies should be conducted at the extremes of the ranges.
- Radionuclidic purity: Because radionuclidic impurities may decay away more slowly than the primary radionuclide, the radionuclidic purity may decrease over time. For example, the ratio of Mo-99 (half-life of about 66 hours) to Tc-99m (half-life of about 6 hours) continuously increases over time. *USP* monographs for Tc-99m radiopharmaceuticals require that the radionuclidic impurity Mo-99 not exceed 0.15 μCi Mo-99 per mCi Tc-99m at the time of administration. Calculation of radionuclidic purity at future times is necessary to ensure compliance throughout the assigned BUD.

DOI: https://doi.org/10.31003/USPNF_M11915_05_01
@2024 USPC

- Age of generator eluate: As a generator eluate decays, the desired daughter radionuclide decays to form other nuclides and potential radiolytic products, which may interfere with radiolabeling of kits. For example, Tc-99m undergoes decay to Tc-99. More importantly, increasing amounts of peroxides formed as radiation interacts with water molecules. Increased amounts of Tc-99 and peroxides can interfere with the radiolabeling of many kits. Extension of the BUD for Tc-99m pertechnetate intended for radiolabeling of kits must take into account the build-up of Tc-99 and peroxides over time.
- Number of particles: For radiolabeled particulates, the number of particles per unit radioactivity increases over time as the radionuclide decays. For example, the BUD for Tc-99m albumin aggregated [macroaggregated albumin (MAA)] must take into account the increasing ratio over time of the number of particles per unit radioactivity. For example, if an MAA kit is prepared such that the radioactive patient dose is 200,000 particles at the time of calibration, the same patient dose will contain 700,000 particles at 10.85 hours after calibration. Calculation of the number of MAA particles in the patient dose is necessary to ensure compliance with the prescribed particle range throughout the assigned BUD.
- Specific activity: For some receptor-based radiopharmaceuticals, the mass quantity may influence uptake (i.e., too much mass may result in saturation of receptor sites and reduce target uptake of the radiopharmaceutical). As radioactivity decays over time, specific activity decreases resulting in more mass per unit radioactivity. In such situations, the assigned BUD must ensure that the patient dose contains no more than the specified maximum mass.
- Container type: Because radiochemical stability or other quality attributes of a radiopharmaceutical may be affected by its container characteristics, the BUD for a radiopharmaceutical dose dispensed in a plastic syringe may be different than the BUD of that same radiopharmaceutical maintained in a glass vial. The assigned BUD must be determined in the proper storage container.
- Cell viability: The viability of radiolabeled blood cells (e.g., leukocytes) decreases over time, and may also be affected by other factors such as the suspending medium, temperature, and agitation. The assigned BUD should be as short as circumstances reasonably allow so as to maximize cell viability.
- In the case of manufactured radiopharmaceuticals that are distributed to nuclear pharmacies or other healthcare facilities for terminal distribution/dispensing, the assigned BUD of the dispensed dose cannot exceed the expiration date/time of the manufactured radiopharmaceutical(s).
- In the case of radiopharmaceuticals prepared from kits, the BUD of a dispensed dose cannot exceed the assigned BUD of the finished kit preparation.
- A radiopharmaceutical may not exceed the shortest BUD of any of its components.

The facility must have policies and SOPs appropriate to the assignment of BUD and maintain documentation of applicable study results and calculations. Studies of radiolabeling efficiency and radiochemical stability should employ quality control (QC) testing methods described in the manufacturer's package insert, *USP* monographs and general chapters, or other equivalent testing methods and be sufficiently rigorous to allow statistical confidence in the results.

The facility must have SOPs to collect and evaluate complaints associated with the use of radiopharmaceuticals having assigned BUDs. Policies and SOPs should also be in place to reevaluate the assigned BUD based on complaints, which may include repeating studies and/or performing additional studies on radiolabeling efficiency and/or radiochemical stability.

## 9. DOCUMENTATION

Applicable records (hard-copy or electronic), including policies and SOPs, must be maintained for all activities involved in repackaging, preparing, preparing with minor deviations, compounding, and dispensing radiopharmaceuticals. Such records include, but are not limited to:

- Personnel training and testing, including visual assessment of aseptic technique competency, validation, garbing, hand hygiene, equipment/environment cleaning and disinfecting, gloved fingertip and thumb sampling, and media fill evaluation initially and follow up testing at specified intervals.
- Testing and monitoring of environmental controls, including ISO classification, ACPH, pressure differentials, temperature, humidity and viable air/surface and total airborne particle test results
- Equipment maintenance and cleaning/disinfecting
- End product radiochemical purity and other testing, as applicable, results of preparations, preparations with minor deviations, and compounded preparations
- Master Formulation Record (MFR) for preparation with minor deviation(s) and compounding
- Validation of stability testing to support the assigned BUD from SOPs by the compounder or derived from accepted literature
- Investigations and corrective actions and tracking of events to closure.

### 9.1 Master Formulation Record

A MFR is required only for a preparation with minor deviations or compounding, as described in *11. Compounding*. A MFR is not required for a preparation following the manufacturer's instructions.

Data that must be included in the MFR are as follows:

- Name of the radiopharmaceutical
- Name, identity, strength, purity, quality, and quantity of ingredients with validated documentation (e.g., CoA)
- Detailed procedure (e.g., heating, components, incubation time)
- Range of radioactivity
- Range of volume
- Equipment to be used

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M11915_05_01
@2024 USPC

- PEC and SEC to be used, if applicable
- Quality control tests to be performed for final release of the radiopharmaceutical (e.g., radiochemical purity, pH)
- Procedures for depyrogenation and sterility procedures and validations, as applicable, including limits
- Trained personnel
- Garbing procedure, if different than standard procedure
- Container(s)
- Reference source of the BUD assignment and storage conditions

### 9.2 Records for Preparation with Minor Deviations/Compounding

A record for preparation with minor deviation or compounding must include the following:

- Name of the radiopharmaceutical
- Physical form (e.g., capsule or solution)
- Name and quantity of ingredients including calibration time for radioactive ingredients (e.g., 100 mCi Tc 99m sodium pertechnetate @ 1300)
- Total volume
- Reference to the MFR
- Any deviation from the MFR, if applicable
- Name of vendor or manufacturer, lot numbers, and expiration dates of all ingredients and components
- Name of the person who prepared and name of the supervising personnel (e.g., ANP or AU physician)
- Date and time of preparation
- Assigned internal identification number (e.g., lot number)
- Unique reference [e.g., prescription, order number(s)]
- Assigned BUD and storage requirements
- Documentation of QC results

## 10. PREPARATION

The individual responsible for preparing the radiopharmaceutical(s) must ensure that the final preparation complies with quality and purity specifications throughout the assigned BUD. This includes, as appropriate for the preparation, radionuclidic purity, radiochemical purity, chemical purity, and physical and chemical properties.

### 10.1 Preparation Following Manufacturer Instructions

NONSTERILE PREPARATIONS

For nonsterile preparations, follow manufacturer preparation instructions (e.g., I-131 NaI capsules or solution), taking into account appropriate radiation safety considerations and environmental controls, if applicable (e.g., negative air pressure area, chemical fume hood, activated charcoal filters when handling a potentially volatile radionuclide). The area should be suitably cleaned and uncluttered to ensure the overall integrity and quality of the prepared radiopharmaceutical(s). There should be a documented process for activities (e.g., cleaning) between the preparation cycles of different nonsterile products, to decrease the likelihood of contamination from other prepared products.

STERILE PREPARATIONS

For sterile preparations (including intravascular devices), follow manufacturer preparation instructions, taking into account appropriate radiation safety considerations, appropriate environmental controls, and aseptic handling practices to maintain sterility. The minimum environmental standard for the preparation of sterile radiopharmaceuticals beyond immediate-use is within an ISO Classified area or device (see *Table 7*). Refer to *5. Facilities and Environmental Controls* and *Table 7* on the location of the PEC and the assignment of the BUD.

### 10.2 Preparation with Minor Deviations

In some cases, radiopharmaceuticals are prepared with minor deviations from manufacturer instructions that are necessary to accommodate circumstances not contemplated in the FDA-approved labeling. Note that *General Notices, 5.20.20.1 In Compounded Preparations* includes the statement: “Deviation from the specified processes or methods of compounding, although not from the ingredients or proportions thereof, may occur provided that the finished preparation conforms to the relevant standards and to preparations produced by following the specified process.” However, except for a few receptor-based radiopharmaceuticals where specific activity is an important parameter, there is a very broad range of acceptable values for specific activity and for proportions of ingredients. Deviations from manufacturer preparation instructions for radiopharmaceuticals must maintain the same ingredients but may differ in their proportions.

This requires appropriate in-house QC testing, designed to validate the radiochemical purity of the product for the entirety of the BUD or is supported by appropriate peer-reviewed publications for the minor deviation utilized.

Examples of minor deviations include, but are not limited to, the following:

Official

https://pharmacopeia.cn/

- Altering the quantity of radioactivity or volume added to the vial
- Changes in step-by-step operations (e.g., dilute Tc-99m sodium pertechnetate after rather than before addition to the vial)
- Using alternative devices or equipment (e.g., a heating block rather than a hot water bath, using a different sized needle, different shielding materials)
- Using QC test methods other than those described in the product labeling (e.g., radiochemical purity)
- Filtering Tc-99m sulfur colloid

## 10.3 Preparation of Radiolabeled Blood Components

Handling blood and radiolabeling of blood components requires special attention to biological risks and must be handled with standard precautions using aseptic technique to prevent the introduction of new microorganisms into the preparation that will be administered. Due to the potential presence of microorganisms in the original blood sample, the preparation must be administered as soon as possible but no later than 6 hours after the blood sample is obtained from the patient or blood bank.

The presence of microorganisms in a blood sample may present a risk to the individual performing the preparation as well as cross-contamination to other blood samples or other non-blood related radiopharmaceuticals. Equipment and supplies should never be shared with other activities unless they are first thoroughly cleaned and disinfected. Special precautions when radiolabeling of blood components for non-immediate use include:

- There must be complete physical separation (either fixed or non-fixed wall) of areas where blood products are handled from areas where non-blood products are handled. An ISO Class 5 BSC located in an ISO Class 7 buffer area is required for blood-labeling processes. If more than one ISO Class 5 PEC is located within the ISO Class 7 buffer area, policies and SOPs must be in place to include certification that the SEC meets conditions of air quality at maximum occupancy under dynamic operating conditions.
- One radiolabeling procedure per PEC at a time. Blood products from more than one patient must never be manipulated at the same workstation at the same time. Each area should have dedicated supplies, equipment (including dose calibrator), and waste disposal to eliminate sharing of these items or overlap in pathways.
- Thorough cleaning and disinfection of the ISO Class 5 BSC and all reusable equipment within, prior to starting another blood component radiolabeling procedure.
- If a dedicated dose calibrator is not available, then a means of preventing the blood container(s) from contaminating the dose calibrator must be used or the dose calibrator dipper and liner must be cleaned and disinfected following the radioassay.
- Centrifuge should be located within the ISO Class 7 buffer area that is dedicated for blood component radiolabeling processes.
- Dedicated (per each radiolabeling procedure) consumable products (e.g., 0.9% sodium chloride injection, diluent, tubes, syringes, and other supplies) necessary for each individual patient radiolabeling procedure.
- All tubes and syringes in contact with the patient's blood components must be clearly labeled with the patient's name and at least one additional identifier (e.g., date of birth, medical record number, barcode).
- Dedicated syringe shields and vial shields.
- Remove and replace any garb that enters the ISO Class 5 BSC before handling anything else not related to performing this procedure.
- Removal of all disposable items from the ISO Class 5 BSC utilized in each radiolabeling procedure.
- Cleaning and disinfection of all reusable equipment and components (e.g., BSC, centrifuge, dose calibrator, syringe shields, vial shields, syringe transport shields and delivery cases) after each radiolabeling procedure prior to any further use. Policies and SOPs must address cleaning and disinfection processes including the use of an EPA-registered (or equivalent) one-step disinfectant cleaner with activity against blood-borne pathogens followed by sterile 70% IPA. Sterile 70% IPA alone is not sufficient.
- After the completion of blood radiolabeling procedures, follow all requirements in *4.5 Hand Hygiene and Garbing for Buffer Areas and segregated Radiopharmaceutical Processing Area*.

## 10.4 Preparation of Radiolabeled Red Blood Cells for Immediate Use

In vitro red blood cell labeling must be prepared while following the conditions below:

- A dedicated space for blood handling must be designated through the entirety of the blood radiolabeling process. This area must be free from clutter and not used for any other radiopharmaceutical preparation or handling until the completion of cleaning and disinfection.
- Perform only one radiolabeling procedure at a time or have documented processes that maintain the integrity of samples and environment.
- Dedicated equipment must be used for blood radiolabeling procedure (e.g., L-block, syringe shield, vial shield, forceps, needle recapper).
- If a dedicated dose calibrator is not available, then a means of preventing the blood container(s) from contaminating the dose calibrator or a cleaning and disinfecting procedure with an appropriate product must be used to decontaminate the dipper and liner of the dose calibrator following the radioassay
- A cleaning and disinfecting procedure with an appropriate agent(s) must be used to decontaminate the area and equipment prior to and after the radiolabeling is complete and all disposable components have been discarded
- Follow all requirements in *4.4 Hand Hygiene and Garbing for Immediate Use Preparations*.

Official

https://pharmacopeia.cn/
Printed on: Fri Jan 05 2024 06:40:28 AM(EST)
Printed by: USP NF
Do Not Distribute

- The start time of the preparation must begin with the initial container puncture or the exposure of a critical site (e.g., syringe tip, needle hub or needle) to ambient air, whichever is first.
- BUD of 1 hour (see *Table 7*).

# 11. COMPOUNDING

Each compounding activity must be based on a pre-established written procedure and must include maintenance of compounding records. The compounding record must provide traceability (see *9. Documentation*).

All sterile compounding, using aseptic technique, must be performed in an ISO 5 PEC. Refer to *5.7 Environmental Controls* and *Table 7* for further clarification on the location of the PEC and the applicability of the radiopharmaceutical BUD.

Compounding must not be performed for any radiopharmaceutical(s) that has been withdrawn from the market because of safety or lack of effectiveness, unless part of an institutional review board approved investigational study. Radiopharmaceuticals that are essentially copies of marketed FDA-approved radiopharmaceuticals must not be compounded unless there is a change that produces a clinical difference for an identified individual patient, as determined by a prescriber.

## 11.1 Compounding Nonsterile Radiopharmaceuticals

Compounding nonsterile radiopharmaceuticals is the combining, mixing, diluting, pooling, reconstituting or otherwise altering a drug or bulk drug substance other than as provided by the manufacturer's package insert to create a nonsterile radiopharmaceutical. Examples of compounding nonsterile radiopharmaceuticals include: changing the dosage form of a capsule to a solution, changing an intravenous dosage form to an oral dosage form, and radiolabeling a food for oral administration (e.g., Tc-99m sulfur colloid in eggs). Areas designated for nonsterile compounding must be cleaned and uncluttered and separated from areas designated for sterile radiopharmaceuticals. Compounding should take into account RAM licensing requirements for appropriate radiation safety considerations and utilize appropriate environmental controls, if applicable (e.g., chemical fume hood, activated charcoal filters when handling potentially volatile radionuclides). The placement of equipment and materials must take into account a design that prevents cross-contamination.

When feasible, disposable material should be used to reduce the chance of cross-contamination. Each compound must have a unique MFR (see *9.1 Master Formulation Record*). The preparation information is documented on a compounding record (see *9.2 Records for Preparation with Minor Deviations/Compounding*). The MFR details the selection of all components. The ingredients must be obtained from sources in this preferential order: FDA-approved product; FDA-registered facility; and lastly, if the ingredients for the compound are not available from either of these two sources, the MFR must detail the selection of a material that is suitable for the intended use. The MFR must establish the identity, strength, purity, and quality of the ingredients by validated means (e.g., CoA). Requirements for nonsterile oral meal components are limited to common food grade description and are not required to establish identity by validated means.

A BUD for the compounded radiopharmaceutical must be validated, taking into account the stability of the ingredients, any intermediate containers, the final container, and the storage conditions. A BUD cannot be extended past the labeled expiration date of any component in the compound. If the compounded radiopharmaceutical(s) includes components from other preparations or preparations with minor deviations, the BUD of the final compounded radiopharmaceutical must not exceed the shortest remaining BUD of any of those components.

## 11.2 Sterile Compounding

Some compounding activities involve only the addition of a conventionally manufactured drug product (e.g., *Ascorbic Acid Injection*, *Lidocaine Hydrochloride Injection*, *Sodium Bicarbonate Injection*) approved by the appropriate regulatory agency to a radiopharmaceutical.

Personnel responsible for compounding must consider all possible interactions between the components, such as altered chemical stability, radiochemical stability, solubility, or other parameters (e.g., osmolality) related to changes in pH, excipients, or other factors, in determining an appropriate BUD. In some cases, this may require systematic QC testing over time to validate the appropriateness of a particular BUD.

Another activity that is considered a compounding activity is the splitting of conventionally marketed kits. Kit-splitting (also referred to as "fractionation") may be used to meet patient need. For example, the contents of a kit vial can be reconstituted with 0.9% sodium chloride injection and aliquoted into other containers for storage and subsequent radiolabeling. The individual responsible must consider all possible interactions of kit components with these other containers (e.g., container walls, closures), as well as possible alterations in stability (e.g., physical stability, chemical stability) that may affect radiolabeling yields or performance parameters, when determining an appropriate BUD. Systematic QC testing is required to validate the appropriateness of a particular BUD.

## 11.3 Sterile Compounding Using a Nonsterile Drug Substance or Components

Some sterile compounding activities involve the use of materials other than commercially marketed products, such as drug substances and/or radionuclides. If one or more materials or components are not certified to be sterile and pyrogen-free, a sterilization procedure (e.g., filtration with bubble point testing) and testing described in ⟨85⟩ must be performed. The designated person for compounding is responsible for ensuring that the final preparation complies with pre-established standards or acceptance criteria for identity, quality, and purity, and must consider all possible interactions between the components, such as altered chemical stability, radiochemical stability, solubility, or other parameters (e.g., osmolality) related to changes in pH, excipients, or other factors, in determining an appropriate BUD. This may require testing to validate the appropriateness of a particular BUD.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M11915_05_01
@2024 USPC

If compounding involves a bulk drug substance, the radiopharmaceutical must comply with standards of an applicable *USP* or *NF* monograph, if one exists, or be a component of an approved drug product. For this chapter, a bulk drug substance includes a radionuclide, a ligand, or other substance, such as a precursor that becomes an active ingredient in the final radiopharmaceutical. Each bulk drug substance should be manufactured by drug establishments registered with FDA and be accompanied by a valid CoA or equivalent testing procedures.

If compounding involves excipients or other inactive ingredients, the excipients or other inactive ingredients must comply with standards of an applicable *USP* or *NF* monograph, if one exists. It is also acceptable that any excipients or other inactive ingredients be approved products, manufactured by a drug establishment registered with the FDA.

# 12. DISPENSING

## 12.1 Dispensing and Radioassay

Dispensing refers to the manipulations necessary to transfer the prescribed or ordered amount of radiopharmaceutical into the final container (e.g., syringe or vial). Dispensing can take place from single-dose or multiple-dose containers of prepared, prepared with minor deviations, compounded, or manufactured radiopharmaceuticals, and may involve needle changes, affixing a sterile cap, or dilution (e.g., adding 0.9% sodium chloride injection) in the final container. For nonsterile radiopharmaceuticals, an example is obtaining 1 capsule from a container holding 1 or more capsules. For sterile radiopharmaceuticals, an example is withdrawing a volume of solution from a single-use or multiple-dose container into a syringe. Labeling of the final patient-ready dose or ordered amount of a radiopharmaceutical is also a component of the dispensing process.

Except for an unopened manufacturer container, the final dose or ordered amount must be radioassayed (i.e., in a dose calibrator). The measured activity should be mathematically corrected for radioactive decay to the time of scheduled administration (calibration time) (refer to *14. Quality Assurance and Quality Control*). The activity at calibration time must always be within federal, state, and local variance limits.

## 12.2 Labeling

The labeling of radiopharmaceuticals can fall under the jurisdiction of numerous regulatory agencies. Individual boards of pharmacy and other regulatory bodies may have very specific statutes and/or regulations concerning this process. The requirements specified in this chapter must be considered the minimum requirements for the labeling of the inner container (e.g., syringe, vial) and the outer shielding (e.g., syringe or vial shielding). Therefore, all personnel distributing and/or dispensing radiopharmaceuticals should verify that any labeling is in compliance with regulatory agencies.

The inner container must be labeled with the following:

- Standard radiation symbol
- The words “Caution—Radioactive Material”
- For all therapeutic and blood-products, the patient name/identifier
- Radionuclide and chemical form (generic name)
- Radioactivity at the date and time of calibration

The outer shielding must be labeled with the following:

- Standard radiation symbol
- The words “Caution—Radioactive Material”
- For all therapeutic and blood-products, the patient name/identifier
- Radionuclide and chemical form (generic name)
- Radioactivity at the date and time of calibration
- Volume or number of units dispensed (e.g., 2 capsules), as applicable
- Product expiration or BUD (see *Table 7*), as applicable, and any special storage and handling instructions for non-immediate use (e.g., refrigeration, resuspension)
- Route of administration

## 12.3 Direct Infusion Systems

The information in this section is limited to the sterility and aseptic technique for direct infusion systems. The described infusion systems are FDA-cleared medical devices or FDA-approved direct infusion generators without an ISO-5 environment. The manner in which all necessary solutions (e.g., radiopharmaceutical and eluant/diluent) are used in conjunction with the system was a consideration in the overall approval process for the system. Therefore, all operators of the direct infusion systems must follow the “Instructions for Use” in the device labeling.

- Direct infusion generators (e.g., rubidium chloride Rb 82 injection) may employ a container of eluant (e.g., bag of 0.9% sodium chloride injection) to allow administration of the eluate directly to patient(s).
- Direct infusion devices (e.g., portable PET patient-infusion system) provide a method for dispensing and administration from a multiple-dose container of the radiopharmaceutical (e.g., fludeoxyglucose F 18 injection) and the diluent (e.g., 0.9% sodium chloride injection) directly to patients to reduce the radiation exposure to personnel.

In each of these situations, the radiopharmaceutical container must be attached to or be needle-punctured by the respective direct infusion system. Given that such direct infusion systems are intended for multiple patients over the course of several

Official

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M11915_05_01
@2024 USPC

hours, there could be a sterility concern if not operated properly. Therefore, the following parameters must be considered by the operator of the system:

- Setup attachment or needle-puncture should be performed in a defined environment
- Aseptic handling in ambient air with a maximum BUD of 10 hours is allowed for these direct infusion systems (see *Table 7*)
- The 0.9% sodium chloride bag attached to the device may only be punctured once and may be used for no more than 10 hours. The bag must be labeled with the date and time of puncture and the BUD
- Any nonsterile parts of the device that may encounter the septum of the radiopharmaceutical vial must be disinfected with sterile 70% IPA prior to puncturing the vial with the needle
- The septum of any vial and the ports of any diluent bag must be wiped with sterile 70% IPA prior to puncturing
- When puncturing the vial in ambient air, it must only be punctured once
- If there are problems with the infusion device, no sterile container(s) associated with the system can be repunctured or transferred to a PEC for further manipulations and the container, with contents, must be discarded

### 12.4 Transporting Generators Between Facilities

The following standards must be followed if transporting generators between facilities:

- The generator needle and/or ports must be capped in ISO Class 8 air or better with sterile protectors
- The generator must be packaged and transported in a manner to maintain the integrity and sterility of the generator system

## 13. REPACKAGING

Repackaging refers to the act of removing conventionally manufactured radiopharmaceutical(s) from the container in which it was distributed by the original manufacturer and placing it into a different container without further manipulation of the product. Repackaging also includes the act of placing the contents of multiple containers of the same finished drug product into one container, as long as the container does not include other ingredients. Repackaging may be performed for nonsterile radiopharmaceuticals (e.g., I-131 sodium iodide oral capsules) and for sterile radiopharmaceuticals (e.g., thallous chloride Tl 201 injection).

Except for unopened manufacturer dosage units (e.g., capsules, Xe-133 vials), the repackaged radiopharmaceutical must be radioassayed (i.e., in a dose calibrator). The inner container should be labeled with the following:

- Standard radiation symbol
- The words “Caution—Radioactive Material”
- The radionuclide and chemical form (generic name)
- Radioactivity with units at time of calibration and the calibration time

The outer shielding should be labeled with the following:

- Standard radiation symbol
- The words “Caution—Radioactive Material”
- The radionuclide and chemical form (generic name)
- Radioactivity with units at time of calibration and the calibration time
- Volume, or number of units (e.g., capsules), as applicable
- Product expiration or BUD (see *Table 7*), as applicable
- Special storage and handling instructions

## 14. QUALITY ASSURANCE AND QUALITY CONTROL

Quality assurance (QA) is a system of procedures, activities, and oversight that ensures that radiopharmaceutical processing consistently meets quality standards (see *Quality Assurance in Pharmaceutical Compounding* ⟨1163⟩). Quality control (QC) is the sampling, testing, and documentation of results that, taken together, ensure that specifications have been met before release of the radiopharmaceutical(s).

A facility’s QA and QC programs must be formally established and documented in SOPs that ensure that all aspects of the handling of radiopharmaceuticals are conducted in accordance with this chapter and applicable federal, state, and local laws and regulations. A designated person must ensure that the facility has formal, written QA and QC programs that establish a system of:

1. Adherence to procedures,
2. Prevention and detection of errors and other quality problems,
3. Evaluation of complaints and adverse events, and
4. Appropriate investigations and corrective actions.

The SOPs must describe the roles, duties, and training of the personnel responsible for each aspect of the QA program. The overall QA and QC program must be reviewed at least once every 12 months by the designated person. The results of the review must be documented and appropriate corrective action taken, if needed.

Official

https://pharmacopeia.cn/v-cn/

## 14.1 Notification About and Recall of Out-of-Specification Dispensed Radiopharmaceuticals

If a radiopharmaceutical is dispensed or administered before the results of release testing are known, the facility must have SOPs in place to:

1. Immediately notify the prescriber of a failure of specifications with the potential to cause patient harm (e.g., sterility, strength, purity, bacterial endotoxin, or other quality attributes), and
2. Determine whether a recall is necessary.

The SOP for recall of out-of-specification dispensed radiopharmaceuticals must contain procedures to:

- Determine the severity of the problem and the urgency for the implementation and completion of the recall
- Determine the distribution of any affected radiopharmaceutical, including the date and quantity
- Identify patients who have received the radiopharmaceutical
- Outline the disposition and reconciliation of the recalled radiopharmaceutical

The facility must document the implementation of the recall procedures. The recall must be reported to appropriate regulatory bodies as required by laws and regulations of the applicable regulatory jurisdiction (e.g., state board of pharmacy, state health department).

## 14.2 Complaint Handling

Radiopharmaceutical facilities must develop and implement SOPs for handling complaints. Complaints may include concerns or reports on the quality and container labeling of, or possible adverse reactions to, a specific radiopharmaceutical.

A designated person must review all complaints to determine if they indicate potential quality problems with the radiopharmaceutical. If a complaint does, an investigation into the potential cause of the problem must be completed. The investigation must consider whether the quality problem could extend to other radiopharmaceuticals. Corrective action, if necessary, must be implemented for all potentially affected radiopharmaceuticals. Consider whether to initiate a recall of potentially affected radiopharmaceuticals and whether to cease sterile compounding until all underlying problems have been identified and corrected.

A readily retrievable record (written or electronic) of each complaint must be kept by the facility, regardless of the source of the complaint (e.g., e-mail, telephone, mail). The record must contain the name of the complainant, the date the complaint was received, the nature of the complaint, the response to the complaint, and, if known, the name and strength of the radiopharmaceutical and the assigned internal identification number (e.g., prescription, order, or lot number).

The record must also include the findings of any investigation and any follow-up. Records of complaints must be easily retrievable for review and evaluation for possible trends and must be retained in accordance with the record keeping requirements in *9. Documentation*. A radiopharmaceutical that is returned in connection with a complaint must be quarantined until it is destroyed after completion of the investigation and in accordance with applicable jurisdictional laws and regulations.

## 14.3 Adverse Event Reporting

Adverse events potentially associated with the quality of radiopharmaceuticals must be reported in accordance with the facility's SOPs and all applicable jurisdictional laws and regulations. In addition, adverse events potentially associated with the quality of the radiopharmaceutical preparation should be reported to the applicable jurisdictional regulatory body (e.g., state boards of pharmacy, state health departments, FDA's MedWatch program for human drugs).

## GLOSSARY

**Administration:** The direct and immediate application of a radiopharmaceutical to a patient by injecting, infusing, ingesting, or otherwise providing a radiopharmaceutical in its final form.

**Airlock:** A space with interlocked doors, constructed to maintain air pressure control when items move between two adjoining areas.

**Ante-room:** An ISO Class 8 or cleaner area with fixed walls and doors where personnel hand hygiene, garbing procedures, and other activities that generate high particulate levels are performed. The ante-room is the transition area between the unclassified area in a facility and the classified buffer area.

**Aseptic processing or preparation:** A process by which separate, sterile components (e.g., drugs, containers, or closures) are brought together under conditions that maintain their sterility.

**Aseptic technique:** Methods utilized during the processing of radiopharmaceuticals to keep objects and areas free of microorganisms and thereby minimize infection risk to the patient. It is accomplished through practices that maintain the microbe count at a nearly irreducible number.

**As low as (is) reasonably achievable (ALARA):** The effort to maintain exposures to ionizing radiation as far below the dose limits as practical. These efforts should be consistent with the purpose for which the licensed activity is undertaken, in relation to utilization of licensed materials in the public interest. Limiting exposure time, using adequate shielding, and maintaining the most distance possible from all radioactive sources (i.e., time, distance, shielding) are the basic principles for successfully following ALARA guidelines.

**Authorized nuclear pharmacist (ANP):** A pharmacist recognized by the U.S. Nuclear Regulatory Commission or an Agreement State agency as having met training and experience requirements for the practice of nuclear pharmacy.

**Authorized user (AU):** A physician recognized by the U.S. Nuclear Regulatory Commission or an Agreement State agency as meeting training and experience requirements for specified medical uses of radioactive material.

**Beyond-use date (BUD):** The assigned date and time beyond which the radiopharmaceutical must not be administered.

**Biological safety cabinet (BSC) Class II:** A ventilated cabinet with an open front and inward and downward unidirectional HEPA-filtered airflow and HEPA-filtered exhaust.

**Blood components:** Any constituent of blood that is separated by physical or mechanical means (e.g., red cells, white cells, platelets)

**Buffer area:** An ISO Class 8 or cleaner area with fixed walls and doors where PEC(s) that generate and maintain an ISO Class 5 environment are physically located. The buffer area may only be accessed through the ante-room.

**Chemical purity:** The fraction of the total chemical species present in the radiopharmaceutical as the specified chemical component(s). A chemical impurity is the presence of an unwanted non-radioactive chemical.

**Classified area:** An area that maintains an air quality classification based on the ISO guidelines (i.e., ante-room, buffer area). See *ISO class*.

**Cleaning agent:** A material for the removal of residues (e.g., dirt, debris, microbes, and residual drugs or chemicals) from surfaces.

**Compounding:** The combining, mixing, pooling, or otherwise altering (excluding preparation with minor deviations) of a conventionally manufactured radiopharmaceutical or synthesizing/formulating a radiopharmaceutical from bulk drug substances and radionuclides. See *Preparation with minor deviations*.

**Container–closure system:** The packaging components that contain or come in contact with the radiopharmaceutical and maintain the integrity of the radiopharmaceutical contained within. Examples include (but are not limited to) vials, tubes and syringes.

**Critical site:** A location that includes any component or fluid pathway surface (e.g., vial septa, injection ports) or openings (e.g., needle hubs) that, when exposed is at risk for contamination by direct contact with air (e.g., ambient area or HEPA-filtered), moisture (e.g., oral and mucosal secretions), or touch.

**Designated person:** One or more individuals assigned to be responsible and accountable for the performance and operation of the radiopharmaceutical processing facility and for personnel who prepare, compound, dispense, and repackage radiopharmaceuticals.

**Direct infusion system:** An FDA-cleared medical device used to dispense and/or administer radiopharmaceuticals to multiple patients. The standards of this chapter pertain to devices with ambient air that lack and ISO Class 5 environment.

**Direct processing area (DPA):** An area within the ISO Class 5 PEC where critical sites are exposed to unidirectional HEPA-filtered air, also known as first air.

**Disinfectant:** A chemical or physical agent used on inanimate surfaces and objects to destroy microbiological contamination (e.g., fungi, viruses, and bacteria) when used in the appropriate concentrations and for the appropriate contact times. Sporicidal disinfectant agents are considered a special class of disinfectants that also are effective against bacterial endospores and fungal spores.

**Dispensing:** The manipulation or labeling of a radiopharmaceutical to render it in its final form for administration, typically obtained from a single-dose or multiple-dose container (e.g., withdrawing a volume of finished product or preparation from a vial into a syringe). Dispensing is performed under the supervision of a physician or pharmacist and for radiopharmaceuticals includes dilution with an appropriate diluent or adjusting the activity in an individual dosage.

**Dose pooling:** The combining of doses from two or more syringes to meet one patient's need, also see "repackaging".

**Dose splitting:** The splitting of a patient-ready unit dose for use with more than one patient.

**Dynamic operating conditions:** Conditions in the SRPA or classified area in which operating personnel are present and performing actual or simulated activities. The PEC should contain equipment and materials regularly used for radiopharmaceutical processing (e.g., low-lint absorbent pads, dose calibrator, syringe shields).

**Expiration date:** For conventionally manufactured radiopharmaceuticals, the specified date (and time) beyond which the product must not be administered. The expiration date is determined by the manufacturer.

**First air:** The air exiting the HEPA filter in a unidirectional air stream.

**Garb:** Gloves, gowns, shoe covers, head (covers ears and all hair) and facial hair covers, masks, and other items designed to reduce particle shedding from personnel and minimize the risk of microbiological contamination to radiopharmaceuticals.

**High efficiency particulate air (HEPA) filtration:** Using a tested and certified air filter designed to remove 99.97% of airborne particles measuring 0.3-micron or greater in diameter from the air passing through it.

**Hot-cell:** A device used for the shielding and containment of radioactive materials. The shielding material(s) (e.g., lead) is generally incorporated into the structure of the unit itself. Radiopharmaceutical personnel carry out the majority of the tasks within the hot-cell from the exterior of the unit. This is accomplished by the use of remote manipulation systems (e.g., manipulator arms, automated dispensing system) of various designs. Numerous air quality configurations of the hot-cell may exist, including integrated HEPA filtration systems to render all or a specified portion (DPA) of the device capable of certifying to a controlled ISO Class 5 environment. In other situations, the hot-cell offers only radiation protection and a laminar flow PEC, capable of achieving an ISO Class 5 environment, is placed within the enclosure to allow for safe aseptic manipulations. A hot-cell may also be referred to by other designations (e.g., shielded isolator with laminar flow, PET dispensing station, manipulator hot-cell, shielded isolators for dispensing, radiopharmaceutical dispensing isolator).

**Hot lab:** Unclassified radiopharmaceutical processing area located within a hospital or clinical site that is only appropriate for immediate use radiopharmaceuticals if there is not an ISO 5 PEC within SRPA located within the area.

**Immediate use:** A preparation (including preparations with minor deviations) and/or dispensing of a sterile radiopharmaceutical that is limited for a single patient. Only sterile conventionally manufactured drug products (e.g., NDA, ANDA) or drugs produced under an approved IND or RDRC protocol may be used. Administration must begin within 1 hour of the first container puncture or exposure of any critical site involved (e.g., syringe tip, needle hub or needle) to ambient air, whichever is first.

**Individual dose (unit dose):** A radiopharmaceutical in its final form ready for administration (e.g., capsule, sterile solution in a syringe) consisting of the amount (dose) prescribed, ordered, or other intended for an individual patient or research subject.

**Inverse square law:** The specified physical quantity or intensity of a radiation emission is inversely proportional to the square of the distance from the source of the emission.

**ISO class:** A quality classification from the International Organization for Standardization based on quantity and size of particles per volume of air.

Official

https://pharmacopeia.cn/v-cn/

**Kit:** Conventionally manufactured package containing all ingredients required to prepare a radiopharmaceutical with the exception of the radionuclide.

**Kit-splitting (fractionation):** The act of dividing the contents of a kit vial and transferring aliquots into other containers for storage and subsequent radiolabeling.

**Ligand:** An ion or molecule that incorporates a metal atom to form a coordination complex.

**Line of demarcation:** A visible line on the floor that separates the clean and less clean sides of the ante-room.

**Low-lint wiper:** A wiper exhibiting few, if any, fibers or other particulates, visible without magnification, which are separate from, or easily removed from, the wiper material in a dry condition.

**Master Formulation Record (MFR):** A document or set of documents specifying the starting materials with their quantities and the packaging materials, together with a description of the procedures and precautions required to produce a specified quantity of a finished preparations as well as the processing instructions, including the in-process controls.

**Media-fill test:** A simulation used to qualify processes and personnel engaged in sterile radiopharmaceutical processing to ensure that the processes and personnel are able to prepare radiopharmaceuticals without microbiological contamination.

**Molar mass:** The measured mass that is attained from a molar amount of a given substance (e.g., element, compound). It is generally expressed with units such as g/mol and kg/mol.

**Multiple-dose container:** A container of a radiopharmaceutical for administration that is designed to contain more than one patient dose of the radiopharmaceutical.

**Negative-pressure area:** An area that is maintained at lower pressure than the adjacent spaces, and therefore the net airflow is into the area. This area is appropriate for volatile or gaseous radionuclides and radiopharmaceuticals (e.g., I-131 NaI, N-13 ammonia) and intended to lend a measure of protection for the radiation workers and the general public.

**One-step disinfectant cleaner:** A product with an EPA-registered claim (or equivalent) that it can clean and disinfect a nonporous surface in the presence of light to moderate organic soiling without a separate cleaning step.

**Pass-through:** An enclosure with sealed doors on both sides to ensure that both doors are not opened at the same time. The pass-through is positioned between two spaces creating an airlock for the purpose of minimizing particulate transfer while moving materials from one space to another.

**Perimeter:** A visible demarcation on the floor that defines the boundaries of the SRPA.

**Positive-pressure area:** An area that is maintained at higher pressure than the adjacent spaces, and therefore the net airflow is out of the area.

**Preparation:** The act of combining a conventionally manufactured kit with a conventionally manufactured radionuclide following manufacturer's recommended instructions. Mixing, reconstituting, combining, diluting, or repackaging of a radiopharmaceutical, or other such acts, performed in accordance with directions contained in the FDA-approved labeling.

**Preparation with minor deviations:** The act of preparing a conventionally manufactured kit with a conventionally manufactured radionuclide with volume, and/or radioactivity, and/or step-by-step deviations from the manufacturers recommended labeling while ensuring that the final preparation maintains appropriate radiochemical and radionuclidic purity for the entirety of the BUD. Examples of minor deviations include, but are not limited to, altering the amount of activity or volume added to the vial, changes in step-by-step operations (e.g., dilute Tc-99m solution after, rather than before, addition to the vial, use of a venting needle or filter), using alternative devices or equipment (e.g., a heating block rather than a hot water bath), and using alternative radiochemical purity testing methods.

**Primary engineering control (PEC):** A device or zone that provides an ISO Class 5 air quality environment for sterile processing.

**Pyrogen:** A substance that induces a febrile reaction in a patient.

**Quality assurance (QA):** The system of procedures, activities, and oversight that ensures that radiopharmaceutical processing consistently meets quality standards.

**Quality control (QC):** The sampling, testing, and documentation of results that, taken together, ensure that specifications have been met before release of the radiopharmaceutical.

**Radioactive materials (RAM) license:** A document(s) issued by the US NRC or an Agreement State agency that authorizes various activities involving the use of radioactive materials. These uses can include possession, research and development, distribution, medical use, and other purposes not included in this list. Only those activities specifically authorized are allowed.

**Radioassay:** Measurement of the quantity of radioactivity present in a container using a suitable and calibrated instrument, such as a well-type ionization chamber (i.e., dose calibrator).

**Radiochemical purity:** The ratio, expressed as a percentage, of the radioactivity of the intended active radiopharmaceutical ingredient to the total radioactivity of all radioactive ingredients and impurities present in the radiopharmaceutical preparation (see *Radioactivity* ⟨821⟩).

**Radionuclidic purity:** The ratio, expressed as a percentage, of the radioactivity of the intended radionuclide to the total radioactivity of all radionuclides in the radiopharmaceutical preparation (see ⟨821⟩).

**Radiopharmaceutical (radiopharmaceutical preparation/radioactive drug):** (See ⟨821⟩.) A finished dosage form that contains a radioactive substance in association with one or more other ingredients and that is intended to diagnose, stage a disease, monitor treatment, or provide therapy. A radiopharmaceutical includes any non-radioactive reagent kit or radionuclide generator that is intended to be used in the preparation of any such substance. The terms "radiopharmaceutical" and "radioactive drug" are commonly used interchangeably.

**Repackaging:** The act of removing a conventionally manufactured radiopharmaceutical from the container in which it was distributed by the original manufacturer and placing it into a different container without further manipulation of the product. Repackaging also includes the act of placing the contents of multiple containers (e.g., vials) of the same finished drug product into one container, as long as the container does not include other ingredients. Radiopharmaceutical manipulation in any other way, including reconstitution, dilution, mixing, or combination with another ingredient, is not considered repackaging.

**Restricted area:** Any area to which access is controlled for the protection of individuals from exposures to radiation and radioactive materials.

**Secondary engineering control (SEC):** The area where the PEC is placed (e.g., a classified area or an SRPA). It incorporates specific design and operational parameters required to minimize the risk of microbial contamination.

**Segregated radiopharmaceutical processing area (SRPA):** A designated, unclassified space, area, or room with a defined (by facility procedures) perimeter that contains a PEC. An SRPA is only suitable for radiopharmaceutical preparation (with and without minor deviations), dispensing, and repackaging. If the SRPA is used to elute radionuclide generators it must have ISO Class 8 particle count non-viable particle count air quality.

**Shielding:** Barriers of appropriate radiation attenuating material, used for radiopharmaceuticals, to protect the personnel. These barriers can be general in nature (e.g., L-block, hot-cell), as to afford protection from a radiation field, or specific to a container used to hold a particular radiopharmaceutical (e.g., syringe shield, vial shields, "pigs").

**Single-dose container:** A container of a radiopharmaceutical for administration that is designed for use with a single patient as a single administration.

**Specific activity:** The radioactivity of a radionuclide per unit mass of the compound involved with the radionuclide (see *Radioactivity—Theory and Practice* ⟨1821⟩). The units of specific activity involve those for the activity (e.g., mCi, MBq, Ci, GBq) and those for the unit of mass (e.g., µg, mmol); expressed on an activity per mass basis (e.g., mCi/µg, MBq/µg, Ci/mmol, GBq/mmol).

**Sporicidal agent:** A chemical or physical agent that destroys bacterial and fungal spores when used in sufficient concentration for a specified contact time. It is expected to kill all vegetative microorganisms.

**Start of preparation:** Time at which a vial septum is punctured or a component container is opened (e.g., removal of cap on a pre-filled syringe), whichever comes first.

**Sterility:** The absence of viable microorganisms.

**Strength:** The radioactivity concentration of the radiopharmaceutical at the calibration time (see ⟨821⟩). Strength is expressed as the quantity of radioactivity on a volume basis (e.g., mCi/mL or MBq/mL).

**Unclassified space:** A space not required to meet any ISO air cleanliness classification.

**Unrestricted area:** An area in which a person should not be exposed to radiation levels in excess of 2 millirems in any 1 h from external sources.

**Use-by time:** For radiopharmaceuticals prepared from kits, the time period after preparation during which the radiopharmaceutical should be used or administered, as suggested or stated in the manufacturer's prescribing information.

# ⟨831⟩ REFRACTIVE INDEX

***Change to read:***

## ▲INTRODUCTION

Refractive index is a basic physical property of pharmaceutical materials. This general chapter only applies to the measurement of liquid pharmaceuticals, solutions, solvents, and liquid raw materials with stand-alone instruments and not to detectors of chromatographic systems. Refractive index measurements of liquid pharmaceuticals, solutions, solvents, and liquid raw materials are useful for the following:

- Identifying a pure substance
- Establishing the purity of some substances
- Determining the concentrations of some solutions such as alcohol solutions or sugar solutions (e.g., percentage of sugar in syrup)
- Determining the uniformity of final compounded preparations

The refractive index (*n*) of a substance, or medium, is defined as:

$$n = \frac{c}{v}$$

where *c* is the velocity of light in a vacuum and *v* is the velocity of light in the medium. For example, the refractive index of pure water at a measurement temperature and wavelength of 20° and 589 nm is 1.3330, meaning that light travels proportionately slower in water than in a vacuum.[1] The refractive index of a material is dependent on the temperature and the wavelength of light used to measure it; it is important to have precise control of both of these variables to accurately measure the refractive index. Refractive index is reported as $n_{\lambda}^{T}$, where *T* is the temperature, and λ is the wavelength of the incident beam (in nanometers). For example, the refractive index of water at 20° using the sodium D-line (at 589 nm) may be reported as either $n_{589}^{20}$ or $n_{D}^{20}$ = 1.3330.[1]

## QUALIFICATION OF REFRACTOMETERS

Qualification of refractometers can be divided into three elements: installation qualification (IQ), operational qualification (OQ), and performance qualification (PQ). For further discussion, see *Analytical Instrument Qualification* ⟨1058⟩.

### Installation Qualification

The IQ requirements provide evidence that the hardware and software are properly installed in the desired location.

### Operational Qualification

The OQ for the refractometer should verify the temperature control of the sample and the accuracy and repeatability of the refractive index measurements. The apparatus should provide refractive index readings to ±0.0001, and it should provide a means of operation at the prescribed temperature, with readings accurate to at least ±0.1°. The certified reference materials used must have an equal or better expanded uncertainty than ±0.001. Prior to verifying the operation of the refractometer, perform a full calibration of the instrument as instructed by the manufacturer.

#### ACCURACY

Verify the accuracy of the refractometer by measurement of certified reference materials that bracket the operational range of the instrument. The result should agree with the stated certified value within the limits of the expanded uncertainty of the reference material added to the accuracy specification of the instrument (as provided by the manufacturer). Additional uncertainty components may be included, according to the manufacturer's recommendation.

#### REPEATABILITY

Verify the repeatability of the refractometer by measuring at least two different certified reference materials covering the intended operational range of the instrument. Perform at least six replicate measurements of each certified reference material. The result should be equal to or less than the stated repeatability performance specification of the instrument (as provided by the manufacturer).

[1] The sodium D-line is identified as a doublet at 589.0 and 589.6 nm with a center wavelength at 589.3 nm in air.

Official

https://pharmacopeia.com/

## Performance Qualification

PQ includes two stages: periodic instrument calibration and performance evaluation. Instrument calibration should be performed periodically according to the instrument manufacturer's instructions. The second stage of PQ evaluation should be conducted at regular intervals or on day of use by verifying the refractive index of suitable reference materials.

# PROCEDURES

## Sample Preparation

Samples should be kept in well-closed containers to protect them from any changes in composition due to differences in temperature and/or relative humidity at different locations. If the sample to be evaluated is not homogenous, is hazy, or is known to contain suspended particles or an emulsified phase—factors that influence the measurement—the sample should be clarified by filtration or centrifugation prior to measurement.

## Measurement Procedure

Determine the refractive index of the sample per the instrument manufacturer's instructions. Unless otherwise indicated in the monograph, the refractive index is measured at 25°, with reference to the wavelength of the sodium D-line (at 589 nm).[1] ▲ (USP 1-Dec-2023)

Official

https://pharmacopeia.cn/v29240/

# ⟨841⟩ SPECIFIC GRAVITY

***Change to read:***

▲Specific gravity is the term for the relative density of a substance when water is used as the reference. The measurement of specific gravity necessarily involves the measurement of the density of the sample at a specified temperature as well as the measurement of the density of water.

The density $\rho$ (g/mL or g/cm$^3$) means the mass per unit volume, and the relative density means the ratio of the mass of a sample specimen to that of an equal volume of a standard substance. The relative density and specific gravity are unitless values.

The specific gravity ($d_t^{t'}$) means the ratio of the mass of the sample specimen at $t'$ to that of an equal volume of water ($H_2O$) at $t$.▲ (USP 1-Aug-2020)Unless otherwise stated in the individual monograph, the specific gravity determination is applicable only to liquids and ▲▲ (USP 1-Aug-2020) is based on the ratio of the weight of a liquid in air at 25° to that of an equal volume of water at the same temperature ▲(i.e., $d_{25}^{25}$).▲ (USP 1-Aug-2020) Where a temperature is specified in the individual monograph, the specific gravity is the ratio of the weight of the liquid in air at the specified temperature to that of an equal volume of water at the same temperature. ▲If▲ (USP 1-Aug-2020) the substance is a solid at 25°, determine the specific gravity ▲above the melting point▲ (USP 1-Aug-2020) (at the temperature directed in the individual monograph, ▲if specified).▲ (USP 1-Aug-2020)

Unless otherwise stated in the individual monograph, the density is defined as the mass of a unit volume of the substance at 25°, expressed in kilograms per cubic meter or grams per cubic centimeter (1 kg/m$^3$ = 10$^{-3}$ g/cm$^3$). Where the density is known, mass can be converted to volume, or volume converted to mass, by ▲using▲ (USP 1-Aug-2020) the formula, volume = mass/density.

▲▲ (USP 1-Aug-2020)

***Change to read:***

## METHOD I

### Procedure

Select a ▲▲ (USP 1-Aug-2020)clean, dry pycnometer that has been previously calibrated by determining its weight and the weight of ▲the deaerated▲ (USP 1-Aug-2020) water contained in it at 25°. Adjust the temperature of the ▲sample▲ (USP 1-Aug-2020) liquid to about 20°, and fill the pycnometer with it. Adjust the temperature of the filled pycnometer to 25°, remove any excess liquid, and weigh. When the monograph specifies a temperature different from 25°, the filled pycnometers must be brought to the temperature of the balance before ▲weighing. The specific gravity ($d_t^{t'}$) can be calculated by use of the following equation:

$$d_t^{t'} = \frac{W_1 - W}{W_2 - W}$$

$W_1$ = mass of the pycnometer filled with the sample solution at $t'$
$W$ = mass of the clean, dry pycnometer
$W_2$ = mass of the pycnometer filled with water at $t$

The density of water can be used to calculate the density of the sample of the specimen according to the following equation:

$$\rho_{s,t'} = d_t^{t'} \rho_{w,t}$$

$\rho_{s,t'}$ = density of the sample at $t'$
$\rho_{w,t}$ = density of water at $t$▲ (USP 1-Aug-2020)

***Change to read:***

## METHOD II

The procedure ▲requires▲ (USP 1-Aug-2020) the use of the oscillating transducer density meter. The apparatus consists of the following:

- A U-shaped tube, usually of borosilicate glass, which contains the liquid to be examined
- A magneto-electrical or piezo-electrical excitation system that causes the tube to oscillate as a cantilever oscillator at a characteristic frequency depending on the density of the liquid to be examined
- A means of measuring the oscillation period ($T$), which may be converted by the apparatus to give a direct reading of density or used to calculate density by using the constants $A$ and $B$ described below
- A means to measure and/or control the temperature of the oscillating transducer containing the liquid to be tested

The oscillation period is a function of the spring constant ($c$) and the mass of the system:

$$T^2 = \{(M/c) + [(\rho \times V)/c]\} \times 4\pi^2$$

Official

https://pharmacopeia.cn/v29240/

where ρ is the density of the liquid to be tested, $M$ is the mass of the tube, and $V$ is the volume of the filled tube.

Introduction of two constants $A = c/(4\pi^2 \times V)$ and $B = (M/V)$ leads to the classical equation for the oscillating transducer:

$$\rho = A \times T^2 - B$$

The specific gravity of the liquid is given by the formula:

$$\rho_{(L)}/\rho_{(W)}$$

where $\rho_{(L)}$ and $\rho_{(W)}$ are the densities of the liquid and water, respectively, both determined at 25°, unless otherwise directed in the individual monograph.

▲Samples with high viscosity will dampen the oscillations in the instrument and will introduce an error in the density measurement. Some oscillating transducer density meters are able to provide a correction to the density based on the viscosity of the sample. Samples with viscosities <10 mPa · s can be accurately measured without a density correction. Samples with viscosities >10 mPa · s must be measured with a density correction. If a density correction is not possible for a sample with >10 mPa · s viscosity, use *Method I*.▲ (USP 1-Aug-2020)

## Calibration

The constants $A$ and $B$ are determined by operating the instrument with the U-shaped tube filled with two different samples of known density (e.g., degassed water and air). Perform the control measurements daily, using degassed water. The results displayed for the control measurement using degassed water ▲should▲ (USP 1-Aug-2020) not deviate from the reference value ($\rho_{25}$ = 0.997043 g/cm³) by more than its specified error. Precision is a function of the repeatability and stability of the oscillator frequency. Density meters are able to achieve measurements with an error on the order of $1 \times 10^{-3}$ g/cm³ to $1 \times 10^{-5}$ g/cm³ and a repeatability of $1 \times 10^{-4}$ g/cm³ to $1 \times 10^{-6}$ g/cm³. For example, an instrument specified to $\pm 1 \times 10^{-4}$ g/cm³ must display 0.9970 ± 0.0001 g/cm³ in order to be suitable for further measurement, otherwise a readjustment is necessary. Calibration with certified reference materials should be carried out regularly.

## Procedure

▲Verify the viscosity of the sample to be analyzed. If the viscosity is >10 mPa · s and the oscillating transducer density meter is unable to provide a density correction based on the viscosity, use *Method I*.▲ (USP 1-Aug-2020)

Using the manufacturer's instructions, perform the measurements using the same procedure as for *Calibration*. If necessary, equilibrate the liquid▲▲ (USP 1-Aug-2020) at 25° before introduction into the tube to avoid the formation of bubbles and to reduce the time required for measurement. Factors affecting accuracy include the following:

- Temperature uniformity throughout the tube
- Nonlinearity over a range of density
- Parasitic resonant effects
- Viscosity, if the oscillating transducer density meters used do not provide automatic compensation of sample viscosity influence

▲The oscillating transducer density meter provides the reportable value of the sample density at the selected temperature. The specific gravity of the sample is calculated from this measured density according to the following equation:

$$d_t^{t'} = \frac{\rho_{s,t'}}{\rho_{w,t}}$$

$\rho_{s,t'}$ = density of the sample at $t'$
$\rho_{w,t}$ = density of water at $t$

[NOTE—The density of water used in the calculation of the specific gravity should be the accepted value of the density of water at $t$ (e.g., at 25° use 0.9970 g/cm³) rather than the value reported by the instrument.▲ (USP 1-Aug-2020)]

# ⟨846⟩ SPECIFIC SURFACE AREA

## INTRODUCTION

The specific surface area of a powder is determined by physical adsorption of a gas on the surface of the solid and by calculating the amount of adsorbate gas corresponding to a monomolecular layer on the surface. Physical adsorption results from relatively weak forces (van der Waals forces) between the adsorbate gas molecules and the adsorbent surface of the test powder. The determination is usually carried out at the temperature of liquid nitrogen. The amount of gas adsorbed can be measured by a volumetric or continuous flow procedure.

## BRUNAUER, EMMETT AND TELLER (BET) THEORY AND SPECIFIC SURFACE AREA DETERMINATION

### Multipoint Measurement

The data are treated according to the Brunauer, Emmett and Teller (BET) adsorption isotherm equation:

$$1/[V_a((P_O/P) - 1)] = [(C - 1)/(V_mC)] \times (P/P_O) + (1/V_mC) \quad (1)$$

| | | |
|---|---|---|
| $P$ | = | partial vapor pressure of adsorbate gas in equilibrium with the surface at 77.4 K (b.p. of liquid nitrogen), in Pa, |
| $P_o$ | = | saturated pressure of adsorbate gas, in Pa, |
| $V_a$ | = | volume of gas adsorbed at standard temperature and pressure (STP) [273.15 K and atmospheric pressure ($1.013 \times 10^5$ Pa)], in mL, |
| $V_m$ | = | volume of gas adsorbed at STP to produce an apparent monolayer on the sample surface, in mL, |
| $C$ | = | dimensionless constant that is related to the enthalpy of adsorption of the adsorbate gas on the powder sample. |

A value of $V_a$ is measured at each of not less than three values of $P/P_o$.
Then the BET value

$$1/[V_a((P_o/P) - 1)]$$

is plotted against $P/P_o$, according to equation (1). This plot should yield a straight line usually in the approximate relative pressure range 0.05 to 0.3. The data are considered acceptable if the correlation coefficient, r, of the linear regression is not less than 0.9975; that is, $r^2$ is not less than 0.995. From the resulting linear plot, the slope, which is equal to $(C - 1)/V_mC$, and the intercept, which is equal to $1/V_mC$, are evaluated by linear regression analysis. From these values, $V_m$ is calculated as $1/(slope + intercept)$, while C is calculated as $(slope/intercept) + 1$. From the value of $V_m$ so determined, the specific surface area, S, in $m^2 \cdot g^{-1}$, is calculated by the equation:

$$S = (V_mNa)/(m \times 22400) \quad (2)$$

| | | |
|---|---|---|
| $N$ | = | Avogadro constant ($6.022 \times 10^{23}$ $mol^{-1}$), |
| $a$ | = | effective cross-sectional area of one adsorbate molecule, in square meters (0.162 $nm^2$ for nitrogen and 0.195 $nm^2$ for krypton), |
| $m$ | = | mass of test powder, in g, |
| 22,400 | = | volume, in mL, occupied by one mole of the adsorbate gas at STP allowing for minor departures from the ideal. |

A minimum of three data points is required. Additional measurements may be carried out especially when nonlinearity is obtained at a $P/P_o$ value close to 0.3. Because nonlinearity is often obtained at a $P/P_o$ value below 0.05, values in this region are not recommended. The test for linearity, the treatment of the data, and the calculation of the specific surface area of the sample are described above.

### Single-Point Measurement

Normally, at least three measurements of $V_a$, each at different values of $P/P_o$, are required for the determination of specific surface area by the dynamic flow gas adsorption technique *(Method I)* or by volumetric gas adsorption *(Method II).* However, under certain circumstances described below, it may be acceptable to determine the specific surface area of a powder from a single value of $V_a$ measured at a single value of $P/P_o$ such as 0.300 (corresponding to 0.300 mole of nitrogen or 0.001038 mole fraction of krypton), using the following equation for calculating $V_m$:

$$V_m = V_a[1 - (P/P_o)] \quad (3)$$

The specific surface area is then calculated from the value of $V_m$ by equation (2) given above.

Official

https://pharmacopeia.cn/v29240/

The single-point method may be employed directly for a series of powder samples of a given material for which the material constant C is much greater than unity. These circumstances may be verified by comparing values of specific surface area determined by the single-point method with that determined by the multipoint method for the series of powder samples. Close similarity between the single-point values and multipoint values suggests that 1/C approaches zero.

The single-point method may be employed indirectly for a series of very similar powder samples of a given material for which the material constant C is not infinite but may be assumed to be invariant. Under these circumstances, the error associated with the single-point method can be reduced or eliminated by using the multipoint method to evaluate C for one of the samples of the series from the BET plot, from which C is calculated as (1 + *slope*/*intercept*). Then $V_m$ is calculated from the single value of $V_a$ measured at a single value of $P/P_o$, by the equation:

$$V_m = V_a[(P_o/P) - 1]\,[(1/C) + ((C - 1)/C) \times (P/P_o)] \quad (4)$$

The specific surface area is calculated from $V_m$ by equation (2) given above.

## EXPERIMENTAL TECHNIQUES

This section describes the methods to be used for the sample preparation, the dynamic flow gas adsorption technique *(Method I)* and the volumetric gas adsorption technique *(Method II).*

### Sample Preparation

#### OUTGASSING

Before the specific surface area of the sample can be determined, it is necessary to remove gases and vapors that may have become physically adsorbed onto the surface after manufacture and during treatment, handling, and storage. If outgassing is not achieved, the specific surface area may be reduced or may be variable because an intermediate area of the surface is covered with molecules of the previously adsorbed gases or vapors. The outgassing conditions are critical for obtaining the required precision and accuracy of specific surface area measurements on pharmaceuticals because of the sensitivity of the surface of the materials.

The outgassing conditions must be demonstrated to yield reproducible BET plots, a constant weight of test powder, and no detectable physical or chemical changes in the test powder.

The outgassing conditions defined by the temperature, pressure, and time are chosen so that the original surface of the solid is reproduced as closely as possible. Outgassing of many substances is often achieved by applying a vacuum by purging the sample in a flowing stream of a nonreactive, dry gas or by applying a desorption-adsorption cycling method. In either case, elevated temperatures are sometimes applied to increase the rate at which the contaminants leave the surface. Caution should be exercised when outgassing powder samples using elevated temperatures to avoid affecting the nature of the surface and the integrity of the sample.

If heating is employed, the recommended temperature and time of outgassing are as low as possible to achieve reproducible measurement of specific surface area in an acceptable time. For outgassing sensitive samples, other outgassing methods such as the desorption-adsorption cycling method may be employed.

#### ADSORBATE

The standard technique is the adsorption of nitrogen of analytical quality at liquid nitrogen temperature.

For powders of low specific surface area (< 0.2 $m^2g^{-1}$), the proportion adsorbed is low. In such cases, the use of krypton at the liquid nitrogen temperature is preferred because the low vapor pressure exerted by this gas greatly reduces error. The use of larger sample quantities, where feasible (equivalent to 1 $m^2$ or greater total surface area using nitrogen), may compensate for the errors in determining low surface areas.

All gases used must be free from moisture.

#### QUANTITY OF SAMPLE

A quantity of the test powder is accurately weighed such that the total surface of the sample is at least 1 $m^2$ when the adsorbate is nitrogen and 0.5 $m^2$ when the adsorbate is krypton.

Lower quantities of sample may be used after appropriate validation.

### Measurements

Because the amount of gas adsorbed under a given pressure tends to increase when the temperature is decreased, adsorption measurements are usually made at a low temperature. Measurement is performed at 77.4 K, the boiling point of liquid nitrogen.

### Method I: The Dynamic Flow Method

#### PRINCIPLE

In the dynamic flow method (see *Figure 1*), the recommended adsorbate gas is dry nitrogen or krypton, while helium is employed as a diluent gas, which is not adsorbed under the recommended conditions.

DOI: https://doi.org/10.31003/USPNF_M99635_01_01

A minimum of three mixtures of the appropriate adsorbate gas with helium are required within the $P/P_o$ range 0.05 to 0.30.

The gas detector-integrator should provide a signal that is approximately proportional to the volume of the gas passing through it under defined conditions of temperature and pressure. For this purpose, a thermal conductivity detector with an electronic integrator is one among various suitable types. A minimum of three data points within the recommended range of 0.05 to 0.30 for $P/P_o$ is determined.

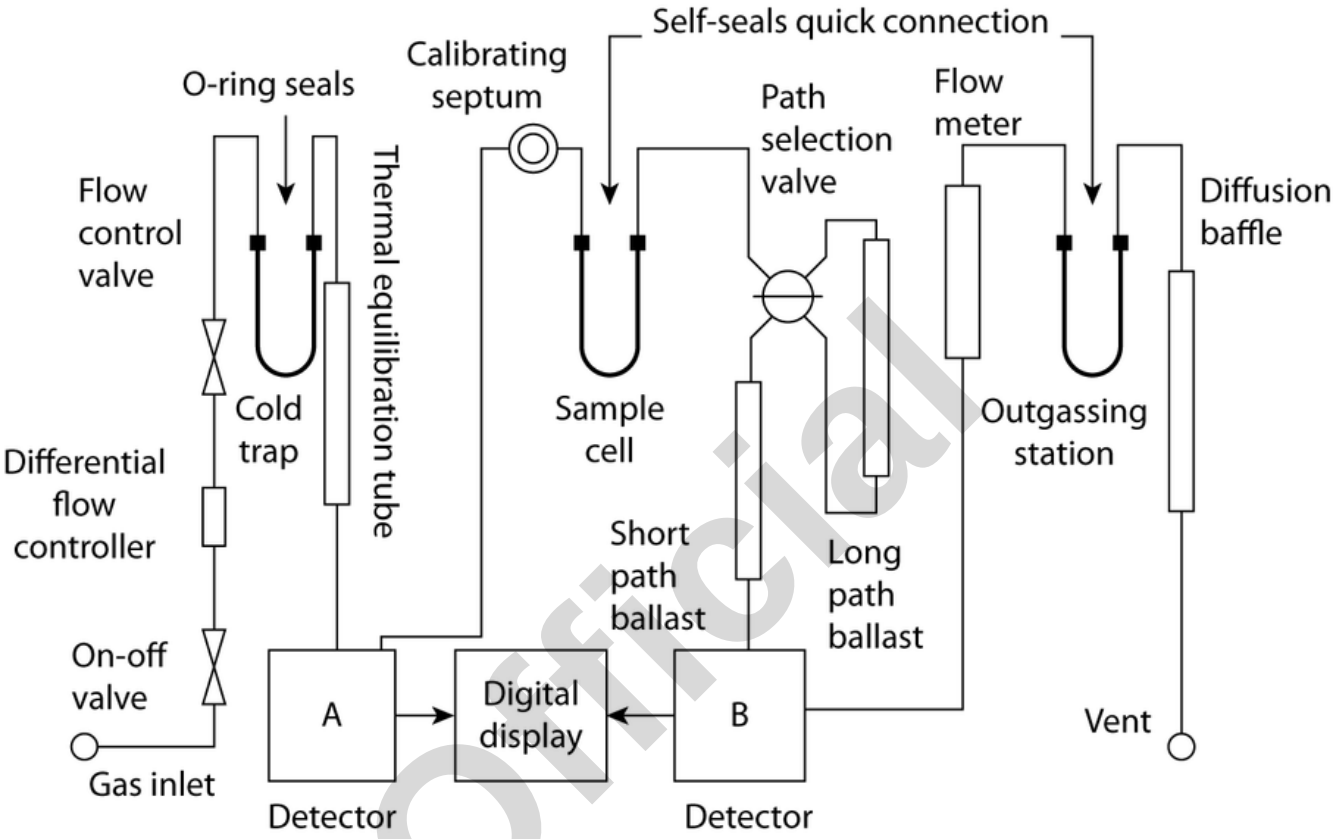

Fig. 1. Schematic diagram of the dynamic flow method apparatus.

PROCEDURE

A known mixture of the gases, usually nitrogen and helium, is passed through a thermal conductivity cell, through the sample again, through the thermal conductivity cell, and then to a recording potentiometer.

The sample cell is immersed in liquid nitrogen, and the sample adsorbs nitrogen from the mobile phase. This unbalances the thermal conductivity cell, and a pulse is generated on a recorder chart.

The sample is removed from the coolant; this gives a desorption peak equal in area and in the opposite direction to the adsorption peak. Because this is better defined than the adsorption peak, it is the one used for the determination.

To effect the calibration, a known quantity of adsorbate, sufficient to give a peak of similar magnitude to the desorption peak, is injected into the system, and the proportion of gas volume per unit peak area is obtained.

A mixture of nitrogen and helium is used for a single-point determination; and several such mixtures or premixing two streams of gas are used for a multipoint determination.

The calculation is the same as the volumetric method.

## Method II: The Volumetric Method

PRINCIPLE

In the volumetric method (see *Figure 2*), the recommended adsorbate gas is nitrogen, which is admitted into the evacuated space above the previously outgassed powder sample to give a defined equilibrium pressure, P, of the gas. The use of a diluent gas, such as helium, is therefore unnecessary, although helium may be employed for other purposes, such as to measure the dead volume.

Because only pure adsorbate gas, instead of a gas mixture, is employed, interfering effects of thermal diffusion are avoided in this method.

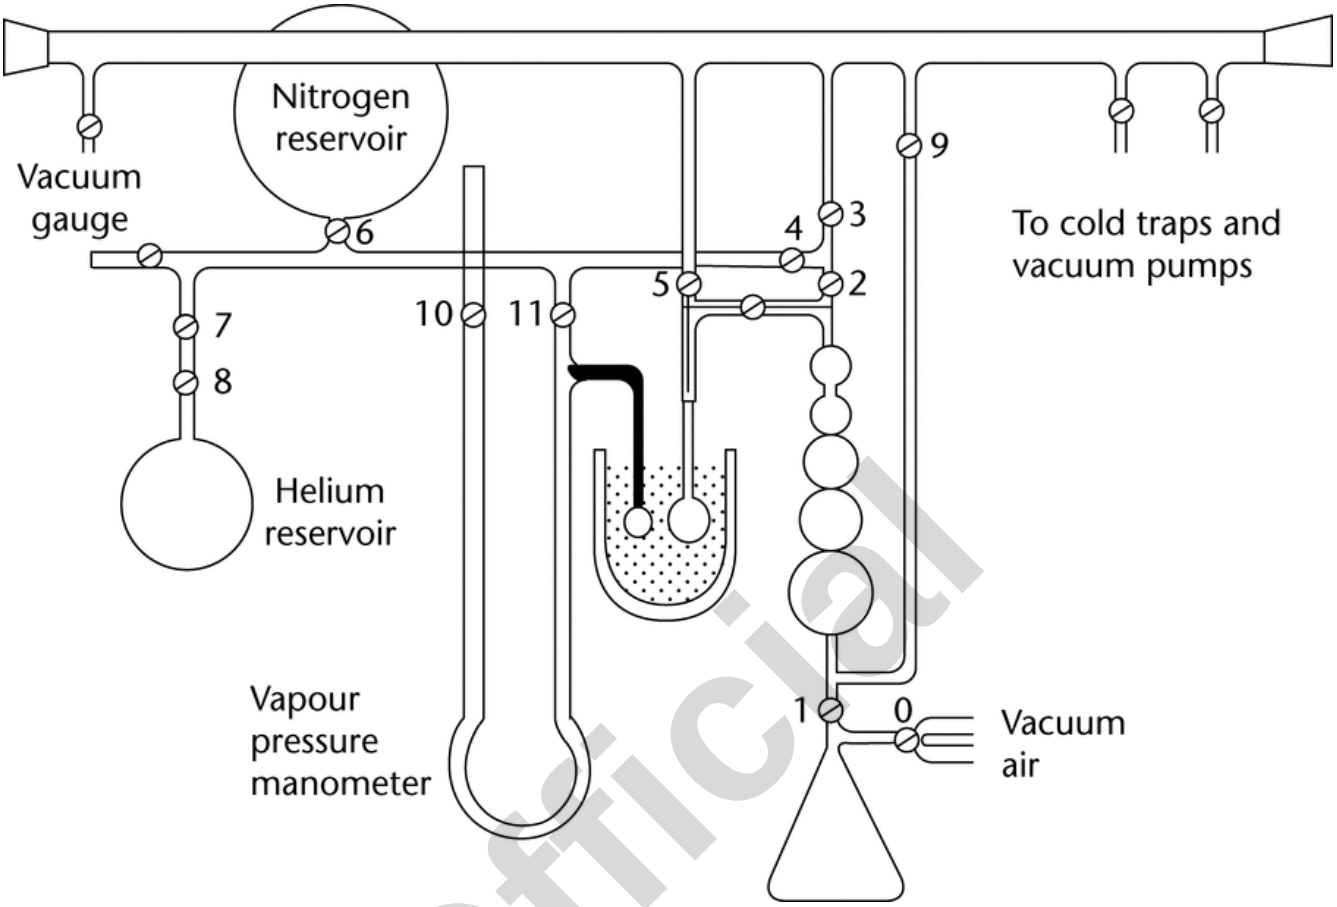

Fig. 2. Schematic diagram of the volumetric method apparatus.

PROCEDURE

A small amount of dry nitrogen is admitted into the sample tube to prevent contamination of the clean surface, the sample tube is removed, a stopper is inserted, the tube is weighed, and the weight of the sample is calculated. Then the sample tube is attached to the volumetric apparatus. The sample is cautiously evacuated down to the specified pressure (e.g., between 2 Pa and 10 Pa). Alternately, some instruments are operated by evacuating to a defined rate of pressure change (e.g., less than 13 Pa/30 s) and by holding for a defined period of time before commencing the next step.

If the principle of operation of the instrument requires the determination of the dead volume in the sample tube, for example, by the admission of a nonadsorbed gas, such as helium, this procedure is carried out at this point, followed by evacuation of the sample. The determination of dead volume may be avoided using difference measurements: that is, by means of reference and sample tubes connected by a differential transducer. The adsorption of nitrogen gas is then measured as described below.

Raise a Dewar vessel containing liquid nitrogen at 77.4 K up to a defined point on the sample cell. Admit a sufficient volume of adsorbate gas to give the lowest desired relative pressure. Measure the volume adsorbed, $V_a$. For multipoint measurements, repeat the measurement of $V_a$ at successively higher $P/P_o$ values. When nitrogen is used as the adsorbate gas, $P/P_o$ values of 0.10, 0.20, and 0.30 are often suitable.

## Reference Materials

Periodically verify the functioning of the apparatus using appropriate reference materials of known surface area that have a specific surface area similar to that of the sample to be examined.

# ⟨852⟩ ATOMIC ABSORPTION SPECTROSCOPY

## INTRODUCTION

Atomic absorption (AA) spectroscopy is an analytical method that supports qualification and/or quantification of elements. In this use, the AA method supports procedures that measure the absorbance of radiation at a characteristic wavelength by a vapor composed of ground state atoms. A typical instrument consists of a primary energy source that produces the spectrum of the element under examination, a monochromator, and a suitable detector.

For discussion of the theory and principles of measurements, see *Atomic Absorption Spectroscopy—Theory and Practice* ⟨1852⟩, a resource that may be helpful but is not mandatory.

## QUALIFICATION OF ATOMIC ABSORPTION SPECTROPHOTOMETERS

Qualification of an atomic absorption spectrophotometer (AAS) can be divided into three elements: installation qualification (IQ), operational qualification (OQ), and performance qualification (PQ); see also *Analytical Instrument Qualification* ⟨1058⟩.

### Installation Qualification

The IQ requirements provide evidence that the hardware and software are properly installed in the desired location.

### Operational Qualification

In OQ, an instrument's performance is characterized using standards of known spectral properties to verify that the system operates within target specifications (see *Table 1* and *Table 2*). The purpose of OQ is to demonstrate that instrument performance is suitable. OQ is a check of the key operational parameters performed following installation and following repairs and/or maintenance.

The OQ tests in the following sections are typical examples only. Other tests and samples can be used to establish specifications for OQ. Instrument vendors often have samples and test parameters available as part of the IQ/OQ package.

**Table 1. OQ Test and Acceptance Criteria for Flame AAS**

| Test | Procedure | Acceptance Criteria |
|---|---|---|
| Sensitivity | Aspirate a 0.3-µg/mL zinc standard and record the absorbance. | ±20% of AU[a] specified by instrument manufacturer |
| Linearity | Aspirate a blank and 0.05-, 0.075-, 0.10-, 0.25-, and 0.50-µg/mL zinc standards. Generate a calibration curve and record the correlation coefficient (*R*). | Correlation coefficient NLT 0.995 |
| Precision | Assay 5 separate replicates of the 0.10-µg/mL zinc standard versus the standard curve generated for the *Linearity* test. Calculate the %RSD of the 5 results in µg/mL. | %RSD[b] NMT 3% |

[a] AU = absorption unit.
[b] %RSD = % relative standard deviation.

**Table 2. OQ Test and Acceptance Criteria for Graphite Furnace AAS**

| Test | Procedure | Acceptance Criteria |
|---|---|---|
| Sensitivity | Prepare a copper standard and measure the characteristic mass as described by the manufacturer. | ±20% of copper characteristic mass as specified by the manufacturer |
| Linearity | Generate a calibration curve from a blank and 25-, 50-, 75-, and 100-µg/L copper standards. Inject each standard in triplicate and record the %RSD. | Correlation coefficient NLT 0.995 |
| | | %RSD of triplicate injections of each copper standard NMT 5% (not including the blank) |
| Precision | Assay 5 separate replicates of the 50-µg/L copper standard versus the standard curve generated for the *Linearity* test. Inject each replicate in triplicate. | %RSD of 5 replicates NMT 3% |
| | | %RSD of triplicate injections NMT 5% |

### Performance Qualification

PQ determines that the instrument is capable of meeting the user's requirements for all the parameters that may affect the quality of the measurement.

Depending on typical use, the specifications for PQ may be different from the manufacturer's specifications. For validated methods, specific PQ tests, also known as system suitability tests, can be used in lieu of PQ requirements.

Specific procedures, acceptance criteria, and time intervals for characterizing AA spectrophotometer performance depend on the instrument and intended application. Demonstrating stable instrument performance over extended periods of time provides some assurance that reliable measurements can be taken from test sample spectra using validated AA procedures.

***Change to read:***

## PROCEDURE

Evaluate and select the type of material of construction, pretreatment, and cleaning of analytical labware used in AA analyses. The material must be inert and, depending on the specific application, resistant to caustics, acids, and/or organic solvents. For some analyses, diligence must be exercised to prevent the adsorption of analytes onto the surface of a vessel, particularly in ultra-trace analyses. Contamination of the sample solutions from metal and ions present in the container also can lead to inaccurate results.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M6959_03_01
@2024 USPC

For the analysis of a ubiquitous element, it is often necessary to use the purist grade of reagent or solvent available. Check all solutions (diluents, matrix modifier solutions, ionization suppression solutions, reactants, and others) for elemental contamination before they are used in an analysis.

**Standard Solution**

Prepare as directed in the individual monograph. [NOTE—Commercially available single- or multi-element standard solutions, traceable to the National Institute of Standards and Technology or to an equivalent national metrology organization, can be used in the preparation of standard solutions.] Standard solutions, especially those used for ultra-trace analyses, may have limited shelf life. ▲Working standard solutions for ultra-trace analyses▲ (USP 1-Aug-2022) should be retained for not more than 24 h unless stability is demonstrated experimentally.

The method of standard additions also can be used. This method involves adding a known concentration of the analyte element to the sample at no fewer than 2 concentration levels against an unspiked sample preparation. The instrument response is plotted against the concentration of the added analyte element, and a linear regression line is drawn through the data points. The absolute value of the *x*-intercept multiplied by any dilution factor is the concentration of the analyte in the sample.

**Sample Solution**

Prepare as directed in the individual monograph.

A variety of digestion techniques may be indicated to dissolve the sample. These may include hot-plate and microwave-assisted digestions, including open-vessel and closed-vessel approaches. Note that open-vessel digestion generally is not recommended for the analysis of volatile metals, e.g., selenium and mercury.

**Analysis**

Follow the procedure as directed in the individual monograph for the instrumental parameters.

The instrument must be standardized for quantification at the time of use. ▲For a Category I assay, the absorbances of standard solutions that bracket the target concentration of the sample solutions are determined. For a Category II quantitative assay, the absorbances of standard solutions that bracket the specification limit concentration of the sample solutions are determined. For a Category II limit test or a Category IV identification test, only a single standard measurement may be required per the specific monograph. For a multiple standard curve, the detector response is plotted as a function of the analyte concentration to generate the standard plot.▲ (USP 1-Aug-2022) Regression analysis of the standard plot should be used to evaluate the linearity of detector response, and individual monographs may set criteria for the residual error of the regression line.

To demonstrate the stability of the system's initial standardization, the analyst must reassay a solution used in the initial standard curve as a check standard at appropriate intervals throughout the analysis of the sample set. Unless otherwise indicated in the individual monograph, the reassayed standard should agree with its expected value to within ±3% for an assay or ±20% for an impurity analysis.

▲When the method of standard additions is applied, a separate system suitability standard is prepared at a concentration within the analytical range of the method. The concentration of the system suitability standard is determined using the method of standard additions in the same manner as the test solutions. The measured concentration of the system suitability standard should agree with its expected value within ±3% for an assay or ±20% for an impurity analysis.▲ (USP 1-Aug-2022)

Sample concentrations are calculated versus the working curve generated by plotting the detector response versus the concentration of the analyte in the standard solutions.

***Change to read:***

## VALIDATION AND VERIFICATION

**Validation**

Validation is required when an AA method is intended for use as an alternative to the official procedure for testing an official article.

The objective of an AA procedure validation is to demonstrate that the measurement is suitable for its intended purpose, including quantitative determination of the main component in a drug substance or a drug product (Category I assays), quantitative determination of impurities or limit tests (Category II), and identification tests (Category IV). [NOTE—For definition of different categories, see *Validation of Compendial Procedures* ⟨1225⟩.] Depending on the category of the test, analytical procedure validation for AA may require the testing of linearity, range, accuracy, specificity, precision, detection limit, quantitation limit, and robustness. These analytical performance characteristics apply to externally standardized methods and to the method of standard additions.

General information chapter ⟨1225⟩ provides definitions and general guidance on analytical procedures validation without indicating specific validation criteria for each characteristic. The intention of the following sections is to provide the user with specific validation criteria that represent the minimum expectations for this technology. For each particular application, tighter criteria may be needed to demonstrate suitability for the intended use.

- **ACCURACY:** For Category I assays or Category II tests, accuracy can be determined by conducting recovery studies with the appropriate matrix spiked with known concentrations of elements. It is also an acceptable practice to compare assay results obtained using the AA procedure under validation to those of an established analytical procedure. In standard addition methods, accuracy assessments are based on the final intercept concentration, not the recovery calculated from the individual standard additions.

  **Validation criteria:** 95.0%–105.0% mean recovery for the drug substance assay and the drug product assay, and 70.0%–150.0% mean recovery for the impurity analysis. These criteria apply throughout the intended range.

- **PRECISION**

  **Repeatability:** The analytical procedure should be assessed ▲using 6 replicate measurements (▲ (USP 1-Aug-2022)measuring the concentrations of 6 independently prepared sample solutions▲)▲ (USP 1-Aug-2022) at 100% of the assay test concentration. Alternatively, ▲3 concentration levels with 3 independently prepared samples for each level▲ (USP 1-Aug-2022)

Official

https://pharmacopeia.cn/

can be used. The 3 concentrations should be close enough that the repeatability is constant across the concentration range. If this is done, the repeatability at the 3 concentrations is pooled for comparison to the acceptance criteria. If validating a procedure by the method of standard additions, the precision criterion applies to the final experimental result, not the accuracy of the individual standard addition levels.

**Validation criteria:** The relative standard deviation is not more than 5.0% for the drug substance assay, not more than 5.0% for the drug product assay, and not more than 20% for the impurity analysis.

**Intermediate precision:** The effect of random events on the analytical precision of the procedure should be established. Typical variables include performing the analysis on different days, using different instrumentation, or having the method performed by two or more analysts. As a minimum, the analytical procedure should be assessed by performing the repeatability test ▲(6 replicate measurements)▲ (USP 1-Aug-2022) in any combination of at least two of the conditions previously mentioned (totaling 12 measurements).

**Validation criteria:** The relative standard deviation is not more than 8.0% for the drug substance assay, not more than 8.0% for the drug product assay, and not more than 25.0% for the impurity analysis ▲based on the 12 measurements.▲ (USP 1-Aug-2022)

- **SPECIFICITY:** The procedure must be able to unequivocally assess each analyte element in the presence of components that may be expected to be present, including any matrix components.
  **Validation criteria:** Demonstrated by meeting the accuracy requirement.
- **QUANTITATION LIMIT:** The limit of quantitation (QL) can be estimated by calculating the standard deviation of no fewer than 6 replicate measurements of a blank solution, divided by the slope of a standard curve, and multiplying by 10. If validating a procedure using the method of standard additions, the slope of standards applied to a solution of the test material is used. Other suitable approaches can be used (see ⟨1225⟩).
  A measurement of a test solution prepared from a representative sample matrix spiked at the estimated QL concentration must be performed to confirm accuracy. If validating a procedure using the method of standard additions, the validation criterion applies to the final experimental result, not the spike recovery of the individual standard addition levels.
  **Validation criteria:** The analytical procedure should be capable of determining the analyte precisely and accurately at a level equivalent to 50% of the specification.
- **LINEARITY:** A response curve between the analyte concentration and absorbance is prepared from no fewer than 5 standard solutions at concentrations encompassing the anticipated concentration of the test solution. The standard curve is then evaluated using appropriate statistical methods, such as a least-squares regression.
  For experiments that do not yield a linear relationship between analyte concentration and AA response, appropriate statistical methods must be applied to describe the analytical response.
  **Validation criteria:** Correlation coefficient (*R*), not less than 0.995 for Category I assays and not less than 0.99 for Category II quantitative tests.
- **RANGE:** Range is the interval between the upper and lower concentrations (amounts) of analyte in the sample (including these concentrations) for which it has been demonstrated that the analytical procedure has a suitable level of precision, accuracy, and linearity. Range is demonstrated by meeting the linearity, precision, and accuracy requirements.
  **Validation criteria:** For Category I tests, the validation range for 100.0% centered acceptance criteria is 80.0%–120.0%. For noncentered acceptance criteria, the validation range is 10.0% below the lower limit to 10.0% above the upper limit. For content uniformity, the validation range is 70.0%–130.0%. For Category II tests, the validation range covers 50.0%–120.0% of the acceptance criteria.
- **ROBUSTNESS:** The reliability of an analytical measurement is demonstrated by deliberate changes to experimental parameters. For AA this can include but is not limited to sample preparation steps and heating programs, including atomization hold time or atomization temperature. Exercise caution when changing fuel and oxidant gas flows and burner hardware, because this could potentially create a flash-back condition.

**Verification**

US current good manufacturing practices regulations [21 CFR §211.194(a)(2)] indicate that users of the analytical procedures, as described in *USP–NF*, are not required to validate these procedures if provided in a monograph. Instead, they must simply verify their suitability under actual conditions of use.

The objective of an AA procedure verification is to demonstrate that the procedure, as prescribed in a specific monograph, can be executed by the user with suitable accuracy, specificity, linearity, and precision using the instruments, analysts, and sample matrices available. According to *Verification of Compendial Procedures* ⟨1226⟩, if the verification of the compendial procedure by following the monograph is not successful, the procedure may not be suitable for use with the article under test. It may be necessary to develop and validate an alternative procedure as allowed in *General Notices, 6.30 Alternative and Harmonized Methods and Procedures*.

# ⟨853⟩ FLUORESCENCE SPECTROSCOPY

## INTRODUCTION

Fluorescence is a two-step process that requires absorption of light at a specific wavelength (excitation) followed by emission of light, usually at a higher wavelength. The emission of light is termed *fluorescence*.

The most common type of fluorescent sample is a submicromolar transparent solution that absorbs light following the Beer–Lambert–Bouguer Law and fluoresces with an intensity that is directly proportional to the concentration, the absorptivity, and the fluorescence quantum yield of the fluorescent species or fluorophore.

Unlike absorption spectroscopy, where deviation from linearity is the exception, fluorescence linearity can be affected by a number of sample-related effects. For additional information, see *Fluorescence Spectroscopy—Theory and Practice* ⟨1853⟩.

Fluorescence methods also are termed *background-free* because little excitation light reaches the detector. This characteristic makes fluorescence detection highly sensitive, down to single-molecule detection in some cases. Fluorescence detection also can be highly specific because a fluorophore emits a characteristic emission pattern. Specificity and sensitivity are two of the more important strengths of fluorescence methods.

## QUALIFICATION OF FLUORESCENCE INSTRUMENTS

Analysts ensure the suitability of a specific instrument for a given procedure by using a stepwise evaluation for the desired application from selection to instrument retirement: design qualification (DQ); installation qualification (IQ); an initial performance-to-specification qualification, also known as operational qualification (OQ); and an ongoing performance qualification (PQ). For additional information, see general chapter *Analytical Instrument Qualification* ⟨1058⟩.

DQ and IQ are not further considered in this chapter. The purpose of this section is to provide test methods and acceptance criteria to ensure that the instrument is suitable for its intended use (OQ) and that it will continue to function properly over extended time periods (PQ).

As with any spectrometric device, analysts must qualify a spectrofluorometer for both wavelength (*x*-axis) and relative intensity (*y*-axis or signal axis) accuracy and precision. They also must establish sensitivity. OQ should span the operational ranges required within the laboratory for both intensity and wavelength scales.

### Instrument Operational Qualification

The tolerances given in both the instrument OQ and PQ are applicable for general use. Specifications for particular instruments and applications can vary depending on the analytical procedure used and the desired accuracy of the final result. Instrument vendors often have samples and test parameters available as part of the IQ/OQ package.

Wherever possible, analysts should use certified reference materials for purposes of calibration in the steps detailed below in preference to laboratory-prepared solutions. When certified reference materials are obtained from a recognized accredited source, they have independently verified traceable value assignments with associated calculated uncertainties.

Two general types of instrumental measurements are differentiated here: spectral (i.e., those that measure intensity versus wavelength) and fixed (i.e., those that measure intensity at a fixed wavelength and bandwidth).

#### CONTROL OF WAVELENGTHS

The level of confidence of measured peak positions is defined by wavelength accuracy for spectral measurements. Determination of the accuracy of many wavelengths across the desired wavelength range demonstrates if further calibration beyond a single point is needed. Multipoint calibration involves measuring wavelength biases at multiple wavelengths and correcting for the wavelength dependence of the bias. A single-point calibration often can be applied to the wavelength axis in an instrument's software before data are collected, but a multipoint calibration may require that the correction be applied to spectra after they are collected.

For fixed measurements, the wavelength position and bandwidth must be reproducible. For filter-based wavelength selection, this requires that only the same filter be used when analysts compare data over time. If a different filter must be used (e.g., when data are compared across instruments and laboratories), then the transmission curves of the filters must be compared.

Wavelength precision should be determined over the operational range using at least six replicate measurements. The standard deviation should not exceed ±1 nm.

#### ATOMIC LINE SPECTRA

This procedure is described as the primary application because the emission lines produced from a discharge lamp are characteristic of the source element, and, as a fundamental physical standard, these wavelengths have been measured with an uncertainty of NMT ± 0.01 nm. In solution spectrofluorometry the wavelength bias required rarely exceeds 1.0 nm. For these reasons, the atomic line standard values are cited without uncertainty. The lamp should be placed at the source position in the spectrofluorometer.

A commonly employed low-pressure mercury lamp has a number of intense lines that cover a large part of the UV and visible range. Manufacturers often use two Xenon lines from the source at 260.5 and 541.9 nm as an internal calibration check, because

https://pharmacopeia.cn/v-cn/

the accuracy of both the excitation and emission monochromators can be verified and can be used for diagnostic purposes (see *Table 1*).[1]

**Table 1. Elemental Line Spectra Wavelengths**

| Element | Wavelength (nm) |
|---|---|
| Hg | 253.7 |
| Xe | 260.5 |
| Hg | 296.7 |
| Hg | 365.0 |
| Hg | 404.7 |
| Hg | 435.8 |
| Xe | 541.9 |
| Hg | 546.1 |
| Hg | 577.0 |
| Hg | 579.1 |

## USE OF RARE EARTH OXIDE SOLUTIONS

This procedure uses a solution of a rare earth oxide prepared by dissolution in acid media. The most frequently used is holmium oxide in perchloric acid in combination with a diffuse reflector located at the sample position. Suitable certified reference materials are available commercially.[2] The wavelength selector not being scanned should be removed; if removal is not practicable, it should be set to zero order (in this position a grating behaves like a mirror reflecting all wavelengths). The diffuse reflector is scanned with and without the rare earth sample in place, and the ratio of the two intensities is calculated to obtain an effective transmittance spectrum. Minima in the intensity ratio correspond to absorption peaks of the sample. For a 4% (w/w) solution of holmium oxide in perchloric acid at 1.0 nm spectral bandwidth and a path length of 1 cm, these minima are in *Table 2*.[3]

**Table 2**

| Wavelength (nm) |
|---|
| 241.1 |
| 249.9 |
| 278.1 |
| 287.2 |
| 333.5 |
| 345.4 |
| 361.3 |
| 385.6 |
| 416.3 |
| 451.4 |
| 467.8 |
| 485.2 |
| 536.6 |
| 640.5 |

If the operational range of the spectrophotometer lies outside 240–650 nm, other certified rare earth oxides or other solutions are used.

Didymium (a mixture of neodymium and praseodymium) is available as a traceable standard in both solution and glass presentations. Didymium is similar in preparation to the holmium materials and has useful peak characteristics in the 730–870 nm region. Useful peaks are found in the didymium solution at approximately 731.6, 740.0, 794.1, 799.0, and 864.4 nm.

[1] The rounded values are taken from ASTM Standard E388-04 (2009).
[2] NIST SRM 2034 is no longer available.
[3] The rounded values are taken from the intrinsic wavelength standard absorption band data from Travis et al. *J Phys Chem Ref Data* 2005;34(1):41. The maximum 95% measurement uncertainty is ±0.06 nm.

### USE OF POLYMETHYLMETHACRYLATE-DOPED REFERENCES

This procedure uses solid reference materials manufactured by polymerization of a variety of fluorescent active aromatic ring compounds into an inert polymethylmethacrylate (PMMA) matrix. These materials are supplied as polished blocks for use in a standard cuvette holder (see *Table 3*).

**Table 3. Dopant, Excitation, and Emission Data for Selected Reference Materials**

| Dopant | Excitation λ (nm) | Emission λ (nm) |
|---|---|---|
| *p*-Terphenyl | 295 | 338 |
| Ovalene | 342 | 482 |
| Tetraphenylbutadiene | 348 | 422 |
| Anthracene | 360 | 402 |

## Performance Verification

Results from day-to-day testing of photostable intensity standards are used to verify the performance of an instrument. If the measured intensity does not change from that observed when the instrument was qualified, then instrument performance has not changed and remains qualified. Using such standards to determine an artifact-based or quasi-absolute intensity scale potentially enables measured intensities and instrument sensitivity to be compared over time or between instruments. Intensity measurements should be within the linear range of the instrument's detection system before analysts attempt intensity comparisons, and will be affected by any instrumental effect directly related to the fluorescence signal, e.g., changes in source intensity, detector response, etc.

For instruments with filter-based wavelength selection, analysts use fluorescence standards for spectral correction to determine expected intensity differences caused by filters with different transmission profiles. By compensating for these intensity differences due to spectral mismatch, the analyst can determine a quasi-absolute intensity scale for these instruments. Analysts should approach instrument-to-instrument comparisons with particular caution because of the relatively large and difficult-to-quantify uncertainties involved.

### USE OF LOW-CONDUCTIVITY (18-MΩ) WATER

The Raman band of water is used to measure signal-to-noise ratios in fluorescent instruments. The Raman band of water is inherently reproducible and does not degrade with time. Water is convenient to obtain in a pure state and allows interlaboratory comparisons to be made with a high level of confidence. No preparation or dilution is required. The Raman band is a low-level signal that provides a good test for both the optics and the electronics of an instrumental system.

The Raman band of water is not caused by fluorescence but is a result of Raman scattering. For water, the Raman band is always red-shifted 3382 $cm^{-1}$ relative to the excitation.[4] This band usually is measured by excitation at 350 nm, resulting in a Raman peak at 397 nm, but radiation up to 500 nm also can be used as the excitation wavelength, and the corresponding emission peak is 602 nm.

### USE OF INTENSITY STANDARDS

Several solid-doped fluorescent materials are available.[5] These polymers or glasses enable the relative spectral correction and day-to-day performance qualification of fluorescence instruments across the UV, visible, and NIR regions from 320 to 830 nm. The high photostability of the materials makes them particularly useful as day-to-day intensity standards, even when spectral correction is not needed or when the excitation wavelength differs from that used for certification. A certified, steady-state emission spectrum is supplied with each certified reference material, along with the estimated total uncertainties. The reference is available in the form of a solid glass, standard-sized cuvette (12.5 mm × 12.5 mm × 45 mm) with three polished long faces for 90° detection and one frosted long face for front-face or epifluorescence detection.

Alternatively, analysts can use fluorophores in solutions that have been shown to be stable.[6, 7]

# QUALITATIVE AND QUANTITATIVE FLUORESCENCE MEASUREMENTS

Two general classes of procedural measurements commonly are performed by fluorescence spectrometry: qualitative and quantitative.

[4] The red-shift value is taken from Parker CA. Raman spectra in spectrofluorimetry. *Analyst*. 1959;84:446–453.
[5] Available from commercial vendors and from NIST as SRMs 2940 (orange emission), 2941 (green emission), 2942 (UV emission), 2943 (blue emission), and 2944 (red/NIR emission).
[6] Commercial vendors provide a 1-mg/L solution of quinine sulfate dehydrate in 0.105 M perchloric acid that has been fully characterized by NIST as SRM 936a.
[7] A series of day-to-day Intensity Standards is available from the German Federal Institute for Materials Research and Testing (BAM).

### Qualitative Fluorescence Measurements

Qualitative fluorescence measurements are used to detect the presence of particular analytes and yield a positive or negative answer. The excitation and emission wavelengths often are selected at the peak maximum of the fluorophore to be detected. The minimum amount of analyte needed for a positive result should be considered by the analyst to ensure that the method is appropriate for the particular application. The observation of fluorescence at the peak position above the limit of detection (usually 3 times the noise level) indicates a positive result.

### Quantitative Fluorescence Measurements

Quantitative fluorescence measurements are used to determine amounts or concentrations of analytes in unknown samples. These quantities may be determined in absolute units, such as moles or moles per L, or in relative units, such as the ratio of the concentrations of two fluorescent analytes contained in a single unknown solution. These determinations use the following proportionality relating fluorescence signal ($S$) at a given pair of excitation and emission wavelengths ($\lambda_{ex}$, $\lambda_{em}$) to fluorescent analyte concentration ($c$):

$$S \propto I_0 \times \Omega \times R_d \times \alpha \times \Phi \times c$$

$I_0$ = intensity of the excitation beam
$\Omega$ = fraction of the fluorescence collected by the detection system
$R_d$ = responsivity of the detection system
$\alpha$ = absorption coefficient
$\Phi$ = fluorescence quantum yield
$c$ = concentration of the fluorescent analyte

This linear proportionality with concentration applies to optically dilute samples (e.g., solutions with an absorbance of less than 0.05 at a path length of 1 cm).

## GOOD SPECTROSCOPIC PRACTICE

Comparisons of a test specimen with a Reference Standard are best made at a peak of spectral emission for the compound of interest. Assays based on spectrofluorometry give the commonly accepted wavelengths for excitation and peak spectral emission of the substance in question. Different spectrofluorometers may show minor variation in the apparent wavelength of this peak. Comparisons should be made at the wavelength at which peak emission occurs. If this differs from the wavelength specified in the monograph by more than ±1 nm in the range of 200–400 nm or by more than ±2 nm in the range of 400–800 nm, recalibration of the instrument may be indicated.

### Use of Reference Standards

With few exceptions, pharmacopeial spectrofluorometric procedures provide results by comparison against a USP Reference Standard. This ensures measurement under identical conditions for the test specimen and the Reference Standard. These conditions could include wavelength setting, spectral bandwidth selection, cell placement and correction, and intensity levels. Cells that exhibit identical optical fluorescence characteristics at a specific wavelength may differ considerably at other wavelengths. Analysts should establish and use appropriate cell corrections where required.

The terms *similar preparation* and *similar solution* in tests and assays that involve spectrofluorometry indicate that the Reference Standard should be prepared and observed in a manner that is identical to that used for the sample under test. Usually when a solution of the specified Reference Standard is prepared at (i.e., within 10% of) the desired concentration, the fluorescence intensity is calculated on the basis of the exact amount weighed out. If analysts have not used a previously dried specimen of the Reference Standard, they should correct this intensity on the anhydrous basis.

The expressions *concomitantly determine* and *concomitantly measured* as used in procedures that involve spectrofluorometry indicate that the fluorescence of both the sample solution and the standard solution, relative to the specified test blank, are to be measured in immediate succession.

### Sample Solution Preparation

For determinations using UV or visible spectrofluorometry, the specimen generally is dissolved in a solvent. Unless otherwise directed in the monograph, determinations are made at room temperature by using a path length of 1 cm. Many solvents are suitable for these ranges, including water, alcohols, chloroform, lower hydrocarbons, ethers, and dilute solutions of strong acids and alkalis. Solvents should be free from contaminants that fluoresce in the spectral region under examination. For the solvent, water-free methanol or alcohol or alcohol that has been denatured by the addition of methanol but does not contain benzene or other interfering impurities should be used. Spectrophotometric-quality solvents that are guaranteed to be free from contaminants are available commercially from several sources, but some analytical reagent-grade organic solvents may contain traces of impurities that fluoresce strongly in the UV region. New lots of these solvents should be checked for their transparency, and analysts should take care to use the same lot of solvent for the preparation of the sample solution, the standard solution, and the blank. Solvents that do not have an interfering fluorescence signature at the wavelength(s) of interest should be used. In normal usage, the fluorescence baseline intensity should not be more than 2% of the expected measurement signal unless a larger value previously has been justified.

DOI: https://doi.org/10.31003/USPNF_M3207_01_01

Assays in the visible region usually call for comparing concomitantly the fluorescence intensities produced by the sample solution with that produced by a standard solution that contains approximately an equal quantity of a USP Reference Standard. In some situations, it may be permissible to omit the use of a Reference Standard. This is true when spectrofluorometric assays are made with routine frequency, when a suitable standard curve is available and is prepared with the appropriate USP Reference Standard, and when the substance assayed conforms to Beer–Lambert–Bouguer Law within the range of about 75%–125% of the final concentration used in the assay. Under these circumstances, the fluorescence intensity found in the assay can be interpolated on the standard curve, and the assay result can be calculated. Such standard curves should be confirmed frequently and always when a new spectrofluorometer or new lots of reagents are put into use.

## VALIDATION AND VERIFICATION

### Validation

Validation is required when a procedure based on fluorescence spectroscopy is intended for use as an alternative to the official procedure. The objective of validation is to demonstrate that the measurement is suitable for its intended purpose, including the following: quantitative determination of the main component in a drug substance or a drug product (Category I assays), quantitative determination of impurities or limit tests (Category II), and identification tests (Category IV). Depending on the category of the test (for additional information, see *Table 2* in *Validation of Compendial Procedures* ⟨1225⟩), the process for analytical procedure validation for fluorescence requires testing for linearity, range, accuracy, specificity, precision, detection limit, quantitation limit, and robustness. These analytical performance characteristics apply to externally standardized procedures and those that use standard additions. Chapter ⟨1225⟩ provides definitions and general guidance about analytical procedures validation without indicating specific validation criteria for each characteristic. The intention of the following sections is to provide the user with specific validation criteria that represent the minimum expectations for fluorescence technology. For each particular application tighter criteria may be needed in order to demonstrate suitability for the intended use.

#### ACCURACY

For Category I, Category II, and Category III procedures, accuracy is determined by conducting recovery studies with the appropriate matrix spiked with known concentrations of the analyte. Analysts also can compare assay results obtained using the fluorescence procedure under validation to those from an established analytical procedure.
**Validation criteria:** 98.0%–102.0% mean recovery for a drug substance, 95.0%–105.0% mean recovery for a drug product assay, and 80.0%–120.0% mean recovery for impurity analysis. These criteria must be met throughout the intended range.

### Precision

#### REPEATABILITY

Repeatability of the analytical procedure is assessed by measuring the concentrations of six independently prepared sample solutions at 100% of the assay test concentration. Alternatively, repeatability is assessed by measuring concentrations of three replicates of three separate sample solutions at different concentrations. The three concentrations should be sufficiently similar so that the repeatability is similar across the concentration range. If this is done, the repeatability at the three concentrations can be pooled for comparison to the acceptance criteria.
**Validation criteria:** The relative standard deviation is NMT 1.0% for a drug substance, NMT 2.0% for a drug product assay, and NMT 20.0% for impurity analysis.

#### INTERMEDIATE PRECISION

The effect of random events on the analytical precision of the procedure should be evaluated. Typical variables include performing the analysis on different days, using different instrumentation, and having the method performed by two or more analysts. As a minimum, any combination of at least two of these factors totaling six experiments will provide an estimation of intermediate precision.
**Validation criteria:** The relative standard deviation is NMT 1.0% for a drug substance, NMT 3.0% for a drug product assay, and NMT 25.0% for impurity analysis.

#### SPECIFICITY

In fluorescence measurements, specificity is ensured by the use of a Reference Standard wherever possible and is demonstrated by the lack of interference from other components present in the matrix.
**Validation criteria:** Demonstrated by meeting the accuracy requirement

#### DETECTION LIMIT

Analysts can estimate the detection limit (DL) by calculating the standard deviation of NLT six replicate measurements of a blank solution and multiplying by 3.3. Alternatively, the standard deviation can be determined from the error of the intercept from a calibration curve or by demonstration that the signal-to-noise ratio is >3.3. Analysts must confirm the estimated DL by analyzing samples at the calculated concentration.

Official

https://pharmacopeia.cn/v29240/

### QUANTITATION LIMIT

Analysts can estimate the quantitation limit (QL) by calculating the standard deviation of NLT six replicate measurements of a blank solution and multiplying by 10. Alternatively, the standard deviation can be determined from the error at the intercept from a calibration curve or by demonstration that the signal-to-noise ratio is >10.

A sample solution prepared from a representative sample matrix spiked at the required QL concentration is measured to confirm sufficient sensitivity and adequate precision. The observed signal-to-noise ratio at the required QL should be >10.

**Validation criteria:** For the estimated limit of quantitation to be considered valid, the measured concentration must be accurate and precise at a level equal to or less than 50% of the specification.

### LINEARITY

A response curve between the analyte concentration and the fluorescence signal is prepared from NLT five Standard solutions at concentrations that encompass the anticipated concentration of the sample solution. Analysts then should evaluate the standard curve for linearity using appropriate statistical methods such as a least-squares regression. Deviation from linearity can result from either instrumental or sample factors, or both, and can be reduced to acceptable levels by reduction of the analyte concentration and thereby the associated absorbance values.

**Validation criteria:** The correlation coefficient ($R$) must be NLT 0.995 for Category I assays and NLT 0.99 for Category II quantitative tests.

### RANGE

The operational range of an analytical instrument (and the analytical procedure as a whole) is the interval between the upper and lower concentrations (amounts) of analyte in the sample (including these concentrations) for which it has been demonstrated that the instrumental response function has a suitable level of precision, accuracy, and linearity.

**Validation criteria:** For Category I tests, the validation range for 100.0% centered acceptance criteria is 80.0%–120.0%. For noncentered acceptance criteria, the validation range is 10.0% below the lower limit to 10.0% above the upper limit. For content uniformity, the validation range is 70.0%–130.0%. For Category II tests, the validation range covers 50.0%–120.0% of the acceptance criteria.

### ROBUSTNESS

Analysts should demonstrate the reliability of an analytical measurement by deliberate changes to experimental parameters. For fluorescence these changes can include measuring the stability of the analyte under specified storage conditions, varying pH, removal of oxygen, and adding possible interfering species, to list a few examples. Analysts should determine robustness concurrently using a suitable design-of-experiments procedure.

## Verification

Analytical procedures described in *USP–NF* do not require validation. Instead, a verification is used to determine a procedure's suitability under actual conditions of use.

Thus the objective of fluorescence procedure verification is to demonstrate the suitability of a test procedure under actual conditions of use. Performance characteristics that verify the suitability of a fluorescence procedure are similar to those required for any analytical procedure. For additional information, see *Verification of Compendial Procedures* ⟨1226⟩ for a discussion of the applicable general principles. Verification should be performed using a reference material and a well-defined matrix. Verification of compendial fluorescence procedures should at a minimum include the execution of the validation parameters for specificity, accuracy, precision, and quantitation limit, when appropriate, as indicated in *Validation*.

## Indirect Measurement Requirements

Some fluorescence procedures employ chromogenic reactions. Generally the requirements for the analytical performance characteristics should be used. In some instances the required accuracy and precision for the direct measurements may not be achievable. Under these circumstances, the accuracy and precision requirements may be widened by as much as 50%. However, any such widening must be justified on scientific grounds and with documented evidence. Under these circumstances, the amount of replication required to produce a scientifically sound reportable value may be increased.

# ⟨854⟩ MID-INFRARED SPECTROSCOPY

## INTRODUCTION

Mid-infrared (mid-IR) spectroscopy is an instrumental method used to measure the absorption of electromagnetic radiation over the wavenumber range between 4000 and 400 $cm^{-1}$ (corresponding to wavelengths between 2.5 and 25 µm). Unless otherwise specified in a monograph or other validated procedure, the region from 3800 to 650 $cm^{-1}$ (corresponding to wavelengths from 2.6 to 15 µm) should be used to ensure compliance with monograph specifications for IR absorption. The absorption of photons causes the promotion of molecules from a ground state of their vibrational mode to an excited vibrational state.

Vibrational modes are defined by the motion of all atoms in a molecule. When molecules contain certain functional groups, IR absorption often occurs in specific narrow spectral ranges. In these cases, the wavenumbers at which these transitions occur are known as group frequencies. When a vibrational mode involves atomic motions of more than just a few atoms, the frequencies occur over wider spectral ranges and are not characteristic of a particular functional group but are more characteristic of the molecules as a whole. Such bands are known as fingerprint bands. All strong bands that absorb at wavenumbers above 1500 $cm^{-1}$ are group frequencies. Strong bands that absorb below 1500 $cm^{-1}$ can be either group frequencies or fingerprint bands.

For discussion of the theory and principles of measurements, see *Mid-Infrared Spectroscopy—Theory and Practice* ⟨1854⟩, which may be a helpful, but not mandatory, resource.

## QUALIFICATION OF IR SPECTROPHOTOMETERS

Qualification of mid-IR spectrophotometers is divided into three components: *Installation Qualification* (IQ), *Operational Qualification* (OQ), and *Performance Qualification* (PQ). For further information, see *Analytical Instrument Qualification* ⟨1058⟩.

### Installation Qualification

The IQ requirements provide evidence that the hardware and software are properly installed in the desired location.

### Operational Qualification

Because the majority of mid-IR spectra are measured with Fourier-transform IR (FTIR) spectrophotometers, only these instruments will be discussed. [NOTE—No recommended values for signal-to-noise ratio or 100% line stability are included in this chapter because these vary with manufacturer, model, and age of the instrument.]

WAVENUMBER ACCURACY

The most commonly used wavenumber standard for IR spectrophotometry is an approximately 35 µm thick, matte polystyrene film. The spectrum of such a film has several sharp bands at 3060.0, 2849.5, 1942.9, 1601.2, 1583.0, 1154.5, and 1028.3 $cm^{-1}$. The most frequently chosen band for wavenumber accuracy determination is located at 1601.2 $cm^{-1}$. Using a suitable polystyrene film or other well-characterized wavenumber standard, scan from 3800 to 650 $cm^{-1}$ wavenumbers, and compare the wavenumber of maximum response of the chosen band using the center-of-gravity, polynomial spline procedure, or other peak-picking algorithms to the known absorption wavenumber of the standard. The acceptable tolerance for the measured wavenumber is ±1.0 $cm^{-1}$.

### Performance Qualification

The purpose of performance qualification (PQ) is to determine that the instrument is capable of meeting the user's requirements for all the parameters that may affect the quality of the measurement.

## PROCEDURE

Mid-IR spectra can be measured by transmission, external reflection, internal reflection (often called attenuated total reflection), diffuse reflection, and photoacoustic spectroscopy. Different sample preparation techniques are available for these options. The most common sample preparation techniques are presented below.

### Potassium Bromide (KBr) Disks

Certain powdered alkali halides such as potassium bromide, potassium chloride, and caesium iodide coalesce under high pressure and can be formed into self-supporting disks that are transparent to mid-IR radiation. The alkali halide most commonly used is powdered, dry, highly pure potassium bromide, which is transparent to mid-IR radiation above 400 $cm^{-1}$.

Commercial presses and dies in a range of diameters are available for the preparation of alkali halide and similar disks.

## Mineral Oil Mulls

A typical procedure to prepare a mull is to place 10–20 mg of the sample into an agate mortar, and then grind the sample to a fine particle-size powder using a vigorous rotary motion of the pestle. A small drop of the mulling agent is added to the mortar. Rotary motion of the pestle is used to mix the components into a uniform paste, which is transferred to the center of a clean IR-transparent window (e.g., potassium bromide, sodium chloride, silver bromide, or caesium iodide). A second matching window is placed on top of the mull, and the mull is squeezed to form a thin, translucent film that is free from bubbles.

The most widely used mulling agent for the mid-IR region is a saturated hydrocarbon mineral oil (liquid paraffin, Nujol).

## Self-Supported Polymer Films

The mid-IR transmission spectrum of many polymers used as packaging materials is at times recorded from samples prepared as thin self-supporting films using hot compression molding or microtoming.

## Capillary Films

Nonvolatile liquids can be examined neat in the form of a thin layer sandwiched between two matching windows that are transparent to mid-IR radiation. The liquid layer must be free of bubbles and must completely cover the diameter of the IR beam focused on the sample.

## Liquids and Solutions in Transmission Cells

For the examination of liquid and solution samples, transmission cell assemblies that comprise a window pair, spacer, filling ports, and a holder are available commercially in both macro- and micro-sample configurations.

For laboratory applications, spacers typically are formed from lead, poly(tetrafluoroethylene), or poly(ethylene terephthalate) and can be supplied, depending on spacer materials, in standard thickness path lengths from approximately 6 µm to 1 mm or larger.

## Gases

Mid-IR transmission cells for static or flow-through gas and vapor sampling are available in a wide range of materials to suit the application, from laboratory to process scale. In the laboratory, the traditional gas cell has been a 10 cm long cylinder made from borosilicate glass or stainless steel with an approximately 40-mm aperture at each end. Each open end is covered with an end cap that contains one of a pair of mid-IR–transparent windows constructed from, e.g., potassium bromide, zinc selenium, or calcium fluoride.

## Attenuated Total Reflection

Attenuated total reflectance spectroscopy relies on the optical phenomenon of radiation passing through a medium of high refractive index at a certain angle of incidence entirely reflected internally at a boundary in contact with a material of lower refractive index. The medium of high refractive index is also known as the internal reflection element (IRE).

The sample under examination should be placed in close contact with the IRE such as diamond, germanium, zinc selenide, or another suitable material of high refractive index. Ensure close and uniform contact between the substance and the whole crystal surface by applying pressure in the case of solid samples or by dissolving the substance in an appropriate solvent and then covering the IRE with the solution and evaporating to dryness.

## Diffuse Reflection

The most important and commonly used form of sample preparation for diffuse reflection is to dilute the sample by intimately mixing it with 90%–99% of nonabsorbing diluents such as finely powdered potassium bromide or potassium chloride. The sample dilution has the added benefit of reducing absorption band intensities to an appropriate level.

## Microscope Sampling

Coupling a light microscope with a mid-IR spectrophotometer allows spectra to be obtained from very small samples. Generally applied in transmittance or reflectance modes, it provides, for example, a powerful tool for obtaining spectroscopic data of contaminants in pharmaceutical samples.

***Change to read:***

# VALIDATION AND VERIFICATION

## Validation

Validation is required when an IR method is intended for use as an alternative to the official procedure for testing an official article.

DOI: https://doi.org/10.31003/USPNF_M3208_04_01

The objective of an IR method validation is to demonstrate that the measurement is suitable for its intended purpose including: quantitative determination of the main component in a drug substance or a drug product (Category I assays), quantitative determination of impurities or limit tests (Category II), and identification tests (Category IV, see *Table 2* in *Validation of Compendial Procedures* ⟨1225⟩). Depending on the category of the test, the validation process for IR may require the testing of linearity, range, accuracy, specificity, precision, detection limit, quantitation limit, and robustness. If the IR procedure employs a chemometrics model calculated against the response of another analytical technology (e.g., HPLC), then the principles of ▲*Near-Infrared Spectroscopy—Theory and Practice* ⟨1856⟩▲ (CN 1-May-2020), specifically the *Method Validation* section, is to be applied.

Chapter ⟨1225⟩ provides definitions and general guidance on analytical procedures validation without indicating specific validation for each characteristic. The following sections are intended to provide the user with specific validation criteria that represent the minimum expectations for this technology. For each particular application, tighter criteria may be needed in order to demonstrate suitability for the intended use.

## ACCURACY

For Category I and II procedures, accuracy can be determined by conducting recovery studies with the appropriate matrix spiked with known concentrations of the analyte. It is also an acceptable practice to compare assay results obtained using the IR procedure under validation with those obtained from an established alternative analytical method.

**Validation criteria:** 98.0%–102.0% mean recovery for drug substances, 95.0%–105.0% mean recovery for drug product assay, and 70.0%–150.0% mean recovery for impurity analysis. These criteria are met throughout the intended range.

## PRECISION

**Repeatability:** The analytical procedure is assessed by measuring the concentrations of six independently prepared sample preparations at 100% of the assay test concentration. Alternatively it can be based on measurements of three replicates of three separate sample solutions at different concentrations. The three concentrations should be close enough so that the repeatability is constant across the concentration range. If this is done, the repeatability at the three concentrations is pooled for comparison to the acceptance criteria.

*Validation criteria:* The relative standard deviation is NMT 1.0% for drug substance, NMT 2.0% for drug product, and NMT 20.0% for impurity analysis.

**Intermediate precision:** The effect on analytical precision caused by changes in variables such as performing the analysis on different days, using different instrumentation, or having the method performed by two or more analysts needs to be assessed. At a minimum, any combination of at least two of these factors totaling six experiments will provide an estimation of intermediate precision.

*Validation criteria:* The relative standard deviation is NMT 1.0% for drug substance, NMT 3.0% for drug product assay, and NMT 25.0% for impurity analysis.

## SPECIFICITY

For Category IV tests, the identity of the analyte should be ensured. Regarding Category I and II procedures, the accuracy requirement also demonstrates specificity for the targeted analytes.

In the case of identification tests, the ability to select between compounds of closely related structure that are likely to be present should be demonstrated. This should be confirmed by obtaining positive results (perhaps by comparison to a known reference material) from samples containing the analyte, coupled with negative results from samples that do not contain the analyte and by confirming that a positive response is not obtained from materials structurally similar to or closely related to the analyte.

## QUANTITATION LIMIT

The quantitation limit can be estimated by calculating the standard deviation of NLT 6 replicate measurements of a blank preparation divided by the slope of the calibration line and multiplying by 10. Other suitable approaches can be used (see ⟨1225⟩). A measurement of a representative sample matrix spiked at the estimated quantitation limit concentration must be performed to confirm accuracy.

**Validation criteria:** For the estimated quantitation limit to be considered valid, the measured concentration must be accurate and precise at a level equal to or less than 50% of the specification.

## LINEARITY

A linear relationship between the analyte concentration and the IR spectral response is demonstrated by preparing NLT 5 standard preparations at concentrations encompassing the anticipated concentration of the test preparation. The standard curve should then be evaluated using appropriate statistical methods such as a least squares regression. For experiments that do not have a linear relationship between analyte concentration and IR spectral response, appropriate statistical methods should be applied to describe the analytical response.

**Validation criteria:** Correlation coefficient ($R$), NLT 0.995 for Category I assays and NLT 0.99 for Category II quantitative tests.

## RANGE

This parameter is demonstrated by meeting linearity, precision, and accuracy requirements.

**Validation criteria:** For Category I tests, the validation range for 100.0% centered acceptance criteria is 80.0%–120.0%. For non-centered acceptance criteria, the validation range is 10.0% below the lower limit to 10.0% above the upper limit. For

Official

https://pharmacopeia.cn/v-download/

content uniformity, the validation range is 70.0%–130.0%. For Category II tests, the validation range covers 50.0%–120.0% of the acceptance criteria.

ROBUSTNESS

The reliability of an analytical measurement should be demonstrated by deliberate changes to experimental parameters. For mid-IR this can include but is not limited to changes in sample preparation procedure or changes in hardware settings.

## Verification

U.S. Current Good Manufacturing Practices regulations [21 CFR 211.194(a)(2)] indicate that users of analytical procedures described in *USP–NF* are not required to validate these procedures if provided in a monograph. Instead, they must simply verify their suitability under actual conditions of use.

The objective of an IR procedure verification is to demonstrate that the method, as prescribed in specific monographs, is being executed with suitable accuracy, sensitivity, and precision. *Verification of Compendial Procedures* ⟨1226⟩ notes that if the verification of the compendial procedure, according to the monograph, is not successful, the procedure is not suitable for use with the article under test. It may be necessary to develop and validate an alternative procedure as allowed in *General Notices, 6.30 Alternative and Harmonized Methods and Procedures*.

Although complete revalidation of a compendial procedure is not required, verification of the compendial Mid-IR procedure includes the execution of certain critical parameters. When the method being verified is for identification purposes, specificity is the only parameter required. For quantitative applications, additional validation parameters are studied. Typically these include accuracy, precision, and quantitation limit, as indicated in *Validation*.

## ▲1. INTRODUCTION

Nephelometry and turbidimetry are analytical techniques that are based on the principles of light-scattering phenomena. Light scattering is the physical phenomenon in which a beam of light changes its direction of propagation (known as deflection) as a result of interaction with sufficiently small matter particles. It has been established from the Maxwell electromagnetic theory that a prerequisite for scattering to occur is that the refractive indexes of the suspended particles must be different from those of the suspending liquid. The larger the difference, the more intense the scattering becomes. There are two types of light scattering: 1) elastic scattering, in which the wavelength of the scattered light and incident light are the same; and 2) inelastic light scattering, in which the wavelength of the scattered light and incident light are different. Only the first type of light scattering (elastic) is relevant to nephelometry and turbidimetry.

In turbidimetry, the intensity of the transmitted light is measured and the attenuation of the intensity of incident light as a result of scattering is measured at the direction of incident light (i.e., 0°) and compared to the intensity of incident light (blank measurement). The measured property is an indirect measurement of the scattering effect of the suspended particles and is referred to as turbidance. Any absorbance of light by the suspended sample will result in additional attenuation of light intensity (see *Ultraviolet-Visible Spectroscopy* ⟨857⟩ and *Ultraviolet-Visible Spectroscopy—Theory and Practice* ⟨1857⟩). Hence, it is important to ensure that the material being measured does not absorb light at the measurement wavelength. Indeed the equations governing absorption and turbidimetry are the same (albeit with different values for the attenuation constants). In nephelometric techniques, the intensity of the scattered light at a 90° angle from the propagation direction of the incident light is measured. Therefore, a nephelometric measurement is a direct measurement of the scattering effect of suspended matter.

## 2. TERMS AND DEFINITIONS

Terms commonly used in describing turbidimetric and nephelometric techniques are:

- Turbidance (symbol, $S$): A measure of the decrease of the transmitted incident light beam intensity as a result of the light-scattering effect of suspended particles. The amount of suspended matter may be measured by observation of either the transmitted light (turbidimetry) or the scattered light (nephelometry).

$$\log I_0/I_t = kbc = T$$

$I_0$ = intensity of incident light
$I_t$ = intensity of transmitted light
$k$ = molar turbidity coefficient
$b$ = cell path length
$c$ = concentration

Printed by: USP NF
Do Not Distribute

$T$ = turbidance

- Turbidity (symbol, $\tau$): In turbidimetric measurements, the turbidity is the measure of the decrease in incident beam intensity/unit length of a given suspension. The International Organization for Standardization defines turbidity as “the reduction of transparency of a liquid caused by the presence of undissolved matter”.
- Turbidity Measurement Units: The turbidity units are stated using a descriptor which indicates the method of measurement.
- Nephelometric Turbidity Units (NTUs): When the turbidity is measured using a nephelometer, which measures the scattered light at a 90° angle from the direction of propagation of incident light, the units of turbidity are called nephelometric turbidity units (NTUs). The magnitude of NTU is defined based on the turbidity generated by primary formazin standard (a suspension made by mixing solutions of hydrazine sulfate and hexamethylenetetramine in water). Safer polymer-bead suspensions are now commercially available and are recognized as an acceptable alternative. However, all those standards are traced to formazin. The primary formazin standard solution has been assigned a turbidity of 4000 NTUs.

Other recognized units for turbidity include the formazin turbidity unit (FTU) and the formazin nephelometric unit (FNU). These units are equivalent to NTU for the range from 0–40 NTUs.

## 3. APPLICATIONS

Turbidimetric and nephelometric techniques have applications that include 1) concentration determination of solutions and/or suspensions (determination of several cations and anions by precipitating and suspending the resulting precipitate at well-controlled reaction parameters); 2) measurement of the degree of turbidity of turbid solutions or suspensions; 3) determination of weight-average molecular weights and dimensions of polydisperse systems in the molecular weight range from 1000 to several hundred million; 4) measurement of immunoassays’ reaction kinetics or kinetics of immunoprecipitations (rate nephelometry); 5) monitoring of cell and bacteria growth; and 6) particle size distribution determination of suspended material, particle counting, etc.

Rate nephelometry is widely used for vaccine components assays and/or quantitation of components in blood serum. It is also used for host cell protein qualification in recombinant biopharmaceuticals. When using the technique, the measurement of the change in the light-scattering response by antigen–antiserum or antigen-purified antibody complexes is used to calculate the amount of antigen (Ag) or antibody (Ab) responsible for the immunological Ab-Ag precipitation reaction or agglutination reaction. Often the antigens under consideration are linked covalently or adsorbed to polymeric microspheres to increase the scattering efficiency; the resulting technique is known as "particle-enhanced immunoassay". Although the technique is described as nephelometry, usually both scattered and transmitted light are measured using the ratio instruments.

Nephelometric measurements are more reliable in low turbidity ranges (relatively low concentration of the scattering medium). In this range, a linear relationship is observed between the sample concentration and the detector’s signal intensity expressed as NTU. As the concentration increases, so does the incidence of multiple scattering that deviates the response from the linearity. The maximum NTU value, which supports a reliable linearity relationship, is in the range of 1750–2000 NTUs. Turbidimetry is preferred for higher turbidity ranges (concentrations of the scattering media). To achieve consistent results, all measurement variables must be carefully controlled. Where such control is possible, extremely dilute suspensions may be measured.

***Change to read:***

## 4. INSTRUMENTATION

Instruments used for turbidimetric and nephelometric measurements are called turbidimeters and nephelometers, respectively. Generally, these instruments consist of a mercury lamp with filters for the strong green or blue lines, a shutter, a set of neutral filters with known transmittance, and a sensitive photomultiplier, which can be mounted fixed at 0° or at a 90° angle from the incident light propagation direction, or on an arm that can be rotated around the solution cell and set at any angle from –135° to 0° to +135° by a dial outside of the light-tight housing. Solution cells are of various shapes, such as square for measuring 90° scattering; semioctagonal for 45°, 90°, and 135° scattering; and cylindrical for scattering at all angles (see *Figure 1*).

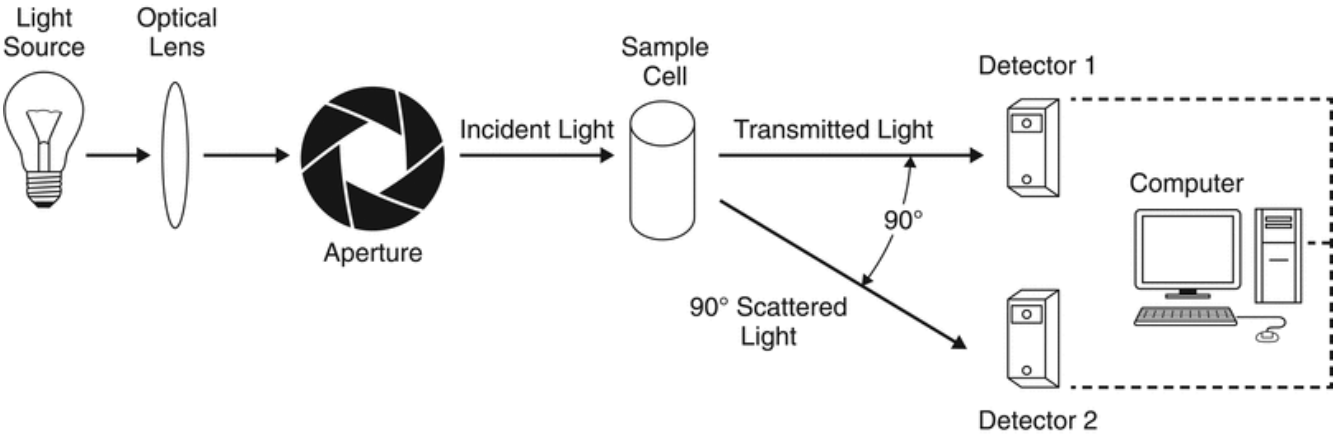

Figure 1. Representative nephelometric (turbidimetric) instrument. Note that Detector 2 may be mounted on a movable arm.

Turbidity also can be measured with a standard photoelectric filter photometer or spectrophotometer, preferably with illumination in the blue portion of the spectrum. Nephelometric measurements require an instrument with a photocell placed so as to receive scattered, rather than transmitted, light. Because this is the same geometry used in fluorometers, they can be used as nephelometers by proper selection of filters. A ratio turbidimeter combines the technology of 90° nephelometry and turbidimetry. It contains photocells that receive and measure scattered light at a 90° angle from the sample as well as receiving and measuring the forward scatter in front of the sample. It also measures light transmitted directly through the sample. Linearity is attained by calculating the ratio of the 90° angle scattered light measurement to the sum of the forward scattered light measurement and the transmitted light measurement. The benefit of using a ratio turbidimetric system is that the measurement of stray light becomes negligible. In addition, the determination of turbidity of colored suspensions is done exclusively using turbidimetric or nephelometric instruments with ratio mode because this procedure compensates for the attenuation of light as the result of the suspension color. Typically, the light source in these instruments is a tungsten lamp with most of the light intensity at about 550 nm operating at the filament temperature of 2700 K. Other suitable light sources are also available. Typically, the detectors are ▲silicon diodes▲ (ERR 1-May-2019) and photomultipliers. An alternative for eliminating the color effect involves using an infrared light-emitting diode as a light source, which yields an emission maximum centered at about 860 nm and a spectral bandwidth of 60 nm. When laser light sources are also used, especially in nephelometric instruments, the technique is commonly known as "laser nephelometry". The advantage of using laser nephelometers is the significant improvement in signal-to-noise ratio at very low detection levels. Usually the light source is a laser diode with a working wavelength at 660 nm. The high-power density of the laser beam gives rise to higher scattered intensity from smaller particles. Combined with a light trap, which absorbs the unscattered light, the system lowers the stray light significantly. When the use of a nephelometer or turbidimeter is indicated for a procedure in a monograph, instruments working in ratio mode may be used instead.

***Change to read:***

## 5. FORMAZIN TURBIDITY STANDARDS

Formazin is the only known primary turbidity standard. All other standards are secondary and must be traced to formazin. The primary standard is defined in the ▲*IUPAC Compendium of Chemical Terminology,*▲ (ERR 1-May-2019) 2nd ed. (the Gold Book) as one that is prepared by the user from traceable materials using well-defined methodologies and conditions.

Formazin suspension has many features that ensure its suitability as a primary standard. It can be consistently and accurately prepared from reagent-grade starting materials. The suspension consists of random polymers with different lengths and of random configurations, which result in moieties of varying shapes and sizes ranging from less than 0.1 μm to more than 10 μm. Although the polymer chain length distribution has been shown to vary from preparation to preparation, the overall resulting turbidity has been very reproducible.

### 5.1 Preparation of the Formazin Standards

[NOTE—All procedures described below must be performed at 20 ± 2° (see *Volumetric Apparatus* ⟨31⟩.]

- **Hydrazine sulfate solution:** Dissolve 1.000 g of ACS grade hydrazine sulfate ($N_2H_4 \cdot H_2SO_4$) in particle-free water in a 100-mL Class A volumetric flask and dilute with particle-free water to volume. Allow this solution to stand for 4–6 h.
- **Primary formazin standard:** Dissolve 2.50 g of analytical grade hexamethylenetetramine [$(CH_2)_6N_4$] in 25.0 mL of particle-free water in a 100-mL flask. Add 25.0 mL of hydrazine sulfate solution using a Class A 25-mL "to deliver" pipette and mix thoroughly. Allow the preparation to stand for 48 h at 25 ± 1° before using. The resulting suspension is stable for 2 months.
- **Formazin stock standard suspension 1:** Using a 15-mL Class A "to deliver" pipette, transfer 15 mL of the *Primary formazin standard* to a 1-L volumetric flask, and dilute with particle-free water to volume and mix. The resulting suspension has a turbidity of 60 NTU.

| Reference suspension IX | — | 70.0 | 30.0 | 700 |
| Stock standard suspension 2 | — | 100 | 0 | 1000 |

## 6. QUALIFICATION OF TURBIDIMETERS AND NEPHELOMETERS

The suitability of a specific instrument for a given procedure is ensured by a stepwise life cycle evaluation for the desired application from selection to instrument retirement. The qualification comprises three components: 1) installation qualification (IQ), 2) operational qualification (OQ), and 3) performance qualification (PQ) (see *Analytical Instrument Qualification* ⟨1058⟩).

The purpose of this section is to provide test methods and acceptance criteria to ensure that the instrument is suitable for its intended use (OQ), and that it will continue to function properly over extended time periods (PQ). As with any spectrometric device, a turbidimetric and nephelometric spectrometer must be qualified for both wavelength (*x*-axis, if not fixed) and photometric (*y*-axis, or signal axis) accuracy and precision, and meet the requirements for the stray light. OQ is carried out across the operational ranges required within the laboratory for both the absorbance and wavelength scales.

Acceptance criteria for critical instrument parameters that establish "fitness for purpose" are verified during IQ and OQ. Specifications for particular instruments and applications can vary depending on the analytical procedure used and the desired accuracy of the final result. Instrument vendors often have samples and test parameters available as part of the IQ/OQ package.

Wherever possible in the procedures detailed as follows, primary reference standards or certified reference materials (CRMs) are to be used. Formazin is the only primary reference standard used in turbidimetry and nephelometry. All the other standards, including the CRMs, must be correlated to formazin. The CRMs should be obtained from a recognized accredited source and include independently verified traceable value assignments with associated calculated uncertainty. CRMs must be kept clean and free from dust. Recertification should be performed periodically to maintain the validity of the certification.

### 6.1 Calibration

All of the turbidimetric and nephelometric instruments are calibrated against standards of known turbidity. The instrument must be calibrated using formazin turbidity standards prior to its first time use and at least every 3 months or as specified by the vendor. Calibration is performed using at least four formazin turbidity standards whose turbidity proportionally covers the range of interest. Many instrument manufactures provide calibration verification standards. They usually consist of sealed sample cells filled with a latex suspension or with metal oxide particles in polymer gel. These standards must be used only for checking the calibration in the time intervals between the instrument recommended calibrations.

### 6.2 Stray Light

Stray light (stray radiant energy) is a very significant error source, especially for measurements in the range of the lower turbidity readings. It is defined as external light that reaches the detector without being scattered from the sample. There are several sources of stray light including the inherent cell surface imperfections, reflections from within the cell that are unaccounted for, optical system parts, light sources, and, to a smaller degree, the electronics fluctuations. Although there are many design features that instrument vendors use to minimize the stray light, a complete mitigation of the stray light cannot be achieved. Unlike spectrophotometric measurements, the stray light cannot be compensated for in turbidimetry. The stray light must be measured and the values should be within the specification range set by the vendor of the particular instrument or <0.15 NTUs for the measurement in the range of 0–10 NTUs and 0.5 NTUs for the measurements in the range of 10–1100 NTUs, whichever is smaller.

Official

https://pharmacopeia.com/

## 6.3 Range of Measuring Capability

The instrument must be able to measure the turbidity in the range of 0.01–1100 NTUs or from 50%–200% of the target turbidity. To demonstrate the linearity for the intended measurements range, choose at least four appropriate reference suspensions from *Table 1*.

## 6.4 Resolution

Instrument resolution must be 0.01 NTU or less for the measurements range of 0–9.99 NTUs; 0.1 NTU or less for the measurements range of 10–99.9 NTUs; and 1 NTU for the measurements above 100 NTUs.

## 6.5 Accuracy

The instrument reading accuracy must be ±10% of the reading + 0.01 NTU for the measurement range from 0–19.9 NTUs, and ±7.5% of the reading for the measurement range from 20–1100 NTUs.

## 6.6 Performance Qualification

The instrument PQ is accomplished periodically or as needed between the calibrations. Primary turbidity standards (formazin) or secondary calibration verification standards (latex suspensions or metal oxide particles in polymer gels contained in sealed sample cells) supplied by instrument manufacturers may be used.

# 7. PROCEDURES

## 7.1 Turbidimetric Procedures

### SAMPLE CELL PREPARATION

The sample cells for sample measurements must be clean. Follow the sample cell or instrument manufacturer recommendations for cleaning the sample cells appropriately. For low turbidity measurements it is a good practice to use a single-indexed sample cell or a flow cell, which help ensure adequate precision and repeatability of the measurements. Using particle-free water, find the sample cell orientation in the sample cell holder that gives the lowest reading. For higher values of turbidity, different sample cells may be used. However, the sample cells must be matched (the difference in readings for a standard prepared at nominal sample concentration from two different sample cells must be within ±0.005 NTU or below the measurement precision requirement, whichever is lower).

### SAMPLE PREPARATION

Prepare the samples as prescribed in the individual monograph. Carefully mix the samples thoroughly by swirling or inverting the volumetric flask slowly several times. Avoid shaking or stirring since it may introduce bubbles. Degassing the samples helps to improve the measurements. For degassing, the samples could stand for several minutes or a vacuum could be applied, or they could be gently sonicated using an ultrasonic bath. After degassing, let the samples stand for several minutes and mix again by carefully inverting two to three times. Transfer the sample to the sample cell and take the readings.

### USE OF FLOW CELLS

Flow cells are mainly used for low turbidity measurements for samples with small particles. When such cells are used, the sample is introduced by carefully pouring it down the interior edge of the inlet reservoir.

In practice, it is advisable to ensure that settling of the particles being measured is negligible. This is usually accomplished by including a protective colloid in the liquid-suspending medium. It is important that results be interpreted by a comparison of readings with those representing known concentrations of suspended matter, produced under precisely the same conditions.

## 7.2 Nephelometric Procedures

Nephelometric procedures are performed similarly to turbidimetric procedures for both direct measurements and measurements in the ratio mode as described above.

### RATE NEPHELOMETRIC PROCEDURES

The overall procedure for monitoring the progress of the reaction consists of three well-defined steps: 1) record a baseline reading of the turbidity of the medium (blank); 2) record the turbidity after the first reagent (antigen) is added, which results in an increase of the turbidity until a plateau is reached; and 3) add the second reagent (antibody), which results in another turbidity increase and a second plateau followed by a final turbidity increase that continues until a third plateau is reached. The measurement zone is selected from the addition of the antibody until the third plateau, depending on the purpose of the assay and the respective component concentrations. *Kinetic nephelometry* and *Endpoint nephelometry* are two general procedures that are used for quantifying the immune complexes formed in the immunoassay methods (also known as immunonephelometry

Official

https://pharmacopeia.com/

because the measured turbidity is due to immunocomplexes that are formed). For each procedure, there are several parameters that need to be optimized in each individual application. The main parameters are 1) with or without particle enhancement; 2) particle types, sizes, and respective optimum wavelength, if applicable; 3) monitoring reaction kinetic or endpoint; 4) antibody/antigen under consideration and, related to that, the optimum level of antigen loading; 5) buffers and other ionic species and respective optimal pH; 6) type and concentration of polymers used to modify the solubility of proteins; and 7) temperature and other environmental factors. Generally these parameters are optimized during the method development and the values are given in specific monograph(s) and/or chapter(s) as applicable.

**Kinetic nephelometry:** The kinetic nephelometry is advantageous compared to the endpoint nephelometry mainly because of the capability to take a sample blank reading in addition to a reagent blank reading. This procedure assesses the rate of the immunocomplex formation based on the increased intensity response of the scattered light of the chosen wavelength. The reaction kinetic may be monitored continuously or a certain number of data points may be taken, depending on the time response of the instrument used and the type of application. At times it may involve only two data points; however, proper care must be exercised because the choice of point selection can influence the overall accuracy in cases where differences in reaction kinetics exist between samples and calibrating standards. Careful consideration should be given to the appropriate choice of specificity control strategy.

**Endpoint nephelometry:** In this method, an initial measurement is performed before adding the reagent, which represents the blank reading. A second measurement is performed after the immune complex is formed after approximately 60 min. The difference between these two measurements is proportional to the content of the component being assayed.

## 8. VALIDATION AND VERIFICATION

### 8.1 Validation

Validation is required when a nephelometric/turbidimetric method is intended for use as an alternative to the official procedure for testing an official article. The objective of nephelometric/turbidimetric method validation is to demonstrate that the measurement is suitable for its intended purpose, including quantitative determination of the main component in a drug substance or a drug product (Category I assays), quantitative determination of impurities or limit tests (Category II), and identification tests (Category IV). Depending on the category of the test (see *Validation of Compendial Procedures* ⟨1225⟩, *Table 2*), the analytical method validation process for nephelometry/turbidimetry requires testing for accuracy, precision, specificity, detection limit (DL), quantitation limit (QL), linearity, range, and robustness. These analytical performance characteristics apply to externally standardized procedures and those that use standard additions.

*Validation of Compendial Procedures* ⟨1225⟩ provides definitions and general guidance on analytical procedures validation without indicating specific validation criteria for each characteristic. The intention of the following sections is to provide the user with specific validation criteria that represent the minimum expectations for this technology. For each particular application, tighter criteria may be needed in order to demonstrate suitability for the intended use.

#### ACCURACY

For Category I, II, and III procedures, accuracy can be determined by conducting recovery studies with the appropriate matrix spiked with known concentrations of the analyte. Analysts can also compare the assay results obtained using the nephelometric/turbidimetric procedure under validation to those from an established analytical procedure.

**Validation criteria:** 98.0%–102.0% mean recovery for the drug substances, 95.0%–105.0% mean recovery for the drug product assay, and 80.0%–120.0% mean recovery for the impurity analysis. These criteria are met throughout the specified range.

#### PRECISION

**Repeatability:** The repeatability of the analytical procedure is assessed by measuring the concentrations of six independently prepared sample solutions at 100% of the assay test concentration. Alternatively, it can be assessed by measuring the concentrations of three replicates of three separate sample solutions at different concentrations. The three concentrations should be close enough so that the repeatability is constant across the concentration range. If this is done, the repeatability at the three concentrations is pooled for comparison to the acceptance criteria.

*Validation criteria:* The relative standard deviation is NMT 1.0% for the drug substance, NMT 2.0% for the drug product assay, and NMT 20.0% for the impurity analysis.

**Intermediate precision:** The effect of random events on the analytical precision of the method must be established. Typical variables include performing the analysis on different days, using different instrumentation, and/or having the method performed by two or more analysts. At a minimum, any combination of at least two of these factors totaling six experiments will provide an estimation of intermediate precision.

*Validation criteria:* The relative standard deviation is NMT 1.5% for the drug substance, NMT 3.0% for the drug product assay, and NMT 25.0% for the impurity analysis.

#### SPECIFICITY

In nephelometric/turbidimetric measurements, specificity is demonstrated by the lack of interference from other components present in the matrix (other components of the matrix produce a true solution).

@2024 USPC

DETECTION LIMIT

The DL can be estimated by calculating the concentration of a solution that would give the signal-to-noise ratio of ≥3.3. The estimated DL must be confirmed by analyzing samples at the calculated concentration.

QUANTITATION LIMIT

The QL can be estimated by calculating the concentration of a solution that would give the signal-to-noise ratio of ≥10.0. The estimated QL must be confirmed by analyzing samples at the calculated concentration. Measurement of a test solution prepared from a representative sample matrix spiked at the required QL concentration must be performed to confirm sufficient sensitivity and adequate precision. The observed signal-to-noise ratio at the required QL should be >10.
**Validation criteria:** For the estimated limit of quantitation to be considered valid, the measured concentration must be accurate and precise at a level ≤50% of the specification.

LINEARITY

A linear relationship between the analyte concentration and measured turbidity response must be demonstrated by preparation of at least four standard solutions at concentrations encompassing the anticipated concentration of the test solution. The standard curve is then evaluated using appropriate statistical methods such as a least-squares regression. Deviation from linearity results from instrumental or sample factors, or both, can be reduced to acceptable levels by reducing or increasing the analyte concentration, thereby respectively decreasing or increasing the turbidity readings to within the nephelometer/turbidimeter instrument linearity range.
**Validation criteria:** The correlation coefficient (*R*) must be NLT 0.995 for Category I assays and NLT 0.99 for Category II quantitative tests.

RANGE

The operational range of an analytical instrument (and the analytical procedure as a whole) is the interval between the upper and lower concentrations (amounts) of analyte in the sample (including these concentrations) for which it has been demonstrated that the instrumental response function has a suitable level of precision, accuracy, and linearity.
**Validation criteria:** For Category I tests, the validation range for 100.0% centered acceptance criteria is 80.0%–120.0%. For non-centered acceptance criteria, the validation range is 10.0% below the lower limit to 10.0% above the upper limit. For Category II tests, the validation range covers 50.0%–120.0% of the acceptance criteria.

ROBUSTNESS

The reliability of an analytical measurement is demonstrated by deliberate changes to experimental parameters. For nephelometry/turbidimetry this can include, for example, measuring the stability of the analyte under specified storage conditions, varying pH, and adding possible interfering species. Robustness is determined concurrently using a suitable design for the experimental procedure.

## 8.2 Verification

Current U.S. Good Manufacturing Practices regulations [21 CFR 211.194(a)(2)] indicate that users of analytical procedures described in the *U.S. Pharmacopeia* and *National Formulary* are not required to validate these procedures if provided in a monograph. Instead, they simply must verify their suitability under actual conditions of use.

The objective of nephelometric/turbidimetric procedure verification is to demonstrate the suitability of a test procedure under actual conditions of use. Performance characteristics that verify the suitability of a nephelometric/turbidimetric procedure are similar to those required for any analytical procedure. A discussion of the applicable general principles is found in *Verification of Compendial Procedures* ⟨1226⟩. Verification is usually performed using a reference material and a well-defined matrix. Verification of compendial nephelometric/turbidimetric procedures includes, at minimum, the execution of the validation parameters for specificity, accuracy, precision, and QL, when appropriate, as indicated in *8.1 Validation*.▲ (USP 1-May-2019)

## 1. INTRODUCTION

Near-infrared (NIR) spectroscopy covers the electromagnetic field wavelength range from 780 to 2500 nm, with the frequencies expressed in wavenumbers (about 12,821–4000 $cm^{-1}$). NIR spectroscopy is a vibrational spectroscopic technique that measures the absorption of radiation in this wavelength range that is resonant with frequencies from molecular dipole changes in the sample; thus, NIR spectroscopy is related to infrared (IR) spectroscopy. The NIR spectroscopic region is dominated by overtone and combination frequencies of the molecular fundamental harmonic frequencies in the mid-IR region. The molar absorptivities in the NIR region tend to be much lower than those in the IR region, and the radiation can penetrate several millimeters into the material, giving rise to a wavelength-dependent scattering signal overlapping the molecular absorbance signals.

Not all materials absorb NIR radiation, and materials such as glass are relatively transparent. These attributes of NIR spectroscopy have been shown to be useful in the area of pharmaceutical analysis for both qualitative and quantitative applications. For further discussion of the theory and applications, see *Near-Infrared Spectroscopy—Theory and Practice* ⟨1856⟩, which may be a helpful, but not mandatory, resource.

The instrument qualification tests and acceptance criteria provided in this chapter may not be appropriate for some instrument configurations. In such cases, alternative instrument qualification and performance checks should be scientifically justified and documented before use. In addition, validation parameters discussed in this chapter may not be appropriate for all applications of NIR spectroscopy. Validation parameters characterized for a specific NIR-spectroscopic application should demonstrate the suitability of the application for its intended use. For further discussion of the theory and applications of chemometrics, see *Chemometrics* ⟨1039⟩.

## 2. QUALIFICATION OF NIR SPECTROMETERS

Qualification of NIR spectrometers is divided into three components: 1) installation qualification (IQ), 2) operational qualification (OQ), and 3) performance qualification (PQ). For further discussion on qualification, see *Analytical Instrument Qualification* ⟨1058⟩.

### 2.1 Installation Qualification

The IQ requirements elicit evidence that the hardware and software are properly installed in the desired location.

### 2.2 Operational Qualification

In OQ, an instrument's performance is characterized using standards to verify that the system operates within target specifications. The purpose of OQ is to demonstrate that instrument performance is suitable. Because there are so many different approaches for measuring NIR spectra, OQ using standards with known spectral properties is recommended. This may be achieved by using the instrument performance checks, and external, traceable certified reference materials (CRMs) as appropriate. As is the case with any spectroscopic device, wavelength accuracy, photometric linearity, and noise characteristics of NIR instruments must be qualified against target specifications for the intended application.

The OQ tests described in the sections that follow are typical examples only. Other tests and samples can be used to establish specifications for OQ. Instrument vendors often have samples and test parameters available as part of the IQ/OQ package. The acceptance specifications given in this section are applicable for general use specifically, whereas specifications for particular instruments and applications can vary, depending on the analytical method used and the desired accuracy of the final result.

#### 2.2.1 CHARACTERIZING INSTRUMENT PERFORMANCE

Use the apparatus according to the manufacturer's instructions, and carry out the prescribed verification at regular intervals. For in-line and on-line applications, the use of alternative means of control of instrument performance must be scientifically justified. For example, use the manufacturer's internal standards or use separate channels/probes, with scientific justification,

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:36:32 AM(EST)
Printed by: USP NF
Do Not Distribute

to demonstrate instrument performance. System suitability tests may be required prior to sample scanning, and the instrument attributes with the most variation (typically photometric noise and wavelength accuracy) must be tested. The frequency at which each performance test is conducted must be assessed for risk, depending on the instrument type, application, and its environment. For example, instruments placed in harsh environments, such as environments with changing temperature and humidity, will need frequent performance testing.

Wherever possible, in the procedures for determining wavelength accuracy and linearity, analysts must use CRMs rather than laboratory-prepared solutions. These CRMs should be obtained from a recognized, accredited source and should include independently verified, traceable value assignments with associated calculated uncertainty. CRMs are to be kept clean and free from dust. Recertification is to be performed periodically to maintain the validity of the certification.

#### 2.2.2 WAVELENGTH ACCURACY

NIR spectra from sample and/or reference standard materials can be used to demonstrate an instrument's suitable wavelength-dispersion performance against target specifications. Typically, wavelength accuracy is characterized from a single spectrum (collected with the same spectral resolution used to obtain the standard value) using a minimum of three peaks that cover a suitable spectral range of the instrument.

**Verification of wavelength scale (except for filter apparatus):** Verify the wavelength scale utilized, which is generally in the region between about 780 and about 2500 nm (about 12,800 to about 4000 $cm^{-1}$) or in the intended spectral range using one or more suitable wavelength standards that have characteristic maxima or minima within the range of methodology wavelengths to be used. Fourier transform (FT) instruments have a linear frequency range; therefore, wavelength certification at a single frequency is sufficient. The USP Near IR System Suitability RS can be used for wavelength verification. Suitable materials for demonstrating wavelength dispersion performance must be used. With appropriate justification, alternative standards may be used. Additional information on calibration considerations may be found in ⟨1856⟩.

Typical tolerances for agreement with standard values are:

- ±1.0 nm at 780 nm (±16 $cm^{-1}$ at 12,800 $cm^{-1}$)
- ±1.0 nm at 1200 nm (±8 $cm^{-1}$ at 8300 $cm^{-1}$)
- ±1.0 nm at 1600 nm (±6 $cm^{-1}$ at 6250 $cm^{-1}$)
- ±1.5 nm at 2000 nm (±4 $cm^{-1}$ at 5000 $cm^{-1}$)
- ±3.0 nm at 2500 nm (±2 $cm^{-1}$ at 4000 $cm^{-1}$)

For the reference material used, apply the tolerance for the nearest wavelength (or wavenumber) from the above information for each peak used. For diode array instruments, the pixel resolution (wavelength between pixels) can be as large as 10 nm. The pixel resolution must be consistent with the required spectral resolution. The peak-finding algorithms are critical to wavelength accuracy. From a practical standpoint, ±2 nm is appropriate for peak wavelength accuracy when using such instrumentation. Alternatively, refer to the manufacturer's specifications for acceptance.

#### 2.2.3 PHOTOMETRIC LINEARITY AND RESPONSE STABILITY

Photometric linearity is typically characterized in the range from 10% to 90% reflectance (or transmittance). NIR applications based on measuring an absorbance larger than 1.0 may require standards with reflectivity properties between 2% and 5% reflectance (or transmittance) for characterizing instrument performance at low reflectance. The purpose is to demonstrate a linear relationship between NIR reflectance and/or transmittance and instrument response across the scanning range of the instrument. Subsequent verifications of the photometric model can use the initial observed absorbance values as the established values.

Measure four photometric standards across the working method absorbance range. Typical tolerances for a linear relationship are 1.00 ± 0.05 for the slope and 0.00 ± 0.05 for the intercept of a plot of the measured photometric response versus the standard photometric response. Alternative tolerances may be used when justified for specific applications. A tolerance of ±2% is acceptable for long-term stability.

#### 2.2.4 PHOTOMETRIC NOISE

NIR instrument software may include built-in procedures to automatically determine system noise and to provide a statistical report of noise or signal-to-noise ratio (S/N) over the instrument's operating range. In addition, it may be desirable to supplement such checks with measurements that do not rely directly on manufacturer-supplied procedures. Typical procedures involve measuring spectra of traceable reference materials with both high and low reflectance. Determine the photometric noise using suitable reflectance standards. Tolerances for these procedures should demonstrate suitable S/N for the intended application. Follow the manufacturer's methodology and specifications.

**High-flux noise:** Instrument noise is evaluated at high-light flux by measuring reflectance or transmittance of the reference standard, with the reference material (e.g., 99% reflectance standard) acting as both the sample and the background reference.

**Low-flux noise:** The same procedure may be used with a lower-reflectivity reference material (e.g., 10% reflectance standard) to determine system noise at reduced-light flux. The source, optics, detector, and electronics make significant contributions to the noise under these conditions.

### 2.3 Performance Qualification

The objective of PQ is to ensure that the instrument is performing within specified limits with respect to critical operational parameters. In certain cases, when the instrument has been set up for a specific measurement, it might no longer be possible or desirable to measure the wavelength and photometric (signal) qualification reference standards used in the OQ. Provided that the instrument OQ has shown that the equipment is fit for use, a single external performance verification standard can be

Official

https://pharmacopeia.cn/
Printed on: Fri Jan 05 2024 06:36:32 AM(EST)
Printed by: USP NF
Do Not Distribute

used on a continuing basis (e.g., daily or before use). The performance verification standard must match the format of the samples in the current analysis as closely as possible and must use similar spectral acquisition parameters. Quantitative measurements of an external performance verification standard can be used to check both the wavelength accuracy and the photometric precision. Favorable comparison of a series of performance verification spectra demonstrates proper continued operation of the instrument.

Specific procedures, acceptance criteria, and time intervals for characterizing and monitoring NIR instrument performance are selected based on the instrument and intended application. Many NIR applications use previously validated models that relate NIR spectral response to a physical or chemical property of interest. Demonstrating stable instrument performance over extended periods of time provides some assurance that reliable measurements can be taken from sample spectra using previously validated chemometric models.

## 3. PROCEDURE

NIR spectra can be obtained from several sample presentations, including solids, powders, slurries, gels, liquids, films, and gases. In addition, measurement can be performed through glass or plastic films that are normally used for containment. Typically, NIR spectroscopy does not require any sample preparation because the detectors have a wide dynamic range, and the collection time can be adjusted by the user. Acceptable acquisition parameters or ranges hereof, must be included as a part of the analytical test procedure. Equally important, data pretreatment must be properly implemented such that the intended measurement sensitivity is not subsequently degraded. Specific values for tests such as spectrometer noise and bandwidth will be dependent on the instrument chosen and the purpose required. For this reason, specific instrument tests for these parameters are not indicated here. Additional details can be found in ⟨1856⟩.

***Change to read:***

## 4. VALIDATION AND VERIFICATION

The objective of NIR procedure validation, as is the case with validation of any analytical procedure, is to demonstrate that it is suitable for its intended purpose. NIR spectroscopy is somewhat different from conventional vibrational spectroscopic techniques, because it is not a primary technique. Validation can be achieved by the assessment of variability (precision) and comparison to a reference standard or the result of a validated primary method (accuracy). The procedure for validation is related to the fundamental validation characteristics required for any analytical procedure. Data pretreatment is often a vital step in the chemometric analysis of NIR spectral data. Many suitable data pretreatments exist; the selection should be based on sound scientific judgment and suitability for the intended application.

### 4.1 Validation

The validation criteria described below are only required when an NIR spectroscopic procedure is intended for use as an alternative to the monograph procedure for testing an official article. The objective of procedure validation is to demonstrate that the measurement is suitable for its intended purpose, including: quantitative determination of the main component in a drug substance or drug product (Category I assays); quantitative determination of impurities or limit tests (Category II); and identification tests (Category IV; see *Validation of Compendial Procedures* ⟨1225⟩, *Table 2*). Depending on the category of the test, the analytical procedure validation process for an NIR spectroscopic method requires the testing of accuracy, precision, specificity, detection limit, quantitation limit, linearity, range, and robustness as appropriate. Note that validated NIR spectroscopy procedures may not be transferrable to all configurations of NIR spectrometers because of differences in their inherent performance characteristics.

Chapter ⟨1225⟩ provides definitions and general guidance on analytical procedures validation without indicating specific validation criteria for each characteristic. The following sections are intended to provide the user with specific validation criteria that represent the minimum expectations for this technology, assuming use of the typical Category I USP specifications of 98.0%–102.0% for a drug substance and 90.0%–110.0% for a drug product. The actual validation performance characteristics will depend on the specifications in place and must provide adequate evidence that the measurement capability is sufficient for those specifications. For certain particular applications, tighter criteria may be needed in order to demonstrate suitability for the intended use.

#### 4.1.1 ACCURACY

Accuracy is demonstrated by showing the closeness of agreement between the value that is obtained and either a conventional true value or an accepted reference value from a reference procedure. Accuracy can be determined by direct comparison between validation results and actual or accepted reference values. Suitable agreement with reference values is based on required measurement capability for a specific application. The purpose is to demonstrate a linear relationship between the NIR spectroscopic results and actual values. If a chemometric model is used, accuracy can be determined by using the methodologies in ⟨1039⟩. The error of the reference procedure may be known 1) on the basis of historical data, 2) through validation results specific to the reference procedure, or 3) by calculating the standard error of the laboratory (SEL).

For Category I and Category II procedures, accuracy can be determined by conducting recovery studies with the appropriate matrix spiked with known concentrations of the analyte. It is also an acceptable practice to compare assay results obtained using the NIR spectroscopy procedure under validation with those obtained from an established alternative analytical method.

**Validation criteria**

*Criteria 1:* Suitable agreement between ▲the standard error of prediction (SEP)▲ (ERR 1-May-2020) and SEL is based on required measurement capability for a specific application. For more information, see ⟨1039⟩.

https://pharmacopeia.cn/

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Nov-2020
DOI Ref: lro4d
DocId: GUID-EC7431B5-E08C-465F-A71D-BD04F30B017F_3_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M8189_03_01
@2024 USPC

*Criteria 2:* In addition to Category I and Category II procedures, 98.0%–102.0% recovery for a drug substance, 95.0%–105.0% recovery for a drug product assay, and 70.0%–150.0% recovery for an impurity analysis. These criteria must be met throughout the intended range.

### 4.1.2 PRECISION

The precision of an NIR spectroscopic procedure expresses the closeness of agreement among a series of measurements under prescribed conditions. Precision measurements are typically expressed as the relative standard deviation of a series of results and should be suitable for the intended application. Two levels of precision should be considered for NIR spectroscopic procedures: repeatability and intermediate precision.

**Repeatability:** Repeatability can be demonstrated by statistical evaluation of multiple NIR procedure results, with each result derived from a replicate analysis of a sample after repositioning between spectral acquisitions. System precision may be obtained directly from the analysis of variance (ANOVA) table. The analytical procedure can be assessed by measuring the concentrations of six independently prepared sample preparations at 100% of the assay test concentration. Alternatively, it can be based on measurements of three replicates of three separate samples at different analyte levels. The three levels should be close enough that the repeatability is constant across the concentration range. If this is done, the repeatability at the three concentrations may be pooled for comparison to the acceptance criteria.

*Validation criteria:* The relative standard deviation is NMT 1.0% for a drug substance assay, NMT 2.0% for a drug product assay, and NMT 20.0% for an impurity analysis.

**Intermediate precision:** Analysts must test the effects of changes in variables, such as performing the analysis on different days, using different instrumentation, or having the method performed by two or more analysts in the repeatability study. At a minimum, any scientifically justified combination of at least two of these factors totaling (based upon intended application) six experiments will provide an estimation of intermediate precision.

*Validation criteria:* The relative standard deviation is NMT 1.0% for a drug substance assay, NMT 3.0% for a drug product assay, and NMT 25.0% for an impurity analysis.

### 4.1.3 SPECIFICITY

The extent of specificity testing depends on the intended application. Specificity is typically demonstrated by using the following approaches:

**Qualitative:** Identification testing is a common application of qualitative NIR spectroscopy. Identification is achieved by comparing a sample spectrum to a reference spectrum or spectra, for instance, by establishing a mathematical relationship (chemometric model). The specificity of the NIR identification procedure is demonstrated by obtaining positive identification from samples, coupled with negative results from materials that should not meet the criteria for positive identification. Materials to demonstrate specificity should be selected on the basis of sound scientific judgment and risk specific to the application (e.g., materials handled in the same area).

**Quantitative:** Quantitative applications of NIR spectroscopy typically first establish a mathematical relationship (chemometric model) between NIR spectral response and a physical or chemical property of interest. Demonstration of specificity against a physical or chemical property of interest is based on interpreting both NIR spectral attributes and chemometric parameters in terms of the intended application. The demonstration of specificity may include the following:

- Spectral regions can be correlated to the property of interest
- Wavelengths used by regression analysis for the calibration (e.g., for multiple linear regression models) or the loading vector for each factor (e.g., for partial least squares or principal component regression models) can be examined to verify relevant spectroscopic information that is used for the mathematical model
- Variation in spectra from samples for calibration should be examined and interpreted
- Variation in material composition and sample matrix may be shown to have no significant effect on quantification of the property of interest within the specified procedure range

For Category I and Category II procedures, the specificity is demonstrated by meeting the accuracy requirements.

For Category IV tests, the identity of the analyte must be confirmed by comparison with appropriate reference substances.

### 4.1.4 QUANTITATION LIMIT

Given that NIR methods are usually macro techniques, there is normally no need for determining the quantitation limit. However, fitness for purpose must be demonstrated over the operational range of the analyte.

### 4.1.5 LINEARITY

Quantitative procedures generally attempt to demonstrate a linear relationship between NIR spectral response function and the property of interest. Although demonstrating a linear response is not required for all NIR applications, the model chosen should properly represent the relationship.

Linearity of NIR spectroscopic procedures depends on variables such as matrix effects and data pretreatment. Validation of linearity in NIR procedures may be accomplished by examining NLT 5 samples that span the operational range and by plotting either the NIR spectral response functions versus actual or accepted values for the property of interest. Many applications may require models of higher order, and various statistical procedures are available for evaluation of the goodness of fit. Applicable statistics and graphical procedures may be used as appropriate.

The Pearson correlation coefficient, $r$, measures the strength and direction of the association between two variables ($x$ and $y$), in this instance, concentration and absorbance. The coefficient of determination, $r^2$, is a measure of the fraction of the data's variation that is adequately modelled and not a measure of linearity. Linearity depends on the standard error of the calibration function (and hence the reference procedure) and on the range of the calibration data. Thus, although values very near 1.00,

Official

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:36:32 AM(EST)
Printed by: USP NF
Do Not Distribute

such as 0.99 or greater, typically indicate a linear relationship, lower values do not distinguish between nonlinearity and variability.

**Validation criteria:** The coefficient of determination, $r^2$, must be NLT 0.995 for Category I assays and NLT 0.99 for Category II quantitative tests. Visual inspection of the residual plots should reveal no significant pattern. For further guidance on multivariate procedures, see ⟨1039⟩.

#### 4.1.6 RANGE

The specified range of an NIR spectroscopic procedure depends on the specific application. The range typically is established by confirming suitable measurement capability (accuracy and precision) over the proposed operational range. Controls must be used to ensure that results outside of the validated range are not accepted. In certain circumstances, it may not be possible or desirable to extend the validated range to include sample variability outside of the validated range. Extending the range of an NIR spectroscopic procedure requires demonstration of suitable measurement capability within the limits of the expanded range. Examples of situations in which only a limited sample range may be available are samples from a controlled manufacturing process and in-process samples. A limited procedure range does not preclude the use of an NIR spectroscopic procedure.

**Validation criteria:** For Category I procedures, the validation range for 100.0% centered acceptance criteria is 80.0%–120.0%. For noncentered acceptance criteria, the validation range is 10.0% below the lower limit to 10.0% above the upper limit. For content uniformity, the range is 70.0%–130.0%. For Category II procedures, the validation range covers typically 50.0%–120.0% of the acceptance criteria.

#### 4.1.7 ROBUSTNESS

The robustness of an analytical measurement must be demonstrated during development by making deliberate changes to experimental parameters. NIR spectroscopic measurement parameters selected to demonstrate robustness will vary depending on the application and the sample's interface with the instrument. Critical measurement parameters associated with robustness often are identified and characterized during method development. Typical measurement parameters include the following:

- Effect of environmental conditions (e.g., temperature, humidity, and vibration)
- Effect of sample temperature
- Sample handling (e.g., fiber-optic probe depth, compression of material, sample depth/thickness)
- Influence of instrument changes (e.g., lamp change, warm-up time)

### 4.2 Verification

US Current Good Manufacturing Practices regulations [21 Code of Federal Regulations (CFR) 211.194(a)(2)] indicate that users of analytical procedures described in *USP–NF* are not required to validate these procedures if provided in a monograph. Instead, they must simply verify their suitability under actual conditions of use.

The objective of method verification is to demonstrate that the procedure, as prescribed in specific monographs, is being executed with suitable accuracy, sensitivity, and precision. *Verification of Compendial Procedures* ⟨1226⟩ notes that if the verification of the compendial procedure, according to the monograph, is not successful, the procedure may not be suitable for use with the article under test. It may be necessary to develop and validate an alternative procedure as allowed in *General Notices*.

Although complete revalidation of a compendial procedure is not required, verification of the compendial NIR spectroscopic procedure includes the determination of certain validation parameters. When the method being verified is for identification purposes, specificity is the only parameter required. For quantitative applications, additional validation parameters, such as accuracy and precision, must be studied as indicated in *Validation of Compendial Procedures* ⟨1225⟩*, Validation* as appropriate.

## INTRODUCTION

For the purposes of this chapter, an ultraviolet-visible (UV-Vis) spectrometer is defined as an optical system capable of producing monochromatic radiation in the range of 200–780 nm and as a device capable of detecting the optical transmittance, usually expressed in absorbance (*A*), whose primary function is to measure the stated absorbance, or transmittance, at defined wavelength(s).

[NOTE—A UV-Vis spectrometer may also be referred to as a spectrophotometer or absorption spectrometer.]

This functionality may be extended to incorporate multiple channel measurements, either by instrumental design or with time, e.g., in dissolution or kinetic studies.

Chromatographic detectors ▲and any type of multichannel plate reader systems (i.e., filter or monochromator systems)▲ (USP 1-Dec-2022) are specifically excluded from this chapter.

For essential supporting information on the best practices and principles of measurements, see *Ultraviolet-Visible Spectroscopy —Theory and Practice* ⟨1857⟩.

The suitability of a specific instrument for a given procedure is ensured by a stepwise life cycle evaluation for the desired application from selection to instrument retirement: design qualification (DQ); installation qualification (IQ); an initial performance-to-specification qualification, also known as operational qualification (OQ); and an ongoing performance qualification (PQ). For more details, see *Analytical Instrument Qualification* ⟨1058⟩. *Acceptance criteria* for "fitness for purpose" are based on the uncertainty of the reference material and the performance specification of the instrument.

***Change to read:***

### PRINCIPLES OF MEASUREMENT

UV-Vis spectra are derived when the interaction between incident radiation and the electron cloud in a chromophore results in an electronic transition involving the promotion of one or more of the outer shell or the bonding electrons from a ground state into a state of higher energy. The UV and visible spectral bands of substances generally are broad and do not possess a high degree of specificity for compound identification. Nevertheless, they are suitable for quantitative assays and, for many substances, are useful as an additional means of identification.

In the Beer–Lambert law, the absorbance ($A_\lambda$) of a solution at a given wavelength, λ, is defined as the logarithm to base 10 of the reciprocal of the transmittance ($T_\lambda$):

$$A_\lambda = \log_{10}\left(\frac{1}{T_\lambda}\right) \text{ and } T_\lambda = \frac{I_\lambda}{I_{\lambda_0}}$$

$T_\lambda$ = transmittance ▲at wavelength $\lambda$▲ (USP 1-Dec-2022)
$I_\lambda$ = intensity of the transmitted radiation at the same wavelength λ
$I_{\lambda 0}$ = intensity of the incident radiation at wavelength λ

In the absence of any other physical or chemical factors, $A_\lambda$ is proportional to path length, *b*, through which the radiation passes, and to the concentration, *c*, of the substance in the solution in accordance with the following:

$$A_\lambda = \epsilon_\lambda c b$$

$\varepsilon_\lambda$ = molar absorptivity
*c* = solute concentration (mol/L)
*b* = path length (cm)

If the concentration, *c*, is expressed in g/L, the constant $\varepsilon_\lambda$ becomes $a_\lambda$, which is called the absorptivity.

The expression $A^{1\%}_{1\text{ cm}}$, which represents the specific absorbance of a dissolved substance, refers to the absorbance of a 10-g/L solution (1%, m/v) in a 1-cm ▲cuvette▲ (USP 1-Dec-2022) measured at a defined wavelength so that:

$$A^{1\%}_{1cm} = 10a_\lambda = \frac{10\epsilon_\lambda}{M}$$

$a_\lambda$ = absorptivity
$\varepsilon_\lambda$ = molar absorptivity
*M* = molar concentration of the solution

When solutions are observed in 1-cm ▲cuvettes,▲ (USP 1-Dec-2022) concentrations of about 10 µg/mL often will produce absorbances of 0.2–0.8 ▲AU▲ (USP 1-Dec-2022) in the UV or visible region.

## QUALIFICATION OF UV-VIS SPECTROMETERS

The purpose of this section of the chapter is to provide test methodologies and acceptance criteria to ensure that the instrument is suitable for its intended use (OQ), and that it will continue to function properly over extended time periods as part of PQ. As with any spectrometric device, a UV-Vis spectrometer must be qualified for both wavelength (*x*-axis) and photometric (*y*-axis, or signal axis) accuracy and precision, and the fundamental parameters of stray light and resolution must be established. OQ is carried out across the operational ranges required within the laboratory for both the absorbance and wavelength scales.

### INSTALLATION QUALIFICATION

Documented proof of the IQ requirements provide evidence that the hardware and software are properly installed in the desired location.

### OPERATIONAL QUALIFICATION

Acceptance criteria for critical instrument parameters that establish "fitness for purpose" are verified during IQ and OQ. Specifications for particular instruments and applications can vary, depending on the analytical procedure used and the desired accuracy of the final result. OQ should establish suitable control over the operational range of wavelength, absorbance, and the evaluation of stray light and resolution, i.e., spectral bandwidth (SBW). Instrument vendors often have reference materials and protocols available as part of the IQ/OQ package.

Wherever possible in the procedures detailed as follows, certified reference materials (CRMs) are to be used in preference to laboratory-prepared solutions. These CRMs should be obtained from a recognized accredited source and include independently verified, traceable value assignments with associated calculated uncertainty. CRMs must be kept clean and free from dust. Recertification should be performed periodically to maintain the validity of the certification.

#### Control of wavelengths

Ensure that the accuracy of the wavelength axis (*x*-axis) over the intended operational range is correct within acceptable limits. The control of wavelength OQ must include at least one method in each operational range where it is intended for use▲, and the wavelengths selected for qualification must bracket the intended range for use.▲ (USP 1-Dec-2022) The options and acceptance criteria are summarized in *Table 1*.

**Table 1. Wavelength Ranges and Procedures for Control of Wavelengths**

| Method | UV (200–400 nm) | Vis (400–780 nm) | Vis/NIR (400–900 nm) |
|---|---|---|---|
| Mercury (Hg) emission lines | Accuracy ±1 nm<br>Precision ≤0.5 nm | Accuracy ±2 nm<br>Precision ≤0.5 nm | — |
| Deuterium ($D_2$) emission lines | — | Accuracy ±2 nm<br>Precision ≤0.5 nm | — |
| Cerium oxide solutions | Accuracy ±1 nm<br>Precision ≤0.5 nm | — | — |
| Holmium oxide solutions or glasses | Accuracy ±1 nm<br>Precision ≤0.5 nm | Accuracy ±2 nm<br>Precision ≤0.5 nm | — |
| Didymium solutions or glasses | — | — | Accuracy ±2 nm<br>Precision ≤0.5 nm |

[NOTE—Certified reference standards, traceable to the National Institute of Standards and Technology (NIST) (www.nist.gov) or to other ▲national metrological institutes▲ (USP 1-Dec-2022)and recognized standards-setting organizations, are commercially available, and should be used where possible.]

For non-diode array instruments, wavelength accuracy and precision are determined over the operational range using at least six replicate measurements. For wavelength accuracy, the difference of the mean measured value to the certified value of the CRM must be within ±1 nm in the UV region (200–400 nm), and in the visible region (400–780 nm) and visible/NIR (near-infrared) region (400–900 nm) must be within ±2 nm.

For wavelength precision, the standard deviation ▲▲ (USP 1-Dec-2022) of the six wavelength measurements must not exceed 0.5 nm.

For diode array instruments, only one wavelength accuracy measurement is required ▲(no replicate measurements are required)▲ (USP 1-Dec-2022), and no precision determination needs to be performed, due to the non-mechanical design of the monochromator.

#### Establishment of acceptance limits (wavelength)—choice of standards

For all *Control of Wavelengths* accuracy procedures, acceptance limits for adequate calibration are established by adding the expanded uncertainty of the CRM to the instrument vendor specification at the wavelength(s) required in a linear manner, and these values must lie within the values specified in *Table 1*. In the case where atomic line spectra are used, this expanded uncertainty of the CRM is deemed to be zero for this process, i.e., the limit simply becomes the instrument vendor specification (*1*).

**Atomic line spectra:** This procedure is described as the primary application because the emission lines produced from a discharge lamp are characteristic of the source element and, as a fundamental physical standard, these wavelengths have been measured with an uncertainty of not more than ±0.01 nm. In solution spectrometry, the wavelength accuracy required rarely exceeds 1.0 nm. For these reasons, the atomic line standard values are cited without uncertainty.

The arc of the atomic emission source, or its image, needs to be located on the same optical path as the image of the primary light source of the spectrometer; thus, it can be used only in spectrometers that can be operated

@2024 USPC

in a single-beam intensity mode and practically should be implemented only on a system designed to accommodate these sources, e.g., as an accessory.

A commonly employed low-pressure mercury lamp has a number of intense lines that cover a large part of the UV and visible spectra. Two deuterium lines from the source at 486.0 and 656.1 nm often are also used by manufacturers as an internal calibration check.▲ In addition, where a xenon source is used as an alternative source, the line at 541.9 nm can be used.▲ (USP 1-Dec-2022) (See *Table 2*) (*2*).

**Table 2. Recommended Atomic Lines from Low-Pressure Mercury (Hg)▲,▲ (USP 1-Dec-2022)Deuterium ($D_2$)▲, and Xenon (Xe)▲ (USP 1-Dec-2022) Lamps for Wavelength Calibration Purposes**

| Hg | 546.1 |
| Hg | 577.0 |
| Hg | 579.1 |
| $D_2$ | 656.1 |

[NOTE—Select the nearest wavelength(s) spanning the operational range required.]

**Rare earth oxide solutions:** This procedure uses solutions of rare earth oxides prepared by dissolution in acid media. The most frequently used is holmium oxide in perchloric acid (*3*). Holmium oxide solution has been internationally accepted as an intrinsic wavelength standard, and suitable CRMs are available commercially (*4*).

The observed peak maxima are determined using the normal scan mode on the spectrometer. The peak maxima for a 4% (m/v) solution of holmium oxide in perchloric acid at 1.0-nm SBW and a path length of 1 cm are shown in *Table 3*.

**Table 3. Recommended Peak Maxima from a 4% Solution of Holmium Oxide in Perchloric Acid for Wavelength Calibration Purposes**

| nm |
|---|
| 241.1 |
| 249.9 |
| 278.1 |
| 287.2 |
| 333.5 |
| 345.4 |
| 361.3 |
| 385.6 |
| 416.3 |
| 451.4 |
| 467.8 |
| 485.2 |
| 536.6 |
| 640.5 |

[NOTE—Select the nearest wavelength(s) spanning the operational range required.]

If the operational range of the spectrometer lies outside the range 240–650 nm, other certified rare earth oxides or other solutions can be used if they are traceable to a national or international standard.

Cerium is available as a traceable solution CRM in acidic media, e.g., in sulfuric acid. It has useful peak characteristics in the 200–300 nm region at approximately 201.1, 211.4, 222.6, 240.4, and 253.7 nm.

Didymium (a mixture of neodymium and praseodymium) is available as a traceable CRM both in solution and as a glass. Didymium is similar in preparation to the holmium materials and has useful peak characteristics in the 730–870-nm region, which may vary from melt to melt of the glass. Useful peaks are found in the didymium solution at approximately 731.6, 740.0, 794.1, 800.0, and 864.4 nm.

**Rare earth glasses:** This procedure uses glasses manufactured by fusing the appropriate rare earth oxide in a base glass matrix. The most frequently used is holmium, for which the reference wavelengths have been well defined. Although manufacturing can cause batch variation in these glasses, traceable CRMs are commercially available and can be used. Typical values for a holmium glass using a 1.0-nm SBW are the following: 241.5, 279.2, 287.5, 333.8, 360.9, 418.8, 445.8, 453.7, 460.2, 536.5, and 637.7 nm.

**Control of absorbance**

▲To establish adequate accuracy, precision, and photometric performance of a given system, it is necessary to verify the absorbance accuracy of a system over its intended operational range by selection and use of the following procedures as appropriate for the wavelength and absorbance ranges required. Demonstrating absorbance accuracy over the system's intended operational range assures proper photometric response.▲ (USP 1-Dec-2022)

The control of absorbance OQ must include at least one assessment at each wavelength range in the 0–2.00 AU region. If absorbance >2.00 AU is to be used for quantitation, then control of absorbance must also be evaluated in the >2.00 AU range.

**Establishment of acceptance limits (absorbance)—choice of standards**

For all *Control of Absorbance* procedures, acceptance limits for adequate calibration are established by adding the expanded uncertainty of the CRM to the instrument vendor specification at the wavelength(s) and absorbance levels required in a linear manner, and these values must lie within the values specified in *Table 4*.

[NOTE—CRMs, traceable to NIST Standard Reference Materials (SRMs), or other international or national standards, are commercially available and should be used where possible.▲When measuring these CRMs, the control of temperature may be important. For more information, see ⟨1857⟩.]

**Table 4. Available CRMs for the Control of Absorbance**

| Nominal Absorbance Range (AU) | Standard | UV (200–400 nm) | Vis (400–780 nm) |
|---|---|---|---|

▲ (USP 1-Dec-2022)

[NOTE—Select the appropriate absorbance CRMs spanning the operational range(s) required.]

**Acidic nicotinic acid solutions in 0.1 ▲N▲ (USP 1-Dec-2022) hydrochloric acid:** ▲In the 6–60 mg/L range, nicotinic acid solutions provide reference values of up to 2.5 AU at one of the certified values of 213 or 261 nm. These solutions are available as CRMs.

Acceptable absorbance accuracy and precision performance can be determined from the calculated mean and the standard deviation of six replicate absorbance measurements at a specified wavelength λ. Measurements should be performed at the upper and the lower absorbance of the operational range of the spectrometer at a specified wavelength λ.

@2024 USPC

For absorbance accuracy, the mean of the six values must not deviate from the certified value by more than ±0.010 AU for values below 1.00 AU, or ±1.0% of this certified absorbance at wavelength λ, $A_\lambda$, for values above 1.00 AU.

For absorbance precision, the standard deviation of the six values must not exceed 0.005 AU for values below 1.00 AU, or 0.50% of $A_\lambda$ for values above 1.00 AU.▲ (USP 1-Dec-2022)

**Acidic potassium dichromate solutions in 0.001 ▲M▲ (USP 1-Dec-2022) perchloric acid:** ▲In the 20–200 mg/L range, potassium dichromate solutions provide reference values of up to 3.0 AU at one of the certified values of 235, 257, 313, or 350 nm. These solutions are available as CRMs or can be prepared according to NIST from appropriate available SRMs, e.g., SRM 935*x*, or SRM 136*x* (where *x* can be any letter from "a" to "z").

Acceptable absorbance accuracy and precision performance can be determined from the calculated mean and the standard deviation of six replicate absorbance measurements at a specified wavelength λ. Measurements should be performed at the upper and the lower absorbance of the operational range of the spectrometer at a specified wavelength λ.

For absorbance accuracy, the mean of the six values must not deviate from the certified value by more than ±0.010 AU for values below 1.00 AU, or ±1.0% of this certified absorbance at wavelength λ, $A_\lambda$, for values above 1.00 AU.

For absorbance precision, the standard deviation of the six values must not exceed 0.005 AU for values below 1.00 AU, or 0.50% of $A_\lambda$ for values above 1.00 AU.▲ (USP 1-Dec-2022)

**Neutral-density glass filters:** ▲These gray glass filters are manufactured from doped glass and have a nominally flat spectrum in the region of the calibration wavelengths. They provide reference values of up to 3.5 AU at the certified values of 440, 465, 546.1, 590, and 635 nm. These filters are available as CRMs that are traceable to NIST SRM 930e, 1930, and 2930. Other certified standard solutions or optical filters can be used if they are traceable to a national or international standard.

Acceptable absorbance accuracy and precision performance can be determined from the calculated mean and the standard deviation of six replicate absorbance measurements at a specified wavelength λ. Measurements should be performed at the upper and the lower absorbance of the operational range of the spectrometer at a specified wavelength λ.

For absorbance accuracy, the mean of the six values must not deviate from the certified value by more than ±0.008 AU for values below 1.00 AU, or ±0.80% of this certified absorbance at wavelength λ, $A_\lambda$, for values above 1.00 AU.

For absorbance precision, the standard deviation of the six values must not exceed 0.005 AU for values below 1.00 AU, or 0.50% of $A_\lambda$ for values above 1.00 AU.▲ (USP 1-Dec-2022)

**Metal-on-fused-silica filters:** ▲These neutral density filters are manufactured by deposition of a metallic film on a silica substrate and have a substantially flat spectrum in the region of the calibration wavelengths.

[NOTE—These filters may produce significant interreflection errors. They should only be used in spectrometers designed to minimize these optical effects. For more information, see ⟨1857⟩.]

The filters provide reference values of up to 2 AU at the usually certified values of 250, 280, 340, 360, and 400 nm in the UV range and reference values of 465, 500, 546.1, 590, and 635 nm in the visible range. These filters are available as CRMs that are traceable to NIST SRM 2031*x* (where *x* can be any letter from "a" to "z"), or to other national or international standards.

Acceptable absorbance accuracy and precision performance can be determined from the calculated mean and the standard deviation of six replicate absorbance measurements at a specified wavelength λ. Measurements should be performed at the upper and the lower absorbance of the operational range of the spectrometer at a specified wavelength λ.

For absorbance accuracy in the UV range, the mean of the six values must not deviate from the certified value by more than ±0.010 AU for values below 1.00 AU, or ±1.0 % of this certified absorbance at wavelength λ, $A_\lambda$, for values above 1.00 AU.

For absorbance accuracy in the visible range, the mean of the six values must not deviate from the certified value by more than ±0.008 AU for values below 1.00 AU, or ±0.80% of this certified absorbance at wavelength λ, $A_\lambda$, for values above 1.00 AU.

For absorbance precision, the standard deviation of the six values must not exceed 0.005 AU for values below 1.00 AU, or 0.50% of $A_\lambda$ for values above 1.00 AU.▲ (USP 1-Dec-2022)

**Estimation of the limit of stray light (stray radiant energy)**

Although the measurement of absorbance or transmittance is a ratio measurement of intensities and therefore theoretically is independent of monochromatic source intensity, practical measurements are affected by the presence of unwanted radiation called "stray radiant energy" or "stray light". In addition, the adverse effect of stray light increases with aging of optical components and lamps in a spectrometer. The effects are greater at the extremes of detector and lamp operational ranges. The limit of stray light OQ must include evaluation at one or more UV wavelengths, by selection of appropriate material(s) shown in *Table 5* to span the UV operational range required. In the visible region, i.e., above 400 nm, stray light does not need to be evaluated.

[NOTE—Published stray light specifications for a given spectrometer must be verified in the OQ.]

Analysts must choose and use the appropriate reference(s) to monitor the level of stray light as part of PQ. Stray light can be detected at a given wavelength with a suitable liquid filter by either of the two methods (*Procedure A* or *Procedure B*) detailed below.

[NOTE—If measurements are being performed in the 250–330 nm region, on a spectrometer using individual sources for the UV and visible regions of the spectrum, then an additional PQ verification using acetone should be performed▲, using air as reference.▲ (USP 1-Dec-2022)]

These solutions are available as CRMs or can be prepared at the concentrations shown in *Table 5* by using reagent-grade materials.

**Table 5. Spectral Ranges of Selected Materials for Monitoring Stray Light**

| Recommended Wavelength ▲for Procedure B▲ (USP 1-Dec-2022) (nm) | Spectral Range ▲for Procedure B▲ (USP 1-Dec-2022) (nm) | Liquid or Solution ▲Used for Procedures A or B▲ (USP 1-Dec-2022) |
|---|---|---|
| 198 | 190–210 | Aqueous potassium chloride (12 g/L) |
| 220 | 210–270 | Aqueous sodium iodide or potassium iodide (10 g/L) |
| 300 | 250–330 | Acetone |
| 340 | 300–400 | Aqueous sodium nitrite (50 g/L) |

**Procedure A**

The aim of this procedure is to produce the differential spectrum resulting from the subtraction of a spectrum produced by a 5-mm path length ▲cuvette▲ (USP 1-Dec-2022) from that of a 10-mm ▲cuvette,▲ (USP 1-Dec-2022) both filled with the same filter solution ▲specified in *Table 5*.▲ (USP 1-Dec-2022)This spectrum will contain a peak maximum absorbance value ▲($\Delta A$),▲ (USP 1-Dec-2022) and analysts can calculate the stray light value from the observed maximum absorbance using the formula:

$$▲s_\lambda = 0.25 \times 10^{-2\Delta A}▲ \text{ (USP 1-Dec-2022)}$$

$s_\lambda$ = stray light value, in transmittance ($T$)
▲$\Delta A$▲ (USP 1-Dec-2022) = observed maximum absorbance

This procedure requires the ▲5▲ (USP 1-Dec-2022)-mm ▲cuvette▲ (USP 1-Dec-2022) measurement to be subtracted from the ▲10▲ (USP 1-Dec-2022)-mm ▲cuvette,▲ (USP 1-Dec-2022) both filled with the same cut-off solution filter. This measurement can be achieved by either using the physical capabilities of the spectrometer, i.e., using the double-beam capability, with the 5-mm ▲cuvette▲ (USP 1-Dec-2022) as the reference, or by mathematically subtracting the spectra of the 10-mm ▲cuvette▲ (USP 1-Dec-2022) from the 5-mm ▲cuvette,▲ (USP 1-Dec-2022) chronologically produced by sequential measurement of both the 5- and 10-mm ▲cuvettes,▲ (USP 1-Dec-2022) using the single-sample beam, with the spectrometer referenced to air (blank holder).

**Acceptance criteria:** $s_\lambda \leq 0.01$ or ▲$\Delta A$▲ (USP 1-Dec-2022) $\geq 0.7$ AU

▲See ⟨1857⟩ for additional discussion.▲ (USP 1-Dec-2022)

**Procedure B**

Analysts can measure the absorbance of the cut-off solution filters specified in *Table 5* against a 10-mm ▲cuvette▲ (USP 1-Dec-2022) filled with an appropriate reference, and record the maximum absorbance value ($A_{max}$) or the minimum %Transmittance ($\%T_{min}$) ▲within▲ (USP 1-Dec-2022) the recommended wavelength ▲range▲ (USP 1-Dec-2022) listed in *Table 5*.

**Acceptance criteria:** $A_{max} \geq 2.0$ AU or $\%T_{min} < 1\%T$

**Control of Resolution**

If accurate absorbance measurements must be made on benzenoid compounds or other compounds with sharp absorption bands (natural half-bandwidths of <15 nm), the SBW of the spectrometer used should not be greater than 1/8$^{th}$ the natural half-bandwidth of the compound's absorption; i.e., this equates to a spectrometer with a SBW of 2 nm or less.

Determine the resolution of the spectrometer in the UV region by using the following procedure. Using UV-grade *n*-hexane as the reference, measure the absorbance of a 0.020% (v/v) solution of toluene in UV-grade *n*-hexane at the maximum, about 269 nm, and minimum, about 266 nm. The ratio of the absorbance at the maximum to the absorbance at the minimum will typically fall in the 1.0–2.6 range.

For most compendial quantitative purposes, a SBW of 2 nm or less is sufficient, and the *Acceptance criteria* for the ratio is not less than 1.3.

**PERFORMANCE QUALIFICATION**

The purpose of PQ is to determine that the instrument is capable of meeting the user's requirements for all the ▲critical▲ (USP 1-Dec-2022) parameters that may affect the quality of the measurement and to ensure that it will function properly over extended periods of time. ▲Statistical evaluation is recommended, and trend analysis can be used to confirm ongoing fitness for purpose of the instrument. See *Analytical Data—Interpretation and Treatment* ⟨1010⟩, *Appendix 1: Control Charts*.▲ (USP 1-Dec-2022)

***Change to read:***

## PROCEDURE

With few exceptions, compendial spectrometric tests and assays call for comparison against a USP Reference Standard. This helps ensure measurement under identical conditions for the test specimen and the reference substance. These conditions could include wavelength setting, SBW selection, ▲cuvette▲ (USP 1-Dec-2022) placement and correction, and transmittance levels. ▲Cuvettes▲ (USP 1-Dec-2022) that exhibit identical transmittance at a given wavelength may differ considerably in transmittance at other wavelengths. Appropriate ▲cuvette▲ (USP 1-Dec-2022) corrections should be established and used where required.

Official

https://pharmacopeia.cn/

Comparisons of a test specimen with a reference standard are best made at a peak of spectral absorption for the compound concerned. Assays that prescribe spectrometry give the commonly accepted wavelength for peak spectral absorption of the substance in question. Different spectrometers may show minor variation in the apparent wavelength of this peak. Good practice demands that comparisons be made at the wavelength at which peak absorption occurs. Should this differ by > ±1 nm (in the range 200–400 nm) or ±2 nm (in the range 400–800 nm) from the wavelength specified in the individual monograph, recalibration of the instrument may be indicated.

The expressions "similar preparation" and "similar solution" as used in tests and assays involving spectrometry indicate that the reference comparator, generally a USP Reference Standard, should be prepared and observed in an identical manner for all practical purposes to that used for the test specimen. Usually when analysts make up the solution of the specified reference standard, they prepare a solution with a concentration of about the desired concentration (i.e., within 10%), and they calculate the absorptivity on the basis of the exact amount weighed out. If a previously dried specimen of the reference standard has not been used, the absorptivity is calculated on the anhydrous basis. The expressions "concomitantly determine" and "concomitantly measure" as used in tests and assays involving spectrometry indicate that the absorbances of both the solution containing the test specimen and the solution containing the reference specimen, relative to the specified test blank, must be measured in immediate succession.

#### SAMPLE SOLUTION PREPARATION

For determinations using UV or visible spectrometry, the specimen generally is dissolved in a solvent. Unless otherwise directed in the monograph, analysts make determinations at room temperature using a path length of 1 cm. Many solvents are suitable for these ranges, including water, alcohols, lower hydrocarbons, ethers, and dilute solutions of strong acids and alkalis. Precautions should be taken to use solvents that are free from contaminants that absorb in the spectral region under examination. For the solvent, analysts typically should use water-free methanol or alcohol or alcohol denatured by the addition of methanol but without benzene or other interfering impurities. Solvents of special spectrometric quality, guaranteed to be free from contaminants, are available commercially from several sources. Some other analytical reagent-grade organic solvents may contain traces of impurities that absorb strongly in the UV region. New lots of these solvents should be checked for their transparency, and analysts should take care to use the same lot of solvent for preparation of the test solution, the standard solution, and the blank. The best practice is to use solvents that have not less than 40% transmittance (39.9% $T = 0.399$ *AU*) at the wavelength of interest.

Assays in the visible region usually call for concomitantly comparing the absorbance produced by the assay preparation with that produced by a standard preparation containing approximately an equal quantity of a USP Reference Standard. In some situations, analysts can omit the use of a reference standard (e.g., when spectrometric assays are made with routine frequency) when a suitable standard curve is available and is prepared with the appropriate USP Reference Standard, and when the substance assayed conforms to the Beer–Lambert law within the range of about 75%–125% of the final concentration used in the assay. Under these circumstances, the absorbance found in the assay may be interpolated on the standard curve, and the assay result can be calculated. Such standard curves should be confirmed frequently and always when a new spectrometer or new lots of reagents are put into use.

## VERIFICATION AND VALIDATION

#### VERIFICATION

Current Good Manufacturing Practices regulations [21 CFR §211.194(a)(2)] indicate that users of analytical procedures described in *USP–NF* are not required to validate these procedures if provided in a monograph. Instead, they simply must verify their suitability under actual conditions of use.

The objective of a UV-Vis procedure verification is to demonstrate the suitability of a test procedure under actual conditions of use. Performance characteristics that verify the suitability of a UV-Vis procedure are similar to those required for any analytical procedure. A discussion of the applicable general principles is found in *Verification of Compendial Procedures* ⟨1226⟩. Verification is usually performed using a reference material and a well-defined matrix. Verification of compendial UV-Vis procedures includes at minimum the execution of the validation parameters for specificity, accuracy, precision, and quantitation limit, when appropriate, as indicated in *Validation*.

#### VALIDATION

Validation is required when a UV-Vis method is intended for use as an alternative to the official procedure for testing an official article or when no official procedure exists in the current *USP–NF*.

The objective of UV-Vis method validation is to demonstrate that the measurement is suitable for its intended purpose, including quantitative determination of the main component in a drug substance or a drug product (Category I assays), quantitative determination of impurities or limit tests (Category II), and identification tests (Category IV). For dissolution procedures, see *The Dissolution Procedure: Development and Validation* ⟨1092⟩. Depending on the category of the test (see *Validation of Compendial Procedures* ⟨1225⟩*, Table 2*), the analytical method validation process for UV-Vis requires testing for linearity, range, accuracy, specificity, precision, detection limit, or quantitation limit. These analytical performance characteristics apply to externally standardized procedures and those that use standard additions.

⟨1225⟩ provides definitions and general guidance on analytical procedures validation without indicating specific validation criteria for each characteristic. The intention of the following sections is to provide the user with specific validation criteria that represent the minimum expectations for this technology. For each particular application, tighter criteria may be needed in order to demonstrate suitability for the intended use.

**Accuracy**

For Category I, II, and III procedures, accuracy can be determined by conducting recovery studies with the appropriate matrix spiked with known concentrations of the analyte. Analysts also can compare assay results obtained using the UV-Vis procedure under validation to those from an established analytical procedure.

**Validation criteria:** 98.0%–102.0% mean recovery for the drug substances, 95.0%–105.0% mean recovery for the drug product assay, and 80.0%–120.0% mean recovery for the impurity analysis. These criteria are met throughout the intended range.

Official

https://pharmacopeia.cn/

**Precision/Repeatability**

The repeatability of the analytical procedure is assessed by measuring the concentrations of 6 independently prepared sample solutions at 100% of the assay test concentration. Alternatively, it can be assessed by measuring the concentrations of 3 replicates of 3 separate sample solutions at different concentrations. The three concentrations should be close enough so that the repeatability is constant across the concentration range. If this is done, the repeatability at the 3 concentrations is pooled for comparison to the acceptance criteria.

**Validation criteria:** The relative standard deviation is not more than 1.0% for the drug substance assay, not more than 2.0% for the drug product assay, and not more than 15.0%–20.0% for the impurity analysis

**Precision/Intermediate precision**

The effect of random events on the analytical precision of the method must be established. Typical variables include performing the analysis on different days, using different instrumentation, and/or having the method performed by two or more analysts. At a minimum, any combination of at least two of these factors totaling 6 experiments will provide an estimation of intermediate precision.

**Validation criteria:** The relative standard deviation is not more than 1.5% for the drug substance assay, not more than 3.0% for the drug product assay, and not more than 15.0%–25.0% for the impurity analysis.

**Specificity**

In UV-Vis measurements, specificity is ensured by the use of a reference standard wherever possible and is demonstrated by the lack of interference from other components present in the matrix.

**Detection limit**

The detection limit (DL) can be estimated by calculating the standard deviation of not less than 6 replicate measurements of a blank solution and multiplying by 3.3. Alternatively, the standard deviation can be determined from the error of the intercept from a calibration curve or by determining that the signal-to-noise ratio is >3.3. The estimated DL must be confirmed by analyzing samples at the calculated concentration.

**Quantitation limit**

The quantitation limit (QL) can be estimated by calculating the standard deviation of not less than 6 replicate measurements of a blank solution and multiplying by 10. Alternatively, the standard deviation can be determined from the error of the intercept from a calibration curve or by determining that the signal-to-noise ratio is >10.

Measurement of a test solution prepared from a representative sample matrix spiked at the required QL concentration must be performed to confirm sufficient sensitivity and adequate precision. The observed signal-to-noise ratio at the required QL should be >10. [NOTE—A suitable procedure for measuring the signal-to-noise ratio is given in ASTM E1657-98 (*5*).]

**Validation criteria:** For the estimated limit of quantitation to be considered valid, the measured concentration must be accurate and precise at a level ≤50% of the specification.

**Linearity**

A linear relationship between the analyte concentration and UV-Vis response must be demonstrated by preparation of not less than 5 standard solutions at concentrations encompassing the anticipated concentration of the test solution. The standard curve is then evaluated using appropriate statistical methods such as a least-squares regression. Deviation from linearity results from either instrumental or sample factors, or both, and can be reduced to acceptable levels by reducing the analyte concentration and thereby the associated absorbance values.

The (Pearson) correlation coefficient, $r$, measures the strength and direction of the association between two variables ($x$ and $y$), in this instance, concentration and absorbance.

The coefficient of determination, $r^2$, is a measure of the fraction of the data's variation that is adequately modeled and not a measure of linearity. Linearity depends on the standard error of the calibration equation (and hence the reference procedure) and on the range of the calibration data. Thus, although values very near 1.00, such as 0.99 or greater, typically indicate a linear relationship, lower values do not distinguish between nonlinearity and variability.

**Validation criteria:** The coefficient of determination, $r^2$, must be not less than 0.995 for Category I assays and not less than 0.99 for Category II quantitative tests. Visual inspection of the residual plots should not reveal any significant pattern.

**Range**

The operational range of an analytical instrument (and the analytical procedure as a whole) is the interval between the upper and lower concentrations (amounts) of analyte in the sample (including these concentrations) for which it has been demonstrated that the instrumental response function has a suitable level of precision, accuracy, and linearity.

**Validation criteria:** For Category I tests, the validation range for 100.0% centered acceptance criteria is 80.0%–120.0%. For noncentered acceptance criteria, the validation range is 10.0% below the lower limit to 10.0% above the upper limit. For content uniformity, the validation range is 70.0%–130.0%. For Category II tests, the validation range covers 50.0%–120.0% of the acceptance criteria.

**Robustness**

This parameter is evaluated during method development.

The reliability of an analytical measurement is demonstrated by deliberate changes to experimental parameters. For UV-Vis, this can include measuring the stability of the analyte under specified storage conditions, varying pH, and adding possible interfering species, to list a few examples. Robustness is determined concurrently using a suitable design for the experimental procedure.

## INDIRECT MEASUREMENT REQUIREMENTS

For certain UV-Vis procedures, chromogenic reactions are employed. Generally, the requirements for the analytical performance characteristics are used. In some instances, the required accuracy and precision criteria for the direct measurements may not be achievable. Under these circumstances, the accuracy and precision requirements can be widened by as much as 50%. Any such widening must be justified on scientific grounds and with documented evidence. It may be necessary to increase the amount of replication required to produce a scientifically sound reportable value.

# ▲⟨858⟩ RAMAN SPECTROSCOPY

INTRODUCTION
QUALIFICATION OF RAMAN SPECTROMETERS
Installation Qualification
Operational Qualification
Performance Qualification
PROCEDURE
VALIDATION AND VERIFICATION
Validation
Verification

## INTRODUCTION

Raman is a vibrational spectroscopic technique and is complementary to infrared (IR) and near-infrared (NIR) spectroscopy. The Raman effect itself arises as a result of a change in the polarizability of molecular bonds during a given vibrational mode and is measured as inelastically scattered radiation. The appearance of a Raman spectrum is much like that of an IR absorbance spectrum. The intensities, or the number of Raman photons counted, are plotted against the shifted energies. The Raman shift is usually expressed in wavenumber and represents the energy difference between the incident photon energy and the inelastically scattered photon energy. Unlike IR or NIR spectra that arise when vibrational modes in a molecule have a dipole change, Raman spectra have frequencies and intensities that arise when these same modes cause a change in polarizability. The spectrum is interpreted in the same manner as the corresponding mid-infrared spectrum. The positions of the (Raman-shifted) wavenumbers for a given vibrational mode are theoretically identical to the wavenumbers of the corresponding bands in an IR absorption spectrum. However, the stronger peaks in a Raman spectrum are often weak, or not present in an IR spectrum, and vice versa. Similarly, wavenumbers above 1500 $cm^{-1}$ are group frequencies, and strong bands that absorb below 1500 $cm^{-1}$ can be either group frequencies or fingerprint bands for the molecule. Thus, the two spectroscopic techniques are often said to be complementary. For discussion of the theory and principles of measurements, see ▲*Raman Spectroscopy—Theory and Practice* ⟨1858⟩▲ (CN 1-Aug-2020), which may be a helpful, but not a mandatory, resource. For further discussion of the theory and applications of chemometrics, see *Chemometrics* ⟨1039⟩.

## QUALIFICATION OF RAMAN SPECTROMETERS

Qualification of Raman spectrometers is divided into three components: 1) installation qualification (IQ); 2) operational qualification (OQ); and 3) performance qualification (PQ). For further discussion, see *Analytical Instrument Qualification* ⟨1058⟩ and ▲⟨1858⟩▲ (CN 1-Aug-2020).

### Installation Qualification

The IQ requirements provide evidence that the hardware and software are properly installed in the desired location.

### Operational Qualification

The requirements for OQ are application and user dependent. Therefore the user needs to specify fitness for purpose requirements for that application and use selection from below as appropriate. For example, applications for establishing the identity of materials may have different requirements than those for quantitative purposes.

Acceptance criteria given in this section are applicable for general use. Acceptance criteria for particular instruments and applications can vary, depending on the analytical method used and the desired accuracy of the final result. American Society for Testing and Materials (ASTM) Standard Reference Materials (SRMs) are also specified, with the understanding that in some circumstances (specifically, remote online applications), calibration using one of these materials may be impractical and other suitably verified materials can be used.

#### WAVELENGTH ACCURACY

The accuracy of the wavelength axis is ensured via calibration to maintain the integrity of Raman peak positions, see ▲⟨1858⟩▲ (CN 1-Aug-2020). The instrument wavelength accuracy can be determined by using a Raman-shift standard or other suitably high-purity material (e.g., acetaminophen, cyclohexane, or polystyrene). Selection of a standard with bands present across the full Raman spectral range is recommended so that instrument wavelength accuracy can be evaluated at multiple locations within the spectrum. Using a suitable, well-characterized wavenumber standard, the analyst conducts the calibration scans over the spectral range of the analytical system wavenumbers and compares the wavenumber of maximum response of several chosen bands using the appropriate peak-picking algorithms to the known Raman shift of the standard (see *Table 1*). Instrumentation for quantitative purposes must perform to these requirements. For qualitative requirements, the maximum allowable acceptance

criteria for all wavelengths contained in *Table 1* is ±3.0 $cm^{-1}$. Under these circumstances the user is required to demonstrate fitness for purpose of the derived calibration model over the operational range.

**Table 1. Wavenumber Shifts of Polystyrene, Acetaminophen (paracetamol), and Cyclohexane with Acceptance Criteria[a]**

| Wavenumber Shifts[b] ($cm^{-1}$) | | Acceptance Criteria ($cm^{-1}$) |
|---|---|---|
| Polystyrene[c] | 620.9 | ±1.5 |
| | 1001.4 | ±1.5 |
| | 1031.8 | ±1.5 |
| | 1602.3 | ±1.5 |
| | 3054.3 | ±3.0 |
| Acetaminophen[d] | 797.2 | ±1.5 |
| | 857.9 | ±1.5 |
| | 1168.5 | ±1.5 |
| | 1236.8 | ±1.5 |
| | 1323.9 | ±1.5 |
| | 1648.4 | ±1.5 |
| | 2931.1 | ±2.0 |
| Cyclohexane[e] | 801.3 | ±1.5 |
| | 1028.3 | ±1.0 |
| | 1266.4 | ±1.0 |
| | 1444.4 | ±1.0 |
| | 2852.9 | ±2.0 |

[a] Range testing during wavelength accuracy can be adjusted to the application for which instrument is being used. For instance, if the method does not use wavelengths above 2900 $cm^{-1}$, the wavelength accuracy test may only consider reference peaks below that value.
[b] *Standard Guide for Raman Shift Standards for Spectrometer Calibration* (ASTM E1840).
[c] Polystyrene foil (30 mil, 76 µm) or polystyrene pellets [National Institute of Standards and Technology (NIST) 706a], or Certified Reference Materials (CRMs), traceable to NIST SRMs, or other international or national standards, are commercially available and should be used where possible.
[d] Acetaminophen for equipment qualification CRS.
[e] Cyclohexane reference material.

[NOTE—For scanning dispersive instruments, calibration might need to be performed more frequently, and precision in both a scanning and static operation mode may need to be verified.]

PHOTOMETRIC PRECISION

Laser variation in terms of the total emitted photons occurring between two measurements can give rise to changes in the photometric precision of the instrument. Unfortunately, it is very difficult to separate changes in the photometric response associated with variations in the total emitted laser photons from the sample and sampling-induced perturbations. This is one of the reasons why the photometric precision acceptance criteria are set relatively loosely; a maximum tolerance of 10% from reference measurements made from the reference material is applied.

## Performance Qualification

The objective of PQ is to ensure that the instrument is performing within specified limits with respect to wavelength accuracy and photometric precision. In certain cases, when the instrument has been set up for a specific measurement, it might no longer be possible or desirable to measure the wavelength and photometric (signal) qualification reference standards used in the OQ. Provided that instrument OQ has shown that the system is fit for use, a single external performance verification standard may be used on a continuing basis (e.g., daily or before use). The performance verification standard must match the format of the samples in the current analysis as closely as possible and must use similar spectral acquisition parameters. Quantitative measurements of an external performance verification standard can be used to check both the wavelength accuracy and the photometric precision.

# PROCEDURE

Raman spectra can be obtained from several sample presentations, including solids, powders, slurries, gels, liquids, films, and gases. In addition, measurement can be performed through glass or plastic films that are normally used for containment. Typically, Raman spectroscopy does not require any sample preparation because it is relatively insensitive to physical state solid or emulsion, slurry, etc. Furthermore, Raman uses back scattering geometry, right angle geometry, or transmission geometry, so the frequency and intensity are not affected much. Any intensity difference may arise from sample non-homogeneity and sampling area difference. The detectors have a wide dynamic range, and the collection time can be adjusted by the user.

Official

https://pharmacopeia.com/

Considerations about exposure of the sample to the laser must be taken into account because high-intensity lasers and small measurement spots may result in burning of the sample.

Acceptable acquisition parameters and a summary of the validation results must be included as part of the respective analytical test procedure. Specific values for tests will depend on the instrument chosen and the required purpose. For this reason, specific instrument tests for these parameters are not indicated here. For additional details, see ▲⟨1858⟩▲ (CN 1-Aug-2020), which provides a detailed discussion of Raman spectroscopy.

## VALIDATION AND VERIFICATION

The objective of Raman procedure validation, as is the case with validation of any analytical process, is to demonstrate that the measurement is suitable for its intended purpose. The procedure for validation is related to the fundamental validation characteristics required for any analytical procedure. Data pretreatment is often a vital step in the chemometric analysis of Raman spectral data. Many suitable data pretreatments exist; the selection should be based on sound scientific judgment and suitability for the intended application. See ⟨1039⟩ and *Mid-Infrared Spectroscopy* ⟨854⟩.

### Validation

The validation criteria described below are only required when a Raman procedure is intended for use as an alternative to the official procedure for testing an official article. The objective of a Raman procedure validation is to demonstrate that the measurement is suitable for its intended purpose, including the following: quantitative determination of the main component in a drug substance or a drug product (Category I assays); quantitative determination of impurities or limit tests (Category II); and identification tests (Category IV); see *Validation of Compendial Procedures* ⟨1225⟩, *Table 2*. Depending on the category of the test, the process for analytical procedure validation for Raman spectroscopy may require the testing of accuracy, precision, specificity, detection limit, quantitation limit, linearity, range, and robustness. Validated Raman procedures may not be transferable to all models and configurations of Raman spectrometers because of differences in their inherent performance characteristics.

⟨1225⟩ provides definitions and general guidance on analytical procedures validation without indicating specific validation criteria for each characteristic. The sections that follow are intended to provide the user with specific validation criteria that represent the minimum expectations for this technology, assuming the typical Category I USP acceptance criteria of 98.0%–102.0% for a drug substance and 90.0%–110.0% for a drug product. The actual validation performance characteristics would depend on the acceptance criteria in place and must provide sufficient evidence that the measurement capability is sufficient for these acceptance criteria. For each particular application, tighter criteria may be needed to demonstrate suitability for the intended use.

#### ACCURACY

For Category I and II procedures, accuracy can be determined by conducting recovery studies with prepared samples or appropriate reference materials over the operational concentration range taking into account matrix effects. Comparison of assay results obtained using the Raman procedure under validation with those obtained from an established alternative analytical procedure may also be used to determine accuracy. See ⟨1039⟩ for more information.

**Validation criteria:** 98.0%–102.0% recovery for drug substances, 95.0%–105.0% recovery for drug product assays, and 70.0%–150.0% recovery for impurity analyses. These criteria should be met throughout the intended range.

#### PRECISION

**Repeatability:** The analytical procedure can be assessed by measuring the concentrations of six independently prepared sample preparations at 100% of the assay test concentration. Alternatively, this assessment can be based on measurements of three replicates of three separate samples at different concentrations. The three concentrations should be close enough that the repeatability is constant across the concentration range. If this is done, the repeatability at the three concentrations is pooled for comparison to the acceptance criteria.

*Validation criteria:* The relative standard deviation is NMT 1.0% for a drug substance, NMT 2.0% for a drug product, and NMT 20.0% for an impurity analysis.

**Intermediate precision:** Analysts test the effect on analytical precision of changes in variables, such as performing the analysis on different days, using different instrumentation, or having the procedure performed by two or more analysts. At a minimum, any scientifically justified combination of at least two of these factors based upon intended application, totaling at least six experiments, will provide an estimate of intermediate precision.

*Validation criteria:* The relative standard deviation is NMT 1.0% for a drug substance, NMT 3.0% for a drug product assay, and NMT 25.0% for an impurity analysis.

#### SPECIFICITY

The extent of specificity testing depends on the intended application. Specificity is typically demonstrated by using the following approaches:

**Qualitative:** Identification testing is a common application of qualitative Raman spectroscopy. Identification is achieved by comparing a sample spectrum to a reference spectrum or spectra either visually or by, for instance, establishing a "goodness of fit" criterion or use of a chemometric model. The specificity of the Raman identification procedure is demonstrated by obtaining positive identification from samples, coupled with negative results from materials that should not meet the criteria

DOI: https://doi.org/10.31003/USPNF_M8188_02_01
@2024 USPC

for positive identification. Materials to demonstrate specificity should be selected on the basis of sound scientific judgment and risk specific to the application (e.g., materials handled in the same area).

**Quantitative:** Quantitative applications of Raman spectroscopy typically first establish a mathematical relationship (chemometric model) between Raman spectral response and a physical or chemical property of interest. Demonstration of specificity against a physical or chemical property of interest is based on interpreting both Raman spectral attributes and chemometric parameters in terms of the intended application. The demonstration of specificity may include the following:

- Spectral regions can be correlated to the property of interest
- Wavelengths used by regression analysis for the calibration (e.g., for multiple linear regression models) or the loading vector for each factor (e.g., for partial least squares or principal component regression models) can be examined to verify relevant spectroscopic information that is used for the mathematical model
- Variation in spectra from samples for calibration should be examined and interpreted
- Variation in material composition and sample matrix should be shown to have no significant effect on quantification of the property of interest within the specified procedure range as part of robustness studies

For Category I and Category II procedures, the specificity is demonstrated by meeting the accuracy requirements.

For Category IV tests, the identity of the analyte must be confirmed by comparison with appropriate reference substances.

### QUANTITATION LIMIT

Given that Raman methods are typically multivariate, there is no need for determining a defined quantitation limit. However, fitness for purpose is demonstrated over the operational range of the analyte.

### LINEARITY AND CALIBRATION MODELS

Quantitative procedures generally attempt to demonstrate a linear relationship between Raman spectral response function and the property of interest. Although demonstrating a linear response is not required for all Raman applications, the model chosen should properly represent the relationship.

Linearity of Raman spectroscopic procedures depends on variables such as matrix effects and data pretreatment. Validation of linearity in Raman procedures may be accomplished by examining NLT 5 samples that span the expected concentration range and by plotting either the Raman spectral responses versus actual or accepted values for the property of interest. Many applications may require models of higher order, and various statistical procedures are available for evaluation of the goodness of fit. Applicable statistics and graphical procedures may be used as appropriate.

The Pearson correlation coefficient, $r$, measures the strength and direction of the association between two variables ($x$ and $y$), in this instance, concentration and absorbance. The coefficient of determination, $r^2$, is a measure of the fraction of the data's variation that is adequately modeled and not a measure of linearity. Linearity depends on the standard error of the calibration function (and hence the reference procedure) and on the range of the calibration data. Thus, although values very near 1.00, such as 0.99 or greater, typically indicate a linear relationship, lower values do not distinguish between nonlinearity and variability.

**Validation criteria:** Visual inspection of the residual plots should reveal no significant pattern. For further guidance on multivariate procedures, see ⟨1039⟩.

### RANGE

The specified range of a Raman spectroscopic procedure depends on the specific application. The range typically is established by confirming suitable measurement capability (accuracy and precision) over the proposed operational range. Controls must be used to ensure that results outside of the validated range are not accepted. In certain circumstances, it may not be possible or desirable to extend the validated range to include sample variability outside of the validated range. Extending the range of a Raman spectroscopic procedure requires demonstration of suitable measurement capability within the limits of the expanded range. Examples of situations in which only a limited sample range may be available are samples from a controlled manufacturing process and in-process samples. A limited procedure range does not preclude the use of a Raman spectroscopic procedure.

**Validation criteria:** For Category I procedures, the validation range for 100.0% centered acceptance criteria is 80.0%–120.0%. For non-centered acceptance criteria, the validation range is 10.0% below the lower limit to 10.0% above the upper limit. For content uniformity, the range is 70.0%–130.0%. For Category II procedures, the validation range typically covers 50.0%–120.0% of the acceptance criteria.

### ROBUSTNESS

The robustness of an analytical measurement must be demonstrated during development by making deliberate changes to experimental parameters. For Raman spectroscopy, this can include, but is not limited to, changes in sample position, laser–sample interaction, or hardware settings. See ▲ ⟨1858⟩▲ (CN 1-Aug-2020) for additional factors impacting measurement.

## Verification

United States Current Good Manufacturing Practice regulations [21 CFR §211.194(a)(2)] indicate that users of analytical procedures described in *USP–NF* are not required to validate these procedures if provided in a monograph. Instead, the users must verify suitability under actual conditions of use.

The objective of a Raman spectroscopic procedure verification is to demonstrate that the procedure, as prescribed in specific monographs, is being executed with suitable accuracy, sensitivity, and precision. *Verification of Compendial Procedures* ⟨1226⟩

Official

https://pharmacopeia.cn/v-download/

notes that if the verification of the compendial procedure, according to the monograph, is not successful, the procedure may not be suitable for use with the article under test. It may be necessary to develop and validate an alternative procedure as allowed in *General Notices and Requirements, 6.30 Alternative and Harmonized Methods and Procedures*.

Although complete revalidation of a compendial procedure is not required, verification of the compendial Raman spectroscopic procedure includes the demonstration of certain validation parameters. When the procedure being verified is for identification purposes, specificity is the only parameter required. However, for quantitative applications, additional validation parameters must be studied as appropriate; these may include accuracy and precision over the expected concentration range.

# ⟨861⟩ SUTURES—DIAMETER

***Change to read:***

▲Diameters of surgical sutures can be determined by either contact or noncontact methods.

## CONTACT METHODS

The gauge for determining suture diameter shall be mechanical or electrical, equipped with a direct-reading dial, a digital readout, or a printed readout. The gauge shall have a minimum accuracy of 0.002 mm, an anvil 50 ± 5 mm in diameter, and a flat contact point (presser foot) 12.70 ± 0.02 mm in diameter. The flat contact point and anvil surfaces shall be plane to within 0.005 mm and parallel to each other to within 0.005 mm. For suture sizes 7-0 and larger, the presser foot and moving parts attached to it shall apply a force of 210 ± 3 g to the specimen. For sutures of size 8-0 and smaller, the presser foot and moving parts attached to it shall apply a force of 60 ± 3 g to the specimen.

Measure sutures, whether packaged in dry or fluid form, immediately after removal from the container and without prior drying or conditioning. Do not stretch the suture before measuring.

## MONOFILAMENT SUTURES (ABSORBABLE AND NONABSORBABLE)

For monofilament sutures, lay the strand across the center of the anvil (see *Figure 1*). Apply tension to the suture NMT required to straighten the suture. Measure the diameter of the suture by slowly lowering the presser foot to avoid crushing the suture. Measure the suture diameter at 3 locations corresponding to approximately one-fourth, one-half, and three-fourths of its labeled length. Each location is considered an individual measurement.

Repeat the test on a total of 10 suture strands. Compare each individual measurement to the individual specifications in the appropriate monograph. Compare the average of the 30 individual measurements to the average specification in the appropriate monograph.

# MULTIFILAMENT SUTURES (ABSORBABLE AND NONABSORBABLE)

## Diameter Measurement Strategy

Refer to *Table 1* for the diameter measurement strategy for various suture lengths.

**Table 1. Diameter Measurement Strategy**

| Condition | Suture Length as Noted on Package (inches) | Number of Data Points/Strand | Number of Suture Strands | Sample Type |
|---|---|---|---|---|
| 1 | <4 | 1 | 30 | Use a noncontact method |
| 2 | 4 to ≤12 | 1 | 30 | Strand |
| 3 | >12 to ≤48 | 3 | 10 | Strand |
| 4 | >48 | 3 | 10 | Random subsection |

For Condition 1, where the suture length is less than 4 inches during diameter testing, use a noncontact method. For Condition 2, measure the suture diameter at a single location on 30 strands for a total of 30 individual diameter measurements. For Condition 3, measure the suture diameter at 3 locations corresponding to approximately one-fourth, one-half, and three-fourths of the labeled length. Measure 10 strands for a total of 30 individual diameter measurements. For Condition 4, measure the suture diameter at 3 locations corresponding to approximately one-fourth, one-half, and three-fourths on a random subsection NLT 48 inches in length from the total suture product. Measure 10 strands for a total of 30 individual diameter measurements.

## Preparation

Mount the suture on a tensioning board by clamping one end of the suture so that the strand lies across the center of the anvil in the same plane as the surface of the anvil and routing the free end of the suture to be tensioned, such as by passing the suture around a cylinder or a pulley and attaching a weight to the free end, ensuring the strand does not twist or untwist. Apply a load of about one-half of the knotted tensile strength for the nonsterilized Class I suture as given in *Table 2*. Class III sutures do not require tension.

## Measurement

Measure the diameter of the suture by slowly lowering the presser foot to avoid crushing the suture. Measure the suture diameter as specified in *Diameter Measurement Strategy*.

For suture sizes 2-0 and larger: Take 2 measurements at right angles to each other at each location. Average the 2 measurements taken at each location and record as the observed diameter at that location for comparison to the individual specifications. For suture sizes 3-0 and smaller, take a single measurement at each location for comparison to the individual specifications. Each location is considered an individual measurement. The average diameter of the samples are within the limits on average diameter (for all 30 measurements) per the monograph for the size stated on the label. None of the observed individual measurements should be less than or greater than the limits on individual diameter in the monograph. None of the individual observed measurements should be less or greater than the tolerances in the monograph.

## Data Analysis

Compare each individual measurement to the individual specifications in the appropriate monograph. Compare the average of the 30 individual measurements to the average specification in the appropriate monograph.

# NONCONTACT METHODS

The laser micrometer (optical micrometer) for determining suture diameter shall be equipped with a digital or printed readout. The laser micrometer shall have a minimum accuracy of 0.002 mm, and be capable of dual axis measurements. The test method should be correlated with the contact method and the appropriate specifications should be established based on the correlation.

Place the suture without any preconditioning into the path of the laser beam, ensuring the suture is appropriately aligned. For a monofilament suture, hold the suture with minimal applied tension. For a multifilament suture, apply a tensile load of about one-half of the knotted tensile strength (see *Tensile Strength* ⟨881⟩) for the nonsterilized Class I suture of the given size. Measure each suture at 3 points corresponding roughly to one-fourth, one-half, and three-fourths of its length.

# TENSIONS

Tensions for both contact and noncontact methods are calculated to represent approximately one-half of the knot-pull limit for nonsterile Class I sutures of the designated size in *Table 2*.

# ⟨871⟩ SUTURES—NEEDLE ATTACHMENT

Absorbable and nonabsorbable surgical sutures with standard needle attachment are such that the needles are firmly attached and are not intended to be separated. Sutures supplied with eyeless needles attached fall into either the category of standard needle attachment or the category of removable needle attachment. Removable needle attachment of both absorbable and nonabsorbable surgical sutures is such that the needle may be deliberately separated from the suture by means of a quick tug. Both types of attachments are tested on equipment as specified in *Tensile Strength* ⟨881⟩.

## PROCEDURE

Clamp each of 5 sutures in the tensile testing device so that the needle is in the fixed clamp with all of the swaged portion exposed and in line with the direction of force applied to the suture by the moving clamp. Determine the force required to detach the suture from the needle. In the case of standard needle attachment, the suture may break without needle detachment.

### Standard Needle Attachment

The requirements are met if neither the average of the 5 values nor any individual value is less than the limits given for the designated size in *Table 1*.

**Table 1. Standard Needle Attachment for Absorbable and Nonabsorbable Sutures**

| Metric Size (gauge no.) | | Limits on Needle Attachment | | | | |
|---|---|---|---|---|---|---|

***Change to read:***

### Removable Needle Attachment

For USP sizes 5-0 through 2▲▲ (ERR 1-Aug-2022), the requirements are met if the individual values of the 5 sutures are NLT 0.028 kgf (0.275 N) and NMT 1.59 kgf (15.6 N).

[NOTE—For either type of attachment, if NMT one of the individual values falls outside the prescribed limits, repeat the test on an additional 10 sutures. The requirements of the test are met if none of the 10 additional values falls outside the individual limit requirements.]

# ⟨881⟩ TENSILE STRENGTH

***Change to read:***

▲Testing devices▲ (USP 1-Dec-2019) for measurement of tensile strength used in the United States may be calibrated in the English units of measure. The following directions are given in metric units with the understanding that the corresponding English equivalents may be used.

***Change to read:***

## SURGICAL SUTURE

Determine the tensile strength of surgical suture on a motor-driven tensile strength testing machine having suitable clamps for holding the specimen firmly and using ▲▲ (USP 1-Dec-2019) the principle of constant rate of elongation of specimen, as described below. The apparatus has two clamps for holding the strand. One of these clamps is mobile. The clamps are designed so that the strand being tested can be attached without any possibility of slipping. Gauge length is defined as the interior distance between the two clamps. For gauge lengths of 125–200 mm, the mobile clamp is driven at a constant rate of elongation of 30 ± 5 cm/min. For gauge lengths of less than 125 mm, the rate of elongation per minute is adjusted to equal 2 times the gauge length per minute. For example, a 5-cm gauge length has a rate of elongation of 10 cm/min.

Determine the tensile strength of the suture, whether packaged in dry form or in fluid, promptly after removal from the container, without prior drying or conditioning. ▲Except where straight pull (no knot required) is indicated in the suture monographs, tie the test suture into a simple knot formed by placing one end of a strand held in the right hand over the other end held in the left hand. Then pass one end over the strand and through the loop that is formed (see *Figure 1*), and pull the knot tight so as not to affect the integrity of the suture.

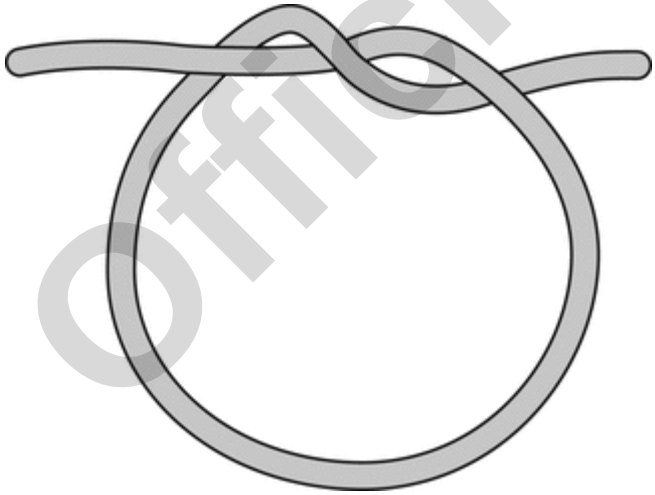

Figure 1. Knot for test suture.

Place the specimen in the testing device with the knot approximately midway between the clamps.▲ (USP 1-Dec-2019) Attach one ▲free▲ (USP 1-Dec-2019) end of the suture to the clamp at the load end of the machine, pass the other ▲free▲ (USP 1-Dec-2019) end through the opposite clamp, applying sufficient tension so that the specimen is taut between the clamps, and engage the second clamp. Perform as many breaks as are specified in the individual monograph. If the break occurs at ▲or in▲ (USP 1-Dec-2019) the clamp, discard ▲and replace with an additional pull with a new test suture. The discarded result should be noted and recorded, but not included in the averaging of the results.

For suture devices that are not knotted, a straight pull should be used for testing. Strength should be compared to the knot tie values for labeled sizes in the monograph table.▲ (USP 1-Dec-2019)

***Add the following:***

## ▲BARBED SUTURES

Barbed suture type devices that do not require the use of knots in their application should not be tested for USP knot-pull tensile strength by the use of knots. The alterations to the surface (i.e., barbing) of these devices would lead to testing bias were a USP knot pull be applied to the device. For these types of devices, refer to the manufacturer's specifications with respect to the USP size designation identified and perform straight pull testing accordingly. Compare results generated to the identified USP size knot-pull specifications.▲ (USP 1-Dec-2019)

https://pharmacopeia.cn/

***Change to read:***

## TEXTILE FABRICS AND FILMS

Determine the tensile strength of textile fabrics, including adhesive tape, on a constant-speed or pendulum type of testing ▲device▲ (USP 1-Dec-2019) of the following general description.

The clamps for holding the specimen are smooth, flat, parallel jaws that are NLT 25 mm in length in the dimension parallel to the direction of application of the load. When the width of the strip being tested does not exceed 19 mm, the jaws of the clamp should be at least 25 mm wide. If the width of the strip is greater than 19 mm and NMT 44 mm, the width of the jaws of the clamp should be at least 50 mm. If the width of the specimen is greater than 44 mm, cut a 25-mm strip, and use a clamp with jaws NLT 50 mm wide. Round all edges that might have a cutting action on the specimen to a radius of 0.4 mm. The jaws are 76.2 mm apart at the beginning of the test, and they separate at the rate of 30.5 cm ± 13 mm/min. The machine is of such capacity that when the break occurs, the deviation of the pendulum from the vertical is 9°–45°.

# ⟨891⟩ THERMAL ANALYSIS

## INTRODUCTION

Precisely determined thermodynamic events, such as a change of state, can indicate the identity and purity of drugs. Compendial standards have long been established for the melting or boiling temperatures of substances. These transitions occur at characteristic temperatures, and the compendial standards therefore contribute to the identification of the substances. Because impurities affect these changes in predictable ways, the same compendial standards contribute to the control of the purity of the substances.

Thermal analysis in the broadest sense is the measurement of physical–chemical properties of materials as a function of temperature. Instrumental methods have largely supplanted older methods dependent on visual inspection and measurements under fixed or arbitrary conditions, because they are objective, provide more information, afford permanent records, and are generally more sensitive, precise, and accurate. Furthermore, they may provide information on desolvation, dehydration, decomposition, crystal perfection, polymorphism, melting temperature, sublimation, glass transitions, evaporation, pyrolysis, solid-solid interactions, and purity. Such data are useful in the characterization of substances with respect to compatibility, stability, packaging, and quality control. The measurements used most often in thermal analysis, i.e., transition and melting point temperatures by differential scanning calorimetry (DSC), thermogravimetric analysis, hot-stage microscopy, and eutectic impurity analysis, are described here.

## TRANSITION AND MELTING POINT TEMPERATURES

As a specimen is heated, transitions can be observed using differential scanning calorimetry (DSC), differential thermal analysis (DTA), or hot-stage microscopy. In heat-flux DSC, the heat differential between the sample and reference material is determined. In power compensation DSC, the sample and reference materials are maintained at the same temperature, using individual heating elements, and the difference in power input to the two heaters is recorded. DTA monitors the difference in temperatures between the sample and the reference. The transitions that may be observed include those shown in *Table 1* below. In the case of melting, both an “onset” and a “peak” temperature can be determined objectively and reproducibly, often to within a few tenths of a degree. Although these temperatures are useful for characterizing substances, and the difference between the two temperatures is indicative of purity, the values cannot be directly compared to visual “melting-range” or “melting-point” values or with constants such as the triple point of the pure material.

Furthermore, caution should be used when comparing results obtained by different methods of analysis. Optical methods may measure the melting point as the temperature where the last trace of solid coalesces. In contrast, melting points measured by DSC may refer to the onset temperature or the temperature where the maximum melting rate (vertex) was observed. However, the vertex is sensitive to sample weight, heating rate, and other factors, whereas the onset temperature is less affected by these factors. With thermal techniques, it is necessary to consider the limitations of solid solution formation, insolubility in the melt, polymorphism, and decomposition during the analysis.

**Table 1**

| | | |
|---|---|---|
| Solid to liquid | Melting | Endothermic |
| Liquid to gas | Vaporization | Endothermic |
| Liquid to solid | Freezing | Exothermic |
| | Crystallization | Exothermic |
| Solid to gas | Sublimation | Endothermic |
| Solid to solid | Glass transition | Second order event |
| | Desolvation | Endothermic |
| | Amorphous to crystalline | Exothermic |
| | Polymorphic | Endothermic or Exothermic |

### Reporting Results of Instrumental Methods

A complete description of the conditions employed should accompany each thermogram, including make and model of instrument; record of last calibration; specimen size and identification (including previous thermal history); container; identity, flow rate, and pressure of gaseous atmosphere; direction and rate of temperature change; and instrument and recorder sensitivity.

Official

https://pharmacopeia.cn/

# DETERMINATION OF TRANSITION TEMPERATURE (MELT ONSET TEMPERATURE) AND MELTING POINT TEMPERATURE

## Apparatus

Use DTA or DSC instrumentation equipped with a temperature-programming device, thermal detector(s), and a recording system that can be connected to a computer, unless otherwise prescribed by the specific monograph for which this chapter is being used.

## Calibration

Calibrate instrumentation for temperature and enthalpy changes, using indium or another suitable certified material. Temperature calibration is performed by heating a standard through the melting transition and comparing the extrapolated onset of melting point of the standard to the certified onset of melting point. The temperature calibration should be conducted at the same heating rate as the experiment. Enthalpy calibration is performed by heating a standard through the melting transition and comparing the calculated heat of fusion to the theoretical value.

## Procedure

Accurately weigh an appropriate quantity of the substance to be examined in the sample pan, as described in the specific monograph. Set initial temperature, heating rate, direction of temperature change, and final temperature as specified in the monograph. If not specified in the monograph, these parameters are determined as follows: make a preliminary examination over a wide range of temperatures (typically, room temperature to decomposition temperature, or about 10° to 20° above the melting point) and over a wide range of heating rates (1° to 20° per minute) to reveal any unexpected effects. Then determine a lower heating rate such that decomposition is minimized and the transition temperature is not compromised. Determine a temperature range bracketing the transition of interest such that the baseline can be extended to intersect with the tangent of the melt (see *Figure 1*).

Figure 1. Thermogram.

In examining pure crystalline materials, rates as low as 1° per minute may be appropriate, whereas rates of up to 20° per minute are more appropriate for polymeric and other semicrystalline materials. Begin the analysis, and record the differential thermal analysis curve with the temperature on the *x*-axis and the energy change on the *y*-axis. The melting temperature (melt onset temperature) is the intersection (188.79°) of the extension of the baseline with the tangent at the point of greatest slope (inflexion point) of the curve (see *Figure 1*). The vertex is the temperature at the peak of the curve (190.31°). The enthalpy of the event is proportional to the area under the curve after application of a baseline correction.

## THERMOGRAVIMETRIC ANALYSIS

Thermogravimetric analysis involves the determination of the mass of a specimen as a function of temperature, or time of heating, or both. It is often used to investigate dehydration/desolvation processes and compound decomposition. When thermogravimetry is properly applied, it provides more useful information than loss on drying at fixed temperature, often for a fixed time and in what is usually an ill-defined atmosphere. Usually, loss of surface-absorbed solvent can be distinguished from solvent in the crystal lattice and from degradation losses. The measurements can be carried out in atmospheres having controlled humidity and oxygen concentration to reveal interactions with the drug substance, between drug substances, and between active substances and excipients or packaging materials.

### Apparatus

While the details depend on the manufacturer, the essential features of the equipment are a recording balance and a programmable heat source. Equipment differs in the ability to handle specimens of various sizes, the means of sensing specimen temperature, and the range of atmosphere control.

DOI: https://doi.org/10.31003/USPNF_M99680_02_01

## Calibration

Calibration is required with all systems: that is, the mass scale is calibrated by the use of standard weights, and calibration of the temperature scale involves the use of standard materials, because it is assumed that the specimen temperature is the furnace temperature. Weight calibration is conducted by measuring the mass of a certified or standard weight and comparing the measured mass with the certified value. Temperature calibration is performed by analyzing a high-purity magnetic standard such as nickel for its curie temperature and comparing the measured value to the theoretical value.

## Procedure

Apply the method to the sample, using the conditions described in the monograph, and calculate the mass gain or loss, expressing the change in mass as percentage. Alternatively, place a suitable quantity of material in the sample holder, and record the mass. Because the test atmosphere is critical, the pressure or flow rate and the composition of the gas are specified. Set the initial temperature, heating rate, and final temperature according to the manufacturer's instructions, and initiate the temperature increase. Alternatively, conduct an examination of the thermogram over a wide range of temperatures (typically, from room temperature to the decomposition temperature, or 10° to 20° above the melting point at a heating rate of 1° to 20° per minute). Calculate the mass gain or loss, expressing the change in mass as percentage.

# HOT-STAGE MICROSCOPY

Hot-stage microscopy is an analytical technique that involves monitoring the optical properties of the sample using a microscope as a function of temperature. Hot-stage microscopy may be used as a complementary technique to other thermal analysis techniques such as DSC, DTA, and variable temperature X-ray powder diffraction for the solid-state characterization of pharmaceutical compounds. It is useful to confirm transitions such as melts, recrystallizations, and solid-state transformations using a visual technique. The hot-stage microscope must be calibrated for temperature.

# EUTECTIC IMPURITY ANALYSIS

The basis of any calorimetric purity method is the relationship between the melting and freezing point depression and the level of impurity. The melting of a compound is characterized by the absorption of latent heat of fusion, $\Delta H_f$, at a specific temperature, $T_o$. In theory, a melting transition for an absolutely pure crystalline compound should occur within an infinitely narrow range. A broadening of the melting range, due to impurities, provides a sensitive criterion of purity. The effect is apparent visually by examination of thermograms of specimens differing by a few tenths percent in impurity content. A material that is 99% pure is about 20% molten at 3° below the melting point of the pure material (see *Figure 2*).

DOI: https://doi.org/10.31003/USPNF_M99680_02_01

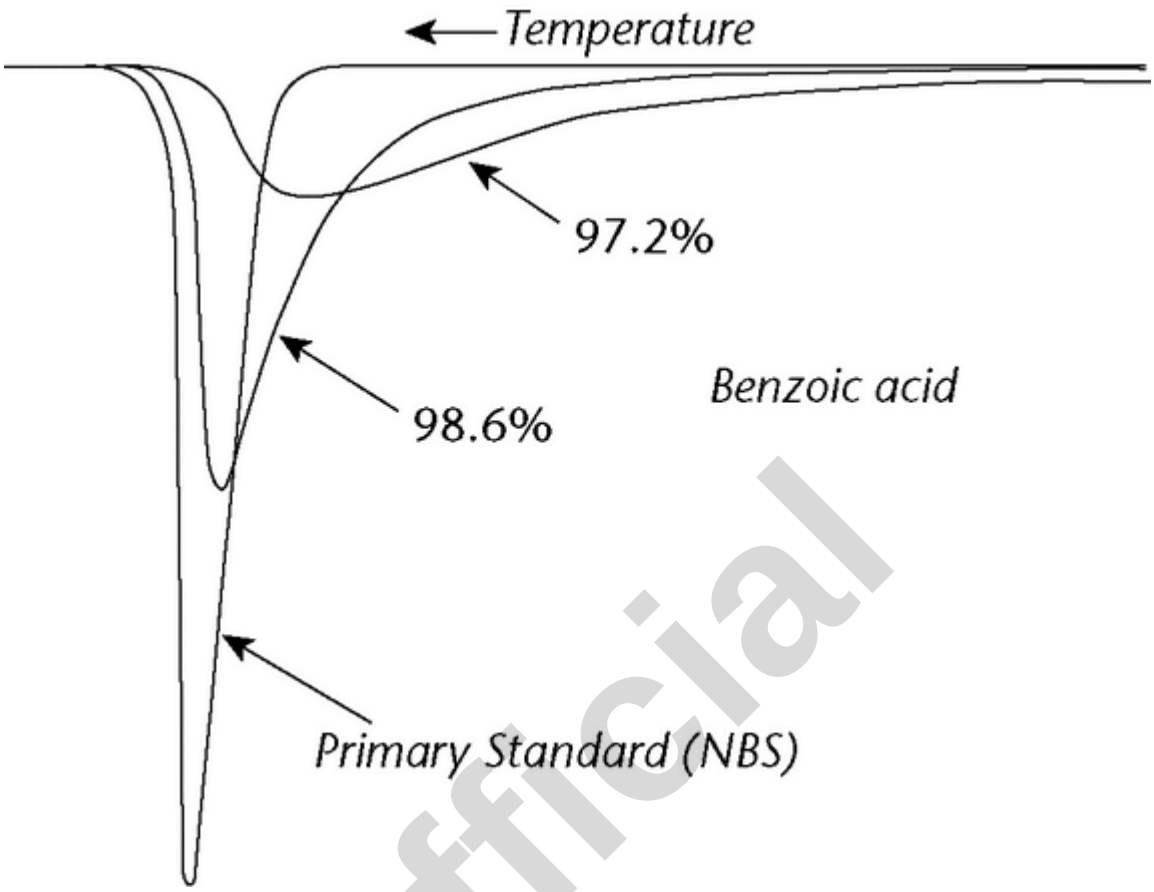

Figure 2. Superimposed thermograms illustrating the effect of impurities on DSC melting peak shape.

The parameters of melting (melting range, $\Delta H_f$, and calculated eutectic purity) are readily obtained from the thermogram of a single melting event using a small test specimen, and the method does not require multiple, precise actual temperature measurements. Thermogram units are directly convertible to heat transfer, millicalories per second.

The lowering of the freezing point in *dilute solutions* by molecules of nearly equal size is expressed by a modified van't Hoff equation:

$$\frac{dT}{dX_2} = \frac{RT^2}{\Delta H_f} \cdot \left(K_D - 1\right) \quad (1)$$

in which T = absolute temperature in kelvins; $X_2$ = mole fraction of minor component (solute, impurity); $\Delta H_f$ = molar heat of fusion of the major component in Joules per mol: R = gas constant in Joules per mol × kelvins; and $K_D$ = distribution ratio of solute between the solid and liquid phases.

Assuming that the temperature range is small and that no solid solutions are formed ($K_D = 0$).

Integration of the van't Hoff equation yields the following relationship between the mole fraction of impurity and the melting-point depression:

$$X_2 = \frac{\left(T_o - T_m\right)\Delta H_f}{RT_o^2} \quad (2)$$

in which $T_o$ = melting point of the pure compound, in kelvins, and $T_m$ = melting point of the test specimen, in kelvins.

With no solid solution formation, the concentration of impurity in the liquid phase at any temperature during the melting is inversely proportional to the fraction melted at that temperature, and the melting-point depression is directly proportional to the mole fraction of impurity. A plot of the observed test specimen temperature, $T_s$, versus the reciprocal of the fraction melted, 1/F, at temperature $T_s$, should yield a straight line with the slope equal to the melting-point depression ($T_o - T_m$). The theoretical melting point of the pure compound is obtained by extrapolation to 1/F = 0:

$$T_S = T_o - \frac{RT_o^2 X_2 (1/F)}{\Delta H_f} \quad (3)$$

DocId: GUID-F8E49188-1329-4A1E-9BB3-45F85D6623C3_2_en-US
@2024 USPC
DOI: https://doi.org/10.31003/USPNF_M99680_02_01

Substituting the experimentally obtained values for $T_o - T_m$, $\Delta H_f$, and $T_o$ in equation (2) yields the mole fraction of the total eutectic impurity, which, when multiplied by 100, gives the mole percentage of total eutectic impurities.

Deviations from the theoretical linear plot also may be due to solid solution formation ($K_D \neq 0$), so that care must be taken in interpreting the data.

To observe the linear effect of the impurity concentration on the melting-point depression, the impurity must be *soluble* in the liquid phase or melt of the compound, but *insoluble* in the solid phase, i.e., no solid solutions are formed. Some chemical similarities are necessary for solubility in the melt. For example, the presence of ionic compounds in neutral organic compounds and the occurrence of thermal decomposition may not be reflected in purity estimates. The extent of these theoretical limitations has been only partially explored.

Impurities present from the synthetic route often are similar to the end product, hence there usually is no problem of solubility in the melt. Impurities consisting of molecules of the same shape, size, and character as those of the major component can fit into the matrix of the major component without disruption of the lattice, forming solid solutions or inclusions; such impurities are not detectable by DSC. Purity estimates are too high in such cases. This is more common with less-ordered crystals as indicated by low heats of fusion.

In addition, the method is reliable when the purity of the major component is greater than 98.5 mol% and the materials are not decomposed during the melting phase.

Impurity levels calculated from thermograms are reproducible and generally reliable within 0.1% for ideal compounds.

Compounds that exist in polymorphic form cannot be used in purity determination unless the compound is completely converted to one form. On the other hand, DSC and DTA are inherently useful for detecting, and therefore monitoring, polymorphism.

## Procedure

The actual procedure and the calculations to be employed for eutectic impurity analysis are dependent on the particular instrument used. Consult the manufacturer's literature and/or the thermal analysis literature for the most appropriate technique for a given instrument. In any event, it is imperative to keep in mind the limitations of solid solution formation, insolubility in the melt, polymorphism, and decomposition during the analysis.

# ▲⟨901⟩ DETECTION OF ASBESTOS IN PHARMACEUTICAL TALC

To view the Notice from the Expert Committee that posted in conjunction with this chapter, please click https://www.uspnf.com/notices/talc-official-dates-20230601.

This chapter provides procedures to detect the presence of asbestos in pharmaceutical talc using the analytical procedures of X-ray diffraction (XRD)—also termed X-ray powder diffraction (XRPD)—coupled with polarized light microscopy (PLM). Both *Procedure 1: X-Ray Diffraction* and *Procedure 2: Polarized Light Microscopy* are mandatory. For supporting information on the best practices and principles of measurements, see *Theory and Practice of Asbestos Detection in Pharmaceutical Talc* ⟨1901⟩.

## Procedure 1: X-Ray Diffraction

### INTRODUCTION

XRD is used to determine whether amphibole and/or serpentine minerals are present in a talc powder matrix and, when applicable, to estimate the percentage present. It is intended to be used in combination with a microscopy technique capable of determining whether asbestos is present. [NOTE—For additional information, see *Characterization of Crystalline and Partially Crystalline Solids by X-Ray Powder Diffraction (XRPD)* ⟨941⟩.]

With regard to sampling and subsampling, see *Bulk Powder Sampling Procedures* ⟨1097⟩.

### SAMPLE PREPARATION

Using the sample holders provided by the XRD manufacturer, fill the cavity using back-, front-, or side-filling techniques depending on the specific holder used. Be sure to use the same sample filling technique for reference standards (if used) and the samples being tested.

### SAMPLE ANALYSIS (QUALITATIVE AND QUANTITATIVE SCANS)

Qualitative scans are used to assess overall mineralogy (see ⟨1901⟩ for a list of peak positions for common minerals that may occur with talc). Quantitative scans are used to determine the presence of trace levels of amphibole and serpentine minerals (above minimum detection limits).

The following conventional XRD instrument conditions and parameters can be used to determine the detection limits outlined below.

- *X-ray tube voltage:* 45–50 kilovolts
- *X-ray tube current:* 30–45 milliamperes (consult tube manufacturer recommendations; do not exceed tube rating)
- *Target:* copper
- *Monochromator:* graphite or multilayer (tungsten/silicon, nickel/carbon, or similar); curved or flat diffracted or primary beam
- *Detector:* scintillation counter or alternative high-speed detector
- *Receiving slit:* 0.6 or 0.3 mm, none if using a high-speed detector
- *Scintillation or anti-scatter slit:* 1° or matched to the size of the high-speed detector
- *Divergent height-limiting slit or beam mask:* 10 mm
- *Divergent slit:* 1°, or smaller to ensure no sample overshoot
- *Scan mode:* fixed time (FT)
- *Single-stage or multi-position sample changer attachment*
- *Spin speed of sample:* 30 or 60 rpm

Any variation due to vendor limitations should be noted and used for samples, references, and standards. Additionally, use of high-speed detectors can permit much less analysis time for qualitative and quantitative testing. For example, a full qualitative scan from 3°–85° 2-theta (2θ) can be done in fewer than 35–40 min, and a quantitative evaluation for amphibole and serpentine can be accomplished within 2–3 h. *Table 1* outlines the target peak positions and scan ranges for XRD scans.

**Table 1. Target Peak Positions and Scan Ranges for Qualitative and Quantitative XRD Scans**

| Scan Type | Target Phase(s) | Target Peak(s) (2-Theta) | Start Angle (2-Theta) | End Angle (2-Theta) | Step Size (2-Theta) | Count Time per Step(s) |
|---|---|---|---|---|---|---|
| Qualitative scan | All (full scan) | All | 3 | 65 (minimum) | 0.02 | 2 |
| Quantitative scans | Amphibole[a] | 10.5<br>10.7 | 9.8 | 11.2 | 0.02 | 100 |
| | Serpentine<br>Chlorite | 12.1<br>12.5 | 11 | 13.2 | 0.02 | 100 |
| | Serpentine<br>Chlorite | 24.4<br>25.1 | 23.5 | 25.6 | 0.02 | 100 |
| | Orthorhombic amphibole (optional) | 29.3 | 28.8 | 29.8 | 0.02 | 100 |

[a] Both monoclinic (e.g., tremolite) and orthorhombic (e.g., anthophyllite) amphiboles are included in this scan and can be distinguished from each other. Monoclinic amphibole species may not necessarily be distinguished from each other at the trace level.

### LIMIT OF DETECTION AND QUANTIFICATION

Detection limits were verified using 0.25% spiked standards and the instrument conditions outlined above.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M16455_02_01

@2024 USPC

Limit of detection for:

- Amphiboles (tremolite and anthophyllite): 0.2%
- Serpentine with no chlorite interference: 0.2%
- Serpentine with 1% chlorite interference: 0.5%
- Serpentine with >1% to 15%–20% chlorite interference: 1%, with resolution of the two phases confirmed using a 2θ range of 23.5–25.6

A detection limit of 0.1% has also been achieved using this method; however, use of lower limits will need to be verified by individual labs using a 0.1% spiked standard.

[NOTE—See more information in ⟨1901⟩.]

**REPORTING RESULTS**

- If no detectable peak is present for monoclinic or orthorhombic amphiboles (tremolite or anthophyllite), then report "amphibole not detected (<0.2%)".
- If no detectable peak is present for serpentine without a chlorite interference, then report "serpentine not detected (<0.2%)".
- If no detectable peak is present for serpentine with 1%–15% chlorite interference, then report "serpentine not detected (<1%)".
- If a peak is present for serpentine, then report "serpentine detected".
- If a peak is present for an amphibole, then report the type, i.e., "monoclinic amphibole detected" or "orthorhombic amphibole detected".

[NOTE—Alternative detection limits can be determined and reported using operating parameters at individual laboratories.]

Only report the detected and not detected result limit, not the quantitative result.

[NOTE—The limits are based on limits of detection.]

## Procedure 2: Polarized Light Microscopy

**INTRODUCTION**

This procedure uses PLM to identify asbestos particles in a talc powder matrix. It is intended to be used with *Procedure 1* as a complementary microscopy technique. Both *Procedure 1* and *Procedure 2* are mandatory.

**CONCENTRATION USING WET SIEVING**

Concentration of asbestos using the wet sieving technique has been found to be effective for PLM analysis (see supporting information in ⟨1901⟩). Use 76-mm (3-inch) sieves, precleaned in a beaker filled with detergent and water in a sonic bath for 15 min. Rinse thoroughly with deionized water.

1. Measure approximately 2 g of talc powder into a 100-mL plastic bottle with a removable lid.
2. Because talc is hydrophobic, wet the powder completely with isopropyl alcohol (IPA), then fill three quarters full of deionized water (approximately 75 mL total); shake vigorously for 30 s.
3. Slowly pour the suspension onto a 400-mesh (37-µm) sieve. The passing fraction should be collected and disposed of properly according to local regulations. Work in batches, alternately rinsing with water or IPA (if foaming) to avoid screen blinding. Optimal rinsing is accomplished by using a standard kitchen sink sprayer or by squeezing the end of a flexible hose attached to the faucet. In either case, water should be set to deliver a gentle spray to avoid splash back.
4. Repeatedly fill the plastic suspension bottle with water and IPA (if foaming) and replace the lid. Shake and pour onto the sieve until the bottle is washed clean.
5. Continue rinsing the sieve under gentle pressure until the water passing through appears clear. [NOTE—A very small amount of residue should be visible by eye, but continuously sprayed water should pass through the screen unimpeded. The optimum amount of residue retained on the screen can be determined by eye with experience.]
6. Rinse the residue from the screen using a squirt bottle with particle-free water into a tared small aluminum pan or glass dish for drying. Dry the sample by air or use an oven at 105°–110°.
7. Once dry, weigh the residue. The objective is to obtain 0.05–0.1 g of residue for subsequent sampling by PLM.
8. If less than 0.05 g is collected from the 400-mesh (37-µm) sieve using 2 g of starting material, one of the following procedures should be used:
   A. Repeat the above until at least 0.05 g is collected for analysis.
   B. Repeat the above using a greater amount of starting material. [NOTE—A 254-mm (10-inch) sieve could be used with up to 100 g of starting material weighed into a 1000-mL bottle.]
   C. Repeat the above using a finer mesh sieve.
9. Sieves should be cleaned and maintained in accordance with manufacturer's recommendations and/or instructions, or disposable sieves can be used. Use of any sieve size other than aforementioned should be validated following *General Notices 6.30. Alternative and Harmonized Methods and Procedures*.

**SAMPLE PREPARATION OF SIEVED RESIDUE**

1. Place a known amount of talc from the sieved residue on a glass slide so that particles cover 30%–50% of the area under the slide. This can be accomplished by taring a lab scale with the glass slide before adding an appropriate amount of sample.
2. Add 1 or 2 drops of refractive index (RI) liquid to the powder (see *Sample Analysis* for use of RI liquids). Swirl with a cleaned metal probe to distribute particles.
3. Place a coverslip on the sample, and, if needed, use a pencil eraser (or equivalent soft-tipped tool) to press gently on the coverslip to remove air bubbles and better disperse the particles.

[NOTE—It may take some trial and error to obtain the optimal loading and starting sample weight. A minimum of 5 mg should be analyzed in total for each RI liquid used. This typically equates to 3–5 slide preparations with 1–2 mg each, using 22-mm × 22-mm square coverslips. Adjust as necessary.]

**SAMPLE ANALYSIS**

**Screen particles using the dispersion staining technique**

1. Configure the microscope in dispersion staining mode [i.e., plane-polarized light (PPL), no condenser lens, centered dispersion staining objective].
   - Confirm that the microscope is set up and aligned properly by obtaining dispersion staining colors on prepared standards of amphibole and chrysotile asbestos before analyzing unknown material.
2. Prepare microscope slides (number determined by the weight of sample on each) in 1.550 and 1.605 RI liquids.
3. Scan each slide in its entirety in an orthogonal fashion in dispersion staining mode, characterizing any suspect particles (see explanation below).
   - Use a mechanical stage to aid in the scanning process.
   - If particles are brought to the center of the field of view for characterization or the stage is rotated during the course of documentation, be sure to return the particle to its original location and orientation before resuming the scan.
4. Observe any suspect particles of amphibole and chrysotile, which will display low relief and dispersion staining colors, as referenced in the International Organization for Standardization's ISO 22262-1 (2012), when immersed in 1.605 and 1.550 RI liquids, respectively (summarized below and in *Table 2*). The appropriate dispersion staining colors are determined when the axis of elongation of the particle is oriented parallel to the lower polarizer (*n*-parallel) and perpendicular to the lower polarizer (*n*-perpendicular) in a standard PLM configuration.
   - 1.550 RI liquid
     - Talc plates lying flat (with their plate surface parallel to the microscope slide) will appear pale yellow during the full rotation of the stage.
     - Chrysotile particles will appear magenta (*n*-parallel) and blue (*n*-perpendicular).
     - Elongate talc particles can appear yellow (*n*-parallel) to blue (*n*-perpendicular). Rotating the stage to observe the yellow color in 1.550 RI liquid will distinguish elongate talc from chrysotile.
   - 1.605 RI liquid
     - Talc plates lying flat (with their plate surface parallel to the microscope slide) will appear pale blue during the full rotation of the stage.
     - Elongate amphibole particles will appear characteristically yellow to pale yellow (*n*-parallel).
     - For *n*-perpendicular, amphiboles can range in color from blue or magenta (tremolite) to golden yellow or yellow (actinolite or anthophyllite).
     - Amphibole particles have a lower relief in the *n*-perpendicular orientation, and the darker dispersion staining colors may be more difficult to see. If this is the case, rotating the stage should reveal the characteristic yellow color (*n*-parallel).
     - Carbonate particles in 1.605 RI liquid can also appear yellow in certain orientations. These particles can be distinguished by their high birefringence. Alternatively, pretreating the sample with 2 M hydrochloric acid will remove carbonate particles with interfering yellow color (refer to ISO 22262-2 for details).

   Typical central stop dispersion staining colors with corresponding $\lambda_0$ in nanometers are observed for talc and amphibole minerals in various Cargille Series E liquids for both parallel and perpendicular directions. The range of colors and $\lambda_0$ are a function of compositional variation for amphiboles in the compositional space for the stated amphibole (e.g., anthophyllite) taken from reported ranges of refractive indices. See ⟨1901⟩.

**Table 2. Typical Color of Particles in Dispersion Staining Mode**

| Name | RI Liquid for Screening | Dispersion Color[a] | |
|---|---|---|---|
| | | ***n*-parallel (approximate wavelengths, nm)** | ***n*-perpendicular (approximate wavelengths, nm)** |
| Talc plates | 1.550 | Pale yellow (≤400) | Pale yellow (≤400) |
| Talc plates (edge view) | 1.550 | Pale yellow (≤400) | Blue–green to light blue–green (≥620) |
| Chrysotile | 1.550 | Orange to blue–green (480–620) | Blue to light blue–green (580–680) |
| Talc plates | 1.605 | Pale blue (≥800) | Pale blue (≥800) |
| Talc plates (edge view) | 1.605 | Pale blue (≥800) | White (≥1000) |
| Tremolite | 1.605 | Pale yellow to yellow (≤400) | Magenta to blue–green (520–620) |

**Table 2. Typical Color of Particles in Dispersion Staining Mode** *(continued)*

| Name | RI Liquid for Screening | Dispersion Color[a] | |
|---|---|---|---|
| | | ***n*-parallel (approximate wavelengths, nm)** | ***n*-perpendicular (approximate wavelengths, nm)** |
| Actinolite | 1.605 | White to pale yellow (≤400) | Pale yellow to yellow (≤400–450) |
| Anthophyllite | 1.605 | White to orange–magenta (≤300–500) | White to light blue–green (≥640) |
| Tremolite | 1.615 | Pale yellow to golden yellow (400–460) | Blue–green to pale blue–green (620–780) |
| Actinolite | 1.615 | White to pale yellow (≤400) | Pale yellow to magenta–purple (400–540) |
| Anthophyllite | 1.615 | White to blue–green (≤620) | Yellow to white (≥420) |
| Tremolite | 1.620 | Yellow to orange–magenta (440–500) | Pale blue–green (≥700) |
| Actinolite | 1.620 | Pale yellow to yellow (≤420) | Yellow to blue (420–590) |
| Anthophyllite | 1.620 | Pale yellow to blue–green (≤620) | Pale yellow to pale blue–green (≤400 to ≥800) |
| Tremolite | 1.635 | Magenta–purple to light blue–green (540–660) | Pale blue–green to white (≥800) |
| Actinolite | 1.635 | Pale yellow to magenta (≤540) | Magenta to pale blue–green (520–800) |
| Anthophyllite | 1.635 | Pale yellow to pale blue–green (≤400 to ≥1000) | Pale yellow to white (≤400 to ≥1000) |
| Tremolite | 1.640 | Blue to pale blue–green (580–760) | White (≥1000) |
| Actinolite | 1.640 | Pale yellow to blue–green (400–600) | Blue to pale blue–green (580 to ≥800 ) |
| Anthophyllite | 1.640 | Pale yellow to pale blue–green (≤400 to ≥800) | Yellow to pale blue–green (420 to ≥800) |

[a] Dispersion colors may vary between microscopes and microscopists. Colors given in printed lists may not correspond to those seen in a particular microscope system. Use of specific matching liquids with freshly mounted standards by the analyst should be used for direct color reference.

5. Rotate the slide 90° and scan the entire slide again, so that any amphibole particles showing colors that are more difficult to see (and possibly missed) in the perpendicular orientation may be more visible in the opposite orientation.
6. For any suspect amphibole particle encountered, confirm that RIs in both *n*-parallel and *n*-perpendicular orientations are greater than the 1.605 RI liquid using the Becke line technique. With the following exception, all amphibole RIs are higher than 1.605, while all talc RIs are lower than 1.605.
    - For the rare case where a specific orientation of low-iron anthophyllite indicates an RI slightly below 1.605, rotating the microscope stage or "tapping" the coverslip with a probe so that the particle rolls around its longitudinal axis will confirm the presence of RIs higher than 1.605, thereby distinguishing a possible amphibole particle from a talc particle. Also, the difference in the alpha prime (α′) RI and the 1.605 liquid will still be close enough to provide a measurable dispersion staining color for determination of $n_D$ (the standard refractive index at the "D" Fraunhofer line of approximately 589 nm).
    - With the Becke line technique, the bright white (or light) Becke line moves into the material (either the particle or the surrounding liquid) that has the higher relative RI during defocusing in the down direction (i.e., when increasing the distance between the objective and the sample). The opposite is true for defocusing in the up direction (i.e., the bright white or lighter colored Becke line moves into the material that has the lower relative RI when decreasing the distance between the objective and the sample). It is often helpful to observe both defocusing conditions to confirm the movement of the Becke lines. Where the RI of the particle and liquid are close enough to observe dispersion, the Becke lines become colored.
7. Document the following optical properties of any confirmed suspect particles (determined using a combination of illumination conditions and magnifications between 100× and 400×):
    - *Morphology and aspect ratio*—observed in all illumination conditions
        - Examples: straight, curved, bundle, wavy, splayed ends, polyfilamentous, etc.
    - *Color and pleochroism*—observed in PPL
    - *Extinction angle and characteristics*—observed in cross-polarized light (XPL)

@2024 USPC

- Inclined extinction may be indicative of monoclinic amphibole. Anthophyllite (orthorhombic amphibole) always has parallel extinction; however, asbestiform amphibole can have anomalous parallel extinction for all types.

- *Sign of elongation*—observed in XPL with first-order wave plate (RPL) inserted
  - Typically, positive for amphibole and chrysotile (blue in orientation parallel to the slow direction of the first-order wave plate and yellow in orientation perpendicular to the slow direction of the first-order wave plate). Crocidolite/riebeckite (not commonly associated with talc) has a negative sign of elongation, where these colors occur in opposite directions.
- *Refractive index (RI)*—observed in dispersion staining mode and in PPL using the Becke line method. In 1.550 and 1.605 RI liquids, indicate if the RI of the particle is higher, lower, or a close match in both *n*-parallel and *n*-perpendicular orientations. For a more precise match, use additional RI liquids. For determination of RIs, proceed as follows:
  A. Use the appropriate RI liquids to determine the RIs of suspect particles encountered and use *Table 2* as a guide.
  B. Qualitatively determine a match of RI using dispersion staining colors and/or Becke lines. (See ⟨1901⟩ for more information about quantitatively determining wavelength of match). The following conditions indicate a close match between particle and liquid: deep blue and magenta dispersion staining colors, colored Becke lines, and low particle relief (particles appear to disappear in plane-polarized light). Light blue and yellow colors in dispersion staining mode can indicate a greater difference between particle and liquid than colored Becke lines. Additional RI liquids may be needed to evaluate a match.
  C. Correlating RI to wavelength of match can also be completed (see ⟨1901⟩). [NOTE—Confirm observed colors with known minerals under the operational conditions at the observation temperature.]
  D. Where monoclinic amphibole is suspected from optical properties, document "monoclinic amphibole". Where orthorhombic amphibole is probable, document "orthorhombic amphibole".
  E. If ambiguity still exists after this analysis, scanning electron microscopy (SEM) with energy dispersive X-ray spectroscopy (EDS) or transmission electron microscopy (TEM) with EDS should be used to determine the elemental composition; TEM with selected area electron diffraction can be used to confirm if a phase is amphibole and establish if it is orthorhombic or monoclinic. Optionally, a heating and cooling stage can be used to vary the RI liquid values to more precisely determine matching indices of the phases analyzed. For more information, see ⟨1901⟩.
- *Birefringence*—Report the difference in the maximum and minimum observed RI of a suspect particle type.

8. Use the definition below to evaluate all of the particles documented to determine if presence of asbestiform amphibole or serpentine is indicated. [The definition of "asbestiform" for this method is taken from the Glossary section of EPA 600/R-93/116 (emphasis in original).]
"Asbestiform (morphology)—Said of a mineral that is like asbestos, i.e., crystallized with the habit of asbestos. Some asbestiform minerals may lack the properties which make asbestos commercially valuable, such as long fiber length and high tensile strength. With the light microscope, the asbestiform habit is generally recognized by the following characteristics:
   - Mean aspect ratios ranging from 20:1 to 100:1 or higher for fibers longer than 5 µm. Aspect ratios should be determined for fibers, not bundles.
   - Very thin fibrils, usually less than 0.5 micrometers in width, and
   - Two or more of the following:
     - Parallel fibers occurring in bundles,
     - Fiber bundles displaying splayed ends,
     - Matted masses of individual fibers, and/or
     - Fibers showing curvature

   These characteristics refer to the population of fibers as observed in a bulk sample. It is not unusual to observe occasional particles having aspect ratios of 10:1 or less, but it is unlikely that the asbestos component(s) would be dominated by particles (individual fibers) having aspect ratios of <20:1 for fibers longer than 5 µm. If a sample contains a fibrous component of which most of the fibers have aspect ratios of <20:1 and that do not display the additional asbestiform characteristics, by definition the component should not be considered asbestos."

[NOTE—This definition of asbestiform is appropriate for light microscopy, including phase contrast and polarized light microscopy. However, it is not generally extendable to fibrils visible in the transmission electron microscope.]

**LIMIT OF DETECTION AND QUANTIFICATION**

The working detection limit of this method is 0.01% weight percentage, 100 ppm by weight (µg/g) established via a round robin study of spiked reference materials.

[NOTE—See more information in ⟨1901⟩.]

**REPORTING RESULTS**

1. All amphibole or serpentine particles must be documented via a digital image capturing system attached to the microscope. The following images should be collected for each particle (if an image cannot be obtained, note this as well):
    - Dispersion staining and/or Becke line color with the fiber oriented parallel to the polarizer
    - Dispersion staining and/or Becke line color with the fiber oriented perpendicular to the polarizer
    - Sign of elongation with the fiber oriented parallel to the slow vibration direction of the first-order wave plate under crossed polarizers
    - Optional: additional images to show morphology (microscope in any configuration)
    - Optional: image(s) showing the extinction angle (inclined versus parallel) to supplement the documented angle (a cross-polarized image taken with first-order wave plate at extinction)
2. The final report should include:
    - Number of particles found
    - Length and width for the individual particles
    - Digital images or photographs of each particle (especially those of bundles or other unique features of asbestos)
    - Either an assessment of “detected” or “not detected” of asbestos with the detection limit of 0.01% weight percentage or 100 ppm by weight (µg/g)
3. If a single particle is observed in an analysis of 5 mg, analysis of an additional 5 mg of the originally received material is required. If the additional analysis results in 1 or fewer particles, report the result as below the detection limit of <0.01% weight percentage or <100 ppm by weight (µg/g). [NOTE—For this method, the typical number of particles found at 100 ppm is 8–16 particles when approximately 2 mg of material is tested.]
4. A single particle, even if conclusively identified as asbestos, is not sufficient to constitute a positive finding as it cannot be proven to be different from contamination. More than 1 particle with conclusive identification (e.g., 2 particles) is necessary to constitute a positive identification. All results with fewer than 2 confirmed asbestos fibers are reported as below the detection limit of <0.01% weight percentage or <100 ppm by weight (µg/g).
5. Determination of the type of amphibole asbestos (i.e., tremolite, actinolite, or anthophyllite) is not required; results will be reported simply as “chrysotile detected” or “amphibole asbestos detected”. Further clarification of the amphibole asbestos type can be achieved using EDS elemental analysis with an electron microscope.

[NOTE—The limits are based on limits of detection.▲ (USP 1-Dec-2023)]

# ⟨905⟩ UNIFORMITY OF DOSAGE UNITS

***Change to read:***

This general chapter is harmonized with the corresponding texts of the *European Pharmacopoeia* and the *Japanese Pharmacopoeia*. Portions of the general chapter text that are national *USP* text, and are not part of the harmonized text, are marked with symbols (•,) to specify this fact.

[NOTE—In this chapter, *unit* and *dosage unit* are synonymous.•,]

To ensure the consistency of dosage units, each unit in a batch should have a drug substance content within a narrow range around the label claim. Dosage units are defined as dosage forms containing a single dose or a part of a dose of drug substance in each unit. The uniformity of dosage units specification is not intended to apply to ▲solutions,▲ (USP 1-Aug-2023) suspensions, emulsions, or gels in unit-dose containers intended for ▲local action following▲ (USP 1-Aug-2023) external, cutaneous administration.

The term "uniformity of dosage unit" is defined as the degree of uniformity in the amount of the drug substance among dosage units. Therefore, the requirements of this chapter apply to each drug substance being comprised in dosage units containing one or more drug substances, unless otherwise specified elsewhere in this Pharmacopeia.

The uniformity of dosage units can be demonstrated by either of two methods, *Content Uniformity* or •*Weight*•,*Variation* (see *Table 1*). The test for *Content Uniformity* of preparations presented in dosage units is based on the assay of the individual content of drug substance(s) in a number of dosage units to determine whether the individual content is within the limits set. The *Content Uniformity* method may be applied in all cases.

The test for •*Weight*•,*Variation* is applicable for the following dosage forms:

| | |
|---|---|
| (W1) | Solutions enclosed in unit-dose containers and into soft capsules; |
| (W2) | Solids (including powders, granules, and sterile solids) that are packaged in single-unit containers and contain no active or inactive added substances; |
| (W3) | Solids (including sterile solids) that are packaged in single-unit containers, with or without active or inactive added substances, that have been prepared from true solutions and freeze-dried in the final containers and are labeled to indicate this method of preparation; and |
| (W4) | Hard capsules, uncoated tablets, or film-coated tablets, containing 25 mg or more of a drug substance comprising 25% or more, by weight, of the dosage unit or, in the case of hard capsules, the capsule contents, except that uniformity of other drug substances present in lesser proportions is demonstrated by meeting the requirements for *Content Uniformity*. |

The test for *Content Uniformity* is required for all dosage forms not meeting the above conditions for the •*Weight*•,*Variation* test.[1]

**Table 1. Application of Content Uniformity (CU) and Weight Variation (WV) Tests for Dosage Forms**

| Dosage Form | Type | Subtype | Dose & Ratio of Drug Substance | |
|---|---|---|---|---|
| | | | ≥25 mg and ≥25% | <25 mg or <25% |
| Tablets | Uncoated | — | WV | CU |
| | Coated | Film | WV | CU |
| | | Others | CU | CU |
| Capsules | Hard | — | WV | CU |
| | Soft | Suspension, emulsion, or gel | CU | CU |
| | | Solutions | WV | WV |
| Solids in single-unit containers | Single component | — | WV | WV |
| | Multiple components | Solution freeze-dried in final container | WV | WV |
| | | Others | CU | CU |
| Solutions in unit-dose containers •and into soft capsules• | — | — | WV | WV |
| Others▲[a] ▲ (USP 1-Aug-2023) | — | — | CU | CU |

[1] •European Pharmacopoeia and Japanese Pharmacopoeia text not accepted by the United States Pharmacopeia: Alternatively, products listed in item (4) above that do not meet the 25 mg/25% threshold limit may be tested for uniformity of dosage units by Mass Variation instead of the Content Uniformity test if the concentration relative standard deviation (RSD) of the drug substance in the final dosage units is not more than 2%, based on process validation data and development data, and if there has been regulatory approval of such a change. The concentration RSD is the RSD of the concentration per dosage unit (w/w or w/v), where concentration per dosage unit equals the assay result per dosage unit divided by the individual dosage unit weight. See the RSD formula in *Table 2*.•,

[a] Dosage forms not addressed by the other categories in this table including but not limited to suppositories, transdermal systems (patches), and semisolid preparations applied cutaneously and intended for systemic distribution of the drug substance.

## CONTENT UNIFORMITY

Select not fewer than 30 units, and proceed as follows for the dosage form designated.

Where different procedures are used for assay of the preparation and for the *Content Uniformity* test, it may be necessary to establish a correction factor to be applied to the results of the latter.

### Solid Dosage Forms

Assay 10 units individually using an appropriate analytical method. Calculate the acceptance value (see *Table 2*).

### Liquid or Semi-Solid Dosage Forms

Assay 10 units individually using an appropriate analytical method. Carry out the assay on the amount of well-mixed material that is removed from an individual container in conditions of normal use, and express the results as delivered dose. Calculate the acceptance value (see *Table 2*).

### Calculation of Acceptance Value

Calculate the acceptance value by the formula:

$$|M - \overline{X}| + ks$$

in which the terms are as defined in *Table 2*.

**Table 2**

| Variable | Definition | Conditions | Value |
|---|---|---|---|
| $\overline{X}$ | Mean of individual contents ($\chi_1$, $\chi_2$, …, $\chi_n$), expressed as a percentage of the label claim | — | — |
| $\chi_1$, $\chi_2$, …, $\chi_n$ | Individual contents of the units tested, expressed as a percentage of the label claim | — | — |
| n | Sample size (number of units in a sample) | — | — |
| k | Acceptability constant | If n = 10, then k = | 2.4 |
| | | If n = 30, then k = | 2.0 |
| s | Sample standard deviation | — | $\left[\frac{\sum_{i=1}^{n}(\chi_i - \overline{X})^2}{n-1}\right]^{\frac{1}{2}}$ |
| RSD | Relative standard deviation (the sample standard deviation expressed as a percentage of the mean) | — | $100s/\overline{X}$ |
| M (case 1) to be applied when T ≤101.5 | Reference value | If 98.5% ≤$\overline{X}$ ≤101.5%, then | M = $\overline{X}$ (AV = ks) |
| | | If $\overline{X}$ <98.5%, then | M = 98.5% (AV = 98.5 – $\overline{X}$ + ks) |
| | | If $\overline{X}$ >101.5%, then | M = 101.5% (AV = $\overline{X}$ – 101.5 + ks) |
| M (case 2) to be applied when T >101.5 | Reference value | If 98.5 ≤$\overline{X}$ ≤T, then | M = $\overline{X}$ (AV = ks) |
| | | If $\overline{X}$ <98.5%, then | M = 98.5% (AV = 98.5 – $\overline{X}$ + ks) |
| | | If $\overline{X}$ >T, then | M = T% (AV = $\overline{X}$ – T + ks) |

**Table 2** *(continued)*

| Variable | Definition | Conditions | Value |
|---|---|---|---|
| Acceptance value (AV) | — | — | General formula: $\lvert M - \bar{X} \rvert + ks$ (Calculations are specified above for the different cases.) |
| L1 | Maximum allowed acceptance value | — | L1 = 15.0 unless otherwise specified |
| L2 | Maximum allowed range for deviation of each dosage unit tested from the calculated value of M | On the low side, no dosage unit result can be less than [1–(0.01)(L2)]M, while on the high side, no dosage unit result can be greater than [1 + (0.01)(L2)]M. (This is based on an L2 value of 25.0.) | L2 = 25.0 unless otherwise specified |
| T | Target content per dosage unit at the time of manufacture, expressed as a percentage of the label claim. Unless otherwise stated, T is 100.0%, or T is the manufacturer's approved target content per dosage unit. | — | — |

## ⋆WEIGHT⋆ VARIATION

Carry out an assay for the drug substance(s) on a representative sample of the batch using an appropriate analytical method. This value is result A, expressed as percentage of label claim (see *Calculation of Acceptance Value*). Assume that the concentration (weight of drug substance per weight of dosage unit) is uniform. Select not fewer than 30 dosage units, and proceed as follows for the dosage form designated.

### Uncoated or Film-Coated Tablets

Accurately weigh 10 tablets individually. Calculate the content, expressed as percentage of label claim, of each tablet from the ⋆weight⋆ of the individual tablet and the result of the *Assay*. Calculate the acceptance value.

### Hard Capsules

Accurately weigh 10 capsules individually, taking care to preserve the identity of each capsule. Remove the contents of each capsule by a suitable means. Accurately weigh the emptied shells individually, and calculate for each capsule the net ⋆weight⋆ of its contents by subtracting the ⋆weight⋆ of the shell from the respective gross ⋆weight⋆. Calculate the drug substance content of each capsule from the ⋆net weight⋆ of the individual capsule ⋆content⋆ and the result of the *Assay*. Calculate the acceptance value.

### Soft Capsules

Accurately weigh 10 intact capsules individually to obtain their gross ⋆weights⋆, taking care to preserve the identity of each capsule. Then cut open the capsules by means of a suitable clean, dry cutting instrument such as scissors or a sharp open blade, and remove the contents by washing with a suitable solvent. Allow the occluded solvent to evaporate from the shells at room temperature over a period of about 30 minutes, taking precautions to avoid uptake or loss of moisture. Weigh the individual shells, and calculate the net contents. Calculate the drug substance content in each capsule from the ⋆weight⋆ of product removed from the individual capsules and the result of the *Assay*. Calculate the acceptance value.

### Solid Dosage Forms Other Than Tablets and Capsules

Proceed as directed for *Hard Capsules*, treating each unit as described therein. Calculate the acceptance value.

### Liquid Dosage Forms

Accurately weigh the amount of liquid that is removed from each of 10 individual containers in conditions of normal use. If necessary, compute the equivalent volume after determining the density. Calculate the drug substance content in each container from the mass of product removed from the individual containers and the result of the *Assay*. Calculate the acceptance value.

### Calculation of Acceptance Value

Calculate the acceptance value as shown in *Content Uniformity*, except that the individual contents of the units are replaced with the individual estimated contents defined below.

Official

https://pharmacopeia.cn/v-prod/

$\chi_1, \chi_2, \ldots, \chi_n$ = individual estimated contents of the units tested, where $\chi_i = w_i \times A/\overline{W}$
$w_1, w_2, \ldots, w_n$ = individual ⋆weights⋆ of the units tested
$A$ = content of drug substance (% of label claim) obtained using an appropriate analytical method
$\overline{W}$ = mean of individual ⋆weights⋆ $(w_1, w_2, \ldots, w_n)$

## CRITERIA

Apply the following criteria, unless otherwise specified.

### Solid, Semi-Solid, and Liquid Dosage Forms

The requirements for dosage uniformity are met if the acceptance value of the first 10 dosage units is less than or equal to L1%. If the acceptance value is > L1%, test the next 20 units, and calculate the acceptance value. The requirements are met if the final acceptance value of the 30 dosage units is ≤ L1%, and no individual content of ⋆any⋆ dosage unit is less than [1 – (0.01)(L2)]M nor more than [1 + (0.01)(L2)]M ⋆as specified⋆ in the *Calculation of Acceptance Value* under *Content Uniformity* or under ⋆*Weight⋆ *Variation*. Unless otherwise specified, L1 is 15.0 and L2 is 25.0.

# ⟨911⟩ VISCOSITY—CAPILLARY METHODS

The following procedures are used to determine the viscosity of a Newtonian fluid, i.e., a fluid having a viscosity that is independent of the rate of shear. [NOTE—For additional information, see *Rheometry* ⟨1911⟩.]

- **METHOD I. SUSPENDED-LEVEL (OR UBBELOHDE-TYPE) CAPILLARY VISCOMETER**

**Apparatus:** The determination may be carried out with a suspended-level capillary viscometer (*Figure 1*).

@2024 USPC

Other viscometers may be used provided that the accuracy and precision is NLT that obtained with the viscometers described in this chapter.

**Procedure:** Fill the viscometer through tube (L) with a sufficient quantity of the sample liquid that is appropriate for the viscometer being used or by following the manufacturer's instructions. Carry out the experiment with the tube in a vertical position. Fill bulb (A) with the liquid, and also ensure that the level of liquid in bulb (B) is below the exit to the ventilation tube (M). Immerse the viscometer in a water or oil bath stabilized at the temperature specified in the individual monograph, and control the temperature to ±0.1°, unless otherwise specified in the individual monograph. Maintain the viscometer in a vertical position for a time period of NLT 30 min to allow the sample temperature to reach equilibrium. Close tube (M), and raise the level of the liquid in tube (N) to a level about 8 mm above mark ($E \equiv h_1$). Keep the liquid at this level by closing tube (N) and opening tube (M). Open tube (N), and measure the time required for the level of the liquid to drop from mark ($E \equiv h_1$) to mark ($F \equiv h_2$), using an appropriate accurate timing device. [NOTE—The minimum flow time should be 200 s.]

**Calibration:** Calibrate each viscometer at the test temperature by using fluids of known viscosities of appropriate viscosity standards to determine the viscometer constant, $k$. The viscosity values of the calibration standards should bracket the expected viscosity value of the sample liquid.

Calculate the viscometer constant, $k$, in $mm^2/s^2$:

$$k = \eta/(\rho \times t)$$

$\eta$ = known viscosity of the liquid (mPa · s)
$\rho$ = density of the liquid (g/mL)
$t$ = flow time for the liquid to pass from the upper mark to the lower mark (s)

**Calculation of kinematic and Newtonian viscosities of sample fluid:** A capillary viscometer is chosen so that the flow time, $t$, is NLT 200 s, and the kinematic energy correction is typically less than 1%. If the viscosity constant, $k$, is known, use the following equation to calculate the kinematic viscosity, $v$, in $mm^2/s$, from the flow time, $t$, in s.

$$v = k \times t$$

If the density of the fluid is known at the temperature of the viscosity measurement, then the Newtonian viscosity, $\eta$, in mPa · s, is calculated:

$$\eta = v \times \rho$$

$\rho$ = density of the fluid (g/mL)

The flow time of the fluid under examination is the mean of NLT three consecutive determinations. The result is valid if the percentage of the relative standard deviation (%RSD) for the three readings is NMT 2.0%.

- **METHOD II. SIMPLE U-TUBE (OR OSTWALD-TYPE) CAPILLARY VISCOMETER**

**Apparatus:** The determination may be carried out with a simple U-tube capillary viscometer (*Figure 2*).

DOI: https://doi.org/10.31003/USPNF_M99700_02_01
@2024 USPC

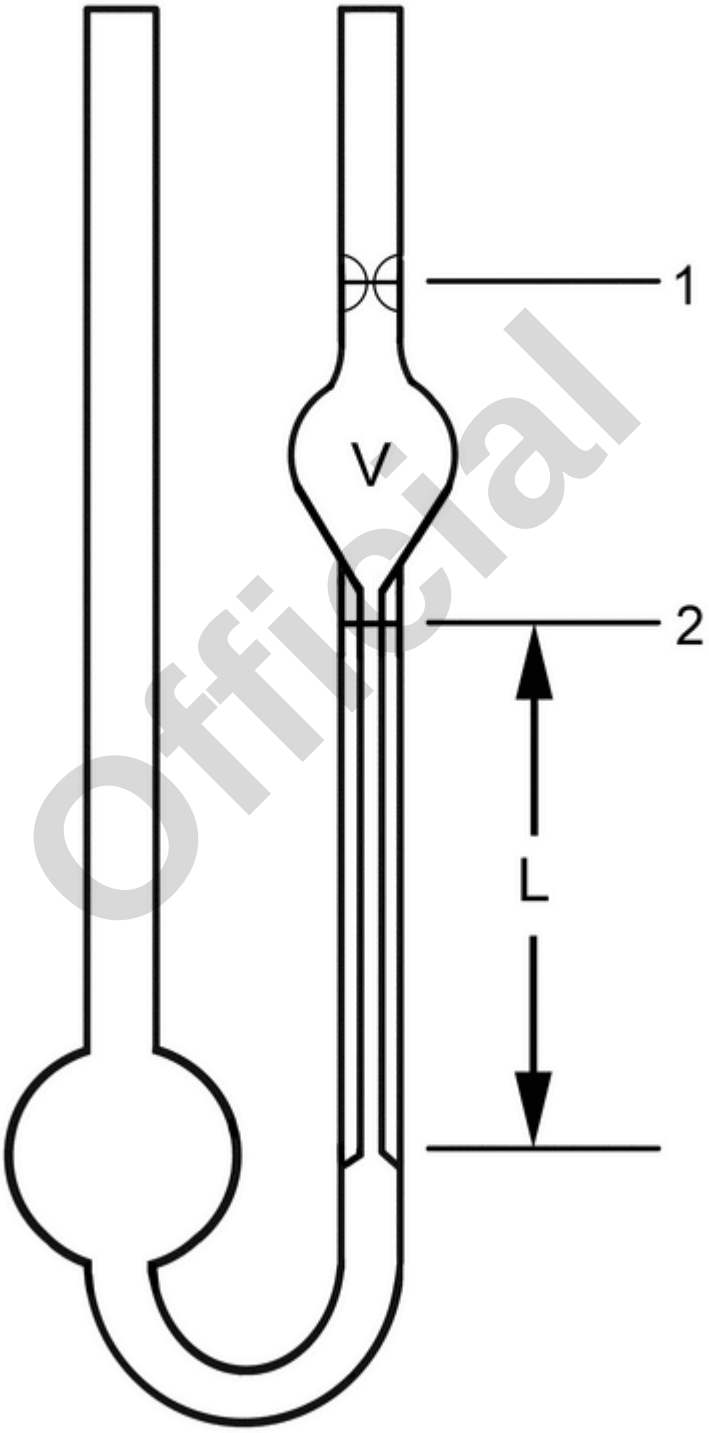

Figure 2. Simple U-tube (or Ostwald-type) capillary viscometer.

Variables and line numbers in *Figure 2* are defined as:

Official

https://pharmacopeia.com/

| | |
|---|---|
| Line 1 | = upper mark in the tube |
| $V$ | = given volume of fluid ($m^3$) |
| Line 2 | = lower mark in the tube |
| $L$ | = capillary tube length (m) |

Other viscometers, such as modified Ostwald-type capillary viscometers,[1] may be used provided that the accuracy and precision is NLT that obtained with the viscometers described in this chapter.

**Procedure:** Fill the tube with an amount of the sample that is appropriate for the viscometer being used or by following the manufacturer's instructions. The volume of fluid used should be such that the lower bulb is not entirely emptied when the fluid is drawn up through the capillary tube to the uppermost graduation mark. Carry out the experiment with the tube in a vertical position. Immerse the viscometer in a water or oil bath stabilized at the temperature specified in the individual monograph, and control the temperature to ±0.1°, unless otherwise specified in the individual monograph. Maintain the viscometer in a vertical position for a time period of NLT 30 min to allow the sample temperature to reach equilibrium. Using suction, draw the fluid up through the capillary tube until the meniscus is at the level of the uppermost graduation. With both the filling and capillary tubes open to atmospheric pressure, record the time, in s, required for the liquid to flow from the upper mark to the lower mark in the capillary tube. [NOTE—The minimum flow time should be 200 s.]

**Calibration** and **Calculation of kinematic and Newtonian viscosities of sample fluid:** Proceed as directed in *Method I*. For certain simple U-tube capillary viscometers, determine the viscometer constant at the same temperature as the sample liquid under test.

Official

[1] For example, the Cannon-Fenske capillary viscometer is one of the simple U-tube capillary viscometers and is also called a modified Ostwald-type capillary viscometer.

https://pharmacopeia.cn/v-download/

# ⟨912⟩ VISCOSITY—ROTATIONAL METHODS

The principle of the method is to measure the force (torque) acting on a rotor when it rotates at a constant angular velocity or rotational speed in a liquid. Rotational rheometers/viscometers are used for measuring the viscosity of fluids, both Newtonian and non-Newtonian. The following procedures are used to determine the viscosity of Newtonian fluids or the apparent viscosity of non-Newtonian fluids. The calculated viscosity of Newtonian fluids should be the same (within experimental error), regardless of the rate of shear (or rotational speed). Given the dependence of viscosity on temperature, the temperature of the substance being measured should be controlled to within ±0.1°, unless otherwise specified in the individual monograph. [NOTE—For additional information, see *Rheometry* ⟨1911⟩.]

• **METHOD I. SPINDLE VISCOMETERS**

**Apparatus:** In the spindle viscometer, the apparent viscosity is determined by rotating a cylinder- or disk (or disc)-shaped spindle, as shown in *Figure 1* and *Figure 2*, respectively, immersed in a large volume of liquid.

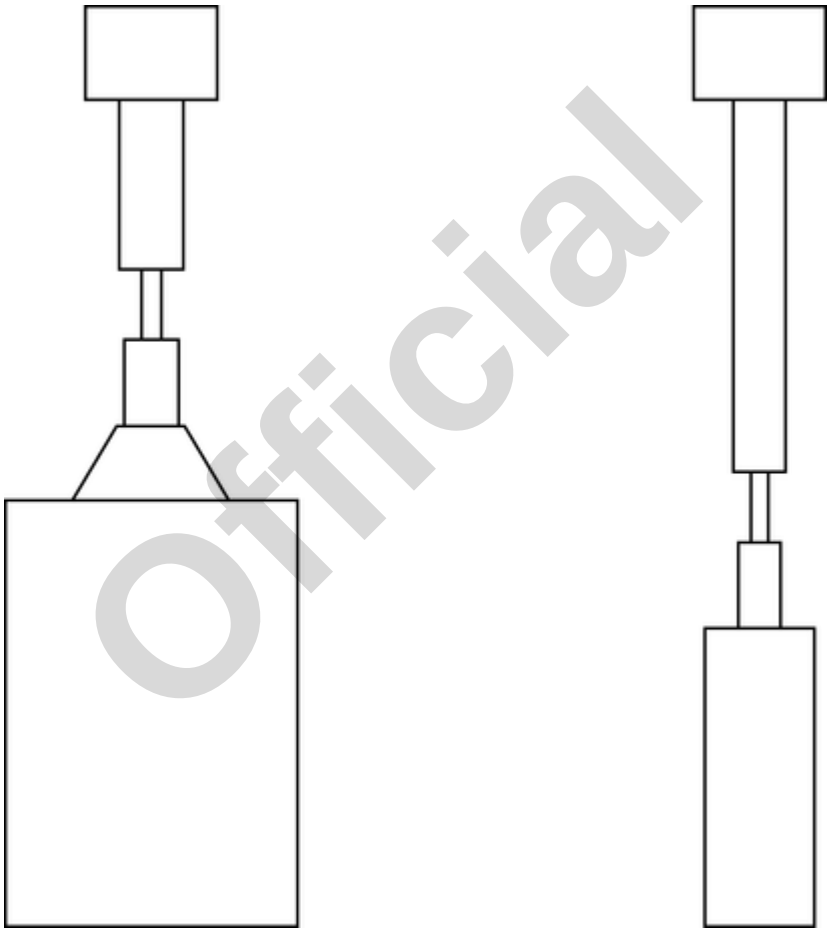

Figure 1. Cylinder-shaped spindles.

Official

DOI Ref: 6cv2l
DocId: GUID-7DB73369-4D3E-41D7-9CE9-C301A1F8A216_1_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M2305_01_01
@2024 USPC

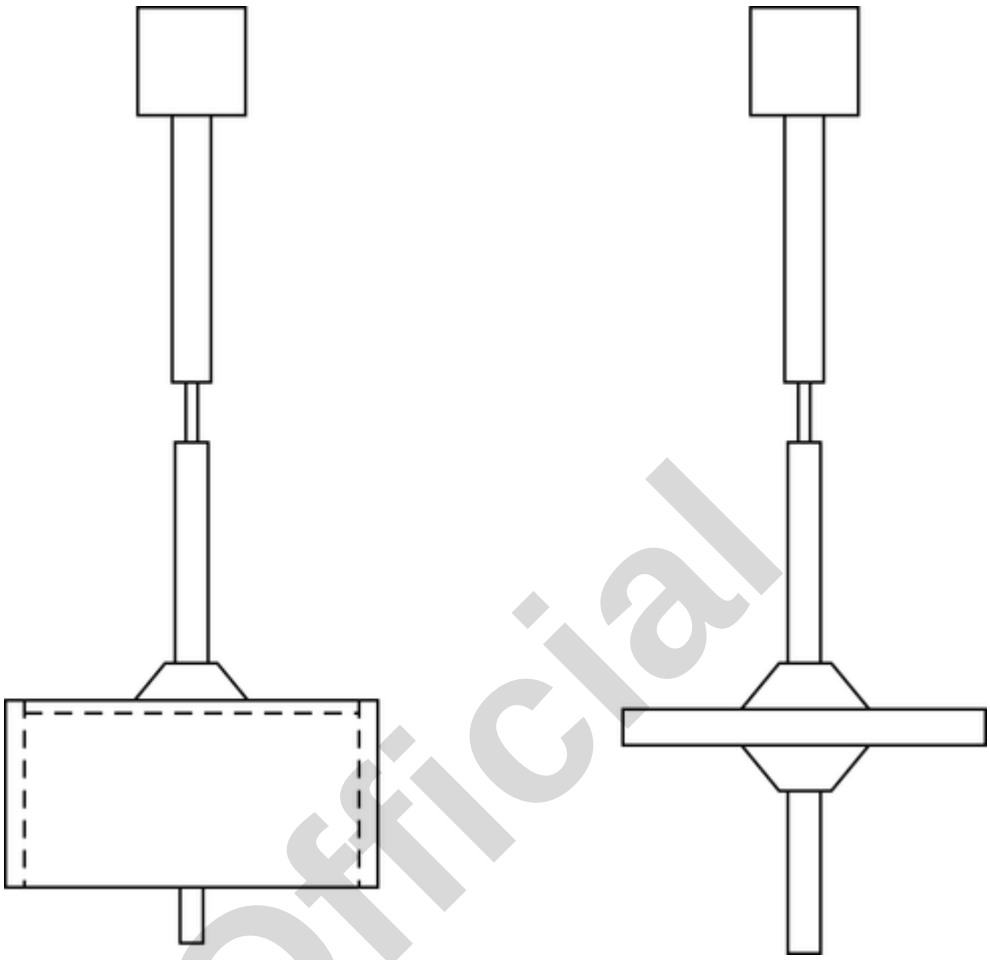

Figure 2. Disk-shaped spindles.

An absolute viscosity cannot be calculated due to the large gap between the spindle and the container wall, or the geometry of the spindle. The torque to maintain a given angular velocity does give a measure of the liquid resistance to flow but is often described as an apparent viscosity.

Other spindle type viscometers may be used provided that the accuracy and precision is NLT that obtained with the viscometers described in this chapter.

**Procedure:** When viscosity measurement is performed in a beaker or cup, as the shear rate is unknown, in order to enable reproducibility among labs that measure viscosity using different instrumentation, these parameters must be reported along with the measured viscosity:

1. Size and geometry of spindle
2. Angular velocity or rotational speed of the spindle
3. Temperature of the test substance

The spindle should be immersed to the recommended depth maintaining at least 1 cm clearance from the bottom and side of the container.

The preparation of the test specimen, including its temperature equilibration, is specified in each individual monograph. Follow the instrument manufacturer's recommendations regarding sample loading, spindle selection, and viscometer operation.

**Calibration check:** Check the calibration of a particular viscometer configuration at the test temperature using one or more fluids of known viscosities (Newtonian viscosity standards). The viscosity values of the calibration standards should bracket the expected viscosity value of the sample liquid. [NOTE—To help verify the linearity of the apparatus, it is suggested to perform measurements of a Newtonian viscosity standard at multiple rotational speeds at the test temperature.]

A viscometer is deemed to be calibrated if the measured apparent viscosities are within ±5% of the stated values.

Generally, calibration, operation, and cleaning of the viscometer should be performed according to the recommendations of the instrument manufacturer.

- **METHOD II. CONCENTRIC CYLINDER RHEOMETERS**

**Apparatus:** In the concentric cylinder rheometer, the apparent viscosity is determined by placing the liquid in the gap between the inner cylinder and the outer cylinder. Both controlled-stress and controlled-rate rotational rheometers are available commercially in configurations with absolute geometries (e.g., very small annular gaps between concentric cylinders) that allow calculation of apparent viscosities for non-Newtonian fluids. Controlled shear stress rheometers

https://pharmacopeia.cn/v-about/

measure the shear rates resulting from the application of a given force or torque (the stress). Controlled shear rate rheometers measure the shear stress (from the torque on the rotor axis) resulting from a given shear rate (or rotational speed). Concentric cylinder rotational rheometers are sometimes referred to as cup-and-bob rheometers. These rheometers involve an additional design consideration depending on whether the outer cylinder (the cup) or the inner cylinder (the bob) rotates. Rotating-cup rheometers are called Couette systems, while rotating-bob rheometers are called Searle systems, as shown in *Figure 3* and *Figure 4*, respectively.

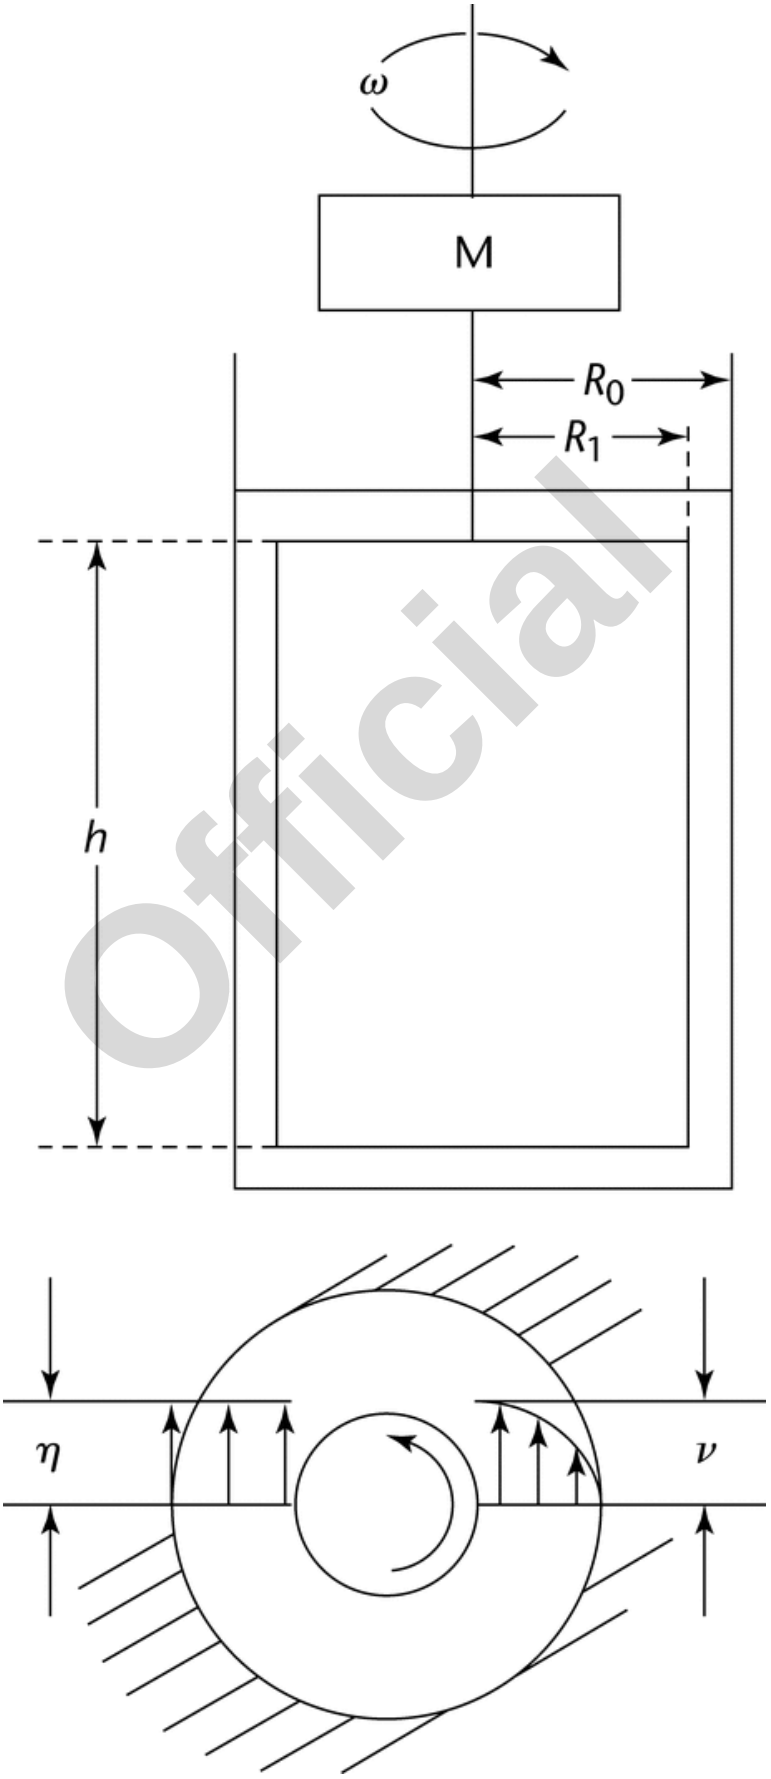

Figure 4. Searle concentric cylinder system for rotational rheometry.

Official

https://pharmacopeia.cn/

Variables in *Figure 3* and *Figure 4* are defined as:

$M$ = torque acting on the cylinder surface ($N \cdot m$)
$R_0$ = radius of the outer cylinder (m)
$R_1$ = radius of the inner cylinder (m)
$h$ = height of immersion of the inner cylinder in the liquid medium (m)
$\omega$ = angular velocity (radians/s)
$\eta$ = viscosity ($Pa \cdot s$)
$v$ = velocity (m/s)

**Procedure:** Place a sufficient quantity of test fluid in the rheometer, and allow the sample to reach thermal equilibrium, as indicated in the individual monograph. Operate the rheometer following the procedure recommended by the instrument manufacturer. For non-Newtonian systems, the monograph indicates the type of rheometer that should be used and the shear rate(s) at which the measurements should be made. Determine apparent viscosities by changing the shear rate (or shear stress, if using a controlled shear stress rheometer) over a range appropriate to the use of the material under test. From a series of such viscosity measurements, the relationship between the shear rate and the shear stress of a non-Newtonian liquid can be obtained.

- **Method III. Cone-and-Plate Rheometers**

**Apparatus:** In the cone-and-plate rheometer, the liquid is introduced into the fixed gap between a flat disk or plate and a cone forming a defined angle. The angle of the cone ensures a constant shear rate due to the increase in both the gap and the linear speed as the distance increases from the origin. Viscosity measurement can be performed by rotating the cone or the plate, as shown in *Figure 5* and *Figure 6*, respectively. [Note—Because the volume of sample is small, even a small absolute loss of solvents can cause a large percentage change in viscosity. Such a loss is particularly relevant for volatile solvents but could be significant even for nonvolatile solvents such as water.]

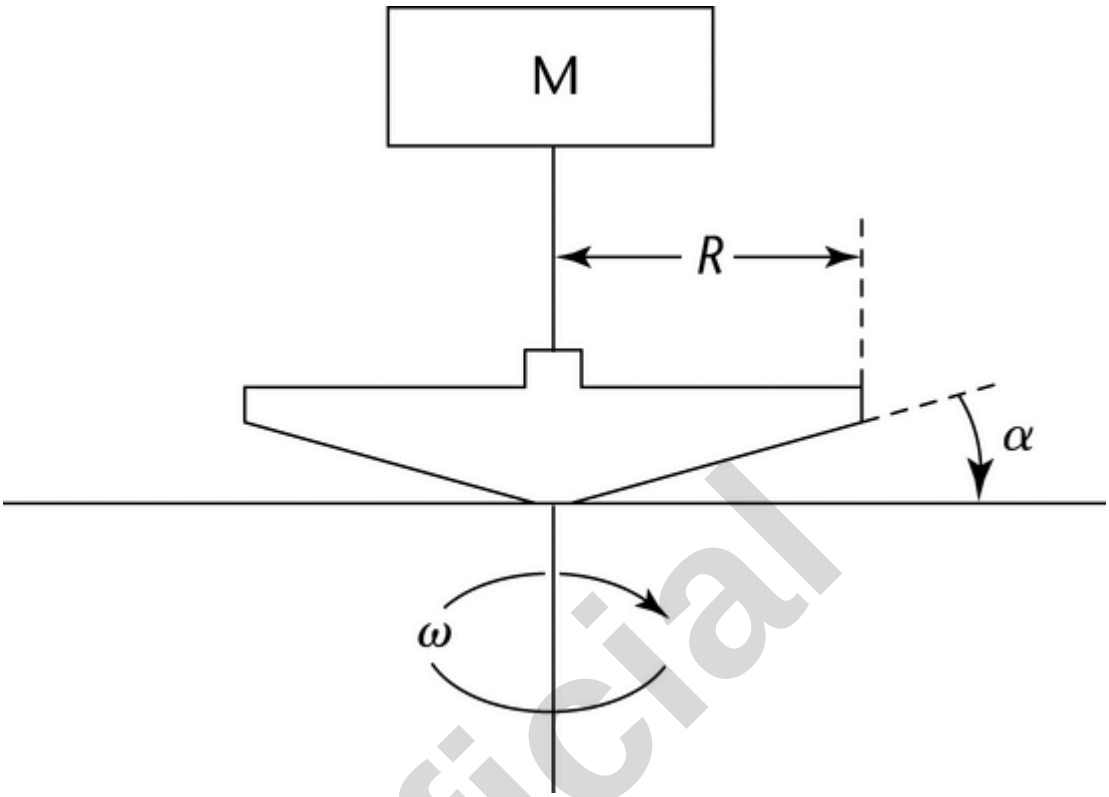

Figure 6. Cone-and-plate rotational rheometer with rotating plate.

Variables in *Figure 5* and *Figure 6* are defined as:

$\omega$ = angular velocity (radians/s)
$M$ = torque acting on the flat plate or cone surface (N · m)
$\alpha$ = angle between the flat plate and cone (radians)
$R$ = radius of the cone (m)

**Procedure:** Proceed as directed for *Method II. Concentric Cylinder Rheometers*.

- **Method IV. Parallel Plate (or Parallel Disk) Rheometers**

**Apparatus:** Parallel plate rheometers are similar to cone-and-plate rheometers except that the sample to be measured is introduced into the gap between a flat plate or disk (or disc) and another parallel flat plate or disk. Measurements are made typically with the lower plate or disk remaining stationary as the upper plate or disk is rotated at a constant angular velocity, $\omega$ (*Figure 7*).

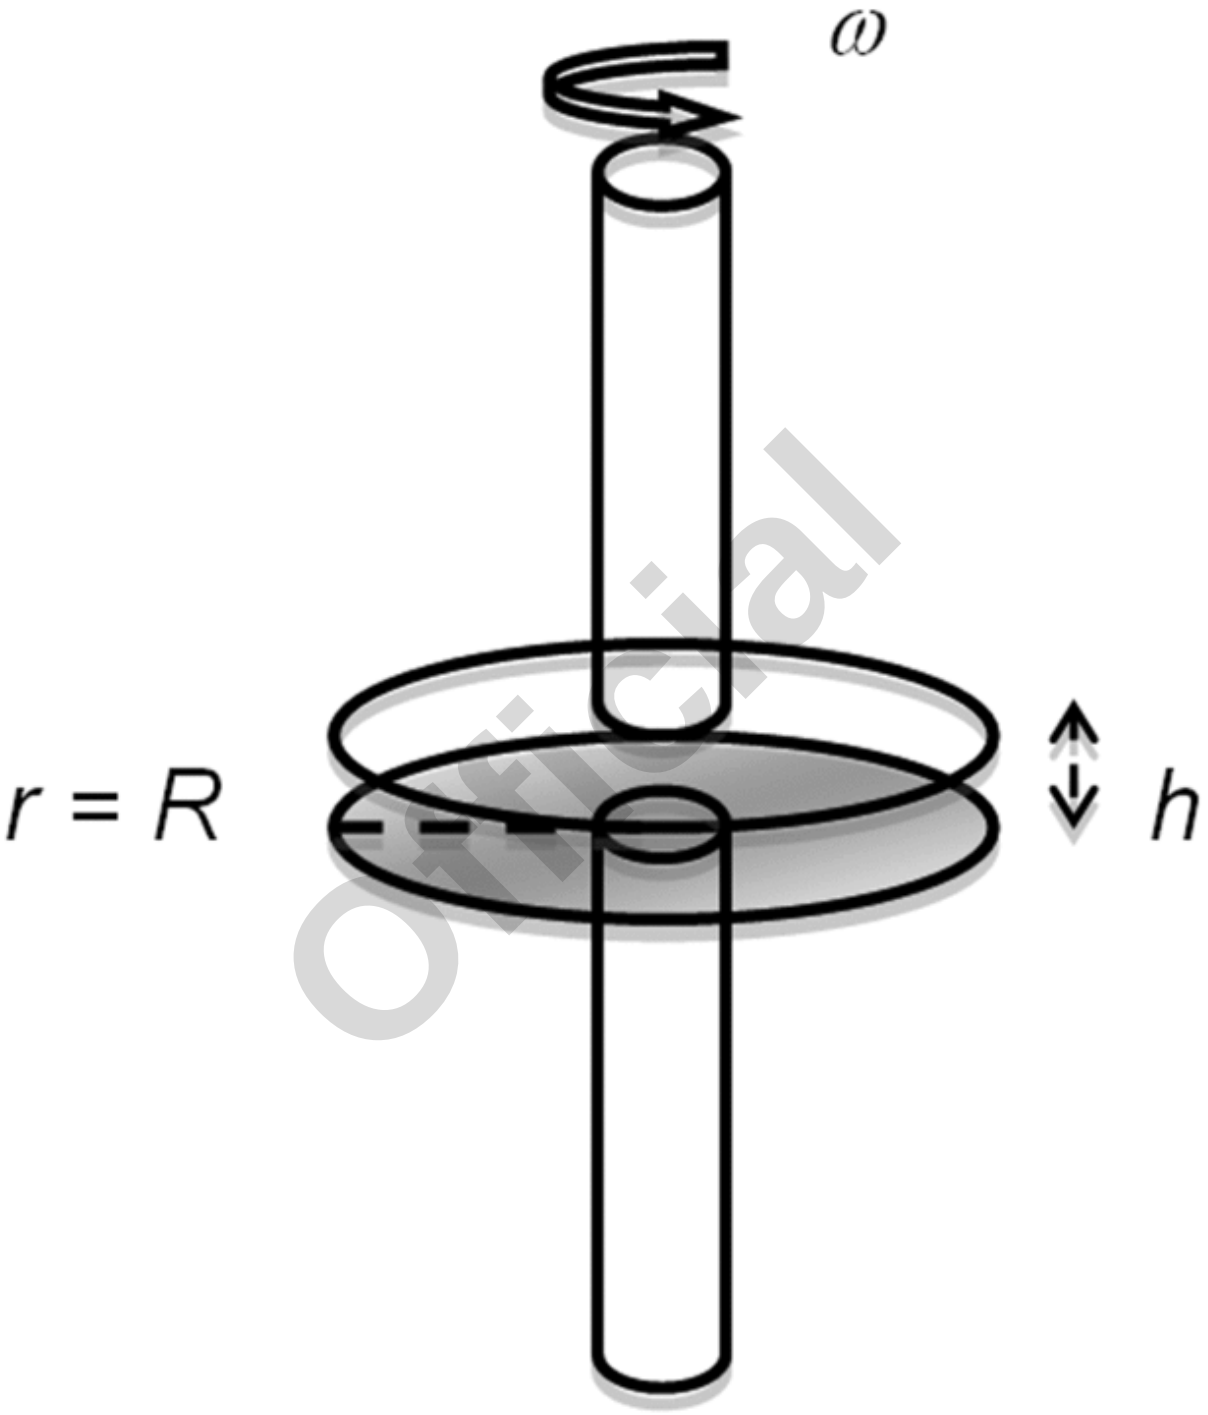

Figure 7. Parallel plate rotational rheometer.

Variables in *Figure 7* are defined as:

ω = angular velocity (radians/s)

*R* = radius of the plate (m)

*h* = distance between the two parallel plates (m)

In contrast to the cone-and-plate rheometer, the shear rate between parallel plates increases with distance from the origin of the axis of rotation due to the increasing linear speeds for a given angular velocity with a constant gap. Thus, an average shear rate is obtained. Nonetheless, some advantages of the parallel plate rheometer include ease of sample loading (especially for very viscous liquids and soft semisolids), and suitability for suspensions of particulates. For

https://pharmacopeia.cn/

suspensions, the gap should be set high enough to avoid grinding particles between the plates. Parallel plates have a user-definable gap (within practical limits) and therefore, in the absence of large particles, may be used at narrower gaps. As with cone-and-plate rheometers, evaporative loss of solvent can markedly affect the viscosity of the sample, so adequate precautions need to be taken to minimize solvent loss.

**Procedure:** Proceed as directed for *Method II. Concentric Cylinder Rheometers*.

# ⟨913⟩ VISCOSITY—ROLLING BALL METHOD

The following procedure is used to determine the viscosity of a Newtonian fluid, i.e., a fluid having a viscosity that is independent of the shearing stress or rate of shear.

[NOTE—For additional information, see *Rheometry* ⟨1911⟩.]

## APPARATUS

See *Figure 1*.

The basic design of a rolling ball viscometer consists of a tube (or capillary) that contains the sample liquid under test and a ball chosen so that it will require a minimum rolling time of 20 s at the measuring angle in the sample liquid.

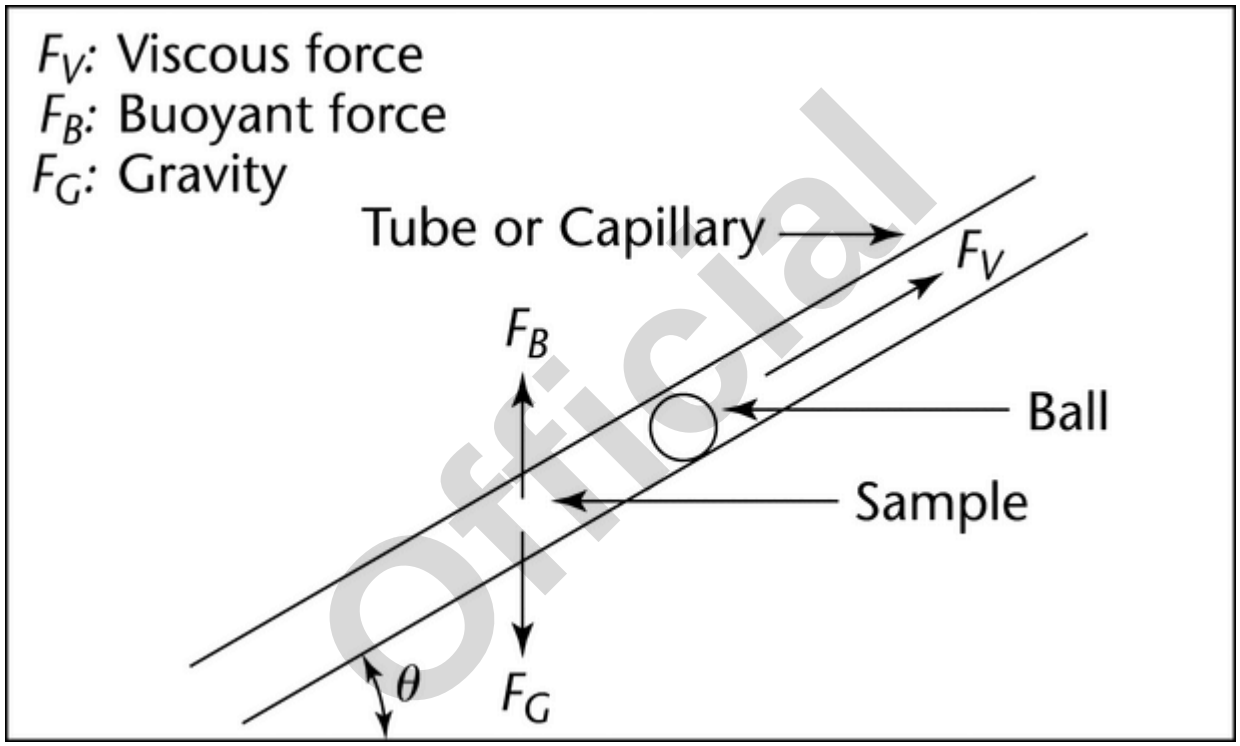

Figure 1. Basic design for rolling ball viscometer.

## MEASURING PRINCIPLE

The rolling ball measurement is based on Stokes's Law, as influenced by the angle of inclination of the tube (or capillary). Calculate the Newtonian viscosity, $\eta$, in mPa · s:

$$\eta = [(\rho_1 - \rho_2) \times g \times r^2 \times \sin\theta]/v_\infty$$

$\rho_1$ = density of the ball used (g/mL)
$\rho_2$ = density of the sample liquid (g/mL)
$g$ = gravitational constant (mm/s$^2$)
$r$ = radius of the ball (mm)
$\theta$ = angle of inclination of the tube (or capillary)
$v_\infty$ = terminal velocity of the ball (mm/s)

Determine the viscosity of a liquid by observing the rolling time of a solid sphere (ball) under the influence of gravity in an inclined cylindrical tube filled with the sample liquid. Measure the time taken by the ball to travel the fixed distance between two ring marks or measuring sensors. For each single measured rolling time, the resulting viscosity can be expressed as dynamic viscosity (mPa · s) as well as kinematic viscosity (mm$^2$/s) for a sample of known density.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M6237_01_01
@2024 USPC

## PROCEDURE

Select a measuring system [tube (or capillary) and ball combination] within the anticipated range of viscosity of the sample liquid. As necessary, heat the clean and dry tube and ball of the viscometer to the temperature specified in the individual monograph, and control the temperature to ±0.1°, unless otherwise specified in the individual monograph. Select a measuring angle to obtain a minimum rolling time of 20 s. Fill the tube with the sample liquid, being careful to avoid bubble formation. Close the tube, and insert it in the instrument. Allow to equilibrate at the specified temperature for NLT 15 min for a rolling ball viscometer with a tube of large diameter. For a micro rolling ball viscometer, follow the instrument manufacturer's instructions regarding temperature equilibration. Release the ball, and record the time required for the ball to roll from the upper to the lower ring mark (or measuring sensor). Repeat the test run at least four times.

The rolling time in the fluid under examination is the mean of NLT four consecutive determinations. The result is valid if the percent relative standard deviation (%RSD) for the four readings is NMT 2.0%.

## CALCULATION AND CALIBRATION

Calculate the Newtonian viscosity, $\eta$, in mPa · s:

$$\eta = k \times (\rho_1 - \rho_2) \times t$$

$k$ = calibration constant of the instrument ($mm^2/s^2$) at a specified measuring angle and temperature
$\rho_1$ = density of the ball used (g/mL)
$\rho_2$ = density of the sample liquid (g/mL)
$t$ = rolling time of the ball (s)

Calibrate each tube (or capillary) and ball combination at the test temperature and test angle using fluids of known viscosities and densities (viscosity standards) to determine the measuring system constant, $k$.

[NOTE—Some automated viscometers use a polynomial function to determine the calibration for different angles and temperatures.]

The viscosity values of the calibration standards should bracket the expected viscosity value of the sample liquid.

Calibrations are specific to the ball radius, ball density, temperature, and test angle. Recalibration is necessary when any of these parameters is changed.

Where no reference values at the required test temperature are available, follow the manufacturer's instructions for mathematical corrections to the calibration function. When the materials of the ball and tube are dissimilar, apply corrections calculated using the linear thermal expansion coefficients of the materials.

# ⟨914⟩ VISCOSITY—PRESSURE DRIVEN METHODS

## INTRODUCTION

The viscometers/rheometers that are included in this chapter can be used to measure the viscosity of both Newtonian and non-Newtonian fluids. The devices include slit viscometers/rheometers and capillary-extrusion viscometers.

Capillary viscometers that are described in *Viscosity—Capillary Methods* ⟨911⟩ are based on the principle that the flow is driven by gravity, and these viscometers can be classified under one of the pressure driven methods. However, limitations of glass capillary viscometers render them inherently unsuitable for use in characterizing non-Newtonian fluids, and their use in measurements of high-viscosity fluids is impractical as well. Chapter ⟨914⟩ does not address such viscometers.

[NOTE—For additional information, see *Rheometry* ⟨1911⟩.]

• **METHOD I. SLIT VISCOMETERS/RHEOMETERS**

**Apparatus:** See *Figure 1*.

The basic design of a slit viscometer/rheometer consists of a rectangular, slit channel with a uniform cross-sectional area. A test liquid is pumped at a constant flow rate through this channel. Multiple pressure sensors that are flush mounted at linear distances along the streamwise direction measure the pressure drop, as depicted in *Figure 1*.

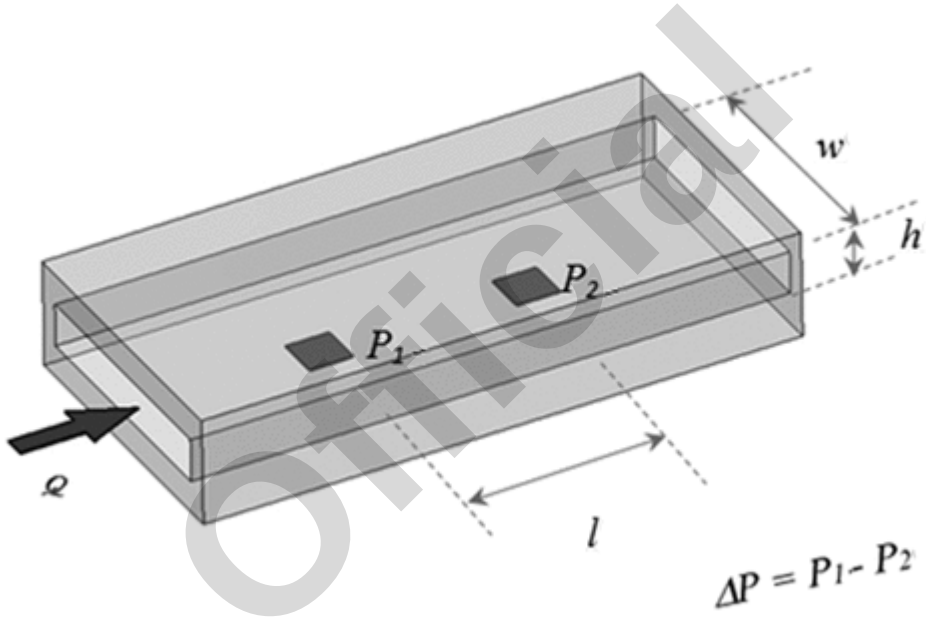

Figure 1. Basic design of the slit viscometer/rheometer.

**Measuring principle:** The slit viscometer/rheometer is based on the fundamental principle that a viscous liquid resists flow, exhibiting a decreasing pressure along the length of the slit. The pressure decrease or drop ($\Delta P$) is correlated with the shear stress at the wall boundary. The apparent shear rate is directly related to the flow rate and the dimension of the slit. The apparent shear rate ($\dot{\gamma}_a$), the shear stress ($\sigma$), and the apparent viscosity ($\eta_a$), respectively, are calculated as follows:

$$\dot{\gamma}_a = \frac{6 \times Q}{w \times h^2}$$

$$\sigma = \frac{h \times w}{2 \times (w + h)} \times \frac{\Delta P}{l}$$

$$\eta_a = \frac{\sigma}{\dot{\gamma}_a}$$

$\dot{\gamma}_a$ = apparent shear rate ($s^{-1}$)
$Q$ = flow rate (µL/s)
$w$ = width of the flow channel (mm)
$h$ = depth of the flow channel (mm)
$\sigma$ = shear stress (Pa)
$\Delta P$ = pressure difference between the leading pressure sensor and the last pressure sensor (Pa)
$l$ = distance between the leading pressure sensor and the last pressure sensor (mm)
$\eta_a$ = apparent viscosity (Pa · s)

https://pharmacopeia.cn/

To determine the viscosity of a liquid, pump the liquid sample through the slit channel at a constant flow rate and measure the pressure drop. Using the equations shown above, calculate the apparent viscosity for the apparent shear rate. For a Newtonian liquid, the apparent viscosity is the same as the true viscosity, and the single shear-rate measurement is sufficient. For non-Newtonian liquids, the apparent viscosity is not true viscosity. To obtain true viscosity, measure the apparent viscosities at multiple apparent shear rates. Calculate true viscosities, $\eta$, at various shear rates using the Weissenberg–Rabinowitsch–Mooney correction factor:

$$\frac{1}{\eta} = \frac{1}{2 \times \eta_a} \times \left(2 + \frac{d\ln\dot{\gamma}_a}{d\ln\sigma}\right)$$

The calculated true viscosity should be the same as the value that is obtained using a cone-and-plate rheometer at the same shear rate.

**Procedure:** Select slit dimensions and full-scale pressure of pressure sensors to attain the desired range of viscosity and shear rates. With a syringe pump to control the flow rate—or interchangeably, the shear rate—load a test sample into a glass syringe. As necessary, control the temperature of the sample with the syringe and the slit viscometer specified in the individual procedure to ±0.1°, unless otherwise specified. Allow to equilibrate at the specified temperature for about 3–5 min. Set each pressure sensor to zero. Select the first flow rate or shear rate. Pump the sample at the flow rate, and measure the pressure readings once the steady-state values are reached. Increase the flow rate (or shear rate) until the pressure reading of the leading sensor is >5% of the full-scale value. Take the average of each pressure sensor over time, and calculate the pressure drops. Calculate the apparent viscosity. If required for the procedure, repeat the measurements four times. If the test sample is non-Newtonian, vary the shear rate and calculate the corresponding apparent viscosities.

**Calculation and calibration:** Calculate the apparent viscosity by dividing the shear stress by the apparent shear rate. For non-Newtonian liquids, apply the Weissenberg–Rabinowitsch–Mooney corrections to obtain the true viscosity curve. Commercial viscometers are provided with a built-in correction.

Calibrate individual pressure sensors by following the recommendations from the manufacturer. The slit viscometer, however, can be calibrated with a Newtonian standard of known viscosity. Choose a standard that covers the viscosity range of interest for the selected slit and pressure sensors. Measure the viscosities at shear rates for 10%, 50%, and 90% of full scale of the leading pressure sensor, and take the average. Calculate a constant ($k$) for the ratio of the reference value ($\eta_{ref}$) to the measured value ($\eta_{meas}$) and record.

$$k = \frac{\eta_{ref}}{\eta_{meas}}$$

$\eta_{ref}$ = reference viscosity (Pa · s)
$\eta_{meas}$ = measured viscosity (Pa · s)

Multiply new viscosity data by $k$, because the value of $k$ will correct for the uncertainty and variation of the slit geometry. Ideally, the value of $k$ should remain constant within a temperature change of 100°. If the $k$ value varies by >1%, consult with the manufacturer regarding the temperature compensation of the pressure sensors.

# ⟨915⟩ MEASUREMENT OF STRUCTURAL STRENGTH OF SEMISOLIDS BY PENETROMETRY

***Change to read:***

## INTRODUCTION

This chapter describes the empirical methods of measuring the structural strength, or consistency, of a semisolid raw material or dosage form with a penetrometer. Viscosity represents the proportionality of the shear stress to the shear rate for a Newtonian fluid, whereas consistency is the term for this proportionality for semisolids that exhibit non-Newtonian rheological behavior. Because the term "consistency" may be confused with "uniformity" or "homogeneity", the term "structural strength" is now the preferred term. In the remainder of this chapter we will use the term structural strength to refer to this property of semisolids. One component of the structural strength of a semisolid is its hardness (yield stress). Penetrometry is one method for quantifying the hardness (yield stress) of semisolid materials.

Penetrometry allows a metal cone, with standardized dimensions and weight, to penetrate into a semisolid until the buoyancy of the cone and the yield stress of the semisolid exactly balance the gravity-applied force driving the penetrating object into the semisolid. This observed yield stress of the semisolid is a measure of the semisolid hardness. The yield stress (hardness) of the semisolid will be inversely proportional to the penetration depth of the cone.

This chapter outlines the method for performing the gravity-driven penetrometry measurements of semisolids. Although the results of the penetrometry measurements may be used to calculate the yield stress of the semisolid (see *Measurement of* ▲*Yield Stress*▲ (CN 1-Dec-2023) *of Semisolids* ⟨1912⟩ for more information), the results of the penetrometry experiment are reported as the observed penetration depth in tenths of millimeters [decimillimeters (dmm)].[1,2,3]

Figure 2. Penetrometer standard cone (mass = 102.5 ± 0.05 g), suitable container ($d$ = 102 or 75 mm; $h \geq 62$ mm) and shaft ($l \approx 162$ mm; mass = 47.5 ± 0.05 g). Dimensions in millimeters. (Adapted with permission from *Pharmeuropa*, Vol. 9 No. 8, July 2019. © Council of Europe, 2019.)

## PROCEDURE

### Sample Preparation

With samples having penetrations <200 dmm, three tests (and sometimes more) may be made in one container by proper spacing. To prevent one test from being affected by the disturbed area of a previous test, the tip of the cone must not be placed nearer the edge of a previous test than the penetration distance of the sample. Some harder samples tend to form a marked depression in the center upon solidifying; such samples should not be tested in this depression because the results obtained may be different from those obtained in off-center positions on the level surface.

With samples having penetrations >200 dmm, only one test may be made in a container by placing the cone tip near the center of the container.

Fill the required number of containers to within 6 mm of their rims.

Prepare the test samples using one of the following procedures:

1. Carefully fill containers without forming air bubbles. Level, if necessary, to obtain a flat surface. Store the samples at 25 ± 0.5° for 24 h, unless otherwise prescribed.
2. Liquefy (i.e., heat to above the melting point) samples, and carefully fill containers without forming air bubbles. Store the samples at 25 ± 0.5° for 24 h, unless otherwise prescribed.

https://nhathuocngocanh.com/

3. If worked (sheared) samples are to be tested, first store samples at 25 ± 0.5° for 24 h. Apply a suitable shear to the samples for 5 min. Carefully and completely fill containers without forming air bubbles, and level, if necessary, to obtain a flat surface.

## Determination of Penetration

Penetration experiments use a gravity-driven apparatus (as shown in *Figure 1* or another functionally equivalent apparatus). *Method I* uses a standard cone as a penetrating object, and *Method II* uses a standard needle as a penetrating object. Unless otherwise directed in the individual monograph, use *Method I*.

### METHOD I (GRAVITY-DRIVEN MEASUREMENT OF STRUCTURAL STRENGTH WITH STANDARD CONE)

1. This method requires the use of a penetrating object that complies with the dimensions of *Figure 2*. The penetrating object should have a total effective mass of 150.0 ± 0.1 g (including the weight of the cone and additional masses firmly attached during the penetration experiment).
2. Place the test sample on the base of the penetrometer, and verify that its surface is perpendicular to the vertical axis of the penetrating object.
3. Bring the temperature of the penetrating object to 23.5 ± 2.0°, and then adjust its position such that its tip just touches the surface of the sample. [NOTE—Watching the shadow of the tip is an aid in accurate setting.]
4. Release the penetrating object and allow it to descend, without restraint, for 5 s.
5. Clamp the penetrating object and measure the depth of penetration.
6. Repeat the test at least two more times to obtain three or more values.

### METHOD II (GRAVITY-DRIVEN MEASUREMENT OF STRUCTURAL STRENGTH WITH NEEDLE)

1. This method requires the use of a polished metal needle weighing 2.50 ± 0.05 g and having a truncated symmetric tapered angle of 9°0′ ± 15′. The needle is tapered, with a length of 25.4 mm, and the shaft attached to the needle is 58 mm in length and 3.17 mm in diameter. The penetrating object should have a total effective mass of 100.0 ± 0.1 g (including the weight of the needle and additional masses firmly attached during the penetration experiment).
2. Place the test sample on the base of the penetrometer, and verify that its surface is perpendicular to the vertical axis of the penetrating object.
3. Bring the temperature of the penetrating object to 23.5 ± 2.0°, and then adjust its position such that its tip just touches the surface of the sample. [NOTE—Watching the shadow of the tip is an aid in accurate setting.]
4. Release the penetrating object and allow it to descend, without restraint, for 5 s.
5. Clamp the penetrating object and measure the depth of penetration.
6. Repeat the test at least two more times to obtain three or more values.

## EXPRESSION OF THE RESULTS

Report the mean and standard deviation of at least three replicate measurements in units of penetration depth. The penetration depth is expressed in dmm. If any of the individual results differ from the mean by >3%, repeat the test and report the mean and standard deviation of six replicate measurements in units of penetration depth.

## GLOSSARY

**Structural strength (Consistency):** The term "consistency" is sometimes used synonymously with "viscosity", albeit incorrectly. Viscosity represents the proportionality of the shear stress to the shear rate for a Newtonian fluid, whereas consistency is the term for this proportionality for semisolids that exhibit non-Newtonian rheological behavior. Because the term consistency may be confused with uniformity or homogeneity the term structural strength is now the preferred term. See ⟨1912⟩ for more information.

**Hardness:** "Hardness" is a term used synonymously with "tensile stress", and yield stress is one type of tensile stress. Hardness is proportional to yield stress—a harder semisolid also exhibits a larger apparent yield stress. In penetrometry, hardness has been more specifically defined as $H = C \times W/p^n$, where $C$ is a constant dependent on the cone geometry, $W$ is the weight of the penetrating cone, $p$ is the depth of penetration, and $n$ is an exponent. When $n = 2$, hardness has the same units as yield stress [pascal (Pa)]. See ⟨1912⟩ for more information.

**Penetrometer:** An instrument that measures the structural strength of semisolid materials by measuring the depth to which a specified cone or needle under a given force falls into the material.

# ⟨921⟩ WATER DETERMINATION

***Change to read:***

Many Pharmacopeial articles either are hydrates or contain water in adsorbed form. As a result, the determination of the water content is important in demonstrating compliance with the Pharmacopeial standards. Generally one of the methods given below is called for in the individual monograph, depending upon the nature of the article. In rare cases, a choice is allowed between two methods. When the article contains water of hydration, *Method I (Titrimetric)*, *Method II (Azeotropic)*, or *Method III (Gravimetric)* is employed, as directed in the individual monograph, and the requirement is given under the heading *Water*. ▲Unless otherwise specified in the monograph, determine the water by *Method Ia* .▲ (USP 1-May-2022)

The heading *Loss on Drying* (see *Loss on Drying* ⟨731⟩) is used in those cases where the loss sustained on heating may be not entirely water.

***Change to read:***

## METHOD I (TITRIMETRIC)

▲▲ (USP 1-May-2022)

### Method Ia (Direct Titration)

PRINCIPLE

The titrimetric determination of water is based upon the quantitative reaction of water with an anhydrous solution of sulfur dioxide and iodine in the presence of a buffer that reacts with hydrogen ions.

In the original titrimetric solution, known as Karl Fischer Reagent, the sulfur dioxide and iodine are dissolved in pyridine and methanol. The test specimen may be titrated with the *Reagent* directly, or the analysis may be carried out by a residual titration procedure. The stoichiometry of the reaction is not exact, and the reproducibility of a determination depends upon such factors as the relative concentrations of the *Reagent* ingredients, the nature of the inert solvent used to dissolve the test specimen, and the technique used in the particular determination. Therefore, an empirically standardized technique is used in order to achieve the desired accuracy. Precision in the method is governed largely by the extent to which atmospheric moisture is excluded from the system. The titration of water is usually carried out with the use of anhydrous methanol as the solvent for the test specimen. In some cases, other suitable solvents may be used for special or unusual test specimens. In these cases, the addition of at least 20% of methanol or other primary alcohol is recommended.

APPARATUS

Any apparatus may be used that provides for adequate exclusion of atmospheric moisture and determination of the endpoint. In the case of a colorless solution that is titrated directly, the endpoint may be observed visually as a change in color from canary yellow to amber. The reverse is observed in the case of a test specimen that is titrated residually. More commonly, however, the endpoint is determined electrometrically with an apparatus employing ▲an▲ (USP 1-May-2022) electrical circuit ▲and▲ (USP 1-May-2022) a pair of platinum electrodes immersed in the solution to be titrated. At the endpoint of the titration a slight excess of the reagent increases the flow of current, ▲which is detected by the electrodes for not less than 30 s.▲ (USP 1-May-2022) The time is shortest for substances that dissolve in the reagent. With some automatic titrators, the abrupt change in current or potential at the endpoint serves to close a solenoid-operated valve that controls the buret delivering the titrant. Commercially available apparatus generally comprises a closed system consisting of one or two automatic burets and a tightly covered titration vessel fitted with the necessary electrodes and a magnetic stirrer. The air in the system is kept dry with a suitable desiccant, and the titration vessel may be purged by means of a stream of dry nitrogen or current of dry air.

REAGENT

Prepare the Karl Fischer Reagent as follows. Add 125 g of iodine to a solution containing 670 mL of methanol and 170 mL of pyridine, and cool. Place 100 mL of pyridine in a 250-mL graduated cylinder, and, keeping the pyridine cold in an ice bath, pass in dry sulfur dioxide until the volume reaches 200 mL. Slowly add this solution, with shaking, to the cooled iodine mixture. Shake to dissolve the iodine, transfer the solution to the apparatus, and allow the solution to stand overnight before standardizing. When freshly prepared, 1 mL of this solution is equivalent to approximately 5 mg of water, but it deteriorates gradually; therefore, standardize it within 1 h before use, or daily if in continuous use. Protect from light while in use. Store any bulk stock of the reagent in a suitably sealed, glass-stoppered container, fully protected from light, and under refrigeration. For determination of trace amounts of water (less than 1%), it is preferable to use a *Reagent* with a water equivalency factor of not more than 2.0, which will lead to the consumption of a more significant volume of titrant.

A commercially available, stabilized solution of Karl Fischer type reagent may be used. Commercially available reagents containing solvents or bases other than pyridine or alcohols other than methanol may be used also. These may be single solutions or reagents formed in situ by combining the components of the reagents present in two discrete solutions. The diluted *Reagent* called for in some monographs should be diluted as directed by the manufacturer. Either methanol or other suitable solvent, such as ethylene glycol monomethyl ether, may be used as the diluent.

Official

https://pharmacopeia.cn/v29240/

## TEST PREPARATION

Unless otherwise specified in the individual monograph, use an accurately weighed or measured amount of the specimen under test estimated to contain 2–250 mg of water. The amount of water depends on the water equivalency factor of the *Reagent* and on the method of endpoint determination. In most cases, the minimum amount of specimen, in milligrams, can be estimated using the formula:

$$\text{Result} = FCV/KF$$

in which $F$ is the water equivalency factor of the *Reagent*, in milligrams per milliliter; $C$ is the used volume, in percent, of the capacity of the buret; $V$ is the buret volume, in milliliters; and $KF$ is the limit or reasonable expected water content in the sample, in percent. $C$ is generally between 30% and 100% for manual titration, and between 10% and 100% for the instrumental method endpoint determination.

[NOTE—It is recommended that the product of $FCV$ be greater than or equal to 200 for the calculation to ensure that the minimum amount of water titrated is greater than or equal to 2 mg.]

Where the specimen under test is an aerosol with propellant, store it in a freezer for not less than 2 h, open the container, and test 10.0 mL of the well-mixed specimen. In titrating the specimen, determine the endpoint at a temperature of 10° or higher.

Where the specimen under test is capsules, use a portion of the mixed contents of not fewer than 4 capsules.

Where the specimen under test is tablets, use powder from not fewer than 4 tablets ground to a fine powder in an atmosphere of temperature and relative humidity known not to influence the results.

Where the monograph specifies that the specimen under test is hygroscopic, take an accurately weighed portion of the solid into the titration vessel, proceeding as soon as possible and taking care to avoid moisture uptake from the atmosphere. If the sample is constituted by a finite amount of solid as a lyophilized product or a powder inside a vial, use a dry syringe to inject an appropriate volume of methanol, or other suitable solvent, accurately measured, into a tared container, and shake to dissolve the specimen. Using the same syringe, remove the solution from the container and transfer it to a titration vessel prepared as directed for *Procedure*. Repeat the procedure with a second portion of methanol, or other suitable solvent, accurately measured; add this washing to the titration vessel; and immediately titrate. Determine the water content, in milligrams, of a portion of solvent of the same total volume as that used to dissolve the specimen and to wash the container and syringe, as directed for *Standardization of Water Solution for Residual Titration* in *Method IB*, and subtract this value from the water content, in milligrams, obtained in the titration of the specimen under test. Dry the container and its closure at 100° for 3 h, allow to cool in a desiccator, and weigh. Determine the weight of specimen tested from the difference in weight from the initial weight of the container.

When appropriate, the water may be desorbed or released from the sample by heat in an external oven connected with the vessel, to where it is transferred with the aid of an inert and dried gas such as pure nitrogen. Any drift due to the transport gas should be considered and corrected. Care should be taken in the selection of the heating conditions to avoid the formation of water coming from dehydration due to decomposition of the sample constituents, which may invalidate this approach.

## STANDARDIZATION OF THE REAGENT

Place enough methanol or other suitable solvent in the titration vessel to cover the electrodes, and add sufficient *Reagent* to give the characteristic endpoint color or ▲the appropriate electrode response.

Either▲ (USP 1-May-2022) *Purified Water*, ▲USP Sodium Tartrate Dihydrate RS, ▲ (USP 1-May-2022)or commercial standards with a certificate of analysis traceable to a national standard may be used to standardize the *Reagent*. The reagent equivalency factor, the recommended titration volume, buret size, and amount of standard to measure are factors to consider when deciding which standard and how much to use.[1] For *Purified Water* or water standards, quickly add the equivalent of between 2 and 250 mg of water. Calculate the water equivalency factor, $F$, in milligrams of water per milliliter of reagent:

$$\text{Result} = W/V$$

in which $W$ is the weight, in milligrams, of the water contained in the aliquot of standard used; and $V$ is the volume, in milliliters, of the *Reagent* used in the titration. For sodium tartrate dihydrate, quickly add 20–125 mg of sodium tartrate dihydrate ($C_4H_4Na_2O_6 \cdot 2H_2O$), accurately weighed by difference, and titrate to the endpoint. The water equivalence factor $F$, in milligrams of water per milliliter of reagent, is given by the formula:

$$\text{Result} = W/V\,(36.04/230.08)$$

in which 36.04 is 2 times the molecular weight of water and 230.08 is the molecular weight of sodium tartrate dihydrate; $W$ is the weight, in milligrams, of sodium tartrate dihydrate; and $V$ is the volume, in milliliters, of the *Reagent* consumed in the second titration. Note that the solubility of sodium tartrate dihydrate in methanol is such that fresh methanol may be needed for additional titrations of the sodium tartrate dihydrate standard.

## PROCEDURE

Unless otherwise specified, transfer enough methanol or other suitable solvent to the titration vessel, ensuring that the volume is sufficient to cover the electrodes (approximately 30–40 mL), and titrate with the *Reagent* to the electrometric or visual

[1] Consider a setup in which the reagent equivalency factor is 5 mg/mL, and the buret volume is 5 mL and an instrumental endpoint. Standard amounts equivalent to between 2.5 and 22.5 mg of water (10%–90% of buret capacity) could be used based on the buret and the reagent equivalency factor. The upper end of this range would involve an excessive amount of sodium tartrate dihydrate. If *Purified Water* or a standard is weighed, an analytical balance appropriate to the amount weighed is required.

endpoint to consume any moisture that may be present. (Disregard the volume consumed because it does not enter into the calculations.) Quickly add the *Test Preparation*, mix, and again titrate with the *Reagent* to the electrometric or visual endpoint. Calculate the water content of the specimen taken, in milligrams:

$$\text{Result} = SF$$

in which $S$ is the volume, in milliliters, of the *Reagent* consumed in the second titration; and $F$ is the water equivalence factor of the *Reagent*.

## Method Ib (Residual Titration)

### PRINCIPLE

See the information given in the section *Principle* under *Method Ia*. In the residual titration, excess *Reagent* is added to the test specimen, sufficient time is allowed for the reaction to reach completion, and the unconsumed *Reagent* is titrated with a standard solution of water in a solvent such as methanol. The residual titration procedure is applicable generally and avoids the difficulties that may be encountered in the direct titration of substances from which the bound water is released slowly.

### APPARATUS, REAGENT, AND TEST PREPARATION

Use *Method Ia*.

### STANDARDIZATION OF WATER SOLUTION FOR RESIDUAL TITRATION

Prepare a *Water Solution* by diluting 2 mL of water with methanol or other suitable solvent to 1000 mL. Standardize this solution by titrating 25.0 mL with the *Reagent*, previously standardized as directed under *Standardization of the Reagent*. Calculate the water content, in milligrams per milliliter, of the *Water Solution* taken:

$$\text{Result} = V'F/25$$

in which $V'$ is the volume, in milliliters, of the *Reagent* consumed, and $F$ is the water equivalence factor of the *Reagent*. Determine the water content of the *Water Solution* weekly, and standardize the *Reagent* against it periodically as needed.

### PROCEDURE

Where the individual monograph specifies that the water content is to be determined by *Method Ib,* transfer enough methanol or other suitable solvent to the titration vessel, ensuring that the volume is sufficient to cover the electrodes (approximately 30–40 mL), and titrate with the *Reagent* to the electrometric or visual endpoint. Quickly add the *Test Preparation*, mix, and add an accurately measured excess of the *Reagent*. Allow sufficient time for the reaction to reach completion, and titrate the unconsumed *Reagent* with standardized *Water Solution* to the electrometric or visual endpoint. Calculate the water content of the specimen, in milligrams, taken:

$$\text{Result} = F(X' - XR)$$

in which $F$ is the water equivalence factor of the *Reagent*; $X'$ is the volume, in milliliters, of the *Reagent* added after introduction of the specimen; $X$ is the volume, in milliliters, of standardized *Water Solution* required to neutralize the unconsumed *Reagent*; and $R$ is the ratio, $V'/25$ (mL *Reagent*/mL *Water Solution*), determined from the *Standardization of Water Solution for Residual Titration*.

## Method Ic (Coulometric Titration)

### PRINCIPLE

The Karl Fischer reaction is used in the coulometric determination of water. Iodine, however, is not added in the form of a volumetric solution but is produced in an iodide-containing solution by anodic oxidation. The reaction cell usually consists of a large anode compartment and a small cathode compartment that are separated by a diaphragm. Other suitable types of reaction cells (e.g., without diaphragms) may also be used. Each compartment has a platinum electrode that conducts current through the cell. Iodine, which is produced at the anode electrode, immediately reacts with water present in the compartment. When all the water has been consumed, an excess of iodine occurs, which usually is detected electrometrically, thus indicating the endpoint. Moisture is eliminated from the system by pre-electrolysis. Changing the Karl Fischer solution after each determination is not necessary because individual determinations can be carried out in succession in the same reagent solution. A requirement for this method is that each component of the test specimen is compatible with the other components, and no side reactions take place. Samples are usually transferred into the vessel as solutions by means of injection through a septum. Gases can be introduced into the cell by means of a suitable gas inlet tube. Precision in the method is predominantly governed by the extent to which atmospheric moisture is excluded from the system; thus, the introduction of solids into the cell may require precautions, such as working in a glove box in an atmosphere of dry inert gas. Control of the system may be monitored by measuring the amount of baseline drift, which does not preclude the need of any blank correction when used as a vehicle for sample introduction. This method is particularly suited to chemically inert substances like hydrocarbons, alcohols, and ethers. In comparison with the volumetric Karl Fischer titration, coulometry is a micro-method.

Official

https://pharmacopeia.cn/v-cn/

When appropriate, the water may be desorbed or released from the sample by heat in an external oven connected with the vessel, to where it is transferred with the aid of an inert and dried gas such as pure nitrogen. Any drift due to the transport gas should be considered and corrected. Care should be taken in the selection of the heating conditions to avoid the formation of water coming from dehydration due to decomposition of the sample constituents, which may invalidate this approach.

### APPARATUS

Any commercially available apparatus consisting of an absolutely tight system fitted with the necessary electrodes and a magnetic stirrer is appropriate. The instrument's microprocessor controls the analytical procedure and displays the results. Calibration of the instrument is not necessary, as the current consumed can be measured absolutely.

### REAGENT

See the manufacturer's recommendations.

### TEST PREPARATION

Where the specimen is a soluble solid, an appropriate quantity, accurately weighed, may be dissolved in anhydrous methanol or other suitable solvents.

Where the specimen is an insoluble solid, an appropriate quantity, accurately weighed, may be extracted using a suitable anhydrous solvent and may be injected into the anolyte solution. Alternatively, an evaporation technique may be used in which water is released and evaporated by heating the specimen in a tube in a stream of dry inert gas. The gas is then passed into the cell.

Where the specimen is to be used directly without dissolving in a suitable anhydrous solvent, an appropriate quantity, accurately weighed, may be introduced into the chamber directly.

Where the specimen is a liquid, and is miscible with anhydrous methanol or other suitable solvents, an appropriate quantity, accurately weighed, may be added to anhydrous methanol or other suitable solvents.

### PROCEDURE

Using a dry device, inject or add directly an accurately measured amount of the sample or sample preparation estimated to contain between 0.5 and 5 mg of water, or an amount recommended by the instrument manufacturer into the anolyte, mix, and perform the coulometric titration to the electrometric endpoint. Read the water content of the liquid *Test Preparation* directly from the instrument's display, and calculate the percentage that is present in the substance. Perform a blank determination, as needed, and make any necessary corrections.

## METHOD II (AZEOTROPIC—TOLUENE DISTILLATION)

### Apparatus

Use a 500-mL glass flask A connected by means of a trap B to a reflux condenser C by ground glass joints (see *Figure 1*).

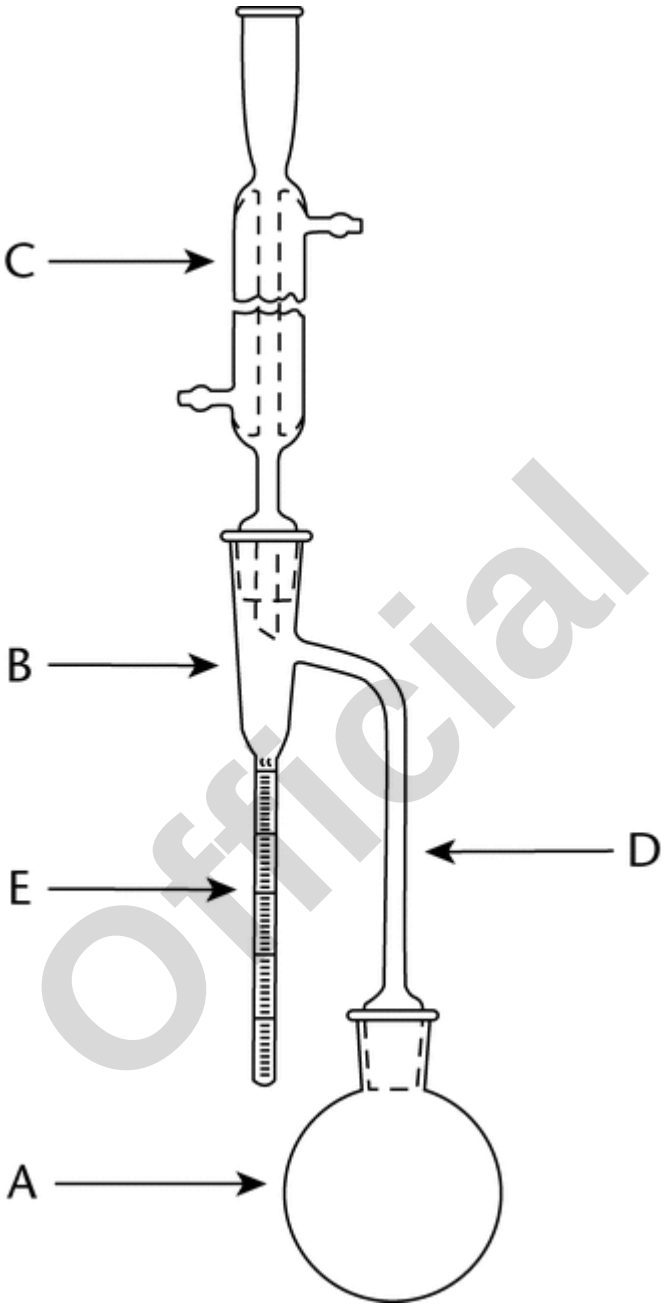

Figure 1. Toluene moisture apparatus.

The critical dimensions of the parts of the apparatus are as follows. The connecting tube D is 9–11 mm in internal diameter. The trap is 235–240 mm in length. The condenser, if of the straight-tube type, is approximately 400 mm in length and not less than 8 mm in bore diameter. The receiving tube E has a 5-mL capacity, and its cylindrical portion, 146–156 mm in length, is graduated in 0.1-mL subdivisions, so that the error of reading is not greater than 0.05 mL for any indicated volume. The source of heat is preferably an electric heater with rheostat control or an oil bath. The upper portion of the flask and the connecting tube may be insulated.

Clean the receiving tube and the condenser with a suitable cleanser, thoroughly rinse with water, and dry in an oven. Prepare the toluene to be used by first shaking with a small quantity of water, separating the excess water, and distilling the toluene.

## Procedure

Place in the dry flask a quantity of the substance, weighed accurately to the nearest centigram, which is expected to yield 2–4 mL of water. If the substance is of a pasty character, weigh it in a boat of metal foil of a size that will just pass through the neck of the flask. If the substance is likely to cause bumping, add enough dry, washed sand to cover the bottom of the flask, or a number of capillary melting-point tubes, about 100 mm in length, sealed at the upper end. Place about 200 mL of toluene

https://pharmacopeia.com/

in the flask, connect the apparatus, and fill the receiving tube E with toluene poured through the top of the condenser. Heat the flask gently for 15 min and, when the toluene begins to boil, distill at the rate of about 2 drops/s until most of the water has passed over, then increase the rate of distillation to about 4 drops/s. When the water has apparently all distilled over, rinse the inside of the condenser tube with toluene while brushing down the tube with a tube brush attached to a copper wire and saturated with toluene. Continue the distillation for 5 min, then remove the heat, and allow the receiving tube to cool to room temperature. If any droplets of water adhere to the walls of the receiving tube, scrub them down with a brush consisting of a rubber band wrapped around a copper wire and wetted with toluene. When the water and toluene have separated completely, read the volume of water, and calculate the percentage that was present in the substance.

## METHOD III (GRAVIMETRIC)

### Procedure for Chemicals

Proceed as directed in the individual monograph preparing the chemical as directed under ⟨731⟩.

### Procedure for Biologics

Proceed as directed in the individual monograph.

### Procedure for Articles of Botanical Origin

Place about 10 g of the drug, prepared as directed (see *Articles of Botanical Origin* ⟨561⟩*, Methods of Analysis*) and accurately weighed, in a tared evaporating dish. Dry at 105° for 5 h, and weigh. Continue the drying and weighing at 1-h intervals until the difference between two successive weighings corresponds to not more than 0.25%.

# ▲⟨922⟩ WATER ACTIVITY

## INTRODUCTION

Many pharmacopeial articles include water within their matrices and are also susceptible to water exchange with the surrounding environment. Total water content is an important quality attribute, and several methods for determining water content are provided in *Water Determination* ⟨921⟩. Some of the water may be tightly bound and not available to participate in chemical, biochemical, or physicochemical reactions (e.g., as hydrate salts), whereas some of the water may be more freely available to participate in reactions such as hydrolysis or may provide an environment that can support microbiological growth. It is important to establish what fraction of the total water is available (active), and the determination of water activity ($a_w$) provides this information. This chapter outlines the recommended methods to qualify, calibrate, and use water activity meters to accurately measure the water activity ($a_w$) of raw materials and products.

## THEORETICAL BACKGROUND

Water activity ($a_w$) is equal to the vapor pressure of water in the sample ($p$) relative to the vapor pressure of pure water ($p_o$) at the same temperature (*1,2*):

$$a_w \equiv \left(\frac{p}{p_o}\right)_T = \left(\frac{RH_{eq}(\%)_{\text{sample}}}{RH_{eq}(\%)_{\text{water}}}\right)_T$$

$p$ = partial vapor pressure of water in the sample at the temperature of the measurement
$p_o$ = saturation vapor pressure of water at the temperature of the measurement
$T$ = temperature of the measurement
$RH_{eq}$ = the equilibrium relative humidity above the sample or pure water

The saturation vapor pressure of pure water depends only on its temperature, so, if $p$ and sample temperature are known, $a_w$ can be readily determined.

Measurement of $p$ is performed by allowing a sample to equilibrate with the moisture in the headspace above the sample at ambient or a standardized temperature and then measuring the vapor pressure of water in the headspace. Water activity meters may measure the relative humidity of the headspace with a moisture-dependent resistor or capacitor, or they may use psychrometry (wet bulb temperature), optical absorption, or dew point temperature.

The relative humidity of the headspace of the instrument cell is defined as:

$$RH = \left(\frac{p_a}{p_{o,a}}\right)_T$$
$$\%RH = RH \times 100$$

$p_a$ = partial vapor pressure of water in the air at the temperature of the measurement
$p_{o,a}$ = saturation vapor pressure of pure water in the air at the temperature of the measurement

When the water vapor in the sample and the headspace are in equilibrium ($p = p_a$), combine the two equations:

$$a_w \equiv \left(\frac{p}{p_o}\right)_T = \frac{\%RH}{100}\left(\frac{Po,a}{Po}\right)_T$$

Use this equation to determine the water activity of a sample from a relative humidity measurement of the headspace. If the air in the headspace is also in temperature equilibrium with the sample, the saturation vapor pressures divide out so that $a_w = RH$. If the temperatures are not equal, and one assumes that water activity equals the air relative humidity, errors can be significant.

If a wet bulb temperature is used to determine the headspace vapor pressure, the psychrometer equation is used, and vapor pressure of the sample is calculated as:

$$p = p_{o,Twb} - \gamma P(T_a - T_{wb})$$

$p_{o,Twb}$ = saturation vapor pressure of pure water at wet bulb temperature
$\gamma$ = psychrometer constant
$P$ = atmospheric pressure
$T_a$ = ambient temperature (temperature of the air in headspace)
$T_{wb}$ = wet bulb temperature

Official

https://pharmacopeia.cn/v-cn/

The wet bulb temperature is lower than the ambient temperature as a result of the cooling provided by the evaporation rate of water. The psychrometric constant has a value of about 0.0006/degree but is reduced as the wet bulb temperature approaches the ambient temperature (*3*).

Optical absorption methods measure water vapor pressure via attenuation of ultraviolet or infrared light by the water vapor molecules in the headspace. The relationship between absorption and vapor pressure of the sample is given by Beer-Lambert law:

$$p = \frac{1}{\kappa x}\ln\left(\frac{I_o}{I}\right)$$

$k$ = extinction coefficient
$x$ = path length (cm)
$I_o$ = unattenuated beam strength
$I$ = attenuated beam strength

The vapor pressure from this equation can be directly used, along with sample temperature, to calculate $a_w$.

Dew point temperature can be used to determine water vapor pressure because the saturation vapor pressure of water at the dew point temperature is equal to the water vapor pressure of the air ($p_{o,Td} = p_a$) at the measurement temperature. For the dew point measurement, calculate the water activity as:

$$a_w = \left(\frac{p_{o,\,Td}}{p_o}\right)$$

$p_{o,Td}$ = saturation vapor pressure of pure water at dew point temperature

If the sample temperature and dew point temperature of the headspace air are known, the water activity can be calculated directly. Water vapor equilibration is still required, but temperatures do not need to be in equilibrium for this measurement to be accurate.

To accurately measure the relative humidity of the headspace above the sample, the temperature of the sample needs to be constant and the headspace being sampled needs to be sealed off from the rest of the laboratory environment. Some instruments only perform measurements at ambient temperature, but other instruments control the temperature in the sample chamber and may perform $a_w$ measurements over a wide range of temperatures. Methods that rely on dew point temperature or wet bulb temperature may not be able to accurately determine these lower temperatures if they are close to (or below) the freezing point of water. Therefore, these instruments may have difficulty accurately measuring samples with very low water activity. Verify the minimum water activity that the instrument manufacturer claims can be accurately measured with these instruments.

Errors in measurement may result from attempting to use the meter in a location where the temperature is not sufficiently stable or with a poor headspace seal (e.g., due to a worn O-ring or sample contamination of the O-ring). Presence of other volatiles (e.g., organic acids, glycerin, alcohol) may adversely affect the measurement unless the sensor is protected appropriately. Contamination of the probe or the sample cup with extraneous water or hygroscopic solids also can affect the accuracy of the measurements.

## FACTORS AFFECTING WATER ACTIVITY

When water is strongly bound to a solute or surface, the $a_w$ is reduced. In solution, this relationship between the $a_w$ and the solute concentration is given by:

$$\ln a_w = -\varphi_m v m M_w$$

$\varphi_m$ = osmolality coefficient
$v$ = stoichiometric coefficient for the solute
$m$ = concentration of the solute (mol of solute/kg of water)
$M_w$ = molar mass of water, 18.01528 g/mol

This relationship between solution osmolality and water activity allows the use of well-defined salt solutions for calibration of instruments. Specific water activity values can be produced by precise preparation of unsaturated salt solutions or by using saturated salt solutions at specific temperatures. Solutions with high osmolality will exhibit low water activity and will not support microbial growth.

When water is adsorbed to the surface of a solid, the relationship between the $a_w$ and the enthalpy of adsorption is given by:

$$\frac{\partial}{\partial T}\ln a_w = \frac{q_{st}}{RT^2} = \frac{\left(Q_{st} - \Delta H_{vap}\right)}{RT^2}$$

$q_{st}$ = net isosteric heat of sorption

Official

https://pharmacopeia.cn/
Printed on: Fri Jan 05 2024 06:37:15 AM (EST)
Printed by: USP NF
Do Not Distribute
Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-May-2021
DOI Ref: ig3jn
DocId: GUID-B5DDDC52-0DC8-4603-B81B-03EA4FB025B8_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M12475_02_01
@2024 USPC

$R$ = universal gas constant
$T$ = temperature (°K)
$Q_{st}$ = isosteric heat of sorption
$\Delta H_{vap}$ = enthalpy of the transition from vapor to adsorption in the sample

Hygroscopic solids may have multiple binding sites for water on a given surface; some water may be tightly bound and unavailable for chemical reactions or to support microbial growth, whereas some water may be more loosely bound and available. At low relative humidities, the stronger binding sites will be occupied first, $q_{st}$ will be >44 kJ/mol, and the water activity will remain low. However, as relative humidity increases and once all the strong binding sites are occupied, additional adsorbed water will be associated with previously adsorbed water, $q_{st}$ will approach $\Delta H_{vap}$ of water (43.99 kJ/mol at 25° C), and the water activity of the solid will increase significantly.

Water activity is measured at a specific temperature, but the temperature to which products are exposed varies greatly. The temperature dependence of the water activity is described by the Clausius–Clapeyron equation:

$$\ln\left(a_{w2}\right) = \ln\left(a_{w1}\right) - \frac{q_{st}}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right)$$

$a_{w1}$, $a_{w2}$ = water activity at $T_1$ and $T_2$, respectively
$q_{st}$ = isosteric heat of sorption
$T_1, T_2$ = temperature (°K)
$R$ = universal gas constant (8.314 J/mol · K)

If the natural logarithm of water activity is plotted as a function of reciprocal Kelvin temperature, a straight line will result, with slope $q_{st}/R$. In hygroscopic solids at low water content, $q_{st}$ will be larger but will approach $\Delta H_{vap}$ of water as the water content increases. As temperature increases, the water activity will also increase, but it will increase more significantly for hygroscopic solids with low water content. Therefore, if the water activity of a product or raw material is an important attribute (i.e., for risk assessments regarding the potential for supporting microbial growth) the risk assessment should be based on the worst-case (i.e., maximum) water activity, which is typically at the highest temperature.

Regardless of the principle of measurement, water activity meters can be calibrated and qualified using standard solutions (either saturated or unsaturated salt solutions) that provide a known and constant $RH_{eq}$. Alternatively, a relative humidity generator may also be used for calibration.

## APPLICATION OF WATER ACTIVITY MEASUREMENTS

The determination of $a_w$ aids in decisions during ingredient and product processes design, ingredient selection, packaging selection, and product storage conditions.[1] These include:

- Selecting ingredient isolation and product manufacturing processes conditions in terms of maintaining $a_w$ below the critical threshold to obtain thermodynamic control of the desired solid form (e.g., hydrate versus anhydrate)
- Selecting excipients for which $a_w$ may impact their material flow, compression characteristics, hardness, and performance characteristics (e.g., disintegration and dissolution) of dosage forms
- Optimizing fluidized bed drying processes
- Reducing the degradation of active ingredients within product formulations (e.g., those susceptible to chemical hydrolysis)
- Establishing the level of protection to product formulations to moisture by primary packaging materials during their shelf life
- Optimizing the shelf-life stability of probiotics
- Providing a complementary method for monitoring changes in water content
- Controlling and monitoring physical, chemical, and microbial product stability
- Optimizing formulations to improve the antimicrobial effectiveness of preservative systems
- Reducing the susceptibility of formulations to microbial contamination
- Providing a tool to justify the reduction of microbial testing of nonsterile drug and dietary supplements formulations (see *Application of Water Activity Determination to Nonsterile Pharmaceutical Products* ⟨1112⟩)

As per *Validation of Compendial Procedures* ⟨1225⟩, water activity methods will typically fall into Category III tests in which precision is a validation requirement; however, accuracy and specificity also may be relevant for fitness of purpose. Specificity may be a concern when other volatiles may affect the result of the water activity measurement and may be addressed by appropriate selection of the instrument type or use of organic filters to protect the water activity sensor. Optimal selection of the type of water activity instrument and the qualification requirements of that instrument will depend on the specific application(s).

## TYPES OF WATER ACTIVITY INSTRUMENTS

### Dew Point Temperature—Chilled Mirror

At the dew point temperature, the relative humidity will be 100%, the evaporation and condensation rates will be equal, and there will not be any net condensation. When the temperature of a surface drops below the dew point temperature, water will condense on it. The dew point temperature can be determined by cooling a mirror in the sample chamber until condensation begins to occur and recording the mirror temperature at that point. The condensation on the chilled mirror is detected by an optical sensor. The difference between the dew point temperature and the temperature of the sample chamber is used to determine the relative humidity. The mirror must be kept clean and protected from contamination by dust or volatiles that may condensate on the chilled mirror. Therefore, measurements on micronized powders may increase the likelihood of mirror contamination issues. The measurement of dew point temperature is a primary method of determining the vapor pressure of the headspace.

### Electronic Hygrometers—Resistive (Electrolytic) Hygrometer

In this instrument, the relative humidity in the sample chamber is measured by a hygroscopic resistor. The resistor is a liquid electrolyte that absorbs or loses water to the air in the sample chamber, and the resulting resistance is proportional to the relative humidity. These sensors provide good precision and typically function over the $a_w$ range of 0.04–1.00. Volatile substances, which are soluble in the liquid electrolyte, may affect the resistance and interfere with the relative humidity measurement. Chemical filters may be used to absorb volatiles and prevent this interference. The response of these instruments is not necessarily linear, so sensors should be calibrated using multiple reference solutions over the entire operating range. Alternatively, a two-point linear calibration over a narrower range that brackets the sample may be used.

### Electronic Hygrometers—Capacitive Hygrometer

In this instrument, the relative humidity in the sample chamber is measured by a hygroscopic capacitor. The capacitor consists of a hygroscopic dielectric polymer held between conductive plates. The polymer absorbs or loses water to the air in the sample chamber, and the resulting capacitance is proportional to the relative humidity. These sensors may become saturated at high $a_w$ and may exhibit hysteresis after measurement of high $a_w$ samples. Capacitive hygrometers are typically less affected by other volatiles than resistive or dew point sensors; however, care should still be used when performing measurements in the presence of other volatile compounds. The response of these instruments is not necessarily linear, so sensors should be calibrated using multiple reference solutions over the entire operating range. Alternatively, a two-point linear calibration over a narrower range that brackets the sample may be used.

### Optical Hygrometer—Tunable Diode Laser

Water molecules in the gas phase above a product absorb UV and NIR radiation. Strong and broad absorption bands exist that can be used to measure the vapor pressure of air, but many of these are near absorption bands of other volatiles that may interfere. Therefore, broadband optical hygrometers are not useful for water activity measurements. The absorption bands are comprised of individual transitions are unique not only to a specific molecule but to a particular isotope of water. A diode laser can produce light at a specific wavelength, with a narrow bandwidth of <1 nm. The wavelength of a tunable diode laser (TDL) can be tuned to a specific isotopic absorption line in the water vapor spectrum by controlling the laser temperature and can be scanned across that line by modulating the laser current (and, therefore, the laser's temperature). This modulation provides both the attenuated and unattenuated laser intensities in the headspace, from which the vapor pressure of the headspace can be calculated. Because the TDL is capable of measuring vapor pressure in the presence of even high concentrations of other volatiles, it is the only method that can correctly measure water activity in these situations. Electronic and dew point hygrometers can sometimes function in the presence of low concentrations of volatiles, but readings are always adversely affected by the volatile. The TDL also can be used to measure water activity non-invasively in transparent sealed containers.

### Near-Infrared Spectroscopy

Near-infrared spectroscopy (NIR) does not measure $a_w$ directly but can be used to infer the $a_w$ simultaneously with the water content. The use of NIR to measure $a_w$ is based on first generating a prediction model for a particular official article (product or raw material) to correlate NIR absorbance spectra to the $a_w$ (measured with one of the previously mentioned direct methods). This prediction model then may be used to rapidly predict the $a_w$ of additional samples. When additional prediction models are available, NIR can be used for simultaneous determination of other components such as the content of active ingredients, additives, or excipients. The NIR method is ideally suited for rapid analysis of raw materials, in-process materials, and end products.

### Other Methods

Other methods for measurement of $a_w$ may be useful but are more rarely employed for routine measurements of pharmaceutical products, dietary supplements, and raw materials. These methods include hair hygrometry, freezing point depression, thermocouple psychrometry, and isopiestic methods. Hair hygrometers may be useful for approximate $a_w$ measurements but not for routine work due to long equilibration times and low accuracy. The freezing-point and thermocouple

psychometry instruments are only useful for measurements at high $a_w$ (>0.8) and, therefore, have limited applicability. The isopiestic methods rely on the measurement of the moisture sorption isotherm and, therefore, entail lengthy procedures that gather information on the $a_w$ over a range of water content.

## QUALIFICATION OF WATER ACTIVITY METERS

Most water activity instruments, namely electronic hygrometers, dew point instruments, and others, are classified as Group B instruments as described in *Analytical Instrument Qualification* ⟨1058⟩. The qualification of a water activity instrument should cover the intended operational range of the instrument, the required accuracy of the instrument, and the required precision of the instrument (for more details, see ⟨1058⟩). Acceptance criteria for fitness for purpose are based on the uncertainty of $a_w$ generated by the reference material and the performance specification of the instrument.

Any type of water activity instrument that is shown to be fit for the intended purpose, by meeting the qualification criteria, may be used to provide $a_w$ results according to the guidelines of this chapter.

In contrast, NIR instruments are classified as Group C instruments as described in ⟨1058⟩. Therefore, the "analytical instrument qualification" described in ⟨1058⟩ and *Near-Infrared Spectroscopy* ⟨856⟩ is not applicable to these instruments.

## OPERATION AND CALIBRATION OF WATER ACTIVITY METERS

### Procedure for Standard Solutions

Water activity meters should be calibrated by using either prepared or purchased standard solutions or by using a calibrated humidity generator. Standard solutions may be prepared or purchased from the instrument manufacturer.

When using purchased solutions, follow the provided use instructions for these standard solutions, including any handling recommendations, storage recommendations, and expiry dating.

*Table 1* lists common saturated salt solutions that may be prepared by the user for calibration or checking the calibration of water activity instruments. Saturated salt solutions may be prepared using *Purified Water* and pure salts (≥99% purity). The salts do not need to be dried prior to use. Standard solutions should be prepared well before use to allow for equilibration of the salt solubility.[1] For previously prepared saturated salt solutions, it should be evident that the solution is still saturated due to the presence of additional undissolved salt, and liquid should completely cover the bottom of the sample container holding the saturated salt solution. Most water activity instrument sample cups are specifically designed to fit that instrument. The saturated salt solution may be prepared in the sample cup or may be prepared in a separate container and transferred to the sample cup for use. In either case, the standard solution should be placed into the sample cup according to the recommendations of the instrument manufacturer with regard to the amount of sample that should be present in the cup during the measurement. In addition to the saturated salt solutions listed in *Table 1*, *Purified Water* may be used as a 1.00 $a_w$ standard solution. It is not required to include a standard at zero water activity; rather, it is acceptable to use an appropriate low $a_w$ standard solution (e.g., lithium bromide or lithium chloride) for samples that have $a_w$ values up to 0.05 $a_w$ below the low $a_w$ standard solution.

**Table 1. Common Saturated Salt Solutions Routinely Used to Calibrate Water Activity Determination Instruments**

| Salt | Approximate Solubility at Saturation (g/100 mL) | $RH_{eq}$ (%) at 25° C[a] | $a_w$ at 25° C[a] |
|---|---|---|---|
| Potassium sulfate ($K_2SO_4$) | 11 | 97.30 | 0.973 ± 0.005 |
| Potassium chloride (KCl) | 34 | 84.34 | 0.843 ± 0.003 |
| Sodium chloride (NaCl) | 36 | 75.29 | 0.753 ± 0.001 |
| Sodium bromide (NaBr) | 91 | 57.57 | 0.576 ± 0.004 |
| Magnesium nitrate [$Mg(NO_3)_2$] | 70 | 52.89 | 0.529 ± 0.002 |
| Potassium carbonate ($K_2CO_3$) | 111 | 43.16 | 0.432 ± 0.004 |
| Magnesium chloride ($MgCl_2$) | 55 | 32.78 | 0.328 ± 0.002 |
| Potassium acetate ($KCH_3CO_2$) | 256 | 22.51 | 0.225 ± 0.003 |
| Lithium chloride (LiCl) | 84 | 11.30 | 0.113 ± 0.003 |
| Lithium bromide (LiBr) | 160 | 6.38 | 0.064 ± 0.005 |

[a] The equilibrium relative humidity for these salts at other temperatures, as well as humidities for other salts, are in Greenspan 1977 (*2*).

#### CALIBRATION OF WATER ACTIVITY METERS

Calibration should be performed annually, as well as any time the calibration check fails.

[1] A default equilibration time of 48 h is recommended for the initial preparation of saturated salt solutions; however, less time may be required if the water activity is confirmed to be stable experimentally. After preparation, the solution will thermally equilibrate to the temperature of use relatively quickly (i.e., 1–2 h).

As described in *Types of Water Activity Instruments*, the sensors in many water activity meters may not provide a linear response over the entire usable water activity range. For instruments with significant non-linearity, a multi-point calibration may be required. However, it is also acceptable to use a two-point, linear calibration over a narrower range that brackets the range of anticipated use. Any time the range of intended use changes, a re-calibration of the instrument should be performed.

Water activity instruments may be adversely affected by significant changes in the atmospheric pressure in the laboratory. Some instruments may be able to correct for changes in the atmospheric pressure while others may require re-calibration. If the instrument includes a correction for atmospheric pressure, verify that the correct atmospheric pressure is used during the calibration, calibration check, and sample measurement procedures.

Perform the instrument calibration according to the directions of the instrument manufacturer using either prepared or purchased standard solutions or using a calibrated humidity generator.

Ideally, the calibration of the water activity instrument should be performed at the temperatures at which it will be used; however, this may not always be feasible. The calibration must be performed at a temperature for which the water activities of the standard solutions are accurately known. (Regardless of the temperature used for the calibration of the instrument, the calibration check should be performed at the temperature of use.)

Following successful calibration, proceed with the *Procedure for Calibration Check*.

## PROCEDURE FOR CALIBRATION CHECK

The purpose of the calibration check is to confirm that the instrument provides a measurement result that is statistically equivalent to the true value of the standard solution. It is acceptable to use either the instrument manufacturer's recommended acceptance criterion for a calibration check or the acceptance criterion described here. A calibration check should be performed each day the instrument is used to perform $a_w$ measurements (e.g., every 24 h during continual use). The results of the calibration check should be recorded so that the performance of the instrument can be monitored over time.

Any purchased or prepared standard solutions may be used to check the calibration of the instrument. It is recommended to use one or more standard solutions on a regular basis as a calibration check so that the performance of the instrument may be followed over time. Use of a low $a_w$ and high $a_w$ standard solution in a calibration check is recommended.

Preferably select a low $a_w$ and high $a_w$ standard solution that brackets the $a_w$ range of the samples to be evaluated or, alternatively, a single standard solution that is close to the expected $a_w$ of the samples. Perform the calibration check at the same temperature as the sample measurements. A successful calibration check may be performed either before or after the sample analysis. If there is a significant concern that sample measurements may adversely affect the water activity sensor (e.g., presence of volatiles or powders in the sample), it is recommended that a calibration check be performed after the sample analysis.

The acceptance criterion is that the absolute error (ABS ERR) must be less than the sum of the instrument repeatability and the uncertainty in the standard solution:

$$\text{ABS ERR} = \left| a_{w^\circ} - a_w \right| \leq (\text{Repeatability of the instrument}) + \left(\text{Uncertainty of } a_{w^\circ}\right)$$

$a_{w^\circ}$ = expected water activity for the standard salt solution at the temperature of the measurement (see *Table 1* or documentation for standard), repeatability of the instrument is twice the standard deviation of the instrument at that water activity,[2] and uncertainty of $a_{w^\circ}$ is either taken from *Table 1* or is provided by the supplier of the purchased standard solution. Because the $a_w$ result will be usually reported to two or three significant digits depending on the precision of the instrument, if the calculated acceptance criterion is calculated to be $\leq 0.01$, then the acceptance criterion of 0.01 should be used.

It is recommended to perform the calibration check with the same number of replicates as will be performed on the samples. For example, if single measurements will be tested and reported, then the calibration check should be performed with a single measurement. If replicate measurements will be performed, then the calibration check should use the same number of replicates and the acceptance criterion applied to the mean result. If the reading falls outside the acceptance range, clean the system and check the age of the standard solution. If the acceptance criterion is still not met, perform a new calibration.

In some use cases (e.g., use of water activity for process analytical measurements), it may be acceptable to allow for some instrument drift over time without requiring the re-calibration of the instrument. In these cases, the ABS ERR acceptance criterion should still be used to initially verify acceptable calibration of the instrument, but an alternative acceptance criterion can be used on subsequent calibration checks to verify acceptable calibration. As an example of a modified criterion:

$$\text{ABS ERR} = \left| a_{w^\circ} - a_w \right| \leq (\text{Repeatability of the instrument}) + \left(\text{Uncertainty of } a_{w^\circ}\right) + (\text{Acceptable drift})$$

Following a successful calibration check, proceed with the *Procedure for Sample Measurement*.

[2] The repeatability of the instrument may be based on the instrument manufacturer's characterization of the instrument capabilities or determined by performing replicate measurements on the standard solution as described in Precision (Repeatability).

## Procedure for Sample Measurement

### SAMPLE PREPARATION

It is very important to ensure that after sampling, during transportation to the laboratory where $a_w$ determinations will take place, samples are kept in well-sealed, water-impermeable containers to protect them from any changes in water composition due to differences in temperature and/or *%RH* at different locations. It is recommended that the sample containers have minimal headspace or a larger sample mass to avoid significant changes in water activity due to re-equilibration of the sample to the environment in the sampling container. Large measurement errors can potentially result from 1) condensation of water on container walls due to temperature gradients in containers with samples that contain high water activity and 2) permeable sample containers exposed to high relative humidity. To prevent variability in the test results due to the exposure of the material to (and rapid re-equilibration with) the surrounding *%RH*, the analyst must be consistent with sample preparation. Performing the water activity test immediately after opening the sealed package is recommended.

To prepare a sample for testing, add the material to the sample container designed for use in the water activity meter. For uniform powders or liquids, it is recommended that the sample material should cover the bottom surface of the sample container entirely unless alternate methods have been verified. Avoid getting testing material on the outside, rim, or above the advised range as per manufacturer's instructions. For non-uniform samples, sample preparation details should be provided within monographs for products that specify the application of $a_w$ determinations. Details should include how the sample should be presented in the instrument (i.e., tablets could be presented as whole units or ground tablets, chewable gels could be sliced in thin pieces, and capsules could also be presented as whole units or capsule contents). The required approach should be specified together with the number of whole units or mass of ground-tablet powder/sliced gels/capsule contents.

### CALIBRATION CHECK

A calibration check should be performed every day the instrument is used to perform measurements. In addition, verify that the instrument is not due for its periodic calibration prior to performing measurements.

### MEASUREMENT PROCEDURE

Analyze the sample per the instrument manufacturer's instructions.

### REPORTING RESULTS

Record the equilibrium $a_w$ and the equilibrium temperature. Report the $a_w$ value or mean value of replicate measurements to two or more significant digits, depending on the application. Report the temperature rounded to the nearest 0.1° C.

## PROCEDURE FOR VERIFICATION AND VALIDATION

It is recommended that the testing laboratory conducts some verification of the $a_w$ method because $a_w$ determinations may be sensitive to variations in sampling procedures, the presence of other volatile components, variations in instrument types and option settings. The recommended parameters to evaluate for verification of the method are *Precision (Repeatability)* and *Intermediate Precision*.

## Precision (Repeatability)

Repeatability is assessed by conducting the $a_w$ determination on six separate aliquots of the same sample while applying the same sample preparation procedure and instrument settings intended for routine sample testing. Repeatability of the instrument can be assessed by repeated measurements of a salt standard solution in the same manner. If repeatability of the $a_w$ measurement on a sample is significantly greater than the repeatability of the instrument, then the instrument may not be suitable for routine measurements of that sample due to the presence of other volatile components interfering with the precision of the instrument.

The acceptance criterion is that the relative standard deviation is NMT 5.0% for $a_w > 0.4$, NMT 15% for $0.15 < a_w \leq 0.4$, and NMT 20% for $a_w \leq 0.15$.

## Intermediate Precision

The effect of random events on the analytical precision of the procedure should be evaluated. Typical variables include conducting the test on different days, using different instrumentation, and having different analysts perform the test. A combination of at least two of these factors totaling six determinations of aliquots taken from the same batch will provide an estimation of intermediate precision. The acceptance criterion is that the relative standard deviation is NMT 6.0% for $a_w > 0.4$, NMT 15% for $0.15 < a_w \leq 0.4$, and NMT 20% for $a_w \leq 0.15$.

## OPERATION, CALIBRATION, AND VALIDATION OF NIR INSTRUMENTS

As described in *Near-Infrared Spectroscopy*, NIR is based on a different physical principle than typical water activity meters and cannot be used for the measurement of the relative humidity of the air above the product. Therefore, the procedure for operation, calibration, and validation described above is not suitable for NIR instruments. More details about operation and

https://pharmacopeia.cn/v-prod/

calibration of NIR can be found in ⟨856⟩. Recommendations for the method development and validation of NIR instruments can be found in *Chemometrics* ⟨1039⟩ and ⟨1225⟩.

# ⟨941⟩ CHARACTERIZATION OF CRYSTALLINE AND PARTIALLY CRYSTALLINE SOLIDS BY X-RAY POWDER DIFFRACTION (XRPD)

***Add the following:***

▲Portions of the chapter text that are national *USP* text, and are not part of the harmonized text, are marked with symbols (◆) to specify this fact.▲ (USP 1-May-2022)

***Change to read:***

## INTRODUCTION

Every crystalline phase of a given substance produces a characteristic X-ray diffraction pattern. Diffraction patterns can be obtained from a randomly oriented crystalline powder composed of crystallites ▲(crystalline regions within a particle)▲ (USP 1-May-2022) or crystal fragments of finite size. Essentially three types of information can be derived from a powder diffraction pattern: the angular position of diffraction lines (depending on geometry and size of the unit cell), the intensities of diffraction lines (depending mainly on atom type and arrangement and ▲preferred▲ (USP 1-May-2022) orientation within the sample), and diffraction line profiles (depending on instrumental resolution, crystallite size, strain, and specimen thickness).

Experiments giving angular positions and intensities of lines can be used for applications such as qualitative phase analysis (e.g., identification of crystalline phases) and quantitative phase analysis of crystalline materials. An estimate of the amorphous and crystalline fractions[1] can also be made.

The X-ray powder diffraction (XRPD) method provides an advantage over other means of analysis in that it is usually nondestructive in nature (to ensure a randomly oriented sample, specimen preparation is usually limited to grinding). XRPD investigations can also be carried out under in situ conditions on specimens exposed to nonambient conditions such as low or high temperature and humidity.

***Change to read:***

## PRINCIPLE

X-ray diffraction results from the interaction between X-rays and electron clouds of atoms. Depending on atomic arrangement, interferences arise from the ▲elastically▲ (USP 1-May-2022) scattered X-rays. These interferences are constructive when the path difference between two diffracted X-ray waves differs by an integral number of wavelengths. This selective condition is described by the Bragg equation, also called Bragg's law (see *Figure 1*).

$$2d_{hkl}\sin\theta_{hkl} = n\lambda$$

[1] There are many other applications of the X-ray powder diffraction technique that can be applied to crystalline pharmaceutical substances, such as determination of crystal structures, refinement of crystal structures, determination of the crystallographic purity of crystalline phases, and characterization of crystallographic texture. These applications are not described in this chapter.

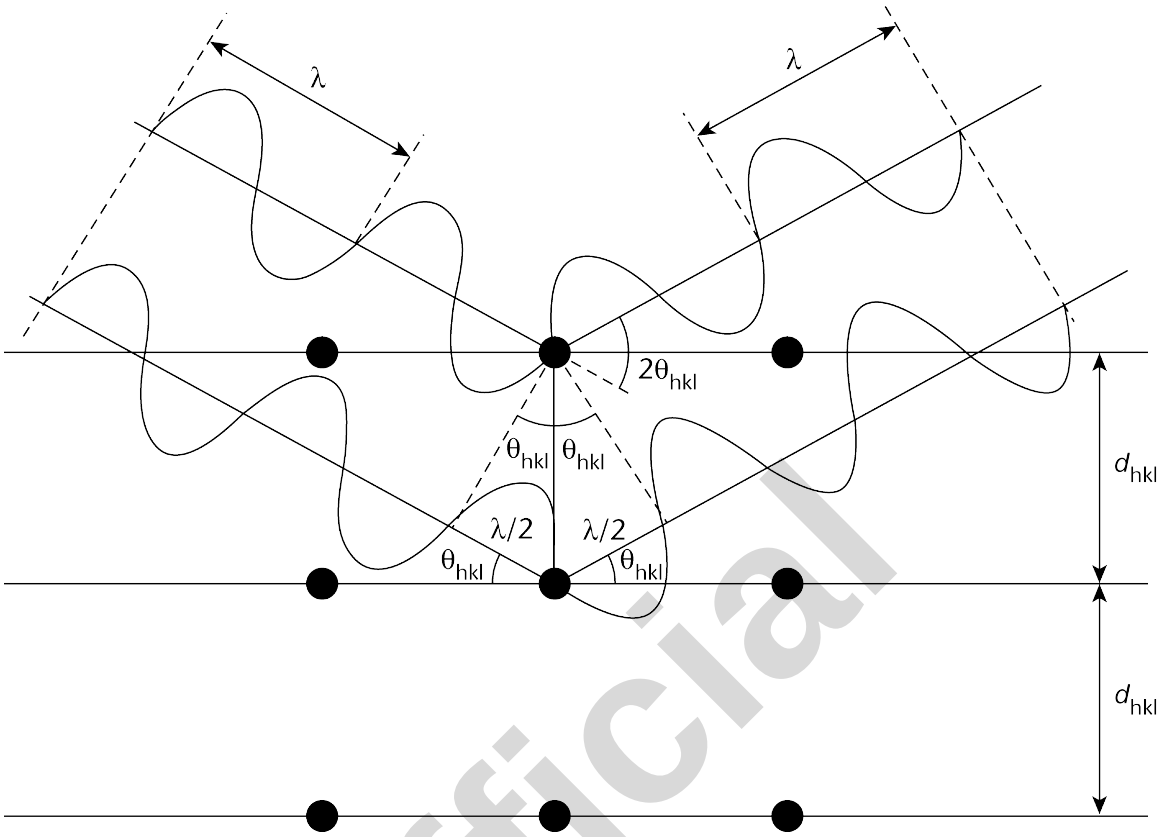

Figure 1. Diffraction of X-rays by a crystal according to Bragg's law.

The wavelength, λ, of the X-rays is of the same order of magnitude as the distance between successive crystal lattice planes, or $d_{hkl}$ (also called d-spacings). $\theta_{hkl}$ is the angle between the incident ray and the family of lattice planes, and sin $\theta_{hkl}$ is inversely proportional to the distance between successive crystal planes or d-spacings.

The direction and spacing of the planes with reference to the unit cell axes are defined by the Miller indices {hkl}. These indices are the reciprocals, reduced to the next-lower integer, of the intercepts that a plane makes with the unit cell axes. The unit cell dimensions are given by the spacings *a*, *b*, and *c*, and the angles between them α, β, and γ.

The interplanar spacing for a specified set of parallel hkl planes is denoted by $d_{hkl}$. Each such family of planes may show higher orders of diffraction where the *d* values for the related families of planes n*h*, n*k*, n*l* are diminished by the factor 1/n (*n* being an integer: 2, 3, 4, etc.).

Every set of planes throughout a crystal has a corresponding Bragg diffraction angle, $\theta_{hkl}$, associated with it (for a specific λ).

▲For a polycrystalline▲ (USP 1-May-2022) powder specimen ▲▲ (USP 1-May-2022) at any angle $\theta_{hkl}$ there are always crystallites in an orientation allowing diffraction according to Bragg's law.[2] For a given X-ray wavelength, the positions of the diffraction peaks (also referred to as "lines", "reflections", or "Bragg reflections") are characteristic of the crystal lattice (d-spacings), their theoretical intensities depend on the crystallographic unit cell content (nature and positions of atoms), and the line profiles depend on the perfection and extent of the crystal lattice. Under these conditions, the diffraction peak has a finite intensity arising from atomic arrangement, type of atoms, thermal motion, and structural imperfections, as well as from instrument characteristics.

The intensity is also dependent upon many factors such as structure factor, temperature factor, ▲▲ (USP 1-May-2022) polarization factor, multiplicity, ▲and Lorentz and microabsorption factors.▲ (USP 1-May-2022)

The main characteristics of diffraction line profiles are 2θ position, peak height, peak area, and shape (characterized by, e.g., peak width, or asymmetry, analytical function, and empirical representation). An example of ▲▲ (USP 1-May-2022) powder patterns obtained for five different solid phases of a substance ▲is▲ (USP 1-May-2022) shown in *Figure 2*.
