It is, however, not generally applicable and will fail in cases where there are significant absorption edges between the wavelengths of the Compton scattered radiation, at the wavelength of the analytical line used. The correction is based on the relationship between Compton scatter and the sample's absorption properties, and it does not correct for enhancement.

#### 7.2.4 INFLUENCE COEFFICIENT ALGORITHMS

Matrix correction methods based on influence coefficients have the general format:

$$C_i = K_i l_i \left[ 1 + \sum_{\substack{j=1 \\ j \neq i}}^{n} \alpha_{ij} C_j \right] \text{[18]}$$

(based on Lachance and Traill [*14*]) where $C_i$ and $C_j$ are the concentrations of the analyte *i* and the interfering element *j*, respectively, and $\alpha_{ij}$ is the influence coefficient, expressing the influence of interfering element *j* on the analyte *i*. All concentrations are expressed as weight fraction. The summation in *Equation [18]* has $n - 1$ terms, for a sample consisting of n elements or compounds; this is a simple yet essential feature of the algorithm. The same set of equations with *n* terms in the summation would lead to a homogeneous set of simultaneous equations, from which only *ratios* rather than absolute values could be derived.

Because the sum of the concentrations of all elements (whether they are measured or not) in a specimen always totals 1, one element can be eliminated. Most influence coefficient algorithms in software are based on this equation, however they may differ in *how the values of the coefficients are calculated*.

#### 7.2.5 EMPIRICAL INFLUENCE COEFFICIENTS

Lachance and Traill [*14*] indicate that the value of the coefficients should be calculated from theory, but they only provide a simple and limited method that fails to consider enhancement or the polychromatic nature of the incident beam. Therefore, in many cases the coefficients were determined using multiple regression methods. Many early variations on influence coefficient algorithms were based on regression techniques that were used to calculate the value of the coefficients. However, the use of regression methods should be discouraged as they often lead to overly optimistic indications of precision and then often fail during validation. This is especially problematic if not enough certified reference materials are used in the calibration. The minimum number of standards used should be at least 3 times the number of parameters. Each of the influence coefficients whose value is determined by regression consumes one degree of freedom, as does the determination of slope and intercept.

The total number of parameters to be determined can grow rapidly for a single analyte. For example, assume that there are three interfering elements, and thus with slope and intercept, a total of five parameters need to be determined. This requires a minimum of 15 *independent* and *uncorrelated* standard samples. Note that replicates of the same standard sample do not count as individual samples, but instead count as a single one; this is a common source of error. Also, care must be taken to ensure that the standards are uncorrelated. This implies that a series of dilutions from a given standard cannot be used when empirical influence coefficients are to be determined. In a dilution series, two (or more) components *A* and *B* increase (or decrease) in the same direction. Thus the effect of component *A* on the intensity of the analyte cannot be distinguished from component *B*'s effects, leading to erroneous values for the influence coefficients.

#### 7.2.6 THEORETICALLY CALCULATED INFLUENCE COEFFICIENTS

De Jongh [*15*] was the first to publish a method detailing the calculation of influence coefficients, using theory only to eliminate a compound other than the analyte. The algorithm is still in common use today. The eliminated compound can be the non-fluorescing matrix, such as cellulose, or the matrix when its concentration is not certified. Note that the concentration range over which the algorithm delivers precise results is rather limited when the matrix effects are severe. This is a direct consequence of the fact that the values of the influence coefficient are calculated for a particular composition of the sample. For routine analysis involving relatively limited concentration ranges, the algorithm delivers excellent results. In contrast to the situation where the values of influence coefficients are determined by regression (see *7.2.5 Empirical Influence Coefficients*) it is feasible to calibrate using dilution series.

### 7.3 Measurement Method Development and Calibration

#### 7.3.1 OVERVIEW

Once the elements of interest have been identified, the spectrometer measurement parameters must be set appropriately. This involves determining the "ideal" measurement conditions for each element. The list of parameters to be selected for each analyte can include, for example, the voltage and current on the X-ray tube, the crystal and the collimator (WDXRF), the type of primary beam filter (if used), and other parameters. For elements that are similar in atomic number, the settings will be quite similar. The precision of XRF measurements is theoretically limited by the CSE. It has been shown that the CSE of a measurement of *N* counts (photons) is given by the square root of *N*. It is a generally accepted practice to determine the measurement times that obtain an acceptable CSE for each element of interest. Sample preparation errors and the CSE are the

@2024 USPC

largest contributors to the total analytical precision. Once the measurement time has been established, it is important to ensure that the background positions and methods for peak fitting are also appropriate.

After the net intensities of the elements of interest have been obtained from a suitable number of reference standards, a calibration can be performed. For low concentrations of analytes in an otherwise constant matrix, linear regression may be appropriate. When evaluating specimens with higher concentrations of analytes, the calibration also involves correction for matrix effects. The fact that the EDXRF technique is not capable of measuring the organic constituents of an actual pharmaceutical composition is of little concern. This is certainly true if the composition of the matrix is constant, and if the total content of measurable elements is low. But if these two conditions are not satisfied, the difference in scattering properties can result in calculation errors if not corrected. Fortunately, there are numerous strategies that accommodate these differences, such as the fundamental parameters method or the Compton correction method. The nature of matrix effects, as well as methods to correct for them, have been discussed above. The application of these methods to calibration and analysis of unknowns will be discussed in the sections below.

### 7.3.2 CALIBRATION USING INFLUENCE COEFFICIENT ALGORITHMS

Calibration using influence coefficients is rather straightforward. Once the values for the coefficients have been calculated for each of the standard samples, the summation

$$M_i = \left[1 + \sum_{\substack{j=1 \\ j \neq e}}^{n} \alpha_{ij} C_j\right] \text{[19]}$$

can be calculated where for standard samples, the concentrations, $C_j$, are known. The value of $M_i$ for one standard sample will be different from the value for another standard sample, and it does not matter whether the difference is significant or slight (large or small). If adequate corrections for background have been made, calibration is then represented by

$$C_i = K_i I_i M_i \text{ [20]}$$

where the product of the measured intensity, $I_i$, and the corresponding value for the matrix effect ,$M_i$, are regressed against the given, known concentration, $C_i$, to determine the slope, $K_i$. This equation assumes that the intensity, $I_i$, is properly corrected for the background. In those cases where the intensity of the background is constant between samples and standards, a slightly modified equation can be used:

$$C_i = B_i + K_i I_i M_i \text{ [21]}$$

where $B_i$ is the intensity of the background. In this case, both $B_i$ and $K_i$ are determined by regression analysis. In situations where the background intensity varies significantly between samples, or between samples and standards, proper background correction must be applied to the measured intensities, and the corrected intensities must be used for the calibration.

### 7.3.3 CALIBRATION USING COMPTON CORRECTION

In this case, both the intensity of the analyte, $I_i$, and the intensity of the Compton scattered line, $I_C$, are measured. The intensity of the Compton is inversely proportional to the mass attenuation coefficient [*12*], or

$$M_i = \frac{1}{I_C} \text{ [22]}$$

Combining this with *Equation [20]* leads to

$$C_i = K_i I_i \frac{1}{I_C} \text{ [23]}$$

The intensity of the analyte and the Compton line are measured on a suite of standard samples and regressed against the analyte concentration to determine the value of the slope of the calibration. A background factor, $B_i$, can be determined as well.

### 7.3.4 CALIBRATION USING FUNDAMENTAL PARAMETER METHODS

The physical processes involved in absorption and excitation during XRF are well understood, and it is possible to calculate the value of the matrix effect based on several factors: the composition of the sample, the type and settings of the tube, the geometry of the spectrometer, and the fundamental parameters:

$$M_i = f(C_i, C_j, \ldots, C_n, \textit{tube}, \textit{geometry}, \textit{fp}) \text{ [24]}$$

This value of $M_i$ is calculated for each standard and for each analyte of interest, and then applied in the usual manner.

Official

https://pharmacopeia.cn/v-cn/

#### 7.3.5 INTERNAL STANDARD METHOD

An alternative to the methods described above is the internal standard method. A fixed quantity of an element *s* (other than the analyte *i*) is added to all specimens. The element *s* is chosen such that it is not present in the specimens, thus ensuring that its concentration is the same for all specimens. In the absence of matrix effects, the measured intensity of its characteristic radiation would also be constant. Any variation in its intensity (other than the variation resulting from the counting statistical error) is attributed to the presence of matrix effects. The idea is to choose the internal standard element *s* in such a way that the intensity of its characteristic radiation is subject to the same matrix effects as the intensity of the analyte element under consideration. Both intensities—of the analyte and of the added element—increase (or decrease) in proportion to one another depending upon the matrix effect. *Equation [22]* can be modified for the internal standard element *s*:

$$C_s = K_s I_s M_s \text{ [25]}$$

In this equation, $C_s$ is a constant. Taking the ratio of *Equation [20]* and *Equation [25]* and solving for the only unknown, $C_i$, yields

$$C_i = \frac{K_i M_i C_s}{K_s M_s} \frac{I_i}{I_s} \text{ [26]}$$

It is important to note that the terms of the first fraction in *Equation [26]* are either all constants ($K_i$, $K_s$, and $C_s$) or are proportional to one another ($M_i/M_s$). *Equation [26]* can thus be reduced to

$$C_i = K_i^* \frac{I_i}{I_s} \text{ [27]}$$

where all of these constants are collated in a single variable $K_i^*$.

The main challenge in applying this method is the selection of the element to be used as the internal standard. This element must not be present in the specimens (or at most, present at very low levels that will not interfere with the analysis). Also, its characteristic radiation must be subject to the same matrix effects as the analyte(s) of interest, and its emission spectrum should not cause interference. In particular, care must be taken to ensure that the analyte element and the internal standard are both subject to (or both *not* subject to) enhancement by a matrix element. In the same fashion, when the analyte is in the presence of matrix elements that strongly absorb the characteristic radiation of the analyte, the same should apply to the characteristic intensity of the internal standard element.

When the samples are organic matrices typical of pharmaceuticals, it is easy to satisfy the essential requirement that the characteristic radiation of both the analyte(s) and the internal standard are subject to the same matrix effects. These organic matrices do not exhibit characteristic radiation of their constituent elements, which makes it easier to find a suitable internal standard element. A simple guideline is to choose an element that is not present in the samples and that has an emission line close to the one of the analyte's (with regard to either wavelength or energy). The characteristic lines themselves do not have to be the same or even from the same series, and the method also works when the analytical line is a Kα and the line of the internal standard is, for example, an Lβ. It must be noted that there is no requirement for the internal standard element to be a pure element. Stable compounds that are easily soluble in a solvent can be used. The solvent is, in many cases, the same as the base material of the specimens and the calibration standards. If more than one internal standard element is to be used, it is recommended that both elements/compounds are added in a single internal standard solution, to minimize errors.

### 7.4 System Suitability Criteria

Performance characteristics that demonstrate the suitability of an XRF method are similar to those required for any analytical procedure. A discussion of the applicable general principles is found in *Validation of Compendial Procedures* ⟨1225⟩.

#### 7.4.1 LIMIT OF DETECTION AND LIMIT OF QUANTITATION

The lower limit of detection may be expressed as:

$$LLD = \frac{3.3 \times CSE}{S} = \frac{3.3 \times C}{I_{net}} \sqrt{\frac{I_b}{t_b}} \text{ [28]}$$

with $I_{net}$ representing the net count rate at the concentration, *C*; $I_b$ as the count rate of the background; and $t_b$ as the background measurement time. It is noteworthy that the detection limit will improve with the square root of the measuring time.

The limit of quantitation can be estimated by calculating the standard deviation of NLT six replicate measurements of a blank and multiplying by 10. Other suitable approaches may be used (see ⟨1225⟩).

#### 7.4.2 LONG-TERM STABILITY AND DRIFT CORRECTION

Under standard operating conditions, instrumental drift of X-ray spectrometers is less than 1% relative and can be as small as 0.1% relative for high-end instrumentation in well-maintained laboratories over the same time period. To monitor instrument drift, one or more stable sample(s) with reasonable intensities (to minimize the CSE) for the analytes of interest can be measured on a regular basis. It is not necessary to use *in-type* drift correction samples. It is common to use glassy samples and alloys. Most instruments have drift correction routines within the software, and because XRF is a very robust technique, it may only be

Official

https://nhathuocngocanh.com/

necessary to utilize a drift-monitor once per month. However, it is recommended that most laboratories practice drift monitoring more frequently.

### 7.4.3 ANALYSIS

Once a method has been established through the calibration procedure, a sample analysis may be performed. It is essential to ensure that samples and standards are treated in exactly the same manner. This includes specimen preparation and specimen presentation to the instrument.

### 7.4.4 CALCULATIONS AND REPORTING

In the event that the free-pressed-pellet sample method is used (i.e., pressed without binder), the spectrometer results represent final sample concentrations, and no further calculations are required. Similarly, both loose powders (i.e., pure, fine materials) and undiluted liquids measured in disposable sample containers require no further calculation and the spectrometer results represent final sample concentrations. Any material that has been diluted, such as a liquid or pressed pellet, will require additional calculation. Most modern XRF instrumentation comes with software packages that include calculation functions that accommodate dilution factors and automatically back-calculate sample concentrations. For diluted, pressed-pellet samples, the reported units may be weight % or ppm. The actual units for the concentrations are of little importance, as long as care has been taken to work with the proper conversion factors. If a calibration for liquid samples is setup to deliver results in µg/mL, the final concentration of a given element can be calculated in µg/g from the solution element concentration in µg/mL.

# ⟨1736⟩ APPLICATIONS OF MASS SPECTROMETRY

## 1. INTRODUCTION

Mass spectrometry (MS) is an integral part of modern pharmaceutical research and development in academic, industrial, and clinical laboratories. Trace analytical measurement (both qualitative and quantitative), specifically the demand for trace-mixture analysis, has increased the need for this powerful tool. In many cases, the analytical demands of trace-mixture sample analysis has made MS the method of choice for qualitative and quantitative assays for target analytes such as proteins, peptides, drug substances, metabolites, impurities, and degradation products. Because of its analytical capabilities, MS has found widespread application in the pharmaceutical industry. Specifically within the compendial context, MS has been, or has the potential to be, applied to both qualitative (identification tests) and quantitative measurements (assays).

For qualitative tests, MS-based methods can provide molecular mass information via the detection of the molecular ion or ions related to the molecular mass of the analyte as a first level or step of identification. A variety of instrumental methods permit molecular mass determinations for a wide range of materials, up to and including large biomolecules (e.g., proteins) and polymers. Along with the molecular mass information, MS also can provide unique structural information via the generation of fragment ions. The diversity of fragmentation approaches available in modern MS allows structurally significant fragmentation approaches for a wide variety of compendially relevant materials (e.g., small molecules and peptides).

Molecular mass thus can become a surrogate for confirmation or can even be used for the identification of a targeted compound, particularly when used in conjunction with an authentic standard or a chromatographic method. Advanced studies that involve one or two more dimensions of mass analysis also can be used to obtain specific structural detail (fragment ions that correspond to structurally unique portions of the target molecule) or more selectivity to enable powerful approaches for quantitation. Moreover, higher resolution methods that feature mass spectrometry and chromatography can routinely provide a benefit to the scientific community.

Modern analytical MS includes a diverse range of available instrumentation and experimental approaches. The specific mass spectrometer, and, of course, specific chemistries (i.e., sample preparation, chromatography, and ionization) define the final analytical procedure.

## 2. MASS SPECTROMETERS

The following sections describe the principles of MS, including the general layout of modern MS instrumentation used in the pharmaceutical industry and the specific components (sample introduction, ionization, and mass analyzer). This section also includes a brief description of the operational modes of a mass spectrometer, focusing on fragmentation production and analysis.

### 2.1 Overview

Analytical measurements that use MS generally involve the following processes: sample preparation, chromatography or sample introduction, ionization, and mass analysis and detection. The resulting output from the mass spectrometer is depicted in a mass spectrum, a survey of ions made in the ion source, and is represented in a graphic representation of mass-to-charge ratio ($m/z$) versus intensity.

Ions are separated by a property of mass such as $m/z$, where $m$ is the mass of the ion and $z$ is the number of charges on the ion. The method by which ions are separated typically defines the mass spectrometer type. Regardless of type, the mass analyzer separates ions according to the $m/z$. The mass analyzer continuously acquires data across a predefined range of masses to generate the resulting mass spectra.

### 2.2 General Layout

A general layout of a mass spectrometer platform for pharmaceutical analysis is shown in *Figure 1*. Samples are prepared via a procedure defined for the specific sample and analyte. The resulting sample then is injected into the mass spectrometer via a chromatographic system such as high-performance liquid chromatography (HPLC) or gas chromatography (GC) or via direct injection. From the inlet, the discrete analytes are ionized for subsequent analysis by the mass spectrometer. All mass spectrometers require four components:

1. Sample introduction technique
2. An ionization source to charge the analyte
3. A mass analyzer to separate the analytes on a mass/charge ($m/z$) scale
4. A detector to measure the ions.

@2024 USPC

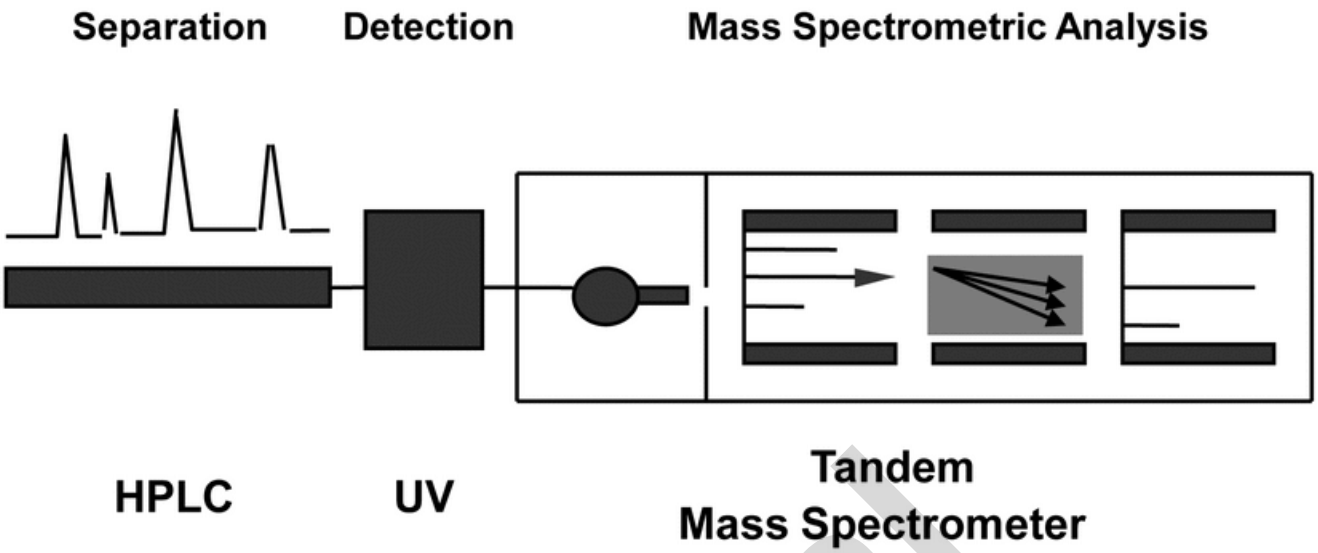

Figure 1. General MS system. HPLC = high-performance liquid chromatography; UV = ultraviolet detector. (Courtesy of Milestone Development Services, Newtown, PA)

MS can be categorized by the dimensions of mass analysis: single-stage mass spectrometers, hybrid or tandem mass spectrometers (MS/MS), and multiple stages of mass analysis ($MS^n$). These mass spectrometer formats are described in this section.

### 2.2.1 SINGLE-STAGE MS

A single-stage mass spectrometer provides one dimension of mass analysis. As shown in the schematic in *Figure 2*, a single mass spectrometer can be viewed simply as providing a survey of all ions generated in the ion source. For example, if a 10-component mixture is injected into a chromatograph and each component is separated with adequate resolution, then the mass spectrometer would provide discrete measurement of mass-to-charge of each of the 10 components. The resulting mass spectrum of each component is generated for subsequent interpretation and assignment of molecular mass.

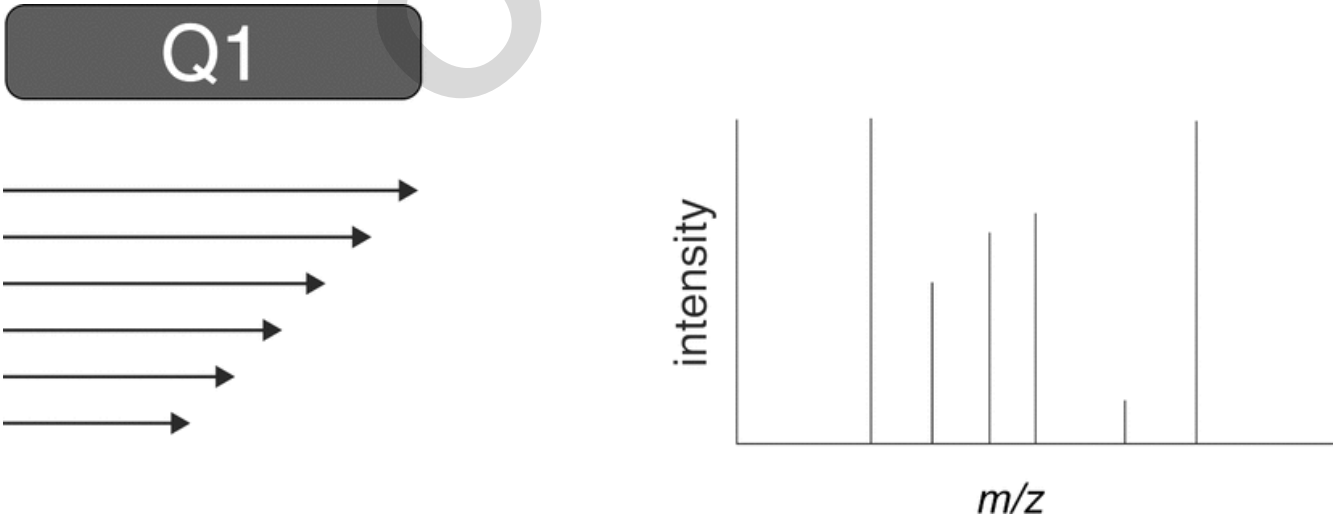

Figure 2. One-dimensional MS scan. Q1 = single-stage mass spectrometer or a single stage of analysis. (Courtesy of Milestone Development Services, Newtown, PA)

### 2.2.2 TANDEM MASS SPECTROMETRY (MS/MS)

A system capable of carrying out two sequential *m/z* analysis events (i.e., a tandem mass spectrometer) provides increased selectivity for detailed structure elucidation or quantitative analysis.

### 2.2.3 MULTIPLE STAGES ($MS^n$)

A unique feature of some MS formats is the capability to perform multiple stages of MS and to generate further fragment information. These mass spectrometers are capable of isolating an ion of interest, inducing fragmentation, isolating a specific product ion and then repeating this process on the resulting or selected product ion.

## 2.3 Sample Introduction

Several approaches can be used to introduce the sample into the mass spectrometer. The direct, infusion, and chromatographic procedures are described in this section.

### 2.3.1 DIRECT INTRODUCTION

For some sample types and applications, a direct insertion probe is used to introduce the sample into the mass spectrometer. The sample, usually a pure compound or relatively pure compound, is dissolved in an appropriate solvent. A small amount of the sample (typically 1 µL or less) is deposited onto the probe. Typically, the probe consists of a metal filament, such as platinum, located at its tip. The metal filament is heated, and the sample is desorbed into the ion source of the mass spectrometer. The probe then is removed from the mass spectrometer and is prepared for the next sample.

### 2.3.2 INFUSION INTRODUCTION

Sample introduction via infusion typically is done to provide a relatively long analysis time or perhaps to conduct a quick survey of a sample. Infusion introduction also can be done when analysts optimize the instrumental conditions (source and mass spectrometer operational parameters) for a specific analyte as well as to obtain greater numbers of spectra. This sample introduction method may require more sample than conventional flow rates. However, infusion sample introduction is widely practiced for nanospray ionization applications for the analysis of proteins and peptides as well as during specialized nanospray applications with small molecules in drug metabolism to determine structure or equimolar response ratios.

### 2.3.3 CHROMATOGRAPHIC INTRODUCTION

The use of chromatography methods for sample introduction into the mass spectrometer is perhaps the most common approach.

**2.3.3.1 Gas chromatography:** GC procedures are preferred for nonpolar, volatile analytes (see *Chromatography* ⟨621⟩. Samples contained in solvent are injected onto the injection port of the GC. The sample is volatilized, and a nonreactive, inert gas such as helium carries the sample through the GC column, which is contained in a temperature-controlled oven. The combination of carrier gas and heat moves the analyte through the column. Capillary GC columns are commonly used in pharmaceutical applications. Molecules separate within the capillary column and are introduced directly into the ion source of the mass spectrometer.

**2.3.3.2 High-performance liquid chromatography:** A popular approach for sample introduction into the mass spectrometer involves HPLC (see ⟨621⟩). HPLC procedures are preferred for nonvolatile and thermally labile analytes, but are suitable for use with any analyte that is readily ionizable in a solution environment with the appropriate chemical modifiers. Samples are prepared in solution and then injected onto the HPLC column. Analytes are separated based on the partitioning between the mobile phase and stationary phase and are introduced into the ion source of the mass spectrometer. The effluent is volatilized in the ion source and ionization occurs. The subsequent ions then are introduced into the mass spectrometer for analysis.

**2.3.3.3 Capillary electrophoresis:** Capillary electrophoresis (CE), also called capillary zone electrophoresis (CZE), is a separation method that exploits subtle differences in the ionic composition of analytes to separate them based on electrophoretic mobility in a conductive liquid. Details regarding the principles and use of this methodology can be found in *Capillary Electrophoresis* ⟨1053⟩. During the past 15 years this separation method periodically has been used with MS as an alternative to LC–MS for certain classes of compounds. However, with the widespread use of HPLC in analytical and MS laboratories, CE-coupled MS methods often are superseded by LC–MS methods.

## 2.4 Ion Polarity

Ionization involves the process of converting the analyte into the gas phase and depositing a charge onto the molecule. The final charge of the analyte determines the ion polarity to be used in the mass analysis. Generally, selection of the ionization mode depends on the ability of the desired analyte to accept or lose a proton during the ionization process. MS can be performed in the positive or negative ion polarity mode.

### 2.4.1 POSITIVE ION MODE

Many MS pharmaceutical analyses use the positive ion mode. For example, compounds that contain a basic functional group such as an amine (e.g., proteins and peptides) are excellent candidates for MS analyses in the positive ion mode because under acidic conditions these compounds readily accept a proton to form positively charged ions.

### 2.4.2 NEGATIVE ION MODE

The negative ion mode is well suited for compounds that can easily lose a proton. Compounds that contain a carboxylic acid, phosphate, or a sugar, for example, are good candidates for negative ion MS.

## 2.5 Ionization Procedures

A variety of ionization procedures can be used with a mass spectrometer for pharmaceutical analysis. The various ionization procedures are described in this section.

### 2.5.1 ELECTRON IONIZATION

Electron ionization (EI) is used mostly with GC applications when the analytes of interest are nonpolar and are easily volatilized. Mass spectra produced by EI procedures are characterized by extensive fragmentation. Because EI typically produces extensive fragmentation, EI is considered a hard-ionization mode. Mass spectra are obtained when a 70 eV electron beam enters the source and impacts the analyte molecules present in the gas phase:

$$M + e^- \rightarrow M^{+\cdot} + 2e^-$$

Nearly all EI applications are conducted in the positive ion mode. These spectra are highly reproducible. Thus, EI spectral libraries can be used to determine the structure and to confirm the identity of unknown compounds. Additionally, fragmentation patterns have been extensively studied for electron ionization and can help determine structure of unknown compounds.

### 2.5.2 CHEMICAL IONIZATION

Chemical ionization (CI) procedures rely on electron ionization of reagent ions such as methane, ammonia, or isobutene. The reagent ions react with the analyte molecules (ion–molecule reaction) in the source of the mass spectrometer. In the positive ion mode, analyte molecules are ionized via proton transfer and/or adduct formation, producing even electron molecular ion species or adduct ions. Depending on the analyte, both positive and negative ion spectra can be obtained with CI procedures. CI is considered a softer ionization (less fragmentation of the molecular ions) mode than EI although some approaches can induce fragmentation depending on the CI gas chosen and the structure of the analyte molecule. CI is very useful for reactive and unstable compounds where a molecular mass determination is desired. Representative CI ionization reactions for both GC–MS and LC–MS methods follow.

Protonated molecule formation (GC–MS example):

$$CH_4 + e^- \rightarrow CH_4^+ + 2e^-$$
$$CH_4^+ + CH_4 \rightarrow CH_5^+ + CH_3$$
$$CH_3^+ + CH_4 \rightarrow C_2H_5^+ + H_2$$
$$M + C_2H_5^+ \rightarrow [M + H]^+ + C_2H_4$$

Protonated molecule formation (LC–MS example):

$$M + NH_4^+ \rightarrow NH_3 + [M + H]^+$$

Adduct ion formation (LC–MS example):

$$M + NH_4^+ \rightarrow [M + NH_4]^+$$

### 2.5.3 ATMOSPHERIC PRESSURE IONIZATION

Atmospheric pressure ionization (API) procedures allow the direct introduction of samples into the mass spectrometer from a liquid interface such as an HPLC. The two most common forms of API used in pharmaceutical analyses are electrospray ionization (ESI) and atmospheric pressure chemical ionization (APCI).

**2.5.3.1 Electrospray ionization:** ESI is a method that produces fine charged droplets of a liquid phase that carries the analyte of interest. The liquid phase typically is a volatile combination of water and organic solvent (e.g., acetonitrile or methanol). A small percentage of a reagent (e.g., 0.1% formic acid) also is included to increase the conductivity of the solution. ESI typically is used with HPLC and involves the nebulization of the sample delivered at flow rates that range from nL/min to mL/min to produce a fine spray of droplets (radius = 0.5–1.0 µm). Solvent evaporation results in an increased charge concentration at the droplet surface until ions are liberated directly from the droplet. Ions are transported or focused directly into the mass spectrometer, and the resulting spectra contain ions that are typically indicative of the molecular mass of the analyte.

ESI often is referred to as a soft-ionization procedure because typically it does not result in fragmentation of the analyte during the ionization process. The development of this ionization technology was crucial for the analysis of large biopolymers (e.g., proteins) because it allows the addition of multiple charges to a single molecule, thus bringing the $m/z$ of the analyte into a suitable $m/z$ range for many types of mass analyzers. For example, *Figure 3* shows the ESI charge state distribution for equine heart apomyoglobin as analyzed on a simple single quadrupole instrument with an upper scan limit of $m/z$ 2000. The series of multiply charged ions allows the spectrum to be collected within the instrument's working $m/z$ range. The ability to calculate the intact mass of the protein from a combination of all the charge states allows a more accurate average mass (see inset in *Figure 3*) to be determined (within 0.1% on a simple quadrupole instrument). Thus ESI methods are critically important for the analysis of large biomolecules.

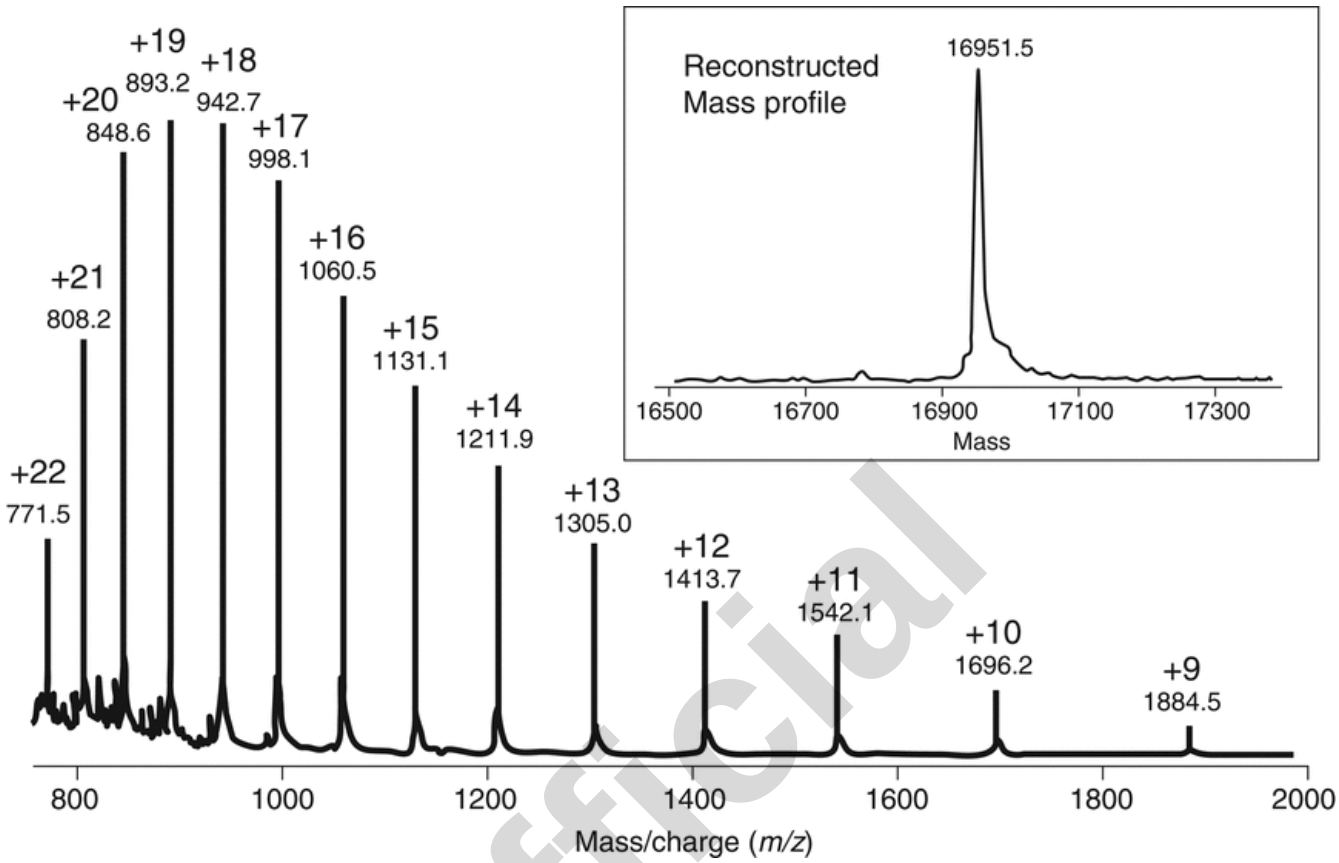

Figure 3. Electrospray ionization mass spectrum for equine heart apomyoglobin.

**2.5.3.2 Atmospheric pressure chemical ionization:** APCI procedures are used with HPLC and involve the nebulization and heating of the sample to liberate neutral molecules. A corona discharge produces reagent ions (e.g., $H_3O^+$ or $NH_4^+$) from the mobile phase. The reagent ions react with analyte molecules via proton transfer or adduct formation. The resulting positive ion spectrum typically contains $[M + H]^+$ ions that are indicative of molecular mass and fragment ions that correspond to unique substructure(s) of the analyte molecule. Negative ion spectra are generated when reagent ions (e.g., $OH^-$ or $CH_3COO^-$) react with the analyte molecule to produce $[M – H]^-$ ions.

## 2.5.4 MATRIX-ASSISTED LASER DESORPTION IONIZATION

Matrix-assisted laser desorption ionization (MALDI) is a soft-ionization procedure used primarily for biomolecules that relies on the addition of a chemical matrix dried with the analyte of interest. This matrix compound can absorb laser energy at a particular wavelength during the laser ablation process. By a mechanism that has not been fully elucidated, some of the ions generated in the matrix can transfer protons to the analyte, and the resulting gas-phase ions are focused into the mass spectrometer. Specific matrices have been empirically developed for various classes of analytes, including 3,5-dimethoxy-4-hydroxycinnamic acid (sinapinic acid) and α-cyano-4-hydroxycinnamic acid for proteins and peptides and picolinic acid for oligonucleotides. Unlike ESI, MALDI typically produces lower charge-state ions, with singly charged ions being the most favorable.

## 2.5.5 AMBIENT IONIZATION PROCEDURES

Ambient ionization generally refers to a collection of MS procedures that permit direct sampling and interrogation of analytes from sample matrices or surfaces under ambient conditions with little or no pretreatment. In recent years, the number and type of ambient ionization procedures have rapidly expanded. This is evident from the proliferation in recent literature of acronyms that represent various ambient ionization procedures. Ambient ionization has enjoyed broad application in fields that include forensics; food safety; monitoring of environmental contaminants; polymers; fuels; detection of explosives and drugs of abuse; molecular imaging of surfaces and tissues; profiling and characterization of metabolites, proteins, and biomolecules; as well as monitoring of chemical reactions and processes.

Ambient ionization procedures typically produce analyte ions directly from sample surfaces or require initial production of analytes that subsequently are ionized by any of several processes. Therefore, ambient ionization procedures can be broadly categorized as representing either direct or multistage ionization mechanisms. Direct ionization procedures generate analyte ions from a sample solution or droplet in an electric field, or desorb analyte ions by impinging a sample surface with charged droplets or solvent ions, photons, or metastable atoms. Multistage ionization procedures initially produce analyte particle or droplets with a liquid or gas stream, thermal desorption, irradiation or ablation with a laser, or nebulization. Analytes

subsequently react with a charged species or with metastable atoms generated by ESI, APCI, or photoionization to produce analyte ions.

*Table 1* is a representative, but not comprehensive, listing of ambient ionization procedures and illustrates the diversity and similarity among various approaches.

**Table 1. Ambient Ionization Procedures**

| Acronym | Description | Mechanisms |
|---|---|---|
| APGDDI | Atmospheric pressure glow discharge desorption ionization | Thermal desorption, gas discharge ionization |
| APPeI[a] | Atmospheric pressure Penning ionization | Similar to APCI |
| AP–TD/ESI[a] | Atmospheric pressure thermal desorption/electrospray ionization | Thermal desorption, ESI |
| ASAP[a] | Atmospheric pressure solids analysis probe | Thermal desorption |
| DAPCI | Desorption atmospheric pressure chemical ionization | Thermal desorption, APCI |
| DAPPI[a] | Desorption atmospheric pressure photoionization | Thermal desorption, photoionization |
| DART[a] | Direct analysis in real time | Gas discharge ionization |
| DBDI | Dielectric barrier discharge ionization | Thermal desorption, gas discharge ionization |
| DCBI | Desorption corona beam ionization | Thermal desorption, APCI |
| DESI | Desorption electrospray ionization | Similar to ESI |
| EADESI | Electrode-assisted desorption electrospray ionization | Similar to ESI |
| EASI | Easy ambient sonic spray ionization | Supersonic spray ionization |
| EESI[a] | Extractive electrospray ionization | Similar to ESI |
| ELDI[a] | Electrospray laser desorption ionization | Laser desorption or ablation, ESI |
| FD–ESI[a] | Fused droplet electrospray ionization | Similar to ESI |
| IR–LADESI[a] | Infrared laser-assisted desorption electrospray ionization | Laser desorption or ablation, ESI |
| LAESI[a] | Laser ablation electrospray ionization | Laser desorption or ablation, ESI |
| LD–APCI[a] | Laser desorption atmospheric pressure chemical ionization | Laser desorption, APCI |
| LD–ESI[a] | Laser desorption electrospray ionization | Laser desorption, ESI |
| LDSPI[a] | Laser desorption spray postionization | Laser desorption or ablation |
| LDTD[a] | Laser diode thermal desorption | Thermal desorption |
| LEMS[a] | Laser electrospray mass spectrometry | Laser desorption or ablation |
| LESA[a] | Liquid extraction surface analysis | Similar to ESI, surface extraction with solvent droplet |
| LIAD–ESI[a] | Laser-induced acoustic desorption electrospray ionization | Laser desorption or ablation, similar to ESI |
| LPI–MS[a] | Liquid surface Penning ionization mass spectrometry | Similar to APCI |
| LSI | Laser spray ionization | Laser desorption or ablation |
| MALDESI[a] | Matrix-assisted laser desorption electrospray ionization | Laser desorption or ablation |
| PADI | Plasma-assisted desorption ionization | Thermal desorption, gas discharge ionization |
| SESI[a] | Secondary electrospray ionization | Similar to ESI |
| TDAMS[a] | Thermal desorption based ambient mass spectrometry | Thermal desorption |
| TD/APCI[a] | Thermal desorption/ atmospheric pressure chemical ionization | Thermal desorption, similar to APCI |

[a] Multistage ionization procedure.

## 3. MASS ANALYSIS

The method by which ions are separated typically defines the mass spectrometer type. Essentially, the mass analyzer is responsible for filtering the ions generated during the ionization process. The various mass analyzers that typically are used in the pharmaceutical industry are described in this section.

### 3.1 Quadrupole

A quadrupole mass spectrometer consists of a set of four parallel rods. When a combination of constant (DC) and alternating (AC) voltage are applied to the opposing rods respectively, the resulting electric fields allow ions of a specific $m/z$ to stably transit the quadruple and to pass through to the detector. Quadrupole mass spectrometers are relatively low-cost instruments and provide good qualitative and quantitative analytical capabilities. Generally, quadrupole mass spectrometers are limited to production of low-resolution mass spectra.

### 3.2 Magnetic Sector

A magnetic sector mass spectrometer filters ions by the means of the application of a magnetic field. The magnetic field is varied, and ions are deflected to follow a curved path so that ions with different $m/z$ ratios are separated.

### 3.3 Ion Traps and Ion Cyclotron Resonance

Most commercial mass spectrometers fall broadly into two categories: those that rely on continuous beams of ions being sent to a detector for sequential $m/z$ detection (like cars on a highway driving from point A to point B), and those devices that "trap" ions in discrete, repeating orbits (like cars on a race track). The latter devices are broadly referred to as *ion traps*. The orbital paths are complex and unique to each device. The ions can be trapped by static electric fields (DC voltage), dynamic quadrupole electric fields [radio frequency (RF) AC voltage], magnetic fields, or some combination of the types. Detection of the ions may take place by sequential ion ejection (after trapping, by $m/z$) or by detection of all ions simultaneously [while trapped, i.e., by image current detection and subsequent Fourier transformation (FT) of the data]. Examples include the popular linear and 3D ion trap MS systems (RF AC voltage only with ion ejection for detection), the FT Orbital Trapping MS (which uses DC voltage and a quadrupole field for trapping, with image current detection), and the less common FT Ion Cyclotron Resonance MS (which uses a superconducting magnet to provide the primary trapping field). The FT devices generally provide very high mass resolution (e.g., $10^5$–$10^6$ at $m/z$ 400) at reasonable scan speeds (1 Hz), and the RF-based devices generally offer fast scan rates (0.1 Hz) but lower resolution ($10^3$). Lastly, the most popular FT equipment is now hybridized with a quadrupole RF device (especially the linear trap) to yield instrumentation with multiplexed experiment capabilities (multiple sequential MS–MS experiments with accurate $m/z$ determinations for structure elucidation).

#### 3.3.1 TIME-OF-FLIGHT

A time-of-flight (TOF) mass spectrometer uses differences in transit time through a field-free drift region to separate ions. Ions generated in the ion source are pulsed into the field-free drift region (flight tube) by an electric field. Lighter ions have a higher velocity and reach the detector sooner. The TOF mass spectrometer has benefited significantly from the use of fast electronics and fast computers to provide systems characterized by high speed, high sensitivity, and high resolution.

## 4. MS/MS AND $MS^N$ SPECTROMETRY INSTRUMENTATION

A wide variety of tandem MS instruments are available to the pharmaceutical research and development community. Each of the tandem instruments has some unique features that make it particularly suited for some specific applications, but this does not preclude the use of other tandem instruments to meet a specific analytical need. The appropriate selection of a tandem instrument that is suitable to meet a specific need depends on the type of analysis required (e.g., quantitation or structural elucidation), a variety of sample-specific factors (e.g., analyte concentration or the complexity of the matrix), and whether sample fractionation is incorporated before the introduction in the mass spectrometer (e.g., by LC–MS). A brief summary of some of the common types of tandem instruments follows, highlighting some of the typical applications.

### 4.1 MS/MS and $MS^n$ Spectrometers

#### 4.1.1 TRIPLE QUADRUPOLE

The triple quadrupole mass spectrometer is used for both qualitative and quantitative analysis. A triple quadrupole mass spectrometer features a first stage of mass analysis (Q1) for the selection of a precursor ion, followed by an RF-only collision quadrupole region (Q2). A second stage of mass analysis (Q3) is used for product ion analysis. Most quantitative LC–MS-based analyses feature the use of triple quadrupole mass spectrometers. Furthermore, the triple quadrupole mass spectrometer is capable of providing all the most common qualitative scan modes: full scan, product ion, precursor ion, and neutral loss (see *Figure 4* and *4.2 MS/MS and $MS^n$ Spectrometry Operational Modes*).

Q3 scans the resulting fragments. The product ion spectrum contains all the fragments of the selected precursor ion(s). (C) *Precursor ion scan*—Q1 scans the ions produced in the ion source. Ions fragment in the collision cell (Q2). Q3 is set to select a specific product ion (derived from the product ion spectrum). The scan results in a spectrum that contains all precursor ions that generate the specific product ion. (D) *Neutral loss scan*—Q1 scans the ions produced in the ion source, and ions fragment in the collision cell (Q2). Q3 also scans, but at a difference in mass equal to a selected neutral loss (as derived from the product ion spectrum). The scan results in a spectrum that contains all molecular ions that generate a specific neutral loss fragment. (Courtesy of Milestone Development Services, Newtown, PA)

### 4.1.2 TOF–TOF SYSTEM

A tandem configuration for TOF systems typically is used for the characterization and sequencing of peptides and other biomolecules from fairly simple mixtures (e.g., proteolytic digestion of a single-protein therapeutic). These systems often are

DOI: https://doi.org/10.31003/USPNF_M8166_01_01
@2024 USPC

configured for ionization by MALDI, which allows peptide sequence confirmation without the need for an initial separation. The relative ease of use of such instruments and the robust fragmentation data collected for confirmation of peptides may allow TOF–TOF instruments to be used for monograph identification testing in the future.

#### 4.1.3 MAGNETIC SECTOR

Tandem configurations for magnetic sector instruments traditionally have been used for analyses that require high resolution and mass accuracy, such as structural elucidation of unknowns. However, because of greater resolution and mass accuracy becoming available in other tandem MS platforms (e.g., ion traps and quad-TOF devices), magnetic sector instruments are now less commonly used for these purposes.

#### 4.1.4 ION TRAP

The tandem configuration for ion trap systems allows the isolation and fragmentation of ions in a time-dependent manner, unlike other tandem instruments that have spatially distinct mass analyzers in the path of the ion beam. One advantage of the trap-isolate-fragment-detect mechanism in an ion-trap instrument is the ability to re-isolate product ions from the initial precursor ions for further fragmentation. This sequential fragmentation allows more detailed structural determination to assist in elucidating structural unknowns. For protein and peptide applications, ion-trap instruments have been widely used to identify and sequence peptides and to characterize protein modifications (e.g., phosphorylation and glycosylation).

#### 4.1.5 FOURIER-TRANSFORM ION CYCLOTRON RESONANCE

Fourier-transform ion cyclotron resonance (FT–ICR) mass spectrometers, like ion traps, facilitate a time-dependent isolation of ions. FT–ICR mass analyzers offer high resolution (typically $10^5$–$10^6$) and can achieve sub-ppm mass accuracy, which permits determination of accurate mass and elemental composition for unknown compounds with a high degree of certainty. Ions can be selectively excited or ejected from the ICR cell by generation of a waveform that contains resonant frequencies of the $m/z$ values of the ions of interest. Several fragmentation procedures are available for achieving the structural characterization of small and large molecules with FT–ICR MS, including collision-induced dissociation (CID), electron capture dissociation (ECD), and infrared multiphoton dissociation (IRMPD). Some commercial FT–ICR MS systems use a tandem ion trap to isolate and fragment precursor ions, the product ions of which are subsequently transferred to the ICR cell for detection or additional fragmentation by other procedures. The high resolution and mass accuracy of FT–ICR MS make this instrument particularly well suited for the structural characterization of components that comprise highly complex mixtures of small and large organic molecules. FT–ICR MS also has been widely used in the characterization of lipids and carbohydrates and in the characterization and sequencing of peptides and proteins, including examination of unique features such as post-translational modifications.

#### 4.1.6 HYBRIDS

A variety of hybrid tandem mass spectrometers have emerged to either enhance specific applications or to broaden the overall utility of the instrument in a variety of applications. Currently the most common hybrid instrument used for pharmaceutical characterization is the quadrupole TOF (Quad-TOF) MS, which combines the scanning speed of a quadrupole mass filter with the resolving power and mass accuracy of the TOF mass analyzer. This combination is well suited for structural elucidation because the improved resolution and mass accuracy of the TOF (by comparison with a quadrupole) allow a greater degree of certainty in determining the probable elemental makeup of both the precursor and product ions. In addition, the use of a quadrupole mass filter in this tandem configuration allows scanning functions like those outlined for a triple-quadrupole instrument (*Figure 4*), although additional postprocessing of the data is required. An increasing number of hybrid configurations have been marketed to take advantage of the unique feature of the combinations for resolution, mass accuracy, and quantitation. Some of these configurations include Quadrupole–Trap, Trap–TOF, Trap–IRC, and orbital trapping mass spectrometers.

### 4.2 MS/MS and $MS^n$ Spectrometry Operational Modes

#### 4.2.1 FRAGMENTATION PRODUCTION MODES

Collision-Induced Dissociation (CID) or Collisionally Activated Dissociation (CAD) is the process by which a selected precursor ion undergoes collisions with neutral gas molecules in a collision region to yield product ions. Fragmentation occurs at relatively low energies (1–100 eV) primarily at the site(s) of ionization to yield a fragment ion and a neutral molecule. Nitrogen, argon, or helium typically is used as the collision gas with collision energies in the 10–50 eV range.

Electron Capture Dissociation (ECD) and Electron Transfer Dissociation (ETD) are two distinct but related fragmentation methods used primarily to fragment proteins and peptides to generate *c*- and *z*-type ions that are useful for determining protein sequence and characterization of protein modifications. The fragmentation in each case relies on the introduction of either a free electron (ECD) or a radical anion (ETD) into the gas phase of positively charged molecules to induce chemical fragmentation. The advantage of these methods for proteins and peptides versus CID is that the chemical fragmentation occurs almost exclusively along the peptide backbone, thereby preserving the position and context of protein modification that often are lost during CID.

**4.2.2 fragmentation analysis modes**

The most common MS/MS scan modes are described in this section.

*4.2.2.1 Product ion:* The product ion scan mode is illustrated in *Figure 4B* for a triple-quadropole (QQQ) instrument. Application of the product ion scan mode is performed when the first mass analyzer (Q1) is held at a specific $m/z$. This ion, typically the protonated molecule, $[M + H]^+$, is fragmented in the collision cell (Q2). The second mass analyzer (Q3) scans the

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M8166_01_01
@2024 USPC

resulting product ions. For a trapping device such as an ion trap mass spectrometer, ions of a specific $m/z$ are isolated and are collisionally activated, followed by scanning of the product ions. In either case, the resulting product ions' MS–MS spectrum contains the diagnostic fragment ions indicative of the characteristic substructures of the selected analyte. This scan mode requires that a full scan mass spectrum be obtained before the product ion experiment to determine the appropriate selection of the molecular ion (typically $[M + H]^+$). The product ion scan mode is available in all mass spectrometers capable of MS–MS operation.

*4.2.2.2 Precursor ion:* The precursor ion scan mode is illustrated in *Figure 4C*. Application of the precursor ion scan mode is performed when the first mass analyzer (Q1) is scanned and allows all ions created in the ion source to pass into the collision cell (Q2). The second mass analyzer (Q3) is held at a specific $m/z$ ratio that corresponds to a diagnostic or unique fragment ion of the molecule or class of molecules. The resulting precursor ion MS–MS spectrum contains all molecular ions that contain a diagnostic fragment ion. The precursor ion scan mode requires that the product ion experiment be performed to confirm the diagnostic fragment ion(s). This scan mode can be used to screen for molecules that contain a specific substructural feature such as a peptide residue. The precursor ion scan mode is available on triple-quadrupole, magnetic sector, and some hybrid instrumentation.

*4.2.2.3 Neutral loss:* The neutral loss scan mode is illustrated in *Figure 4D*. Application of the neutral loss scan mode is performed when both mass analyzers (Q1 and Q3) are scanned at the same rate. The second mass analyzer (Q3) is offset (lower) from the first by a constant $m/z$ difference. Molecular ions enter Q1 and fragment in the collision cell (Q2), and the resulting fragment ions are detected after passage through Q3. Because of the offset scan function described above, the resulting spectrum presents all molecular ions that have undergone the selected neutral loss. This scan mode also requires that the product ion scan be performed to confirm the diagnostic neutral loss(es). Like the precursor ion scan mode, this scan mode is used to screen for molecules with a diagnostic structural feature such as phosphate or glucuronide conjugation. The neutral loss ion scan mode is available on triple-quadrupole, magnetic sector, and some hybrid instrumentation.

*4.2.2.4 $MS^n$:* The $MS^n$ acquisition mode is essentially a sequential application of the product ion scan discussed in *4.2.2.1 Product ion*. That is, it is used to further fragment product ions from a previous product ion experiment. Thus it can be utilized to obtain additional structural information for identification of analytes. This acquisition mode typically is available only on ion trap or FT–ICR instruments.

## 5. QUALITATIVE ANALYSIS

MS is a powerful method and important tool for structure identification because of its ability to provide information about the mass, elemental composition, and structural features of known and unknown molecular entities. In its simplest terms, an MS separates and mass-measures ions related to the sample. A mass spectrometer separates, detects, and records the presence of ions, not neutral molecules. For the purposes of small-molecule organic MS, the charge state ($z$) typically is 1.

A wide range of mass spectrometers and ionization interfaces are available for specific types of MS measurements. Thus a diverse range of experimental approaches can be employed for any given MS measurement needed. Some of the more common and applicable approaches are presented in this section. The appropriateness of a given MS experimental approach is demonstrated by the respective validation data provided in the submission supporting a new monograph or monograph procedure.

### 5.1 The Mass Spectrum

The mass spectrum typically is displayed as a plot of $m/z$ on the abscissa versus ion intensity as the ordinate and frequently is normalized to the most intense ion in the spectrum. Some characteristic features in a typical full-scan mass spectrum include (depending on ionization procedure) the molecular ion (e.g., $M^+$), protonated or deprotonated molecules ($[M + H]^+$ or $[M - H]^-$), or adduct ions (e.g., $[M + NH_4]^+$), all of which are indicative of the molecular mass of the analyte. Mass spectra may be more or less complex, depending on the specific analyte(s) and ions detected. EI mass spectra typically are rich in fragment ions, but API and soft-ionization procedures may produce spectra that are sparse in fragment ions but often feature more prominent or base peak ions that are indicative of MW. Therefore, the interpretation of mass spectra may be more or less straightforward. Typically, the availability of any supporting information about the sample (e.g., origin, history, preparation, stability, solubility) can greatly assist with interpretation. Two primary considerations merit initial discussion because of their importance in the interpretation of mass spectra: resolution and mass accuracy.

#### 5.1.1 MASS RESOLUTION

In MS, resolution is the extent to which two ions of adjacent $m/z$ can be distinguished from each other, and has been expressed in different ways. Two adjacent peaks in a spectrum at values $m$ and $m - \Delta m$ may be separated by a valley, which at its lowest point is a specified maximum amount of overlap between the peaks. The resolution would be expressed as $m/\Delta m$. For example, the term "10% valley" describes a 10% amount of overlap between two peaks and is appropriate when the peaks are of equal height and shape. In practice, however, adjacent peaks of equal height and shape are rarely observed. Therefore, resolution also can be calculated by using the apparent width of a single peak at a given point in mass range as $\Delta m$, and it often is expressed as the measured width of a peak at half-height (full-width half-height maximum, or FWHM). Resolution is an important factor in establishing mass accuracy, evaluating isotope patterns and abundance, determining charge state of multiply charged ions, and distinguishing nominally isobaric interferences.

Nominal mass spectrometers instruments typically provide mass resolution on the order of 1000, whereas for high-resolution mass spectrometry (HRMS) this can range from 5000 to 1,000,000. Improved resolution includes the ability to separate and distinguish isobaric interferences (analytes with the same nominal mass but with different empirical formulae) and to mine complex data sets more efficiently (using increased specificity).

**5.1.1.1 Nominal resolution:** A number of different types of mass spectrometers are capable of generating nominal resolution mass spectra. Probably the most common mass spectrometer employed for nominal mass resolution work is the quadrupole mass spectrometer. In a quadrupole mass spectrometer, ions pass through a set of four rods such that opposing rods ramp through RF or DC, effectively scanning through the desired $m/z$ range and allowing only a single $m/z$ to pass at any given instant. The net effect is to obtain nominal mass resolution (e.g., $m/z$ 400 can be reliably distinguished from $m/z$ 399 and $m/z$ 401) and to obtain a spectrum that can define monoisotopic mass and associated isotopic cluster (e.g., A + 1 and A + 2). With this type of mass spectrometer (nominal resolution), the primary information obtained is an indication of the molecular mass of the analyte and, depending on the experimental approach used (e.g., EI ionization), ion fragments related to the structure of the analyte.

**5.1.1.2 High resolution:** HRMS has important advantages for the identification of analytes. The various forms of this technology allow determination of the mass of small molecules to the third or fourth decimal place (i.e., approximately 0.1 to 10 ppm mass error). This provides an added degree of specificity (certainty) that, when combined with isotope ratio information and chemical sense, results in elucidation of the analyte's empirical formula as a starting point for further analysis. Thus HRMS offers advantages compared to nominal MS, for which nominal mass is the starting point. HRMS can be performed with a number of different technologies, including TOF–MS, as well as orbital-trapping MS and ion cyclotron resonance MS, where the latter two approaches utilize Fourier transformation to process the raw data. These systems have different advantages, including improved sensitivity for full spectrum data collection (versus scanning instruments like quadrupoles), as well as resolution, mass accuracy, and calculation of the isotopic ratio intensities.

### 5.1.2 MASS ACCURACY

Mass accuracy is the comparison of an experimentally determined $m/z$ to the true $m/z$ ratio. Mass accuracy is influenced by a number of factors, including mass resolution, signal abundance, calibration type and algorithms, choice and number of calibrants used, interferences such as chemical noise, and linear dynamic range inherent with a particular type of mass spectrometer. Mass accuracy may be expressed as millimass unit (0.001 μ) differential or ppm. Mass accuracy, as ppm, is given by the following:

$$\Delta m_{acc} = m_{true} - m_{meas}$$

$$ppm = (\Delta m_{acc}/m_{true}) \times 10^6$$

$m_{meas}$ = measured value

$m_{true}$ = calculated or true mass

Although resolution and accuracy may not be directly correlated, HRMS typically allows improved assignment of exact mass. In practice, high resolution and high mass accuracy are both necessary to minimize error introduced into the mass measurement by isobaric interferences. Sufficiently high resolution and mass accuracy together can facilitate assignment of elemental composition to ions in a mass spectrum, assisting with confirmation or elucidation of structure, respectively, for known or unknown compounds.

## 5.2 Interpretation of Mass Spectra

When interpreting the mass spectra of unknown compounds, analysts typically can differentiate unknowns into two broad categories.

The first category, representing the situation more commonly encountered, can be described as known unknowns or compounds for which supportive information may be available or can be determined by comparison with standards, related substances, metabolites, synthetic impurities, or intermediates. In this case, the objective is verification of a compound's identity by demonstrating its consistency with a standard material by using predetermined criteria. This objective often is achieved by the direct comparison of mass spectral features of an unknown with either a concurrently analyzed standard or an archived library standard mass spectrum generated with similar instrumentation and conditions. For high-resolution accurate mass spectra, confirmation of identity may include the verification of elemental composition. Characteristic fragmentation patterns obtained under consistent conditions also can be used for the confirmation of identity by providing a fingerprint that indicates functional groups, substituents, and structural differences or modifications. The importance of chromatographic separation (i.e., demonstration of retention characteristics that are similar to a standard) also should be considered as part of an overall identification confirmation. The importance of chromatographic separation is particularly evident with the identification of various structural isomers or enantiomers for which MS alone may not provide sufficient distinction.

The second category comprises true unknowns or compounds for which no or very limited information about structure or background is available and presents the most complex cases for spectral interpretation. True unknowns are encountered less frequently and often necessitate the combination of multiple spectral procedures in order to achieve a complete structural elucidation. For true unknowns, any relevant information (e.g., origin, preparation, matrix, solubility, other compounds if the sample is a mixture) can aid interpretation.

The first step in the interpretation of mass spectra is the determination of monoisotopic mass. This peak is highly dependent on the ionization procedure employed, analytical conditions, and characteristics of the molecules from which the ions are formed. There are prominent differences between EI and API mass spectra, which, for purpose of this discussion, generally result from hard- and soft-ionization procedures, respectively. EI forms primarily an odd-electron radical molecular cation, $M^{+\cdot}$, and API and other soft-ionization procedures typically produce characteristic even-electron protonated $[M + H]^+$ or deprotonated $[M - H]^-$ molecules.

The Nitrogen Rule can be useful in identifying the molecular ion peak: it states that an odd-electron ion containing either no nitrogen or an even number of nitrogen atoms will be observed at even nominal mass and that an odd-electron ion with an odd number of nitrogen atoms will appear at odd nominal mass because nitrogen has an even integer mass (14) and an

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M8166_01_01
@2024 USPC

odd valence (3). This rule holds for all compounds that contain carbon, hydrogen, oxygen, nitrogen, sulfur, and the halogens, as well as phosphorous, boron, silicon, sulfur, and alkaline earth metals. Applied to even-electron ions (e.g., $[M + H]^+$ or $[M - H]^-$), the Nitrogen Rule states that an even-electron ion containing either no nitrogen or an even number of nitrogen atoms will be observed at odd nominal mass and that an even-electron ion with an odd number of nitrogen atoms will appear at even nominal mass.

The formation of molecular adducts can assist with determining and verifying mass in both positive and negative ionization modes. Some common adducts observed in positive ion mass spectra are $[M + Na]^+$, $[M + K]^+$, and $[M + NH_4]^+$ adducts. Adducts with other inorganic or organic cations, such as Li, Ag, Cs, $H_2O$, acetonitrile, methanol, isopropanol, and small organic protonated or quaternary amines, also can be generated. Adducts present in negative ion mass spectra include those formed with Cl, Br, and formic or triflouoroacetic acid. Multiple adducts are not uncommon in either positive or negative ionization mode mass spectra from API and other soft-ionization procedures and can include combinations of protonated or deprotonated molecules accompanied by additional protons, multiple inorganic or organic cations, or anions. For some applications, it may be desirable to deliberately produce adducts by the modification of the sample solution, matrix, or mobile phase to induce characteristic fragmentation or to denote components in a mixture with common or unique structural features. Dimeric or polymeric analyte ions $[2M + H]^+$ or $[2M - H]^-$ may be observed respectively in positive or negative ion API mass spectra, often with high analyte concentrations. Analogous dimeric adducts with Na, K, and other inorganic cations also can be formed and observed and can provide verification of the MW. Overall, adduct formation and ultimately the presence of adduct ion peaks in mass spectra are highly dependent on ionization procedure, ionization source conditions, type of mass spectrometer or analyzer, sample matrix, mobile phase composition, and the analyte itself.

The relative intensity of mass spectral peaks can provide information about molecular and ion structure. The most intense peak in a mass spectrum is referred to as the base peak and represents 100% relative abundance in normalized mass spectra. In EI mass spectra, the base peak may or may not represent the molecular ion. However, with API and softer ionization procedures, $[M + H]^+$ or $[M - H]^-$ often appear as a prominent peak in the mass spectrum. The relative intensities of peaks in EI mass spectra, and to some extent in API and other mass spectra, can indicate ion stability.

## 5.3 Elemental Composition and Structure

Each molecule has a specific elemental formula or composition that by itself does not suggest anything about the structure of the molecule, because completely different molecules can have identical empirical composition. The mass spectrum of an analyte indicates its monoisotopic mass, but the larger the mass, the greater the number of possible empirical formulae or combinations of atoms that could produce that same nominal *m/z* signal.

## 5.4 Isotope Patterns

The relative intensity and position of isotope cluster peaks in a mass spectrum provide orthogonal information to the *m/z* data. Isotopes represent variants of a given element with the same number of protons and a different number of neutrons. The number and relative abundance of isotopes are unique to each element and together comprise the isotope pattern for a particular molecule in a mass spectrum. The relative abundance of each isotope also is a function of the number of each element in a molecule. Natural isotopic abundances depend on the source or provenance of a material and are influenced by variations of the isotopic abundances of its constituent elements. Because a unique elemental formula is consistently indicated by each peak coinciding with the *m/z* and relative abundance of each isotope in a molecular formula, the resulting isotopic fingerprint can be a powerful tool for the prediction of elemental composition.

Chlorine and bromine are examples of elements that produce prominent and easily recognizable isotope patterns in a mass spectrum. Chlorine atoms are characterized by the isotopes $^{35}Cl$:$^{37}Cl$ (approximately 3:1) and bromine atoms by unmistakable doublets ($^{79}Br$:$^{81}Br$ = approximately 1:1) that enable easy identification of ions containing these atoms in a mass spectrum. Combinations of multiple Cl or Br atoms in a molecule yield characteristic isotope peaks that differ by two units and have relative abundances that can be calculated. For some types of HRMS (TOF in particular), the relative intensities of the isotopic cluster can be carefully defined. Because the relative intensity of the isotope cluster is exactly a function of the elemental composition of the molecule (that is easily calculated), isotope fitting of experimental data to theoretical intensity can help provide the correct formula.

*Figure 5* presents the isotopic pattern in the molecular ion region for *n*-butyl benzenesulfonamide collected using ESI with different mass spectrometers, each having different mass resolution. With nominal mass (i.e., quadrupole mass spectrometer) resolution, one can clearly see the A + 1 (*m/z* 215) and A + 2 (*m/z* 216) peaks of the $[M + H]^+$ ion at *m/z* 214. The major contributor to the A + 1 peak results from the occurrence of versions of the molecule containing $^{13}C$, and the major contributor to the A + 2 peak, is naturally occurring $^{34}S$. With a higher-resolution mass spectrum, the more accurately calculated relative abundances of the A + 1 and A + 2 peaks could be used to estimate the number of carbon and sulfur atoms in the molecule, respectively. An examination of the FT–ICR mass spectrum illustrates the additional isotopic information that can be obtained under even higher-resolution conditions. This spectrum clearly shows that the A + 1 peak, seen as one peak with the other two mass spectrometers, also has contributions from other isotopes. At resolutions afforded by ICR or orbital-trapping mass spectrometers, the various contributors to the A + 1 peak can be observed, and one would get a more accurate estimate of the atoms present.

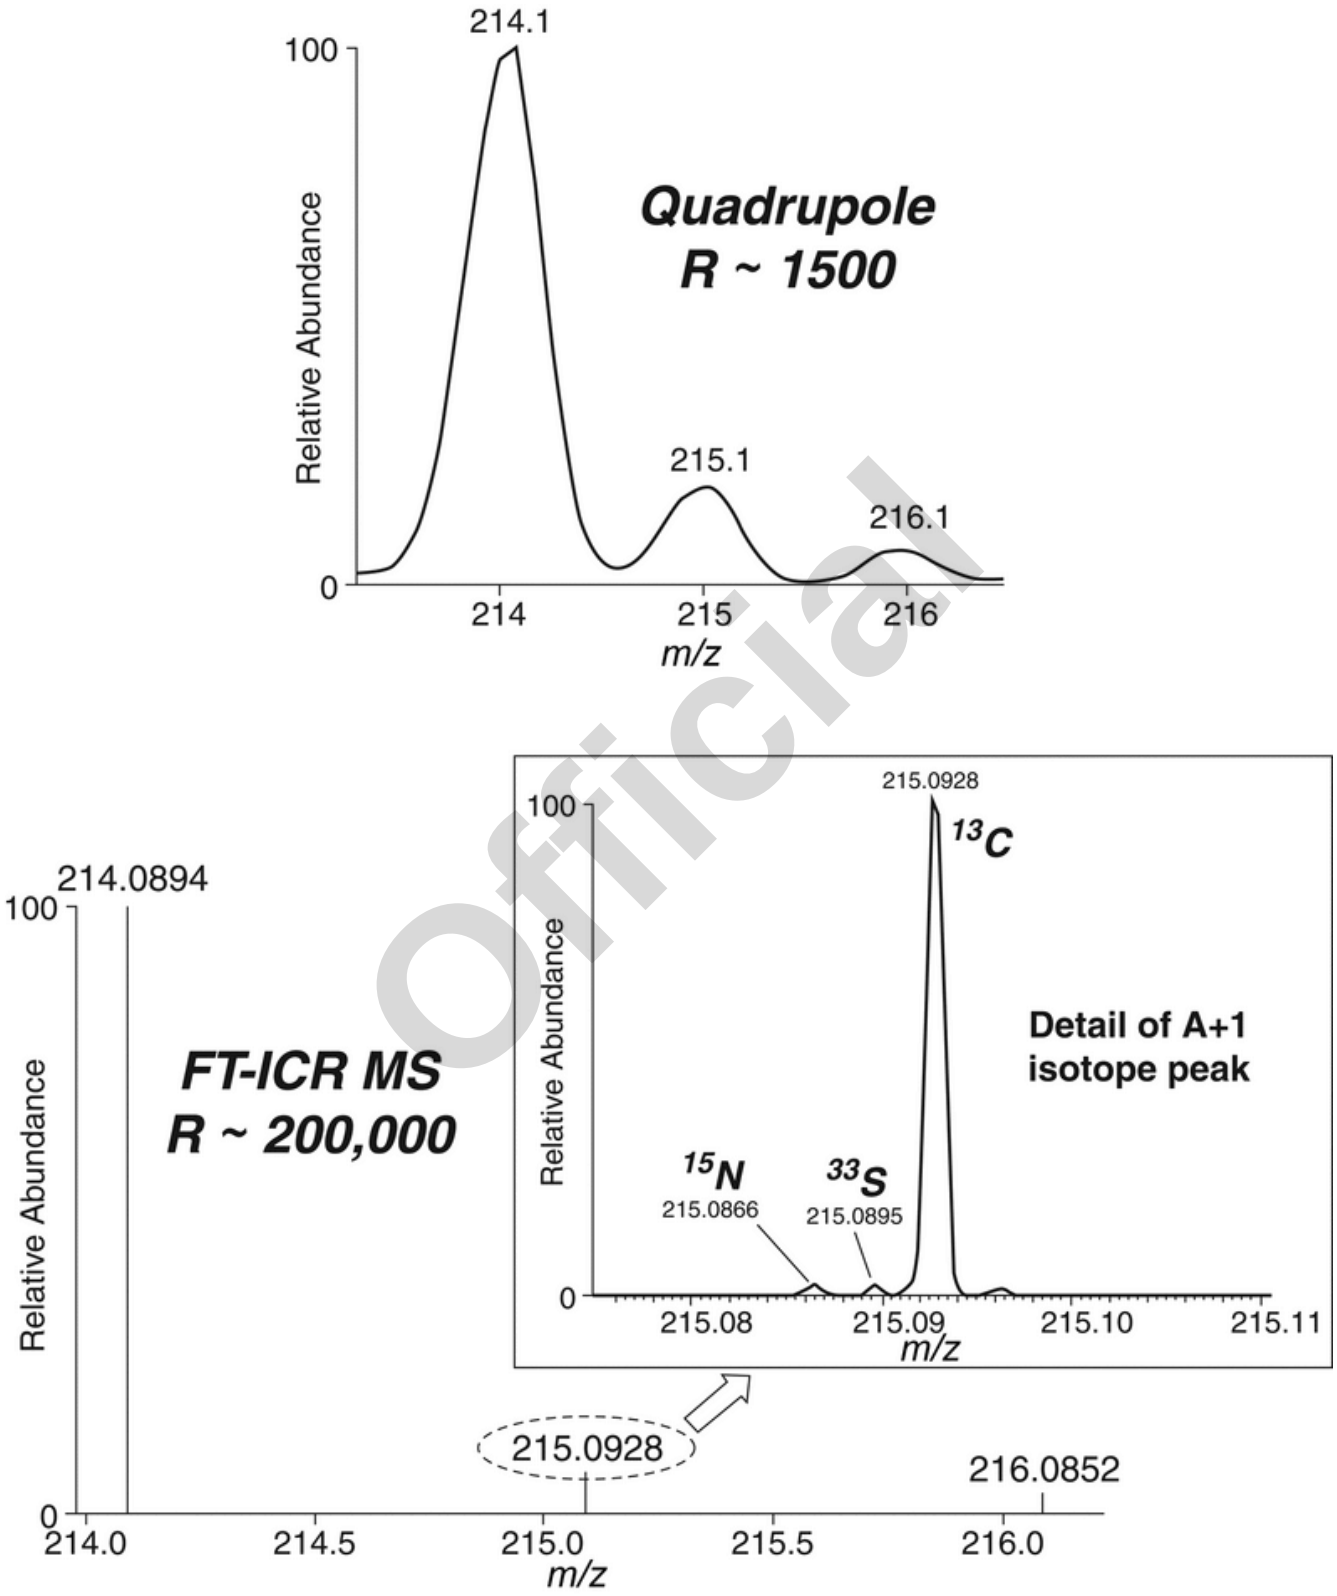

Figure 5. Partial ESI mass spectrum of *n*-butylbenzenesulfonamide under different mass resolution conditions.

Examination of isotope peaks also can reveal information regarding the charge state of an ion. For example, the difference between the A and the A + 1 isotope peaks is 1 *m*/*z* for a singly charged ion, a mass difference of 0.5 *m*/*z* denotes a doubly charged ion, and a mass difference of 0.3 *m*/*z* denotes a triply-charged ion. Thus, the correct charge state can be determined when only one peak or one set of isotope peaks is present, which supports the determination of MW and elemental composition.

Because accurate mass and isotope fitting are orthogonal data that each separately can greatly reduce the number of possible empirical formulae for a given nominal mass, the information used together can reduce experimental data to a single or limited set of possible choices.

## 5.5 The Monoisotopic Ion

The monoisotopic ion is an important feature of a mass spectrum, and recognizing this ion is valuable in determining the elemental composition of a molecule or ion, particularly with accurate mass measurements. The monoisotopic mass of an ion or molecule is the exact mass calculated using the mass of the most abundant naturally occurring isotope of each constituent element. Therefore, the monoisotopic ion is represented by the isotopic peak composed of the most abundant isotopes of its elements. Importantly, MS observes the monoisotopic mass of the analyte, not its molecular weight (i.e., the average including contributions from heavy isotopes). Recognizing the monoisotopic ion peak can be straightforward, and some singly charged ions and elements present simple or easily recognizable isotope patterns. However, the combination of multiply charged ions and multiple elements that collectively contribute to complex isotope patterns occasionally can make determination of the monoisotopic ion peak quite challenging, particularly with polymers and biomolecules. In such cases the benefit of instrumentation that offers higher resolving power is readily apparent.

## 5.6 Fragmentation

Fragmentation of an organic molecule in a mass spectrometer and examination of the ions produced in the fragmentation process can provide detailed information about unique structural features such as functional groups, substituents, and connectivity. Fragmentation generally is the dissociation of an activated analyte ion. Observed fragmentations are quite diverse and can range from simple events such as loss of water or ammonia to highly complex pathways that involve adduction, multiple rearrangements, and atom migration. In MS, fragmentation is highly dependent on the type of instrumentation and operating conditions. Primary considerations include ionization source, collision zone conditions, and type of mass analyzer. To some extent, controlling these factors permits the selection and optimization of conditions that are conducive to generating desired or structurally diagnostic fragmentation.

EI fragmentation results entirely from unimolecular dissociation that occurs in high vacuum. Formation of a radical molecular ion ($M^{+\cdot}$) in an electron beam (typically 70 eV) is accompanied by redistribution and accumulation of energy into different vibrational modes, and as a result the molecular ion may undergo fragmentation. Fragmentation typically occurs by bond cleavage and produces an even-electron cation and a neutral odd-electron radical. The converse also can occur, albeit less frequently: an odd-electron radical cation is observed with an even-electron neutral fragment loss. Fragment ions can further dissociate to generate additional fragments. Generally, fragmentation of odd-electron ions may produce either odd-electron or even-electron ions, but even-electron ions fragment to other even-electron ions. The probability of cleavage of a particular bond in a molecule can be correlated with bond strength and the relative stability of the resulting fragment ions. Some general principles apply with regard to the presence of fragment ion peaks observed in EI mass spectra and can assist with interpretation. These principles have been thoroughly discussed in numerous texts on the topic and are not discussed here.

API and soft-ionization procedures predominantly produce ions such as $[M + H]^+$ or $[M - H]^-$ that exhibit limited fragmentation. API and other softer ionization procedures achieve fragmentation by activating ions in a variety of ways, depending on the type of instrumentation.

## 5.7 Biomacromolecules

Structural elucidation of biomacromolecules using MS offers a number of challenges that are not common among traditional drug substances described previously in the chapter. To start with, biomacromolecular therapeutics encompass many compounds with very different chemical properties that range from proteins and peptides to a variety of glycoconjugates, lipids, and even DNA and RNA complexes. To further complicate the matter, the molecular mass of biomacromolecules can range from under 1000 in the case of some bioactive peptides and lipids to well over 100,000 for vaccines, antibodies, and heparin complexes. Furthermore, many of these biologically derived substances exhibit considerable heterogeneity and thus may not be characterized as a single drug substance but instead as a mixture that is monitored for consistency from batch to batch using a variety of analytical methods.

This section provides guidance about MS characterization of biomacromolecules. Because of the complexity of this broad class of compounds, this section focuses on a few types of compounds to illustrate the benefits of MS, then comments briefly about how MS can be implemented for other biomacromolecular compounds.

### 5.7.1 PEPTIDES AND PROTEINS

Details of the process for characterizing proteins and peptides are provided in *Biotechnology-Derived Articles—Peptide Mapping* ⟨1055⟩ and are only summarized in this section to provide context.

**5.7.1.1 Spectral interpretation:** Mass spectral evaluation of proteins and peptides typically encompasses MS data collected on the intact compound(s) to establish the overall mass of the protein followed by tandem MS to generate information about the primary amino acid sequence of the protein or to characterize sites of protein modification. Interpretation of fragmentation spectra to generate the sequence information is a critical component of this approach, and thus some guidelines for the spectral interpretation of peptide fragments are provided in *5.7.1.2 Database searching*. Primary and secondary MS-based approaches have emerged as the standards for sequencing proteins by fragmentation and are known as bottom-up and top-down sequencing.

*5.7.1.1.1 Bottom-up*—This approach encompasses fractionation of individual peptides generated by proteolytic digestion and sequencing of the peptides by tandem MS. The complete protein sequence then is recapitulated by piecing together the

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M8166_01_01

individual sequences. To get complete coverage of the protein, it is necessary to do separate digestions with multiple proteases with different cleavage specificities to get overlapping sequence coverage to rebuild the overall sequence. This approach is currently the most common MS-based approach used to characterize protein therapeutics.

*5.7.1.1.2 Top-down*—Advances in MS-based technologies and particularly ECD and ETD fragmentation offer another approach for sequencing proteins, whereby the intact protein is fragmented to generate sequence information without prior need to digest the protein into smaller peptides. Current challenges with this approach include the need for purified proteins; difficulty in getting complete sequence coverage, particularly for larger proteins; the need for considerably larger quantities of proteins than for the bottom-up approach; and a requirement for a high-resolution instrument with ECD or ETD capabilities. However, during the development of proteins therapeutics the availability of large quantities of purified protein is a likely scenario, and with the continued advancement of MS technologies, top-down proteomics may offer a direct option for characterization of some proteins therapeutics in the future.

**5.7.1.2 Database searching:** Because of progress in whole-genome sequencing and the computing power of predictive algorithms for the annotation of all possible genes, mRNAs, and proteins from genomic information, the characterization of unknown protein and peptide therapeutics rarely requires complete de novo sequence evaluation. Instead, the compound can be initially identified by digestion and sequencing by peptide fragmentation. This is possible because various fragmentation strategies (e.g., CID and ETD as described previously) produce gas-phase fragment ions from protonated peptides that represent consistent cleavage positions along the peptide backbone. The Roepstorff nomenclature for general peptide fragmentation along the peptide backbone is shown in *Figure 6A*. Peptide fragments that maintain a charge on the C-terminus are the *x*, *y*, or *z* ions, and those that maintain a charge on the N-terminus are known as *a*, *b*, or *c* ions. By optimizing the fragmentation energies and the collision gas to target only a single fragmentation event per protonated peptide molecule, analysts can use the collective fragmentation spectra from a given peptide to produce a set of fragment ions from the same series (i.e., *b* ions or *y* ions) that vary by the residue mass of each amino acid. In this manner they can derive the sequence. A schematic of a peptide fragmentation profile with a complete set of *y* ions is shown in *Figure 6B*. The complete set of *y* ions allows the sequence to be determined from the mass difference between the ions that correspond to residue masses for each amino acid. With the development of complete databases of many genes, transcripts, and proteins, a variety of commercially available computer algorithms have been developed to match the fragmentation masses with protein sequences in databases, along with false discovery rates and confidence probabilities. As a result, confirmation of protein sequences for known proteins can be fully automated for data collection and evaluation.

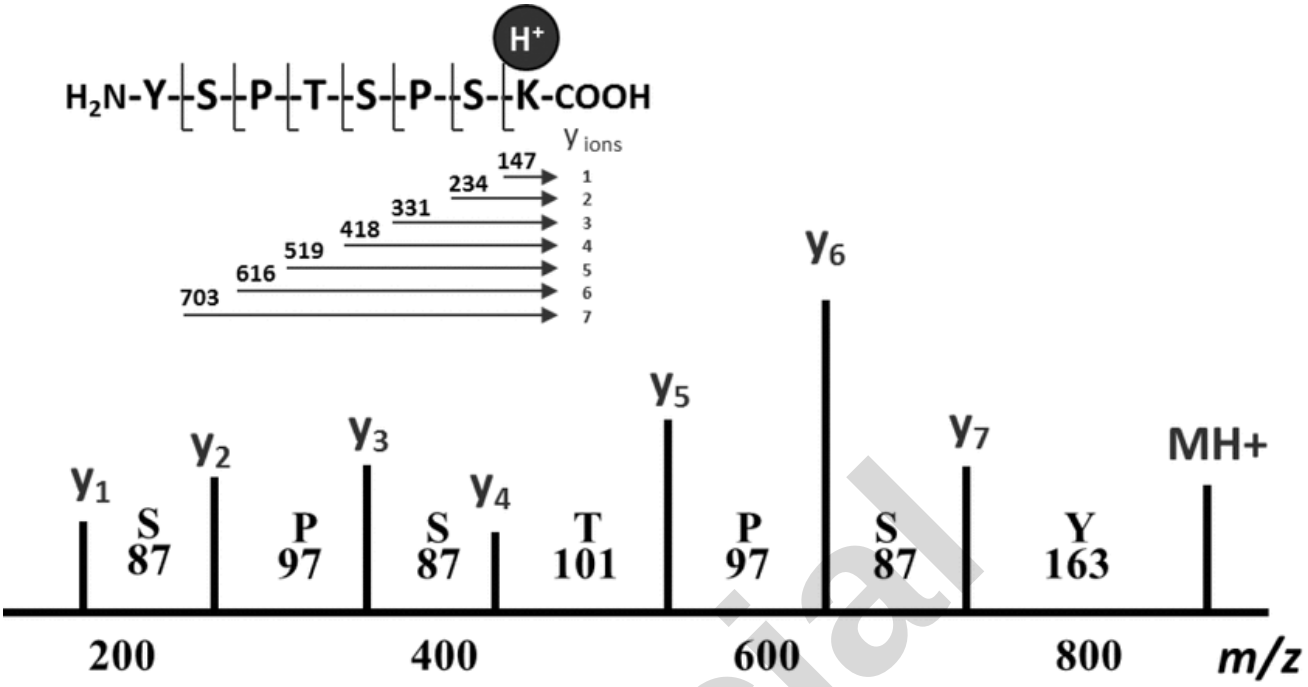

Figure 6B. Peptide fragmentation sequence.

**5.7.1.3 De novo sequencing approaches:** When a protein is completely unknown, MS-based fragmentation can be used to generate sequence information as described. The primary challenge is the inability to always get complete, unambiguous sequence information for some peptides by MS fragmentation because of the inability to assign all amino acids from a given fragmentation spectrum without a template of known sequences. In cases such as these, a combination of chemical sequencing using Edman degradation and MS may be necessary. Alternatively it may be necessary to digest and sequence the protein with multiple proteases in order to generate overlaying sequences to ensure the reliability of the overall sequence assignments.

### 5.7.2 GLYCOCONJUGATES

The analysis of drug substances in this class is discussed in *Glycoprotein and Glycan Analysis—General Considerations* ⟨1084⟩. Thus this section addresses only the application of MS to the characterization of protein glycosylation.

Many biopharmaceuticals are glycoproteins for which glycosylation plays critical roles in maintaining function, stability, and solubility. The most common glycosylations are *N*-linked and *O*-linked glycosylation in addition to other glycosylation modifications such as GPI anchors. *N*-glycosylation refers to glycan modification on the asparagine side chain, and *O*-glycosylation occurs to the side chains of serine and threonine. MS analysis of protein glycosylation can be performed on three different levels: intact proteins, peptides, and glycans. This section provides a brief overview of glycoprotein analysis.

**5.7.2.1 Intact protein analysis:** For proteins with small size or relatively simple glycosylation, direct MS analysis of intact protein provides a mass profile that reflects the protein's primary sequence and major modifications, including glycosylation. This type of experiment usually is performed using TOF analyzers or analyzers with higher mass resolution equipped with ESI or MALDI ionization. MALDI forms mainly singly charged ions and requires MS analyzers with a wide *m*/*z* range for measurement of intact protein mass (e.g.,TOF). ESI–MS is commonly used, because it leads to the formation of multiply charged protein ions in the *m*/*z* range of 700–5000, resulting in better mass accuracy in protein mass measurement (<100 ppm when coupled with a high-resolution mass sepctrometer). MS analysis in many cases can resolve protein peaks by their glycoform distribution because of the mass differences (e.g., hexose 162 Da, HexNAc 203 Da, and *N*-acetyl neuraminic acid 291 Da). The mass information can lead to identification of the monosaccharide composition of the glycoforms. The intensity of the intact protein peaks can be used to roughly estimate the glycoform distribution on the protein. For monoclonal antibodies modified mainly by neutral *N*-glycans, quantification of glycosylation distribution by intact protein analysis appears to be comparable with measurement using glycan separation methods. Antibodies containing multiple glycosylation sites can be enzymatically cleaved into major domains before MS analysis to gain more specific information about the position of the glycosylation on the intact protein.

**5.7.2.2 Peptide analysis:** For proteins with complicated glycoforms and multiple glycosylation sites, site-specific glycosylation information usually is desirable and is achieved by using a bottom-up proteomics approach via analysis of peptides generated by enzymatic digestion. The peptides are separated by reversed-phase LC followed by ESI–MS/MS analysis. MS–MS fragmentation can be performed using CID or ETD. In CID–MS/MS, the peptides can be identified to be glycosylated peptides by the detection of oxonium ions in the peptide MS–MS spectra [e.g., *m*/*z* 163 (hexose), 204 (HexNAc), 292 (sialic acid), and 366 (hexose-HexNAc)]. However, CID–MS/MS spectra of glycosylated peptides usually are dominated with fragmentation from the glycan with minimal fragmentation between the amino acid residues of the peptide backbone, thus hampering the ability to identify the protein sequence. ETD–MS–MS spectra of glycosylated peptides contain mainly fragmentation between the amino acids (e.g., *c*- and *z*-type peptide backbone cleavages), while the attached glycans remain intact. ETD–MS–MS provides

DOI: https://doi.org/10.31003/USPNF_M8166_01_01
@2024 USPC

information about peptide sequence, glycosylation site, and the glycan mass of the glycosylated peptides. CID– and ETD–MS–MS may be used alternatively in the same LC–MS analysis of complicated protein digests, which may provide the information necessary for identification of sequence, glycosylation sites, glycan mass, and glycan branching. *O*-glycosylated peptides also can be analyzed by using similar approaches. Peptide glycosylation can be identified by observation of oxonium ion such as *m*/*z* 204 in CID–MS–MS, and the peptide sequence is identified by ETD–MS–MS when the *O*-glycan moieties remain attached to the peptide.

**5.7.2.3 Glycan analysis:** *N*- and *O*-glycans can be enzymatically or chemically released from proteins followed by MALDI–MS or ESI–MS analysis either directly or after derivatization with chemical tags for enhancement of their ionization.

The direct MALDI–MS analysis of released glycans can be performed in both positive and negative mode for the detection of neutral and acidic glycans, respectively. The commonly used matrices include 2,5-dihydroxybenzoic acid (DHB) and 2′,4′,6′-trihydroxyacetophenone. The neutral glycans usually are detected as $[M + Na]^+$ in positive ion MALDI–MS. ESI–MS analysis of glycans suffers from poor ionization of the glycans and thus are used only following chemical derivatization. For example, derivatization of released glycans from glycoproteins can be performed on the reducing end of glycans by reductive amination using fluorescent tags such as 2-aminobenzamide. The labeled glycans are analyzed using hydrophilic interaction chromatography followed by ESI–MS analysis in positive ionization mode. The molecular mass of the glycans can be determined, and subsequent MS–MS analysis can provide structure information about the glycans. Permethylation is another important glycan derivatization method that neutralizes acidic glycans and allows both neutral and acidic glycans to be detected by MS in positive ion mode. MS/MS spectra of glycans contain ions from two major types of cleavages, as illustrated in *Figure 7*. Glycosidic cleavage occurs at the bonds between two sugar rings and results in *B*, *C*, *Y*, and *Z* ions, which provides important information regarding monosaccharide sequence and glycan branching. Cross-ring cleavages (shown in *Figure 7* by dashed lines) involve rupture of two bonds on the same sugar ring and lead to *A* and *X* ions that assist in identification of the type of sugar linkages in the glycans. With increasing understanding of glycan fragmentation, the identification of glycan from its MS–MS spectrum now is possible via database searches using recently developed computational algorithms.

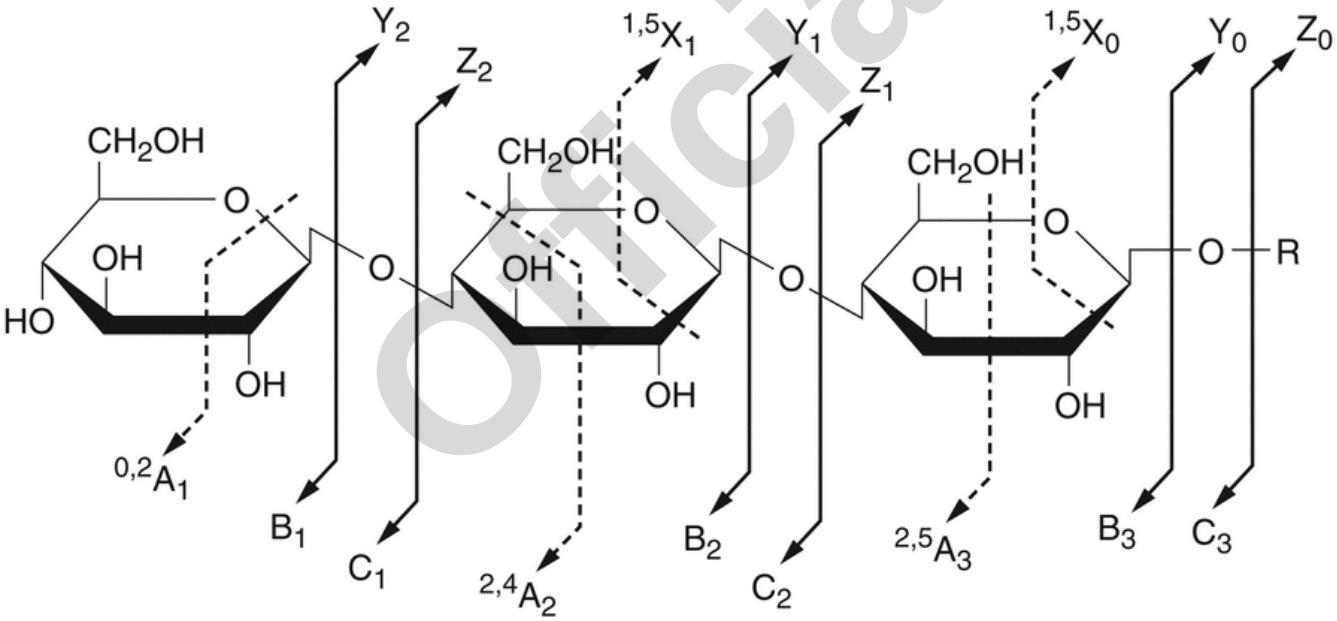

Figure 7. Nomenclature for carbohydrate fragmentation. Source: Adapted from Domon B and Costello CE (1988). *Glycoconj. J. 5*, 397–409.

## 5.7.3 VACCINES

Vaccines present a unique challenge because often they include complex mixtures of proteins, polysaccharides, and lipids in the form of intact bacteria or viruses, outer membrane vesicle preparations, or combinations of recombinant proteins. General information regarding bacterial vaccines is available in *Vaccines for Human Use—Bacterial Vaccines* ⟨1238⟩. Quality control of such mixtures typically relies on characterization by SDS–PAGE, SEC, amino acid or monosaccharide compositional analyses, RP–HPLC, and other analytical methods. However, to date MS has not been used as a primary QC method even though it is frequently used for confirmation of identity and characterization of impurities. Because of the many advantages of MS described in this chapter and its widespread use in the characterization of biotherapeutics and vaccines that contain complex protein mixtures, MS and MS–MS offer the ability to identify product and impurity simultaneously, and likely will be adapted in routine QC environments in the future. Additionally, when a complication occurs (e.g., discrepancy between assays, activity changing after formulation, or posttranslational modification), the quantitation of the recombinant protein (within a complex proteome) or key antigen in a complex protein vaccine via a highly specific procedure such as MS may be desirable. The use of isotope dilution MS–MS in combination with multiple reaction monitoring scans can provide highly specific and accurate quantitation of protein in complex samples.

### 5.8 Monograph Methods for Qualitative Identification

The discussions in this chapter and in *Mass Spectrometry* ⟨736⟩ covering the qualitative capabilities of MS provide strong technical justification for its use as part of a compendial identification strategy for a wide range of molecular classes. The structural information content (e.g., molecular mass, empirical formula, structurally significant fragmentation, and characterization of biomolecular modifications such as glycosylation) has been and will be an integral part of identification strategies. One or more specific aspects of mass spectral information can be combined to increase the specificity and reliability of the proposed test. Development of the MS portion of the compendial identification test should strive to provide unique and complimentary information for use with other identification tests intended in the monograph. Method development also should consider the availability of a reference standard for successful mass spectrometric identification.

## 6. QUANTITATIVE ANALYSIS

MS is useful for the quantitative determination of actives or impurities in a drug substance or a drug product because of its selectivity and sensitivity. The former typically comes into play when target compounds reside in complex matrices (e.g., natural or formulated), and the latter is a benefit when low-level impurities must be measured. Selectivity is achieved in MS-based methods by the combination of well-characterized attributes of the target compound, including molecular mass, intrinsic ionization characteristics, and fragmentation with additional data such as chromatographic retention time. In addition to chromatographic selectivity, use of a chromatographic inlet helps isolate the target compound from other chemical entities within the sample that could create problematic artifacts (e.g., ionization suppression) if they were introduced concomitantly.

This general approach to sample analysis (i.e., chromatography coupled with MS) typically introduces the target compound into the mass spectrometer as a well-defined peak (ideally, Gaussian) that can be reproducibly integrated for optimal quantification. While other forms of sample introduction (e.g., flow injection and direct-insertion procedures such as MALDI) potentially can be employed and may be necessary in some applications, chromatographic introduction systems are more common and are preferred for MS quantification.

Although various mass spectrometer types can be used, the quadrupole and triple quadrupole, in particular, are most commonly employed for quantitative analysis. These instruments provide a combination of specificity, sensitivity, stability, and linear response, which is essential for accurate measurement of target compounds, particularly within complex formulations. For these reasons, the balance of this quantification discussion emphasizes the use of chromatographic separations in concert with quadrupole MS detection.

### 6.1 MS Quantitation Overview

Employing a chromatographic inlet, analysts introduce a sample solution via injection onto an appropriate chromatographic column, and a flowing carrier stream (gas or liquid mobile phase) advances the target compound(s) and other matrix components through the column at various rates that are determined by strength of the carrier (gas characteristics for GC; organic, along with mobile-phase modifiers, for HPLC), temperature, and affinity for a stationary phase (see ⟨621⟩). Pressurized or near-atmospheric-pressure chromatographic effluent is passed through an appropriate interface into the vacuum environment of the mass spectrometer. In this manner, chemical components within the sample enter the mass spectrometer as chromatographic peaks that are subject to ionization as defined by the chosen ionization mode and according to the propensity of each chemical to become ionized under those experimental conditions.

In the case of single-quadrupole MS detection, the mass analyzer is set to pass to the detector an ion with an $m/z$ value that is characteristic of the target compound. In this selected ion monitoring (SIM) mode, a chromatographic profile for a single $m/z$ value is created. This overall process yields a chromatographic peak at the retention time expected for the target compound. When integrated, the area under this peak leads to a measure of target compound concentration in the original sample. Accuracy in an MS-based quantitative assay is achieved by the proper use of a well-characterized reference standard and, ideally, an appropriate internal standard, as described in *6.2.1 Internal Standards*.

For many analyses, the combination of chromatographic separation and SIM MS analysis will provide sufficient selectivity to yield an analysis, which is sufficiently free of chemical interference to meet the measurement need. However, in some situations, it may be necessary to utilize the additional selectivity provided by tandem MS detection that commonly is provided by a triple-quadrupole instrument. The need can be particularly acute in Category II analytical procedures for which a trace impurity must be measured within a complex formulation.

The relative benefit of MS/MS detection is illustrated in the extreme example presented in *Figure 8*. The antitussive dextromethorphan (Dex) is present in a plasma extract at 100 pg/mL. This extract is first analyzed by LC–MS using ESI–SIM at $m/z$ 272 (protonated molecule). In this experiment the SIM chromatographic peak corresponding to Dex is barely discernible above the relatively high background noise. Alternatively, a triple quadrupole can be employed to set up a selected reaction monitoring (SRM) detection scheme for added selectivity. SRM is a special case of product ion MS–MS in which the second mass analyzer is tuned to pass only a selected fragment ion corresponding to Dex ($m/z$ 147 in this example). A marked enhancement in selectivity, and therefore signal-to-noise ratio, is evident and typically leads to improved performance for quantitative analytical methods.

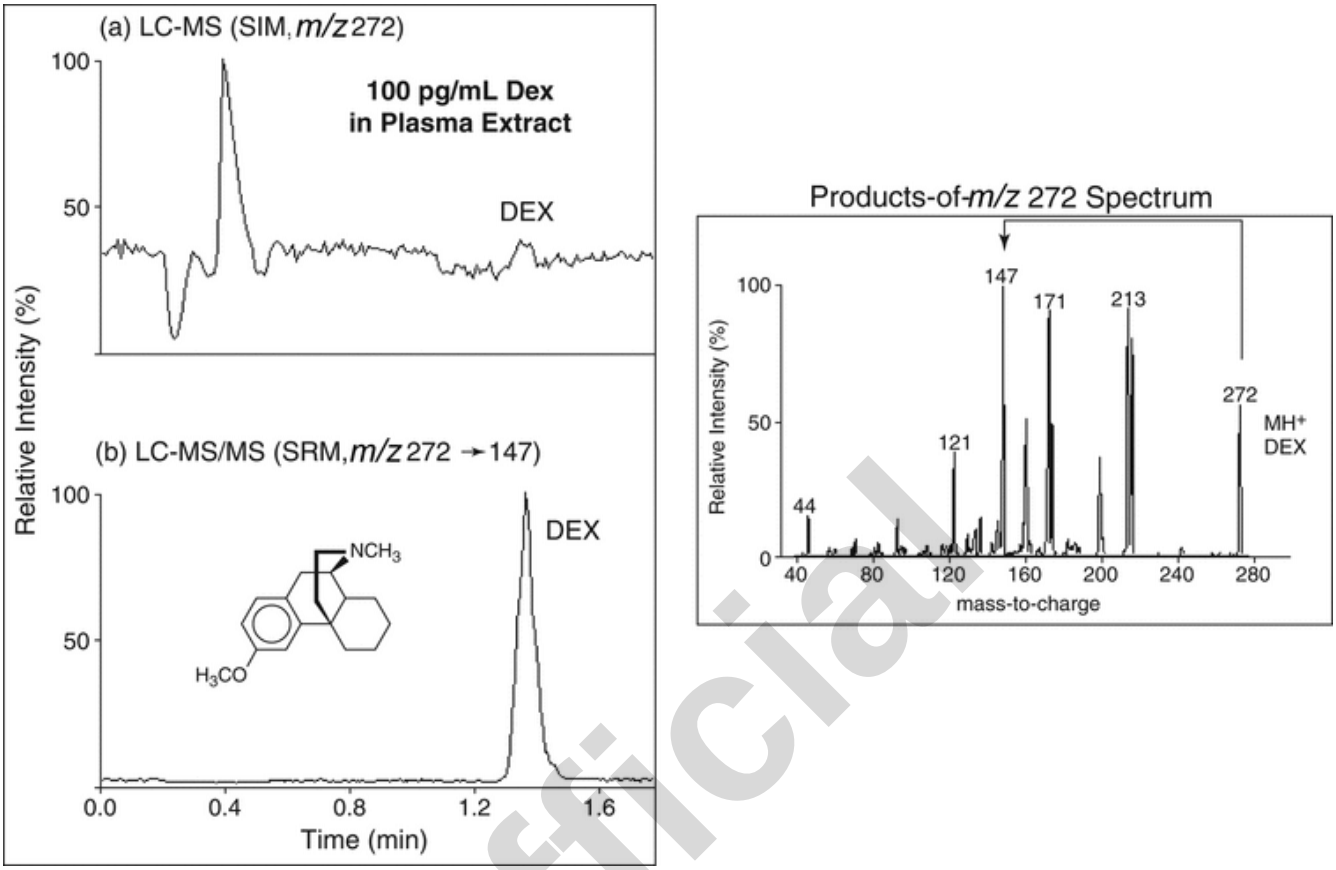

Figure 8. MS (SIM) versus MS–MS (SRM) for quantitative methods.

## 6.2 Quantification Considerations and Procedures

Methods suitable for Category I and Category II applications require the use of a reference standard for each target compound. Quantification of a target compound in an appropriately prepared test sample is achieved by relating its MS response (e.g., SRM-derived chromatographic peak area) to that of similarly prepared reference standards spanning the required concentration range (see *Mass Spectrometry* ⟨736⟩*, Validation and Verification of Mass Spectrometry Analytical Procedures*).

### 6.2.1 INTERNAL STANDARDS

For optimal accuracy and precision, internal standards should be employed at a consistent concentration in both the test samples and reference standards. Internal standards compensate for small sample-to-sample differences in dilution volume or loss of material during sample processing. They also compensate for analysis-to-analysis fluctuations in MS response or sensitivity drift over the course of batch analyses, both of which occur in all MS-based methods. In practice, selective detection schemes are set up to monitor both the target compound (analyte) and its corresponding internal standard. The key instrumental measure for each standard and test sample is, therefore, a ratio of the analyte-to-internal standard chromatographic peak areas. Internal standards can be either structural or stable-isotope-labeled analogs of the target compound. The former may be adequate and often has the advantage of lower cost and availability. The isotopically labeled (e.g., $^{2}H$, $^{13}C$, or $^{15}N$) alternative offers superior method performance, because it is essentially identical to the analyte in chemical and physical properties, with the exception of greater molecular mass. The only requirements are that the isotopic labels are not subject to chemical exchange during storage or sample preparation, are retained in the MS ionization process, and provide a sufficient molecular mass shift (typically 3+ Da using multiple labels) versus the analyte to ensure negligible cross-talk (interference) between analyte and internal standard signals (because of natural isotopes and variable *m*/*z* resolution across different mass analyzers). In addition, care must be taken to ensure that the internal standard contains inconsequential levels of unlabeled target compound impurities that potentially could bias results. Suitability of the internal standard is confirmed after successful completion of the analytical procedure validation.

### 6.2.2 DATA ACQUISITION

For accurate integration of analyte and internal standard chromatographic peaks, the data acquisition parameters (e.g., sampling rate, scan range, or masses monitored) must provide a sufficient number of intensity samples across the peak width. The number of samples may vary depending on method performance requirements (see *Table 1* in general chapter ⟨736⟩) and practical considerations related to chromatography conditions, mass spectrometer type, and the number of analytes and

DOI: https://doi.org/10.31003/USPNF_M8166_01_01
@2024 USPC

internal standards monitored. For example, for single-analyte assays on quadrupole-based instruments, analyte and internal standard SIM or SRM detection schemes are alternately sampled throughout the analytical run. With modern quadrupole instruments, dwell times of 100 ms or less per sampling point are readily achieved and should result in at least eight samples across each peak (this is the suggested minimum for good quantitative representation of the peak).

#### 6.2.3 CALIBRATION

A calibration curve is created by plotting analyte-to-internal standard peak area ratios versus concentration for the reference standards analyzed. For the somewhat narrow calibration range required for Category I and Category II measurements, a simple (nonweighted) linear fit is sufficient to define this response versus concentration function. However, $1/x$ or $1/x^2$ weighting also can be used, as well as nonlinear (e.g., quadratic) functions, as supported by appropriate and provided validation data.

The calibration concentration range is selected based on instrument sensitivity and the required method performance attributes. In general, the lowest concentration should yield sufficient signal for reproducibility, and the highest concentration ideally should be within the linear response range of the MS system. In extreme cases, the upper end of the linear response range may result from limitations of the mass analyzer or detector (e.g., as with TOF and ion trap MS instruments, but much less so with quadrupole mass analyzers). More often, loss of linearity results from diminishing ionization efficiency at higher concentrations. This is a common consideration with, for example, electrospray ionization where high analyte concentrations may increasingly deplete available ionizing adduct ions, leading to a less-than-proportional increase in detected signal with increasing concentration. This so-called self-suppression phenomenon can be somewhat compensated by the use of a stable-isotope-labeled internal standard that co-elutes with the analyte and, therefore, experiences similar proportional suppression. However, best-method performance is achieved when calibration falls within the linear range.

#### 6.2.4 TEST SAMPLE PREPARATION

The scope of acceptable sample preparation procedures for quantitative MS analysis is broad and depends on many factors, including the analyte chemical class, the composition and complexity of the matrix, the target analyte concentration, and the type of analytical instrumentation available. If appropriate, the preferred approach is simple dissolution followed by internal standard addition and then dilution to a target concentration within the calibration range. This simplicity minimizes the potential for analyte recovery issues and contamination or other procedural errors that may compromise the robustness of more complex methods. Provided sufficient instrument sensitivity, optimal method performance typically is achieved with greater dilution factors (lower analyte concentrations in the prepared sample). This approach not only avoids self-suppression issues but also minimizes the potential for ionization suppression due to co-eluting matrix components.

More complex sample preparation procedures may be required to address issues related to the chemical class or concentration of the analyte, as well as the nature of the matrix. In such cases, the use of an internal standard (stable-isotope-labeled standards in particular) is almost essential to ensure adequate method performance. For best results, the addition of the internal standard should take place at the earliest practical stage of sample preparation (e.g., immediately following test sample dissolution).

For example, procedures such as liquid–liquid and solid-phase extraction may be required to enrich (concentrate) target compound(s) for greater assay sensitivity or for isolation from high levels of ionization-suppressing components within the matrix (e.g., salts or other excipients). Chemical derivatization of certain functional groups of a target compound may be desirable to stabilize the sample (e.g., for GC–MS analysis), improve method chromatographic performance, or enhance intrinsic sensitivity for detection (e.g., for ESI). Although such procedures add complexity, they are acceptable provided the overall analytical procedure can be properly validated.

A special case of complex sample preparation that may be required for quantification of macromolecular compounds such as vaccines and biotherapeutics involves the intentional degradation of the target molecule(s) into smaller entities that are more amenable to quantitative MS analysis. For example, partial degradation of a protein therapeutic may be achieved by hydrolytic (chemical) or enzyme-based (e.g., tryptic) digestion to yield peptide fragments that are characteristic of the protein. These smaller molecules can be analyzed by using principles described in this section (including the use of stable-isotope-labeled internal standards of each targeted peptide), and the results can be correlated to determine the concentration of the original target protein. Further, by measuring multiple peptides derived from the protein of interest, analysts can achieve qualitative (identity) verification of the protein by means of the same method. Of course, this indirect approach usually requires some degree of isolation and qualitative identification of the macromolecule to ensure that the subsequent quantitative measure of the representative peptides is relevant.

## 7. EMERGING MS APPLICATIONS

### 7.1 Drug Product Authentication and Contamination Detection

Counterfeit and contaminated or adulterated pharmaceutical materials are a threat to patient safety, consumer confidence, and product security and are therefore of concern to pharmaceutical manufacturers and regulatory agencies. Because increases in the incidence of counterfeited and contaminated pharmaceutical materials have elevated concerns about public health safety and product security, numerous measures have been employed to detect counterfeit and contaminated drug products and to ensure supply chain integrity. Because of its sensitivity and specificity, MS is an effective analytical tool for broad application in the determination of authenticity, source, or contamination of drug products. Approaches include verifying the identity of the active ingredient(s), determining and comparing impurity profiles, and isotopic characterization.

https://pharmacopeia.cn/

### 7.1.1 IDENTIFICATION AND/OR VERIFICATION OF THE ACTIVE INGREDIENT

Counterfeit drug products may contain multiple or different active ingredients or no active ingredient at all. GC–MS, LC–MS, or direct-infusion MS procedures can provide a verification of the presence or absence of an active ingredient or the identity of other active ingredients that may be present. Counterfeit drug products containing multiple active ingredients or very high levels of a single active ingredient (superpotent samples) typically are of greater concern to human safety than those that contain little or none. In cases such as these, MS can provide positive, unequivocal proof of identity, as well as quantitative information sufficient to pursue those responsible for producing the counterfeit products.

### 7.1.2 IMPURITY PROFILING

Impurity profiles can indicate contamination of a drug product or can distinguish an authentic product from a counterfeit. Impurity profiles serve as fingerprints for a drug substance or formulated product from a particular source. Hyphenated techniques such as LC–MS and GC–MS can be used to resolve and identify process-specific impurities that are characteristic of a particular synthetic route, which can be useful in determining the origin and distribution of counterfeit materials. Variations in the impurity profile of the authentic material and changes in the profile with time and process conditions must be considered when analysts use impurity profiles for identification or as indicators of potential contamination. With suspect counterfeit products, similarity of impurity profiles may not necessarily indicate a suspect sample is authentic. In such cases, additional investigation using orthogonal procedures may be necessary.

### 7.1.3 ISOTOPIC CHARACTERIZATION

Stable isotopes of elements such as carbon, nitrogen, hydrogen, and oxygen occur naturally in pharmaceutical products and raw materials. Isotopic ratios principally depend on starting materials and processes used to produce drug substances and drug products and can be highly specific for a given batch. Therefore, isotope ratios can define an isotopic fingerprint for a given material, and observed differences in specific isotope ratios between batches can be used to authenticate materials or indicate potential contamination. Isotope ratio mass spectrometry (IRMS) is a powerful tool for pharmaceutical authentication or detection of potential contamination in drug products and raw materials. IRMS affords a high level of specificity, accuracy, and precision in the determination of certain elemental (e.g., carbon, nitrogen, oxygen, and hydrogen) isotope ratios in drug substances or products. Because specific isotope ratios can be influenced by multiple factors such as location, climate, process differences, and source and quality of raw materials, IRMS is able to provide information that is not only useful in authenticating a drug product but also in indicating the origin of a drug product or material. This is particularly important in determining whether distributed counterfeit drug products obtained at discrete locations originate from the same manufacturing process or when linking a diverted product with its original manufacturing site. *Figure 9* illustrates subtle but notable differences between authentic drug product samples from three global manufacturing sites and overt differences between authentic and three counterfeit drug products. Additionally, IRMS approaches authentication from a postproduction perspective and does not involve marking or altering the drug product, as may be required by other pharmaceutical authentication technologies.

# ⟨1761⟩ APPLICATIONS OF NUCLEAR MAGNETIC RESONANCE SPECTROSCOPY

## PRINCIPLES OF NMR

Nuclear magnetic resonance (NMR) spectroscopy is an analytical technique based on the magnetic properties of certain atomic nuclei. NMR is similar to other types of spectroscopy in that absorption of electromagnetic energy at characteristic frequencies provides analytical information. NMR differs from other types of spectroscopy because the discrete energy levels between which the transitions take place are created by placing the nuclei in a magnetic field of strength $H_0$. Although the initial field strength of the applied field is $H_0$, when the sample is inserted into the magnet, the field strength throughout the sample becomes $B_0$, defined as follows:

$$B_0 = \mu_S H_0 \text{ [1]}$$

in which $\mu_S$ is the magnetic susceptibility of the sample.

Atomic nuclei behave as if they were spinning on the nuclear axis. The angular momentum, $\rho_0$, of the nucleus is characterized by a spin quantum number ($I$). The maximum observable component of the angular vector, $\rho$, is

$$\rho = I\text{h}/2\pi = I\,\overline{\text{h}} \text{ [2]}$$

in which h is Planck's constant and $\overline{\text{h}}$ is modified Planck's constant.

*Table 1* shows the values of $I$ as a function of the mass number and the atomic number.

**Table 1. Nuclear Spin Values as a Function of Mass and Atomic Numbers**

| Mass Number | Atomic Number | Nuclear Spin ($I$) |
|---|---|---|
| Odd | Even or odd | 1/2, 3/2, 5/2 ... |
| Even | Even | 0 |
| Even | Odd | 1, 2, 3 ... |

The angular momentum creates a magnetic moment, $\mu$, which is parallel to and directly proportional to $\rho$.

$$\mu = \gamma\rho = \gamma I\overline{\text{h}} \text{ [3]}$$

where $\gamma$ is the magnetogyric ratio and is a constant for all nuclei of a given isotope, regardless of their position in a molecule.

Nuclei that have a spin quantum number $I \neq 0$, when placed in an external uniform static magnetic field, align with respect to the field in $(2I + 1)$ possible orientations. Thus, for nuclei with $I = 1/2$, which includes most isotopes of analytical significance (*Table 2*), there are two possible orientations, corresponding to two different energy states. The energies of these two states are $\pm \mu B_0$, and their separation is

$$E = \mu B_0 - (-\mu B_0) = 2\mu B_0 \text{ [4]}$$

with more nuclei populating the lower energy state ($-\mu B_0$) than the higher energy state ($+\mu B_0$). The populations are in accordance with the Boltzmann distribution:

$$N_+/N_- = \exp(-E/kT) \text{ [5]}$$

where $N_+$ and $N_-$ are the populations of the high and low energy states, respectively; $k$ is the Boltzmann constant; and $T$ is the temperature in K.

A nuclear resonance is the transition between these states, and upward as well as downward transitions are possible. In a static magnetic field the nuclear magnetic axis precesses (Larmor precession) about the $B_0$ axis. The precessional angular velocity is often referred to as the Larmor frequency, $\omega_0$, and is related to $B_0$:

$$E = h\nu = 2\mu B_0$$
$$= 2\gamma I \bar{h} B_0$$
$$= \gamma \bar{h} B_0$$
$$\nu = \gamma B_0 / 2\pi$$
$$\omega_0 = \gamma B_0 \quad [6]$$

If energy from an oscillating radio-frequency (rf) field is introduced, then resonance is achieved when the rf frequency is the same as the precessional angular velocity. Although the probability of an upward transition is equal to that of a downward transition, more upward transitions take place than downward transitions because $N_-$ is greater than $N_+$. Hence, an overall absorption of energy takes place. As shown in *Table 2*, the resonance frequency of a nucleus increases in direct proportion with the increase of the magnetic field strength.

**Table 2. Properties of Some Nuclei Amenable to NMR Study**

| | | | | Resonance Frequency (MHz) at | | |
|---|---|---|---|---|---|---|
| **Nucleus** | ***I*** | **Natural Abundance (%)** | **Sensitivity** | **1.4093 T[a]** | **7.0463 T** | **11.7440 T** |

[a] T = tesla: 1.4093 T = 14.093 kilogauss.

NMR is a technique of high specificity but relatively low sensitivity. The basic reason for the low sensitivity is the comparatively small difference in energy between the upper and lower energy states (0.08 Joules at 1.5 to 2.0 T field strength), which results in a population difference between the two levels of only a few parts per million. Another important aspect of the NMR phenomenon, with negative effects on sensitivity, is the long lifetime of most nuclei in the excited state. Long lifetimes affect the design of the NMR analytical test, especially in repetitive pulsed experiments. Simultaneous acquisition of the entire range of resonant frequencies instead of frequency-swept spectra can give increased sensitivity per unit time.

All characteristics of the signal–chemical shift, multiplicity, linewidth, coupling constants, relative intensity, and relaxation time contribute analytical information. The analytical usefulness of NMR arises from the observation that the same types of nuclei, when located in different molecular environments, exhibit different resonance frequencies. The reason for this difference is that the effective field associated with a particular nucleus is a composite of the external field provided by the instrument and the field generated by the circulation of the surrounding electrons. The latter field is generally opposed to the external field and lowers the overall field strength at the nuclear site. The phenomenon is termed *shielding*. Hence, the more shielded nuclei have lower Larmor frequencies.

It is not convenient to accurately measure the absolute values of transition frequencies, as is done with other spectroscopic procedures. However, it is convenient to accurately measure the difference in frequencies between two resonance signals. The position of a signal in an NMR spectrum is described by its separation from another resonance signal arbitrarily taken as standard. This separation is called *chemical shift*, which may be expressed in units of magnetic field or in frequency units that are readily interconverted by the equation for the resonance condition, *Equation 6*. This equation shows that when the separation is expressed in frequency units, it is directly proportional to the field strength. It is more convenient, therefore, to express the chemical shift in terms of the dimensional unit δ, which is independent of the field strength, and is defined by

$$\delta = (\nu_{SS} - \nu_{RS})/\nu_0 \quad [7]$$

where $\nu_{SS}$ is the test substance resonance frequency, in Hz; $\nu_{RS}$ is the reference resonance frequency in Hz; and $\nu_0$ is the instrument frequency, in MHz. When $\nu_0$ is expressed in units of MHz, then *Equation 7* is expressed in units as parts per million

(ppm). Hence, it is common to use the unit ppm to express the chemical shift difference between the resonance peak of the test substance and that of the reference.

By using this equation, one can use (with appropriate caution) the chemical shift of any known species (such as the residual $^{1}$H-containing species in a deuterated solvent) as a chemical shift reference. This equation, now in common use, is applicable to nearly all nuclei.

Tetramethylsilane (TMS) is the most widely used chemical shift reference for proton and carbon spectra. It is chemically inert, exhibits only one peak (which is more shielded than most signals), and is volatile, which allows ready specimen recovery. Either 2,2,3,3-$d_4$ sodium 3-(trimethylsilyl)propionate (TMSP) or sodium 2,2-dimethyl-2-silapentane-5-sulfonate (DSS) is used as an NMR reference for aqueous solutions. The resonance frequency of the TMSP or DSS methyl groups closely approximates that of the TMS signal. Where the use of an internal NMR reference material is not desirable, an external reference may be used, such as a reference standard in a separate NMR tube.

Conventional NMR spectra are shown with shielding increasing and chemical shift decreasing from left to right because less shielded nuclei have higher Larmor frequencies than do more shielded nuclei. Resonances on the left are said to be deshielded (i.e., they show lower electron density). Resonance peaks appearing at the right are termed more shielded (i.e., they show greater electron density) than those appearing at the left. Resonances from the more shielded and the less shielded nuclei often are inappropriately called the high-field or upfield peaks and the low-field or downfield peaks, respectively, as a result of the outdated method of acquiring data by sweeping the magnetic field. Today, the overwhelming majority of spectra are acquired on a pulsed Fourier transform (FT) spectrometer, which sweeps neither the magnetic field nor the transmitter frequency. Therefore, it is more appropriate to refer to resonances at the left side of the spectrum as high-frequency or deshielded resonances and those on the right as low-frequency or shielded resonances.

The coupling between two nuclei can be described in terms of the spin-spin coupling constant, *J*, which is the separation (in Hertz) between the individual peaks of the multiplet. When two nuclei interact and cause reciprocal splitting, the measured coupling constants in the two resulting mutiplets are equal. Furthermore, *J* is independent of magnetic field strength.

Coupled spin systems are usually referred to as weak or strong. These terms depend on the separation of the Larmor frequencies of the coupled nuclei compared to the coupling constant between them. Both of these values are easily measured from the spectrum. For a weakly coupled system, the separation expressed in Hz ($\Delta\nu$) is large compared to *J*, which is always expressed in Hz. Thus, the ratio of the two is dimensionless. For a weakly coupled system, the ratio is large. Typically, spectroscopists consider a ratio above 10 to be weak. Only weakly coupled spin systems produce first-order spectra, which are comparatively easy to analyze. The number of individual peaks that are expected to be present in a multiplet and the relative peak intensities are predictable. The number of peaks is determined by $2nI + 1$, where $n$ is the number of identical nuclei on adjacent groups that are active in splitting and $I$ is the spin of those nuclei causing the splitting. For protons this becomes $(n + 1)$ peaks. In general, the relative intensity of each peak in the multiplet follows the coefficient of the binomial expansion $(a + b)^n$. These coefficients can conveniently be found by use of Pascal's triangle, which produces the following relative areas for the specified multiplets: doublet, 1:1; triplet, 1:2:1; quartet, 1:3:3:1; quintet, 1:4:6:4:1; sextet, 1:5:10:10:5:1; and septet, 1:6:15:20:15:6:1. Two examples of first-order spectra arising from weak coupling are shown in *Figure 1*.

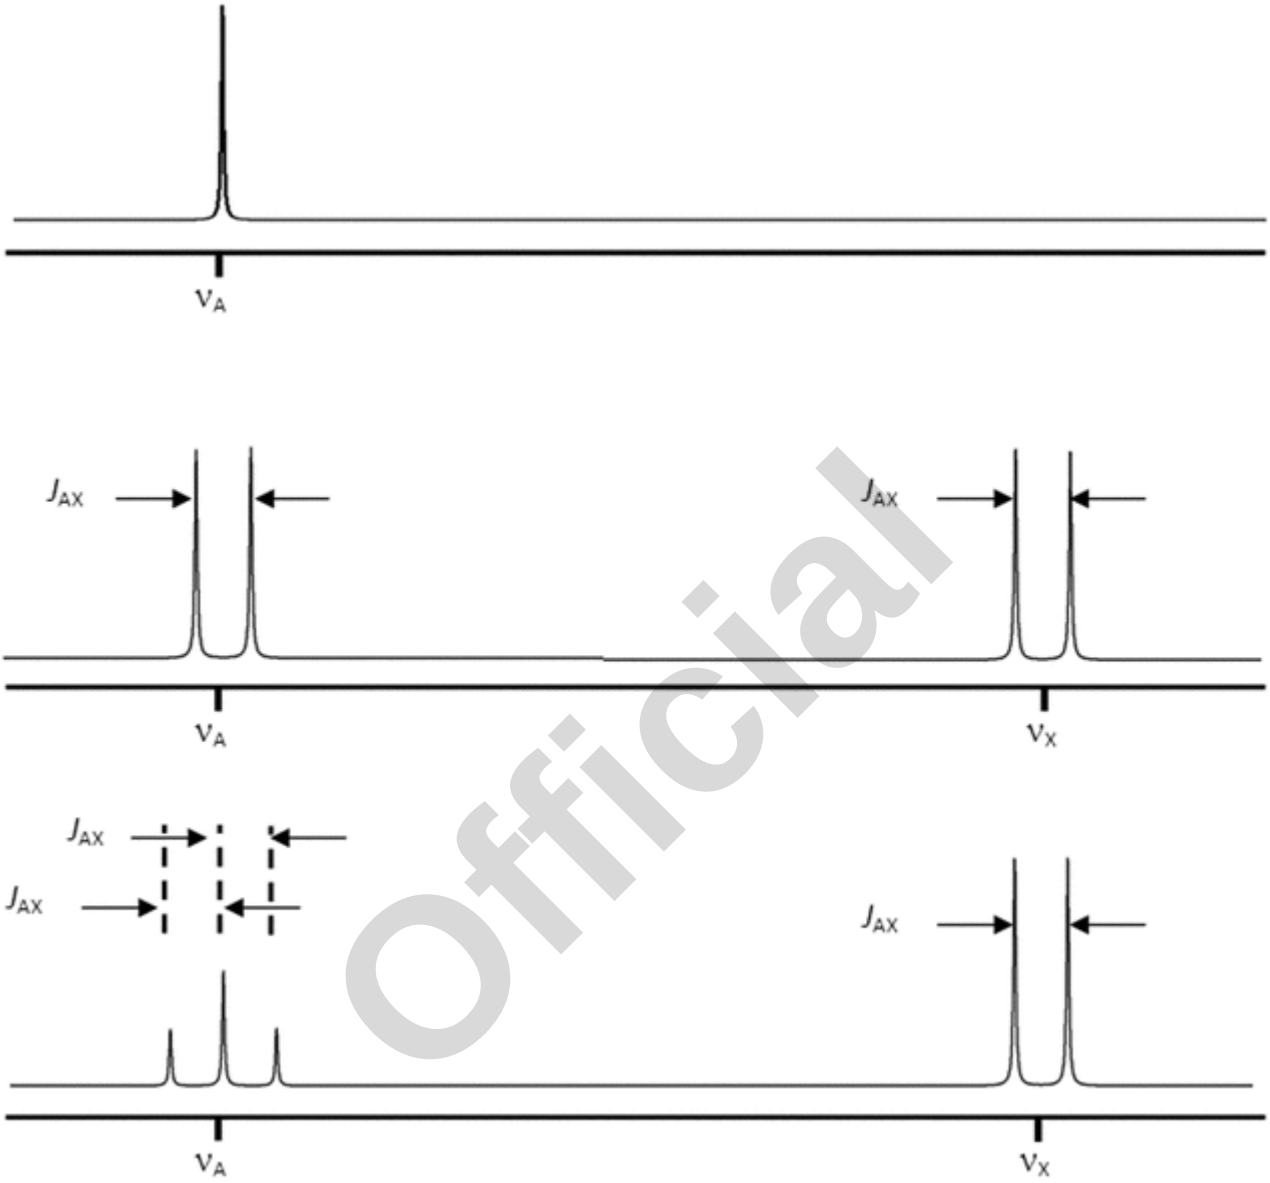

Figure 1. Diagrammatic representation of simple spectra resulting from weakly coupled spin systems.

Coupling may occur between $^{1}H$ and other nuclei, such as $^{19}F$, $^{13}C$, and $^{31}P$. This type of coupling can frequently be observed between nuclei separated by 1–5 bonds.

Magnetically active nuclei with $I \geq 1$, such as $^{14}N$, possess a nuclear quadrupole moment, which produces line broadening of the signals from neighboring nuclei.

Another characteristic of an NMR signal is its relative intensity, which has wide analytical applications. In carefully designed experiments, the area or intensity of a signal is directly proportional to the number of protons that give rise to the signal. As a result, NMR can be used for quantitation (see *Quantitative Analysis* in this chapter and in *Nuclear Magnetic Resonance Spectroscopy* ⟨761⟩, *Qualitative and Quantitative NMR Analysis*. NMR spectra may contain spinning side bands, peaks that appear symmetrically located around each signal. These signals are due to the failure to optimize the off-axis (*x* and *y*) shims. The homogeneity of modern superconducting magnets, coupled with computer shimming techniques, reduce the need for sample spinning and completely eliminate these sidebands.

# NMR SPECTROMETERS

## Introduction

NMR spectrometers have evolved since the first commercial instrument, a Varian HR-30 that operated at 30 MHz, was produced in 1952. Initially NMR spectrometers used a data acquisition technique known as continuous wave (CW), which was based on sweeping the magnetic field. The limitations of a CW spectrometer include low sensitivity and long analysis time.

Today's spectrometers operate at frequencies up to 1 GHz and apply an rf pulse to the sample to produce a time-domain signal known as a free induction decay (FID), which is then Fourier transformed into a frequency-domain signal. This technique is known as FT NMR spectroscopy. Current NMR spectrometers are composed of several key components: the magnet, the probe, the console, and the computer.

The instruments are described by the approximate resonance frequency of the $^{1}H$ resonance, e.g., 600 MHz, or by their field strength, e.g., 14.1 T.

## The Magnet

Until the early 1970s, NMR magnets were either ferromagnetic-core electromagnets or permanent magnets that operated at field strengths of 1.41–2.35 T, corresponding to $^{1}H$ resonance frequencies of 60, 80, 90, and 100 MHz. The first NMR magnets based on superconducting magnets were introduced in the 1960s and allowed access to much higher field strengths that currently are as high as 23.5 T (1 GHz).

The superconducting magnet is the most expensive component of an NMR spectrometer and can cost up to several million dollars. These magnets consist of miles of $Nb_3Sn$ or NbTi wire. When these materials are wound into a solenoid that is immersed in liquid helium at 4.2 K, they become superconducting. That is, an electrical current can be induced in them by an energizing power supply, and that current will persist for many years even after the power supply is removed. This essentially constant electrical current is used to generate high static magnetic fields that can be several times higher than those obtained with ferromagnetic-core magnets. Ensuring that the superconducting coil is immersed in liquid helium at all times is the only maintenance needed to sustain these high fields.

*Figure 2* contains a diagram of a typical superconducting magnet. The superconducting solenoid is immersed in a liquid-helium Dewar at 4.2 K. This unit is itself contained in a liquid-nitrogen Dewar at 77.4 K. Each Dewar is surrounded by a vacuumed space and reflective film coating to prevent outside heat of the laboratory from entering the helium Dewar. The central core or room-temperature bore provides room for the stack that contains the shim coils for room-temperature shimming. Finally the probe is inserted into the stack. Samples are injected or ejected from the probe by means of a jet of filtered and dried air or nitrogen.

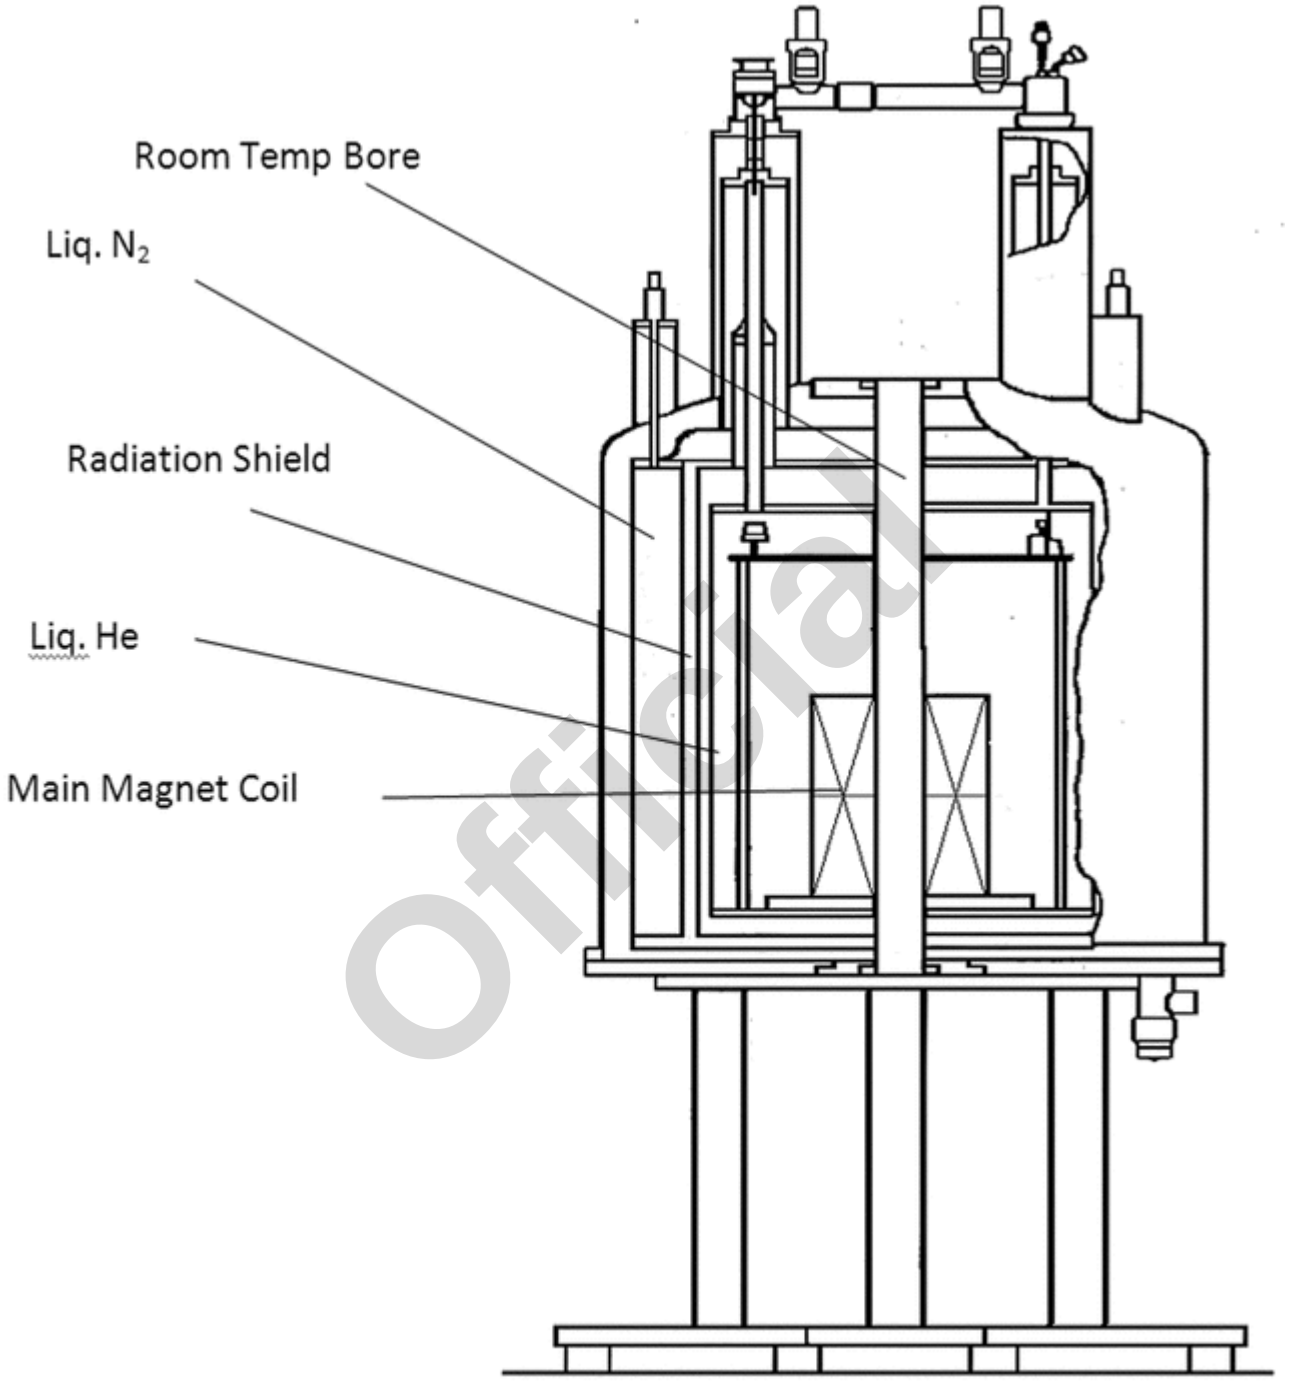

Figure 2. Schematic representation of a superconducting magnet.

An important recent advance in magnet technology has been the construction of shielded magnets with stray fields that can extend only one or two meters from the center of the magnet in three dimensions, thereby making magnet siting a far easier task than it was with unshielded magnets.

In addition to the main solenoid, the helium Dewar also contains several other superconducting coils that are used to shim the main magnetic field as a first step in attaining very high field homogeneity. Further shimming is accomplished by 20–30 shim coils in the room-temperature shim stack that is inserted in the bore of the magnet. These coils operate at ambient temperature and are used to generate small magnetic fields that oppose and cancel inhomogeneities caused by the surroundings, the probe, or the sample itself. Computer software has taken over a large amount of the tedious job of shimming the magnet homogeneity, a critical task for obtaining good NMR data. Using the lock signal from the sample, spectroscopists can generate a field map for each of the shim coils. Using this map, the computer then calculates the amount of current that should be applied to each of the shim coils to maximize the magnet homogeneity. Typically this operation takes less than a

minute for shimming the on-axis ($z_1$ to $z_6$) shim coils. The off-axis ($x/y$) inhomogeneities can be compensated for in a similar manner but usually in a longer period of time (15–20 minutes) because of the larger number of off-axis coils.

## The Probe

The NMR probe may be the most important part of the instrument. The probe consists of one or two rf coils. Each coil, which is inductive (L), is in a circuit that contains several tunable capacitive (C) elements. These elements are adjusted to enable the probe to transmit and receive at the Larmor frequency, $\nu_0$. For a given nucleus, the probe tuning is determined by [$\nu = 1/(2\pi(LC)^{1/2})$]. A pulse of rf at the Larmor frequency results in an applied magnetic field ($B_1$). To induce a transition, $B_1$ must be applied perpendicular to the static field generated by the magnet superconducting coil. The rf coil not only transmits the excitation pulse but is also electronically switched to receive the rf signal from the sample.

The most common NMR sample tube is the 5-mm (od) NMR tube. However, probes have been designed in many forms. Some probes can accommodate 10- or 20-mm tubes for samples that are not in limited supply, such as petroleum and polymers. For limited amounts of precious samples, probes have been made to accept tubes as small as 1 mm, which can accommodate solutions as small as 5 µL. Also, flow probes are available to obtain data directly from a liquid chromatography effluent.

Probes are available in a large number of coil configurations. The most common probe usually contains a broadband observe coil that is tunable over a wide range of frequencies ($^{31}$P to $^{109}$Ag), a decoupler ($^1$H) coil, and a coil tuned to deuterium ($^2$H) for field-frequency lock. Usually, the decoupler coil is double-tuned for both $^1$H and $^2$H. Probe configurations can include as many as four channels for multidimensional work with biological macromolecules.

The probe can come in a format where the X-nucleus observe-coil (e.g., $^{13}$C) is wound closest to the sample for highest sensitivity, and the decoupler coil ($^1$H) is farther away. The inverse configuration is also available to provide the maximum signal-to-noise (S/N) ratio for $^1$H, the detected nucleus in two-dimensional (2-D) indirect heteronuclear experiments, such as heteronuclear single-quantum coherence spectroscopy (HSQC) and heteronuclear multiple-bond correlation (HMBC) where the X-nucleus is indirectly detected via the $^1$H frequency. Recent advances in probe technology have resulted in a single probe combining the sensitivity of the direct and inverse detection probes described above. Another advancement in probe design is the cryogenically cooled probe wherein the rf coils and their preamplifiers are held at close to liquid helium temperatures (20 K). Because rf electronics generate lower noise levels at colder temperatures, S/N ratios can be increased by at least a factor of four in these probes. Because the S/N ratio of a spectrum is given by $n^{1/2}$, where $n$ is the number of acquisitions, an enhancement by a factor of four to the initial S/N ratio translates to a savings of 16 in time or to a four-fold reduction in sample size.

Probes can also be equipped with gradient coils that can apply a magnetic field gradient in the $z$ only or $x$, $y$, and $z$ directions. These gradients are used to study diffusion or, more commonly, to be integral parts of pulse sequences because they provide an efficient means for selecting specific coherences in 2-D experiments.

In addition to the electronic coils, probes usually come equipped with a heater coil that enables variable temperature work from –100° to +150°. Probes also have gas outlets to allow sample insertion and ejection from the probe as well as sample spinning.

For solid-state samples the probes come with cylindrical rotors that are filled with the sample and capped. The entire rotor can then be oriented at an angle of 54.74° (known as the magic angle) relative to the magnetic field direction and spun at rates up to 70 kHz. Rapid rotation at this angle helps remove the chemical shift anisotropy and dipolar coupling so that the very broad resonances observed in the solid state can be reduced considerably.

## The Console and Computer

The NMR console has the primary function of generating the various Larmor frequencies required for a given experiment, amplifying and transmitting these frequencies to the probe, and detecting the resulting signals that are transmitted from the probe so that they can be used to create an NMR spectrum. In addition to these primary functions, the console performs many more operations, all of which are computer-controlled. *Figure 3* contains a schematic diagram illustrating the various components of the current majority of spectrometer consoles.

the various frequencies that are close to the Larmor frequencies of the observed or perturbed nuclei. For a specific experiment, the computer triggers the pulse programmer (***C***), which, in turn, sends timing signals (pulse width, phase, and shape) to the observer transmitter (***D***), the decoupler (***E***), and the gradient amplifier (***F***), depending on which of these units are needed for that experiment. Once the observed nucleus in the probe (***G***) is excited by a pulse from the observed transmitter, the resultant rf signal is amplified in the preamplifier (***H***). Then the signal is mixed (***J***) with a local oscillator (***I***) to generate a lower rf frequency, called the intermediate frequency (IF) that is further amplified (***K***). A second mixing stage, this time with a different local oscillator (***L***), results in an audio signal that is then detected in quadrature (***M***) before being amplified (***N***), converted (***O***) from an analog to a digital signal, and stored in the computer. After the signal is processed to create a spectrum, the digital data can be converted back to an analog signal in a digital-to-analog converter (***P***) and printed.

The output from the phase-sensitive detector (***M***) is the free induction decay (FID), which is a time-domain signal, $f(t)$.

When two detectors are used (***M***) with their reference frequencies shifted from each other by 90°, frequencies that are positive with respect to the reference can be distinguished from those that are negative. This system is referred to as quadrature phase-sensitive detection (QPD). Each detector produces an FID, but they will always be 90° out of phase with respect to each other. One FID is called the real FID, and the other is called the imaginary FID. The Fourier transform that is performed in this case is called a complex Fourier transform. The combination of the real and imaginary FIDs yields the frequency spectrum, $F(\omega)$.

$$F(\omega) = \int_{-\infty}^{+\infty} f(t)\exp^{-i\omega t} dt \qquad [8]$$

In addition to the Fourier transform process, the computer is also used for post-acquisition processing of the data. The frequency-domain spectrum that results from the complex Fourier transform can then be phased, baseline corrected to remove distortions, integrated to obtain peak areas, and peak picked to provide chemical shift information. The computer is also capable of providing spectra calculated from chemical shift and coupling values, curve-fitting resonances, and deconvoluting complex overlapped peaks. Finally, the digital data can be converted to their analog form by a DAC (***O***) and printed.

## RELAXATION

NMR includes two types of relaxation: *Spin-Spin Relaxation*, sometimes referred to as *Transverse Relaxation*, or $T_2$ Relaxation, and *Spin-Lattice Relaxation*, sometimes referred to as *Longitudinal Relaxation*, or $T_1$ Relaxation. At least two mechanisms contribute to *Transverse Relaxation*: loss of signal due to $B_0$ inhomogeneity and the natural relaxation that would take place even in a perfectly homogeneous field. The combined effects of these two mechanisms produce a new time constant for the relaxation, which is referred to as $T_2$*.

### Spin-Spin Relaxation (Transverse Relaxation)

After an rf pulse, the component of $M_0$ in the $(x,y)$ plane, $M_{xy}$, will gradually decay toward zero. The process is first order, and as it is in other types of first-order processes, the instantaneous rate of decay of $M_{xy}$ is directly proportional to its displacement from equilibrium. The further $M_{xy}$ is displaced from zero, the faster it decays, and as it approaches zero it decays more and more slowly. Hence, *Equation 9* applies.

$$dM_{xy}/dt \propto (-M_{xy}) \quad [9]$$

The process is analogous to the decay of a radioactive element. However, spectroscopists do not speak of the rate of decay of an FID in terms of its half-life. Instead, they speak of its 1/e-life, that is, how long it takes for the FID to decay to a value that equals 1/e of its original value at time zero. Standard mathematical manipulations of *Equation 9* yield

$$M_{xy} = M_0\exp(-t/T_2^*) \quad [10]$$

where $M_0$ is the equilibrium distribution given by *Equation 9*, and $T_2$* is the rate constant for the decay. $T_2$* is a *measure* of how fast the signal decays, not how long it takes to decay. The rate of decay is fastest immediately after the pulse because then it is furthest from its equilibrium position, zero. If the rate remained constant at this initial rate, then the signal would be completely decayed after one $T_2$*.

*Table 3* was prepared from *Equation 10*. It shows the percentage of $M_{xy}$ remaining as a function of time after a 90° pulse. In *Table 3* time is given as the number of $T_2$*s.

**Table 3. Percent of $M_{xy}$ Remaining as a Function of Time, in Units of $T_2$***

| Time/$T_2$* | 0.0 | 0.5 | 1.0 | 1.5 | 2.0 | 3.0 | 4.0 | 5.0 |
|---|---|---|---|---|---|---|---|---|
| % Remaining | 100.0 | 60.7 | 36.8 | 22.3 | 13.5 | 5.0 | 1.8 | 0.7 |

$M_{xy}$ asymptotically approaches zero, and it would take infinitely long for complete decay, but the decay is normally considered to be complete when the time has reached 3 to 5 times $T_2$*. Hence, these times are commonly used as acquisition

DOI: https://doi.org/10.31003/USPNF_M4348_01_01
@2024 USPC

times. If acquisition times that are shorter than 3 times $T_2$* are used, the FID is truncated and subsequent Fourier transform leads to visible baseline artifacts.

The decay of the FID produces the peak width in the final spectrum. The faster the decay, the broader is the line. The mathematical relationship is:

$$\Delta\nu_{1/2} = 1/(\pi T_2^*) \text{ [11]}$$

where $\Delta\nu_{1/2}$ is the width of the peak at its half-height.

## Spin-Lattice Relaxation (Longitudinal Relaxation)

After an rf pulse, nuclei are excited from the low-energy state into the high-energy state. The nuclei will eventually relax back to establish the Boltzmann distribution (see *Equation 5*), and this process is called spin-lattice relaxation. The recovery process is first-order, and as it is in other types of first-order processes, the instantaneous rate of growth of $M_z$ is directly proportional to its displacement from equilibrium. The farther $M_z$ is displaced from $M_0$, the faster it grows back, and as it approaches $M_0$ it grows back more and more slowly. Hence, *Equation 12* applies.

$$dM_z/dt \propto (M_0 - M_z) \text{ [12]}$$

Standard mathematical manipulations yield

$$M_z = M_0(1 - \exp(-t/T_1)) \text{ [13]}$$

Note that $T_1$ is a measure of how fast $M_z$ grows back to $M_0$—it is not how long it takes to grow back. *Table 4* was prepared from *Equation 13* and shows the percentage of recovery of $M_z$ as a function of time after a 90° pulse. In this table, time is given as the number of $T_1$*s*.

**Table 4. Percent Recovery of $M_z$ as a Function of Time, in Units of $T_1$**

| Time/$T_1$ | 0.0 | 0.5 | 1.0 | 1.5 | 2.0 | 3.0 | 4.0 | 5.0 |
|---|---|---|---|---|---|---|---|---|
| % Recovery | 0.0 | 39.3 | 63.2 | 77.7 | 86.5 | 95 | 98.2 | 99.3 |

As $M_z$ asymptotically approaches $M_0$, it takes infinitely long for 100% recovery. However, recovery is normally considered to be complete when it has reached 99%. Hence, relaxation delays of $5T_1$ are commonly used in pulse sequences. The rate of return to $M_0$ is fastest immediately after the pulse because that is when $M_0$ is farthest from its equilibrium position. If the rate remained constant at this initial rate, then full recovery would be achieved after one $T_1$.

# TIP ANGLE

During an rf pulse, a magnetic field ($B_1$) is applied to the sample. The magnetization vector *M* precesses about $B_1$ according to

$$\omega_1 = \gamma B_1 \text{ [14]}$$

where $\omega_1$ is the precessional frequency and $B_1$ is the strength of the magnetic field applied to the sample. During the time that the pulse is applied, *M* precesses to an angle ($\alpha$) given by the precessional rate multiplied by the width of the pulse, in time, (*PW*). Then,

$$PW \times \omega_1 = \alpha = PW \times \gamma B_1 \text{ [15]}$$

Tip angles typically are expressed in units of degrees or in radians. For example, a 90° pulse is sometimes referred to as a $\pi/2$ pulse.

## Optimum Tip Angle or Ernst Angle

Time averaging to improve the S/N ratio is accomplished by a delay-pulse-acquire sequence that is repeated as necessary. Suppose that during the first pulse, $M_0$ precesses 30° about $B_1$ before the pulse is turned off. At this time the magnitude of $M_z$ is $M_0\cos 30°$. At the end of the pulse, $M_z$ will begin to grow back toward its equilibrium value, $M_0$. Typically, the second pulse is applied before $M_z$ reaches $M_0$, driving $M_z$ down even farther away from $M_0$. Consequently, $M_z$ begins to grow back faster because it is even farther away from its equilibrium value. After 6–10 pulses, $M_z$ will grow back an amount that is equal to the incremental displacement caused by each succeeding pulse and will reach a new equilibrium or steady state. Each succeeding pulse continues to tip this new steady-state value of $M_z$ by 30°, resulting in signal intensity for each pulse.

The position of the steady-state equilibrium is determined by three factors: the $T_1$, the tip angle, and the time between pulses. On the one hand, for a given $T_1$ and time between pulses, if the tip angle is too large then the steady-state value of $M_z$ will be close to the origin, affording only a small signal. On the other hand, if the tip angle is too small, e.g., 5°, then the steady-state value will be large, but with a small angle the value of $M_z\sin 5°$ will also be small, again affording a small signal. The optimum angle is frequently called the Ernst angle, which is given by:

@2024 USPC

$$\cos \alpha_{opt} = \exp(-PR/T_1) \quad [16]$$

$$\alpha_{opt} = \text{arc cos}[\exp(-PR/T_1)] \quad [17]$$

where *PR* is the time between pulses, or pulse-repetition time. This time is the sum of the acquisition time used to collect the FID plus any relaxation delay used. This angle provides a reasonably large steady-state value combined with a reasonably large angle and will produce the best S/N ratio per unit time. The value of $T_1$ to be used in *Equation 17* should be for the longest relaxing nucleus in the molecule.

## RELAXATION DELAY

Surprisingly, the optimum S/N ratio per unit time is obtained when no relaxation delay is used for a given $T_1$. That is when *PR* equals to *AT*, the acquisition time. However, because the nuclei in most molecules do not have the same $T_1$ values, the relative intensity relationship will be lost.

For typical quantitation experiments, a relaxation delay is used and should be at least five times the longest $T_1$ expected for any of the nuclei in the molecule; and the pulse width should be set to 90°. Further details are provided in the section *Quantitative Applications*.

## RESOLUTION

In NMR spectroscopy the typical definition of resolution is the ability to distinguish between two closely spaced resonance peaks in a spectrum. The industry standard for measuring resolution is to measure the width of a single peak, in units of Hz, at the half-height of the peak.

The uncertainty principle determines the best resolution that can be achieved in an NMR spectrum. The maximum resolution possible, or the minimum separation that can be observed between two frequencies, $\Delta\nu$, in a spectrum is equal to the reciprocal of the acquisition time, *AT*, of the FID.

$$\Delta\nu = 1/\Delta t = 1/AT \quad [18]$$

The time set by the spectrometer operator should not exceed the required *AT*, because this would result in the collection of only noise after the signal has decayed to near zero. Collecting this noise does not improve the resolution.

## POSTACQUISITION DATA PROCESSING

The final appearance of the spectrum can usually be improved by applying a variety of mathematical procedures to the FID before the Fourier transform is performed. The two most common procedures are multiplying the FID by a mathematical function, generally known as a *window* function; or appending zeros to the end of the FID, generally known as *zero filling*.

### Window Functions

Two types are generally used: one for increasing the resolution and another for increasing the S/N ratio.

INCREASING THE RESOLUTION

The decay of the signal produces a peak width in the spectrum, and if this decay can be removed, then the resonance peak would consist of a single point, i.e., an infinitely narrow peak. The decay of the signal can be represented by $\exp(-t/T_2^*)$. Hence the full equation representing the decaying signal is

$$A(t) = A_0\exp(-t/T_2^*)\cos(\omega t + \theta) \quad [19]$$

If the FID is multiplied by an increasing function that exactly cancels the decay, then the peak width will be removed. This can be achieved by multiplying the FID by $\exp(t/T_2^*)$. Then *Equation 19* becomes

$$A(t) = A_0\exp(0)\cos(\omega t + \theta) = A_0\cos(\omega t + \theta) \quad [20]$$

Unfortunately, the application of this function as described above will also disproportionately increase the noise power at the tail of the FID. The S/N ratio in the final spectrum is so poor that this function is not used without modifications. Typically, the beginning of the FID, where the S/N ratio is better, is multiplied up but then the tail of the FID, where S/N ratio is poorer, is multiplied down. Two commonly used functions that accomplish this are the Gaussian function and the transform of reversed-added FIDs (TRAF) function for resolution. The latter is sometimes given the name TRAFR by instrument manufacturers. It affords the same resolution enhancement as the Gaussian function but with much less degradation in overall S/N ratio. Numerous other window functions have been proposed though not always widely used. It should also be noted that in the quantitative experiments increasing the resolution should be used with caution because it may change the accuracy of signal integration in the spectrum.

DOI: https://doi.org/10.31003/USPNF_M4348_01_01
@2024 USPC

INCREASING THE S/N RATIO

The overall S/N ratio in the spectrum can be increased by weighting the points at the beginning of the FID more highly than at the tail. This is because the S/N ratio is the highest in the beginning and the lowest at the tail. The weighting is often accomplished by multiplying the raw FID by a function that decreases with time. A popular function that gives the greatest increase in the S/N ratio is called the *matched filter*. It weights each point in the FID by an amount proportional to the S/N ratio at that point. A function that accomplishes this must match the decay. Hence, the FID is multiplied by $\exp(-t/T_2^*)$.

The penalty for the use of the matched filter is a loss of resolution that equals a doubling of the peak width. When the original decay is multiplied by the matched filter, then the new decay is given by the following:

$$\exp(-t/T_2^*) \times \exp(-t/T_2^*) = \exp(-2t/T2^*) = \exp(-t/0.5T_2^*) \quad [21]$$

The FID then appears to have decayed with a $T_2^*$ equal to one-half of the original, and according to *Equation 11* and *18* the peak width will double. Multiplying the FID by a steeper decay in an attempt to weight the beginning points eore results only in less of an increase in S/N ratio and a greater increase in peak width.

Another function that accomplishes the same increase in S/N ratio, but without any change in resolution, is the TRAF function for sensitivity, which is sometimes given the name TRAFS by instrument manufacturers.

## Zero Filling

Spectroscopists can improve the overall appearance of the spectrum considerably by appending zeros to the end of the FID before the Fourier transform is performed. This process results in placing more points on every resonance peak in the spectrum. The most common procedure is to append a number of zeros equal to the number used to collect the FID. Adding more zeros will result in only a very slight further improvement.

Although all of the peaks are better defined with zero filling, the resolution is not increased. For example, in a case where the separation between two lines is closer than the peak widths, only a single broadened line will result. Zero filling will not resolve these peaks—it will only place more points on an already broadened line. Only an increase in the acquisition time of the signal or the use of a window function could resolve the peaks.

Zero filling has a beneficial effect on quantitation. Integration of a digital spectrum is accomplished by taking the intensity at a given point and adding to it the intensity at successive points. If the number of data points is insufficient to depict the actual peak shape, the resultant integral of that peak will not be accurately determined. Therefore, zero filling until each peak is represented by at least 7–10 data points results in a more accurate integration. To obtain reliable peak representation and quantitative peak integration there should be at least 4–5 data points above the full width at half height of a peak.

# GENERAL PROCEDURE FOR STRUCTURE IDENTIFICATION

NMR spectroscopy is a powerful technique for structure identification because of its specificity of detecting certain nuclei such as $^1H$, $^{13}C$, $^{31}P$, and $^{19}F$. Typically, a routine identification test can be performed by $^1H$ NMR spectroscopy in a short period of time for simple molecules. The basis for identification is provided by a comparison of the signals from the test sample with the expected signals from a qualified reference standard. A positive identification can be concluded when the chemical shifts, multiplicities, and coupling constants of the spectrum of the test sample match those of the reference standard or, in the case of a *USP* monograph, the values listed in the monograph.

Data may be made unacceptable for analysis if incorrect sample preparation or poor adjustment of spectrometer parameters leads to poor resolution, decreased sensitivity, and spectral artifacts. It is preferable that the operator be familiar with the basic theory of NMR and operation of the spectrometer. Frequent checks of instrument performance are essential.

The procedures discussed here refer specifically to $^1H$ and $^{13}C$ NMR, but they are applicable, with modification, to other nuclei. The discussion assumes that the NMR spectra are obtained from solutions in suitable solvents.

## Selection of Solvent

Deuterated solvents are usually used to prepare solutions for NMR analysis because they are readily available, have greatly reduced $^1H$ signals from solvents in $^1H$ spectra, and have the added advantage of providing a lock signal. Select a solvent whose residual $^1H$ signals will not interfere with signals of the analyte. If a residual $^1H$ solvent peak might interfere with any signals from the sample solution and another solvent is not possible, then the $^2H$ isotopic purity of the solvent should be as high as possible. Some solvents (e.g., $D_2O$ or $CD_3OD$) have labile protons that can enter into fast exchange reactions with the labile protons in the analyte. This may eliminate resonance signals from –COOH, –OH, and $–NH_2$ structural groups. The most commonly used solvents for proton and carbon NMR are listed in *Table 5* along with their residual $^1H$ and $^{13}C$ chemical shifts as well as the multiplicities of these resonances caused by coupling to deuterium.

**Table 5. Solvents Commonly Used for $^1H/^{13}C$ NMR Chemical Shifts**

| Solvent | Residual $^1H/^{13}C$ Signal ($\delta^{a,b}$) and Multiplicity | |
|---|---|---|
| | $^1H$ | $^{13}C$ |
| $CDCl_3$ | 7.27 | 77.23 (3) |
| $CD_3OD$ | 3.35, 4.78 | 49.15 (7) |

## Sample Preparation

For *USP* procedures, directions are usually given in individual monographs. The solute concentration depends on the objective of the experiment. Typically, NMR sample solutions are prepared so that they contain from a few to 50 mg/mL. Detection of minor contaminants may require higher concentrations. In some cases such as polymers, even higher concentrations can be used. The solutions are prepared in separate vials and are transferred to the NMR tube. The volume required depends on the size of the NMR tube and on the geometry of the probe. The level of the solution in the tube must be high enough to extend beyond the coils when the tube is inserted in the instrument probe.

The NMR tubes must meet narrow tolerance specifications in diameter, wall thickness, concentricity, and camber. The most widely used tubes have a 5- or 10-mm outside diameter (OD) and a length between 15 and 20 cm, but 1- and 3-mm (OD) NMR tubes are becoming more common, and tubes as large as 20 mm (OD) have been used.

## Procedure

The NMR tube is placed in a probe located in the magnetic field. Although samples traditionally have been spun to average the nonradial field gradients, the quality of the shim coils no longer makes spinning a requirement, and, in the case of many 2-D experiments, the sample should not be spun. The magnetic field's homogeneity is optimized by shimming, a function that is largely being taken over by the computer in most modern spectrometers. Probe tuning is optimized for the frequency being observed and is matched to the impedance of the spectrometer.

The computer serves to control all operations of the spectrometer from running the pulse program to storing and processing the data. The experimental setup involves selecting values for a large number of variables, including the spectral width to be examined, the duration of the excitation pulse (*PW*), the time interval over which data will be acquired (*AT*), the number of transients to be accumulated, and the delay between one acquisition and the next (relaxation delay). The acquisition time for one transient is on the order of seconds. The number of transients is a function of the specimen concentration, the type of nucleus, and the objective of the experiment and can vary from a few for most $^{1}H$ experiments to several thousand for $^{13}C$ spectra. At the end of the experiment, the signal (FID) is stored in digitized form in the computer memory and may be displayed on the monitor. The signal can be processed mathematically to enhance either the resolution or the sensitivity, and it can be Fourier-transformed into a frequency-domain spectrum, which can be further analyzed to obtain peak positions (chemical shifts) and intensities.

## Structure Elucidation by NMR

The simplest case of using NMR spectroscopy to elucidate an unknown structure is to obtain a match with a spectrum from a reference standard or from a database. The informational content of an NMR spectrum is sufficient for deducing structures of organic molecules even when qualified reference standards or spectra are not available. Relatively simple structures can be identified using chemical shifts, coupling patterns, and intensities obtained from one-dimensional (1-D) $^{1}H$ and $^{13}C$ spectra. For more complex structures, spectroscopists may have to obtain two-dimensional (2-D) spectra from experiments that have been developed to determine homo- or heteronuclear connectivities.

Two-dimensional spectra are characterized by two frequency axes. The intensity, which is mathematically another dimension, is not considered to be a dimension in 2-D NMR because it is not an axis that spreads out the chemical shift. All modern 2-D experiments consist of at least two pulses separated by a time period, labeled $t_1$, the evolution period, and a period of time used for collecting the signals, labeled $t_2$, the detection period. A COrrelation SpectroscopY (COSY) sequence is the simplest of all and is shown in *Figure 4*.

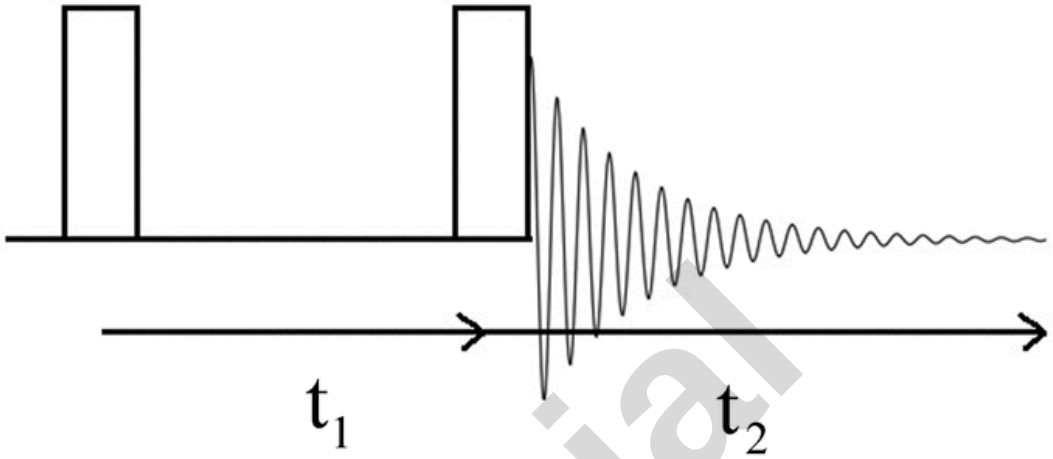

Figure 4. Pulse sequence for a COSY experiment.

A series of such sequences is performed using an incremental increase in the evolution period. Fourier transforms of the FIDs produced during each of the $t_2$ detection periods are stacked, a second Fourier transform is performed along this $t_1$ new axis, resulting in a plot of amplitude along two frequency axes, $F_2$ and $F_1$.

The next simplest addition to the COSY sequence is another pulse. The Nuclear Overhauser Effect SpectroscopY (NOESY) sequence is an example and is shown in *Figure 5*.

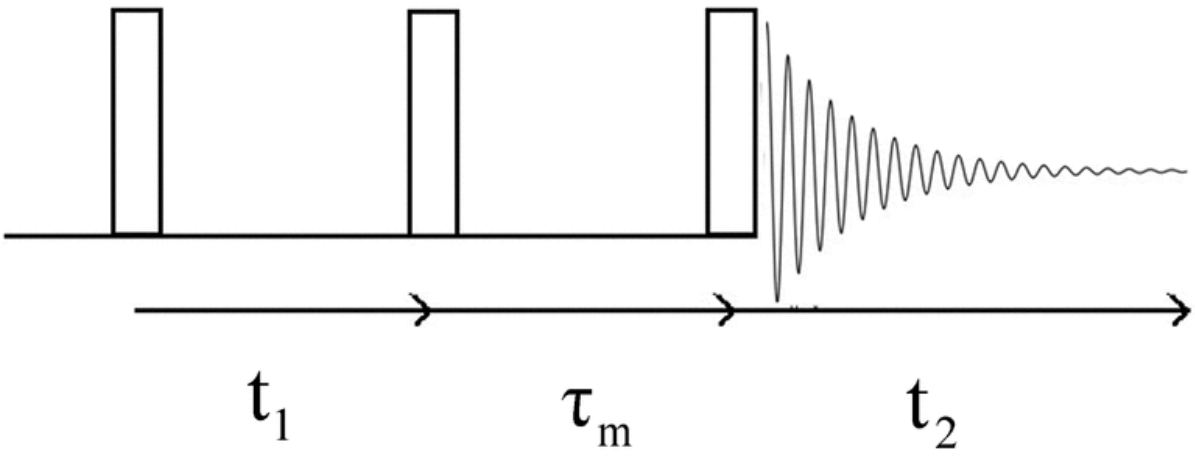

Figure 5. Pulse sequence for a NOESY experiment.

Official

https://pharmacopeia.cn/v-download/

The evolution period is again the time between the first two pulses and is incremented as in the COSY experiment. The time between the second and third pulses is fixed and is not incremented. This period of time is labeled $\tau_m$ and is called the mixing time. Cross-polarization occurs during this period.

The COSY and NOESY sequences described above are the two simplest 2-D experiments to perform. Many other experiments have been developed and contain a very complicated series of pulses with different pulse widths, time delays, gated decoupling, and pulsed field gradients. Some of these experiments are described below.

## Strategies for Establishment of Homonuclear Connectivities

Assigning signals based on chemical shifts, spin multiplicity, and coupling constants serves as a starting point for structural elucidation. Structure elucidation is simplified if one can establish molecular connectivity between homonuclear spins. This can be done using correlations via bonds (scalar coupling, sometimes referred to as *J* coupling) or via spatial (dipolar coupling) interactions. This section describes NMR techniques that can be used for the study of homonuclear connectivity. Popular experiments in this category are COSY, total correlated spectroscopy (TOCSY), NOESY, and rotating frame Overhauser effect spectroscopy (ROESY).

### COSY

COSY has become a routine 2-D $^1$H NMR experiment that can quickly provide the proton–proton connectivity for spin systems connected by two or three chemical bonds. In a COSY spectrum, the contour plot typically shows diagonal and off-diagonal cross-peaks. The diagonal peaks correspond to the places in 2-D space where chemical shifts of the same nucleus in the 1-D $^1$H NMR spectrum intersect. The off-diagonal cross-peaks occur in 2-D space where the chemical shift of one nucleus intersects the chemical shift of a different nucleus to which it is coupled. The COSY spectrum enables the identification of scalar-coupled spins that are in geminal or vicinal positions. Generally, one starts the assignment process by selecting a resonance in the COSY spectrum that has already been identified in the 1-D $^1$H NMR spectrum. Then, the off-diagonal peaks between this resonance and any others determine the resonances of the neighboring protons to which it is coupled. The neighboring protons identified in this way then serve as the next points to examine for cross-peaks to other protons, and so forth. The process continues until all coupled spin systems are identified.

Thus, a COSY experiment can provide useful information about proton–proton connectivity for various fragments of the molecules under examination. The relationship between these fragments may be difficult to establish because of an interruption of the coupling between the two fragments. For instance, if two segments are connected through quaternary carbons or heteronuclei, the very small four-bond coupling between two protons on the two separate fragments usually cannot be detected by COSY. Basic COSY experiments are usually processed using magnitude mode, which results in broad bases to the peaks. The diagonal peaks may be so broad that spin systems with close chemical shifts may not be observable because the broadness of the diagonal peaks will cause them to overlap the off-diagonal peaks. An example of a COSY experiment, specifically a gradient, or gCOSY, is shown in *Figure 6*.

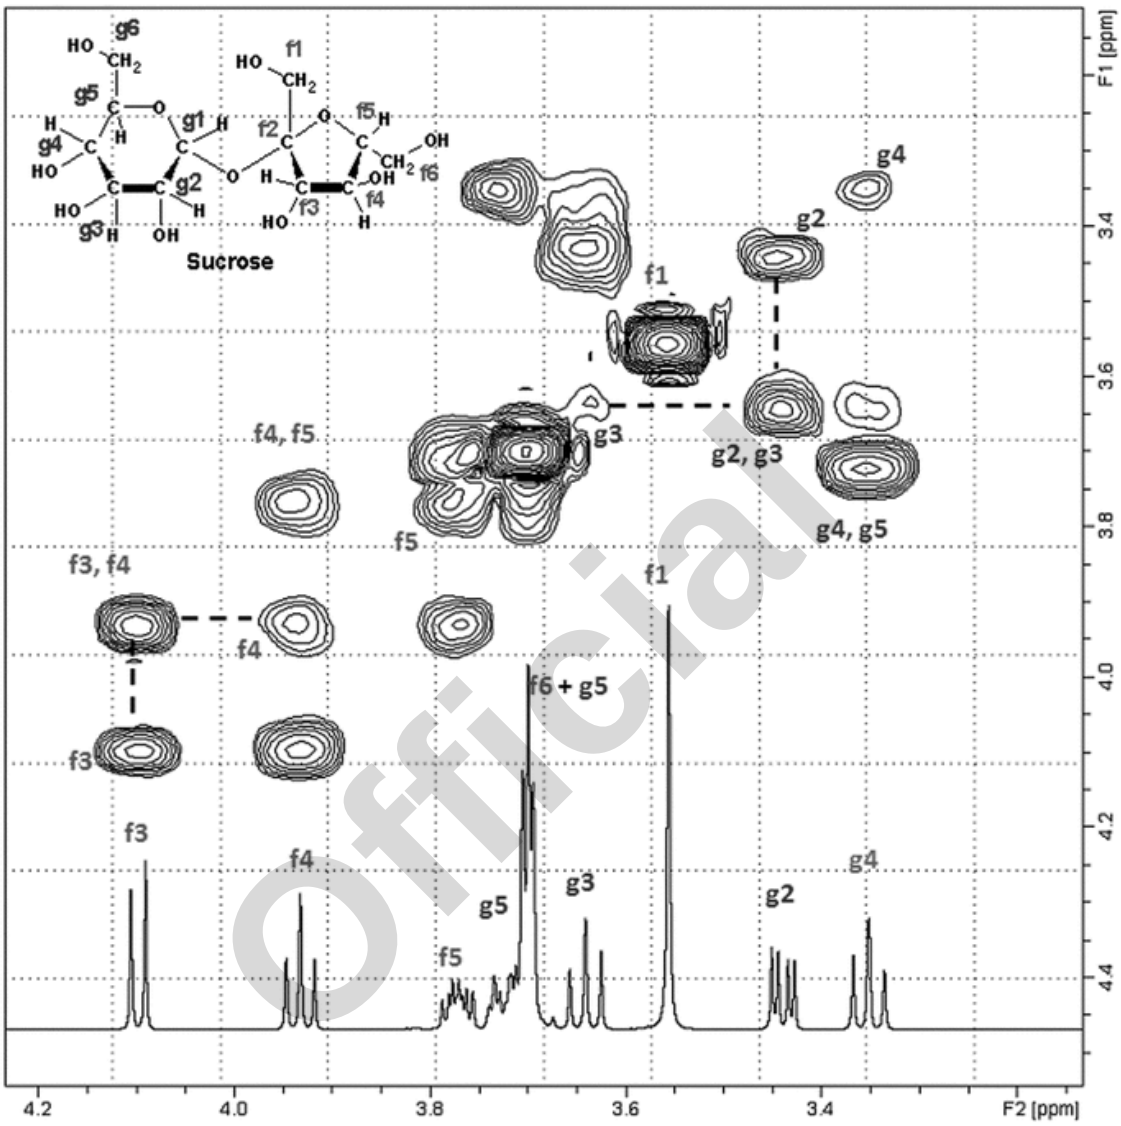

Figure 6. Partial COSY spectrum of sucrose. Dotted lines show how two off-diagonal (f3, f4 and g2, g3) contours are used to determine which nuclei are coupled to each other.

A variety of COSY experiments have been devised to improve upon the original experiment. Perhaps the most important change has been to use gradients to acquire a gCOSY spectrum. The classic COSY experiment uses a 90° pulse to generate transverse magnetization and relies on elaborate phase cycling to cancel unwanted signals over many scans, resulting in long experiment times. In a gCOSY experiment, which requires a probe capable of a pulsed field gradient (PFG), a magnetic field gradient pulse dephases any coherent magnetization in the *xy* plane. If a second gradient pulse of the proper strength is applied in the opposite direction, it will cause any dephased double-quantum magnetization to refocus. Hence, only those signals will be received. The strengths of the gradients can be used to select single-, double- or triple-quantum coherences.

The gradient pulses in a gCOSY experiment can be used to prevent the refocusing of magnetizations that cause the artifacts in the classic COSY experiment. Hence, instead of requiring a minimum of eight phase-cycled acquisitions for each data increment in the second dimension, a gCOSY spectrum requires only a single acquisition per increment. For samples that are sufficiently concentrated to produce an acceptable S/N in only one acquisition, this greatly shortens the experimental time.

Phase-sensitive COSY experiments have been developed to overcome the problem of overlap with closely spaced chemical shifts. A phase-sensitive COSY results in pure absorptive peaks with narrower peaks than are generated by the classic-magnitude COSY. These narrower peaks allow better resolution of resonances that are close to diagonal peaks.

Double-quantum filtered COSY (DQF-COSY) was developed to overcome the problem caused by intense signals from functional groups such as methyls. The singlets from these groups do not provide useful connectivity information, but their intensity often limits the dynamic range of the experiment, making it difficult to observe other weaker signals. The pulse sequences of DQF-COSY detect the spin systems that have only double-quantum transitions. Isolated singlets are not selected

and thus are filtered out of the final 2-D spectrum. In addition, a reduction in the overall intensity of the diagonal signals is achieved with an increase in the intensities of off-diagonal signals.

## TOCSY (OR HOHAHA—HOMONUCLEAR HARTMANN HAHN)

The $^{1}H$–$^{1}H$ TOCSY experiment is closely related to COSY but differs because it yields correlations for every spin in a coupled network. This is especially useful when multiplets overlap or there is extensive strong coupling. For example, consider the network –CHa–CHb–CHc–CHd–CHe–, where each CHn stands for a spin that is coupled through three bonds to the adjacent spin. A COSY spectrum would show correlations for each adjacent pair of hydrogens. On the one hand, the Hb resonance would show connectivities to Ha and Hc but not to Hd. A partial correlation is revealed for each CHn. On the other hand, a TOCSY spectrum would show all off-diagonal contours for every spin in this network. That is, for every peak in this coupling network there would be off-diagonal contours corresponding to CHa, CHb, CHc, CHd, and CHe. Thus, a TOSCY spectrum, such as the one shown in *Figure 7*, affirmatively identifies all of the spins within the same coupling network. This pattern is easily recognized, especially when there is extensive overlap with other coupled networks. However, a TOSCY experiment cannot establish connectivity between separate networks that are interrupted by heteronuclear atoms, quaternary carbons, or a carbon bearing only exchangeable protons. A TOCSY experiment is useful for the study of large molecules with many separated coupling networks such as peptides, proteins, oligosaccharides, and polysaccharides.

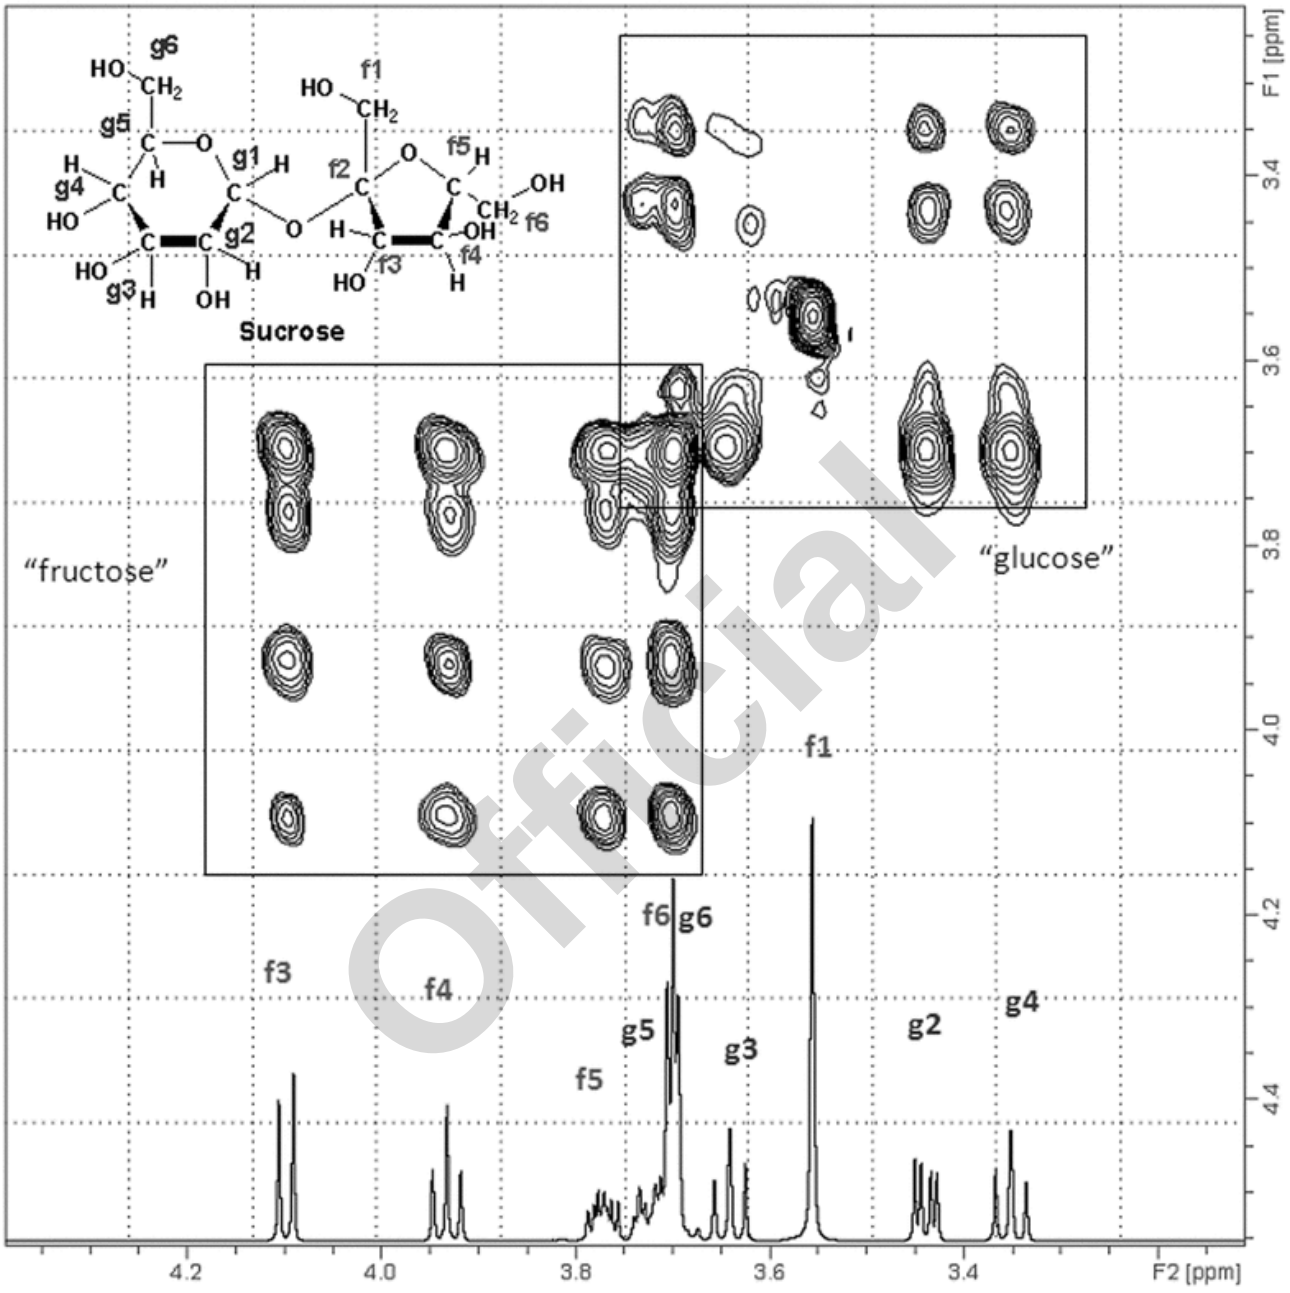

Figure 7. Partial TOCSY spectrum of sucrose showing two sets of contours corresponding to all the coupled nuclei in the glucose and fructose rings in sucrose. The contour for the f1 resonance falls within the glucose spin system and has no coupling.

## NOESY

The NOESY experiment gives correlations between protons that are close to each other in space even though they may not be connected by bonds. These through-space correlations are made via spin-lattice relaxation. Dipole interactions between protons close in space generate NOE transfers, and the magnetization is aligned along the $z$ axis ($B_0$), producing positive or negative intensity changes that yield cross-peaks that are not normally observable in a COSY spectrum. The sign of the NOESY peaks depends on the size and mobility of the molecule under study. Used in combination with other techniques, a NOESY experiment can establish spatial relations for particular spins and can provide critical information about ring structures and conformations.

### $^{1}H–^{1}H$ ROESY

The ROESY experiment is similar to a NOESY experiment insofar as it also provides correlations between protons that are close to each other in space, whether or not they are connected via bonds. A ROESY spectrum yields through-space correlations via spin-spin relaxation in the rotating frame. The ROESY experiment utilizes a spin–lock sequence as a mixing time during which NOE transfer occurs among all components of the spins locked in the *xy* plane. In contrast to a NOESY experiment, in which NOE transfer occurs while magnetizations are aligned along the *z* axis ($B_0$) producing positive or negative intensity changes, the ROESY experiment depends on NOE transfers occurring in the rotating frame under the influence of a $B_1$ magnetic field. This always results in positive signals no matter how large the molecule or whether its motion is fast or slow. Therefore, a ROESY experiment frequently will provide through-space correlations when the same correlations in a NOESY experiment cannot be detected because of molecule mobility.

### INCREDIBLE NATURAL ABUNDANCE DOUBLE QUANTUM TRANSFER EXPERIMENT

The Incredible Natural Abundance Double Quantum Transfer Experiment (INADEQUATE) uses a double quantum coherence to provide information about $^{13}C$ nuclei directly coupled to other $^{13}C$ nuclei. Thus it provides the same sort of information that is available using a COSY experiment for proton couplings. Because of the low probability of two $^{13}C$ nuclei being attached to each other (only 1 in 10,000 molecules), this technique is usually one of last resort. The ever-increasing sensitivity of cryogenically cooled probes used in modern instrumentation makes this experiment practical in some cases.

## Strategies for Establishment of Heteronuclear Connectivities

Although homonuclear $^{1}H–^{1}H$ connectivity is one important aspect of structure elucidation of organic molecules, the establishment of heteronuclear connectivities is equally important, although somewhat more difficult to obtain given the lower abundance of most heteroatoms. If one has partial assignments in either the $^{1}H$ or $^{13}C$ spectrum, the knowledge of this connectivity leads to a much fuller assignment of both spectra. Heteronuclear 2-D spectra do not exhibit a diagonal as is seen in homonuclear correlations. Rather, cross-peaks occur at the point of intersection of the $^{1}H$ and $^{13}C$ chemical shifts in the 2-D space as shown in *Figure 8*.

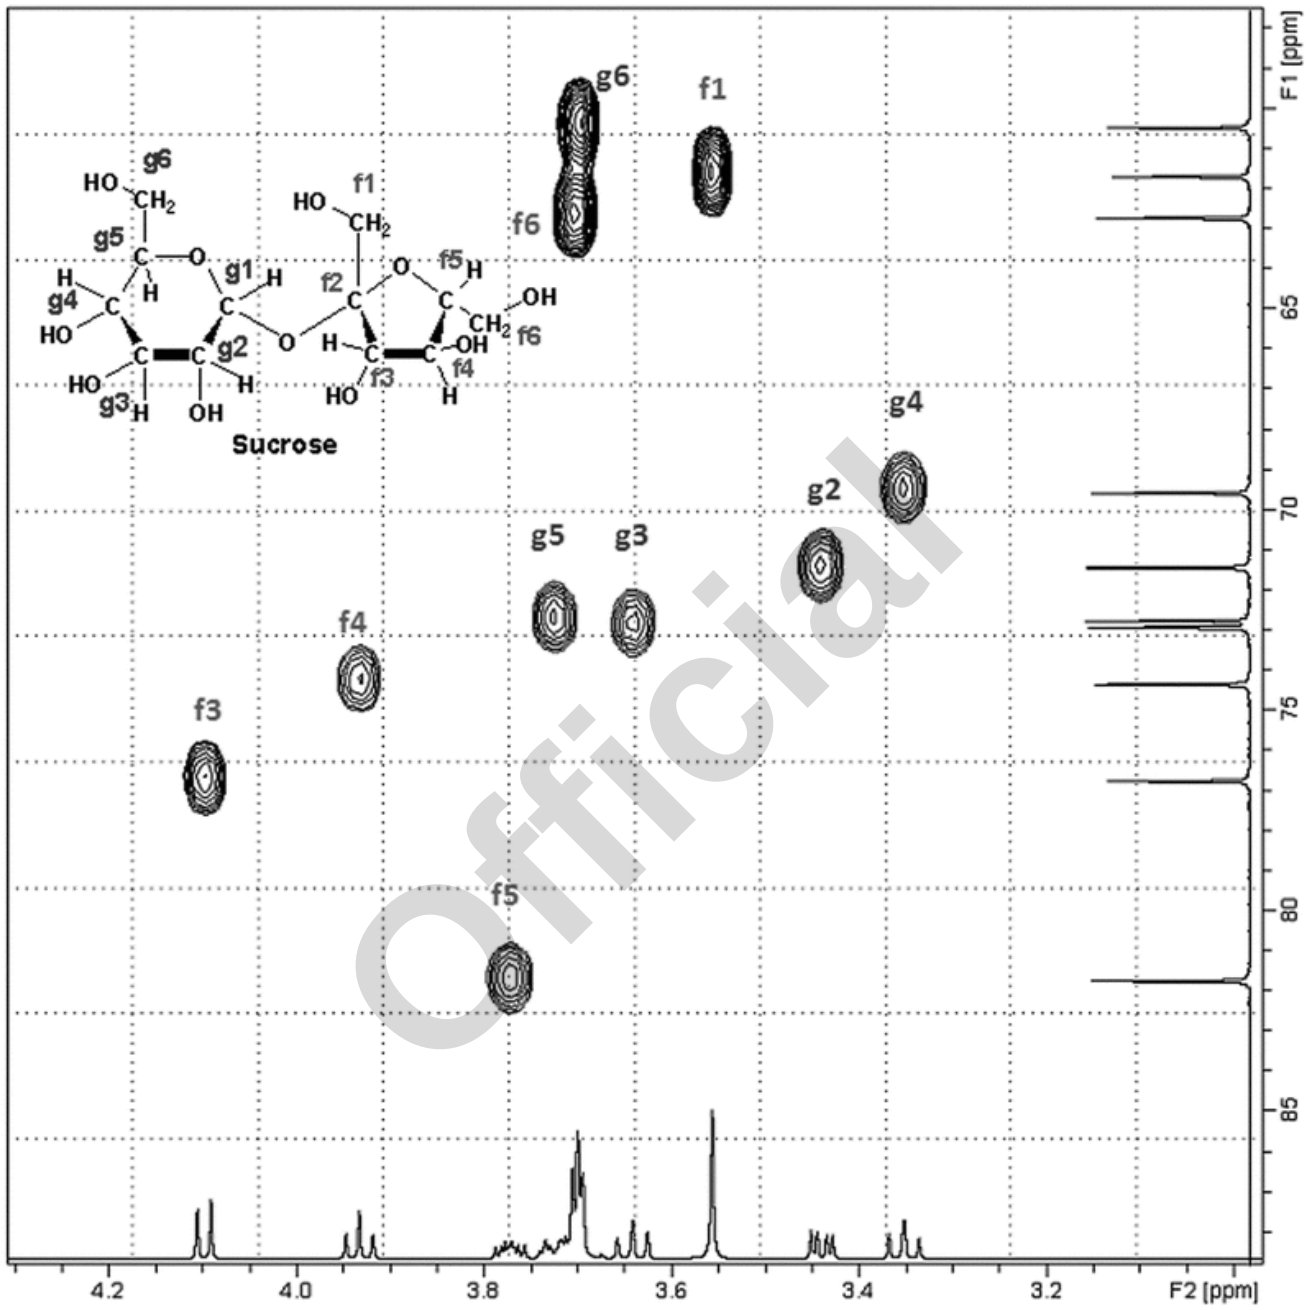

Figure 8. Partial $^{1}H/^{13}C$ HSQC spectrum of sucrose showing contours that indicate the one-bond correlation between a given hydrogen and the carbon to which it is attached.

Heteronuclear 2-D spectra are designed so that $^{1}H$ is the detected nucleus and are usually acquired using inverse- detection probes because the $^{1}H$ coil is wound closer to the sample than the broadband coil. This results in a better filling factor and a greater sensitivity for the $^{1}H$ coil. It should be noted that a newer configuration of coils has been developed that provides the same sensitivity but does not utilize the inverse-detection coil arrangement. Typical heteronuclear 2-D experiments include Heteronuclear Single Quantum Coherence (HSQC), Heteronuclear Multiple Quantum Coherence (HMQC), and Heteronuclear Multiple Bond Correlation (HMBC) experiments.

HMQC

The 2-D HMQC experiment provides information about correlation between protons and their attached heteronuclei via the heteronuclear scalar coupling. The sequence selects double quantum coherence transfer between scalar-coupled spins ($^{13}C–^{1}H$).

HSQC

HSQC spectroscopy is also an inverse chemical shift correlation experiment that yields the same information as HMQC, i.e., the identification of directly bonded hydrogen–carbon interactions. The correlation between heteronuclei is detected via the selection of single quantum coherence transfer using the insensitive nuclear enhancement by polarization transfer (INEPT) sequences. The main advantage of using this sequence instead of the HMQC sequence is that the $F_1$ domain does not contain any proton–proton couplings. Hence, the resolution is improved.

An interesting modification of this sequence is an edited HSQC experiment. This is a phase-sensitive experiment that not only gives one-bond correlations between hydrogen and carbon but also gives methyl and methine correlation peaks that are 180° out of phase with methylene resonances.

HMBC

HMBC spectroscopy is a modified version of HSQC and is suitable for determining long-range (> 1-bond) $^{1}H$–$^{13}C$ connectivity. Long-range heteronuclear correlation spectroscopy can yield signals for those nuclei that are separated by 2–4 bonds. This experiment, in conjunction with the other 2-D experiments discussed above, allows one to define the structure of a molecule in great detail.

## QUANTITATIVE APPLICATIONS

NMR is one of the most useful techniques for quantitative analysis in chemistry. If appropriate experimental conditions are chosen, the relative intensities of resonances are proportional to the population of the nuclei causing those resonances. NMR experiments can be designed for relative or absolute quantitation, either with an internal standard or without one.

### Experimental Design for Quantitative NMR

Design for quantitation involves the elimination or precise measurement of differences in intensities due to spin-lattice relaxation and NOE. The spin-lattice relaxation time ($T_1$) for all resonances used in the procedure can be measured with an inversion recovery pulse sequence. If a 90° pulse is used for excitation, quantitation at the level of 99.3% may be achieved with a recycle time, $T_r$ (the sum of the relaxation delay and aquisition time), of $5 \times T_1$, and improved to even higher levels by using longer recycle times or shorter pulses. The general equation for the degree of quantitation, $Q$, of a resonance as a function of the pulse angle, $\alpha$, and $T_r$, and $T_1$ is given by:

$$Q = \frac{1 - e^{-Tr/T1}}{1 - [e^{-Tr/T1} \cdot \cos(\alpha)]} \qquad [22]$$

If a 45° excitation pulse is used, with a $T_r = 5T_1$, $Q = 0.998$. However, the accuracy of quantitation in the final spectrum depends not only on the $Q$ values of the resonances but also on the accuracy of the integration method and on the S/N ratio in the spectrum. Hence, $Q$ values somewhat less than unity may be warranted and other angles and recycle times should be used.

The minimization of systematic quantitation bias should be sufficient for the intended use of the procedure. Alternatively, quantitative procedures may be developed using conditions for which $Q$ is not unity for some or all resonances, provided the value of $Q$ is precisely known and corrected for.

For quantitative methods using heteronuclei, the possibility of differential NOEs should be avoided by using a $T_r$ at least 5 times the longest $T_1$ value and by using inverse gated decoupling (decoupler gated on only during the acquisition time). Preferably, 90° pulses should be used. For quantitative methods, relaxation agents are often used for shortening the $T_1$ values of heteronuclei.

The reproducibility of an NMR method depends on a variety of acquisition and processing parameters, all of which should be described in the procedure. These include pulse angle, acquisition time, relaxation delay, spectral width, number of points in the FID, number of acquisitions, number of points used (if any) for zero filling, line broadening, baseline correction, integral breaks, and temperature. For best reproducibility, integral breaks should be specified to 0.01 ppm for $^{1}H$ NMR methods and to 0.1 ppm for $^{13}C$ methods.

Quantitative analysis, as well as detection of trace impurities, has markedly improved with modern instrumentation. Stronger magnetic fields and improved probe technology have enhanced the sensitivity of NMR procedures in recent years.

## SOLID-STATE NMR

The analytical usefulness of solid-state NMR spectroscopy for studying solid materials lies in the fact that the same types of nuclei in different *solid-state* environments exhibit different resonance frequencies. Applications of this technique in pharmaceutical analysis range from solid form (polymorph, solvate) identification and quantitation in bulk drug substances to physical/chemical profiling of dosage forms. The technique has the unique ability to probe electronic environments of specific nuclei in the solid state over a large timescale without the requirement of single-crystal substrates or even homogeneous

Official

https://nhathuoclocal.com/

samples. Methods and procedures presented herein are directed at observing $^{13}C$, the most popular NMR nucleus for solids. The concepts may be equally applied to other relevant spin-1/2 nuclei such as low-natural-abundance $^{15}N$ as well as high-natural-abundance $^{31}P$.

## Cross-Polarization Magic Angle Spinning (CPMAS) NMR Technique

The basic principles of NMR are the same for solution and solid-state measurements, but conventional solution-phase 1-D NMR data acquisition techniques do not normally produce detectable spectra for solid samples because of low sensitivity and extensive line broadening. The sensitivity of the solid-state experiment is low for $^{13}C$ based on its 1.1% natural abundance and long spin-lattice ($T_1$) relaxation times. Line broadening arises primarily from dipole–dipole interactions and chemical shift anisotropy (CSA), which are not averaged to zero because of the fixed orientation of molecules in a packed solid sample vs the rapid molecular tumbling of the molecules when they are in solution. If not averaged, CSA results in the simultaneous observation of all different orientations of molecules with respect to the applied magnetic field. CSA patterns may span the width of an entire liquid spectrum. Three modifications to standard solution methods—cross-polarization (CP), magic angle spinning (MAS), and high-power $^{1}H$ decoupling—are routinely used in combination to obtain high-resolution solid-state NMR spectra.

### CROSS-POLARIZATION (CP)

CP addresses the low sensitivity associated with collecting NMR spectra of dilute spin-1/2 nuclei such as $^{13}C$. CP is a double-resonance procedure wherein abundant $^{1}H$ and rare $^{13}C$ spins are brought into resonance by simultaneously applying two spin–locking rf fields ($B_{1H}$ and $B_{1C}$), the magnitude of which will satisfy the Hartmann–Hahn matching condition,

$$\gamma_H B_{1H} = \gamma_C B_{1C} \text{ [23]}$$

During this contact time, polarization transfer occurs allowing the rare $^{13}C$ spins to take on the magnetization and relaxation behavior of the abundant $^{1}H$ spins, leading to a sensitivity enhancement (up to four-fold based on the ratio of the $^{1}H$ and $^{13}C$ magnetogyric ratios) and a reduction in the pulse repetition time. Reducing the pulse repetition time allows a greater number of aquisitions to be accumulated per unit time, which yields a better S/N ratio. In instances where it may be difficult or impossible to record CP spectra because of weak $^{13}C$–$^{1}H$ coupling or short spin-lattice relaxation times in the rotating frame ($T_{1\rho H}$), direct polarization (Bloch decay) may be the only approach to recording solid-state NMR spectra.

### MAGIC ANGLE SPINNING (MAS)

Line broadening in solid-state NMR is eliminated or averaged by both MAS and high-power $^{1}H$ decoupling. MAS involves mechanically rotating the sample at an angle of 54.7° (the magic angle) relative to the static magnetic field in order to simulate rapid molecular tumbling in solution. Rotating a solid sample at the magic angle to minimize line broadening requires that the sample be spun faster (in Hz) than the width of the CSA. High spinning rates are possible with current MAS probe technology, but complications can arise with CP and may require techniques such as ramped-amplitude CP (RAMP-CP) and variable-amplitude CP (VACP) to improve the efficiency of magnetization transfer from $^{1}H$. Additionally, MAS can raise the sample temperature significantly if it is not controlled, and pressures at the periphery of the rotor may be thousands of times the ambient pressure. These stresses may induce phase transformations, loss of solvent, and other effects.

#### SIDEBAND SUPPRESSION

As shown in *Figure 9*, slower spinning rates can be used to avoid compromising the solid sample, but when CSA is incompletely averaged, spinning sidebands will appear in solid-state NMR spectra. These artifacts are separated from the centerbands by integer multiples of the spinning rate (in Hz) and can be readily identified as the peaks that shift in spectra acquired at different spinning speeds. Spinning sideband manifolds contain useful information but can interfere with the signals of interest and may be particularly problematic when one uses higher field instruments. The total suppression of spinning sidebands (TOSS) procedure is commonly used to eliminate spinning sidebands from solid-state NMR spectra.

## HIGH-POWER $^{1}H$ DECOUPLING

High-power $^{1}H$ decoupling is used to further reduce the line broadening from dipolar coupling to $^{1}H$ spins in the solid state. Specialized hardware is required to deliver the rf power needed for $^{1}H$ decoupling in solids, an rf power that is two orders of magnitude greater than that required to remove scalar coupling in liquids. CW decoupling is commonly used in solid-state NMR, although two-pulse phase-modulated and small phase incremental alteration (SPINAL-64) decoupling are increasingly used to improve the sensitivity and resolution of dilute spin spectra.

Typically only $^{1}H$–$^{13}C$ heteronuclear dipolar interactions are significant when one acquires solid-state $^{13}C$ NMR spectra of organic materials. Homonuclear $^{13}C$–$^{13}C$ dipole–dipole and scalar coupling interactions are negligible. Because of their low natural abundance, the probability that two $^{13}C$ nuclei are in close proximity is very small. However, homonuclear $^{13}C$–$^{13}C$ dipolar coupling can be a concern for $^{13}C$-labeled substrates.

## EXPERIMENTAL SETUP

The basic setup for a CPMAS experiment will necessarily include magic angle setting, shimming, pulse calibration, Hartmann–Hahn matching, and spectral referencing, each of which is typically conducted on standard samples. Accurate measurement of the pulse lengths and associated rf power levels is essential for solid-state NMR experiments. Setting up the magic angle, shimming a CPMAS probe, and measuring its sensitivity for different tuning ranges are parts of probe setup and performance assessment. Shimming a solid-state NMR probe for MAS is more complicated than that for a solution probe because shim gradients are designed for the vertical orientation of solution NMR tubes. Solid-state NMR probes have no $^{2}H$ lock channel, so shimming must be performed manually. Because of the intrinsically broad peaks, shimming is not nearly as critical in solid-state NMR as it is in solution NMR.

Standard compounds used for setting the magic angle and optimizing pulse lengths and the associated rf power levels for CP are listed in *Table 6*. KBr is commonly used for magic angle adjustments, observing the $^{79}Br$ resonance and adjusting the sample spinning angle to maximize (to 10 ms and beyond) the duration of the rotational echo train in the FID. Liquid samples can be used to shim solid-state NMR probes, although solid adamantane is commonly used for this purpose. Adamantane,

glycine, and hexamethylbenzene (HMB) are commonly used for Hartmann–Hahn matching and testing sensitivity. Typically, the reference sample for testing sensitivity is permanently packed into a rotor to ensure that the same amount of sample is used.

**Table 6. Standard Samples Commonly Used for Setting Up CPMAS Experiments**

| Setup Procedure | Nucleus | Standard Sample(s) |
|---|---|---|
| Setting the magic angle | $^{79}$Br | KBr |
| Shimming | $^{13}$C | adamantane |
| Pulse calibration | $^{1}$H, $^{13}$C | adamantane, HMB |
| Hartmann-Hahn matching | $^{1}$H/$^{13}$C | adamantane, HMB |
| Sensitivity | $^{13}$C | HMB, adamantane, α-glycine |

Solid-state NMR spectrometers are generally used without field/frequency locking, so the resulting chemical shifts are less accurate than those for solutions. Calibration of the chemical shift can be done using either a primary or secondary standard. Spectral referencing is typically performed by sample replacement (external referencing). Standard compounds commonly used for spectral referencing in solid-state NMR are listed in *Table 7*. Note that glycine is polymorphic, so its crystal form should be ensured before its use in referencing spectra.

**Table 7. Reference Compounds Commonly Used for Solid-State NMR**

| Nucleus | Primary Standard | Secondary Standard(s) | Chemical Shift in ppm from Primary Standard |
|---|---|---|---|
| $^{13}$C | TMS | HMB<br>adamantane<br>α-glycine | 17.35 ($CH_3$)<br>38.48 ($CH_2$)<br>176.45 (carboxyl) |
| $^{15}$N | nitromethane | $NH_4{}^{15}NO_3$<br>$^{15}NH_4Cl$<br>α-glycine-$^{15}$N | –5.1 ($NO_3$)<br>–338.1<br>–349.5 |
| $^{31}$P | 85% $H_3PO_4$ | $CaHPO_4 \cdot 2H_2O$ (brushite) | 1.4 |
| $^{29}$Si | TMS | tetratrimethylsilylmethane | –1.4 |
| $^{19}$F | $CF_3Cl$ | perfluorobenzene | –166.4 |

Official

## General Test Procedure

Spectrometer performance should be demonstrated first for a reference sample as described in *Cross-Polarization Magic Angle Spinning (CPMAS) NMR Technique, Experimental Setup*. The magic angle, pulse lengths, and associated rf power levels for CP that are established using the reference compounds are sample independent. To obtain a CP spectrum of the sample, only the recycle delay needs to be chosen, followed by the contact time. When quantitative signal intensities are not required, an optimum recycle delay, i.e., one that affords the best S/N ratio, is $1.2T_{1H}$, and the contact time is generally that which provides the optimum S/N ratio or that which best shows the features of most interest. For quantitative CP, a recycle delay of at least five times the longest $T_{1H}$ of a heterogeneous mixture is suggested to ensure full relaxation, and a full analysis of the CP signal as a function of contact time must be conducted. See the subsection *Quantitative Analysis.*

### SAMPLE PREPARATION

Sample-handling procedures used in solid-state NMR are substantially different from those used in liquid NMR. Solid samples are packed in ceramic rotors that are capped with fluted drive tips specifically designed for MAS. Fine powders are typically tamped into MAS rotors, although solid plugs, e.g., whole tablets, can be cut to fit the exact inner dimensions of the rotor and can be inserted directly into the rotor. Crushing or grinding may be used to reduce the sample to a fine powder, but caution should be used in order not to induce phase transformations. Depending on the compressibility of the powder and the rotor volume, 40–400 mg of material is typically required to fill a sample rotor.

## Physical Characterization

Specific components in heterogeneous systems can be searched based on unique nuclei or different NMR relaxation properties. The identification of crystalline and amorphous materials can be accomplished by comparison of the solid-state NMR spectrum of the sample preparation with that of a reference standard. Chemical shifts and relative peak intensities can be used in the comparison. Amorphous materials generally give good MAS spectra with broader peaks than those seen for crystalline materials. Highly crystalline samples typically give $^{13}$C linewidths of the order of a few tens of Hz. The shape of the signals generally is between Lorentzian and Gaussian, a fact that should be recognized in deconvoluting overlapped spectra.

## Relaxation

Relaxation parameters of interest in solids include spin-lattice relaxation ($T_1$), spin-lattice relaxation in the rotating frame ($T_{1\rho}$), spin-spin relaxation ($T_2$), and cross-relaxation ($T_{CP}$). In organic solids, $^1$H spin diffusion is generally efficient so that pure compounds normally give single values for each of the relaxation times, $T_1$ and $T_{1\rho}$. For CP experiments, $T_{1H}$ is used to establish the recycle delay between acquisitions. $T_{1H}$ relaxation times can be measured using either progressive saturation or inversion recovery pulse sequences. In CP experiments, $T_{CP}$ and $T_{1\rho H}$ characterize the magnetization build-up and decay, respectively. $T_{1\rho H}$ is measured via the $^{13}$C signal using a delayed contact CP pulse sequence that has a variable delay time before the CP contact.

## Quantitative Analysis

To quantitatively assess solid-state NMR spectra under CP conditions, extra measures must be taken. In addition to ensuring that the sample spinning axis is precisely set to the magic angle (54.7°) to minimize CSA broadening, the temperature and spin rate must be carefully controlled and the MAS probe properly tuned. Suggested recycle delays of $5T_{1H}$ are allotted between successive pulses to ensure that the magnetization has returned to its full equilibrium value. Both $T_{CP}$ and $T_{1\rho H}$ relaxation must then be accounted for in the selection of the contact time. Typically, the CP contact time chosen is that which provides maximum sensitivity for the signals of interest. Quantitative analysis can be performed using either internal or external referencing methods. The use of internal standards can compensate for variability in sample volume and $B_1$ inhomogeneity throughout the sample.

By properly setting data acquisition parameters (recycle time, pulse widths, contact time, Hartmann–Hahn match, and decoupling power for each chemical system), signals can be obtained that are proportional to the number of nuclei producing them. For quantitative analysis, integrated signal intensities should be used rather than peak heights because linewidths in solid-state spectra often vary. When spinning sidebands are not eliminated by MAS, the intensity of the spinning sideband manifold must be added to the centerband intensity.

## Spectral Editing

A key step in the analysis of any NMR spectrum is the assignment of individual resonances to unique phases and, in some cases, to specific atoms in the molecule. Special pulse sequences are available and may assist in simplifying CPMAS spectra and assigning signals. Dipolar dephasing, also known as nonquaternary suppression or interrupted decoupling, yields spectra that typically contain signals only from quaternary and methyl carbons. Spectral subtraction of dipolar dephasing spectra from normal CP spectra or short contact time CP may be used to produce subspectra that contain signals from methylene and methine carbons only. Polarization-inversion techniques can be used to identify methylene and methine carbons.

# LOW-FIELD NMR

Low field NMR (LF-NMR), sometimes referred to as time domain NMR (TD-NMR), experiments are performed by measuring relaxation, relaxometry, or diffusion. Instrumentation for these applications is based on low-field permanent magnet technologies that operate in the 2–25 MHz frequency range. Inexpensive stationary bench-top and portable TD-NMR spectrometers are commercially available. Typical bore sizes are 10–50 mm in diameter. A recent development in spectrometer design uses a mobile mouse probe as an alternative to a stationary magnet. This design allows analysis of samples of unrestricted size.

Most TD-NMR applications are based on simple pulsing sequences, including FID, Hahn–echo, Carr–Purcell– Meiboom–Gill, and solid–echo acquisition. The choice of pulse sequence depends on the physical and chemical properties of the sample as well as the information that is desired from the experiment. These systems can be used to measure longitudinal (spin-lattice, $T_1$) and transverse (spin-spin, $T_2$) relaxation times. Diffusion properties of compounds can be exploited using pulsed field gradient (PFG-NMR) experiments.

The classical application of relaxometry is for the determination of food product components based on differences in longitudinal and transverse relaxation times of water, fats, and proteins.

## Relaxivity

The magnitude of a substance's capacity to enhance the relaxation rate of a nucleus is referred to as relaxivity, expressed in units of $sec^{-1}mM^{-1}$. An example of such a substance commonly used in NMR spectroscopy is paramagnetic chromium acetylacetonate. Paramagnetic species are used in the medical industry as contrasting agents for magnetic resonance imaging. The relaxivity of a substance is determined experimentally by measuring the spin-lattice relaxation time ($T_1$) of a test substance and plotting $1/T_1$ against the concentration in units of mM (mmol/L). The slope of the curve is the numerical relaxivity.

# ⟨1771⟩ OPHTHALMIC PRODUCTS—PERFORMANCE TESTS

## INTRODUCTION

This chapter provides information on performance tests to assess drug release from finished ophthalmic products. These tests are applicable to products that have an extended-release mechanism (beyond 1 day); the dissolution/drug release rate is rate limiting for absorption and is expected to provide a controlled therapeutic response. Examples of such products include intraocular matrix-type and polymer-based bioerodible implants, non-bioerodible intraocular matrix and reservoir implants, intraocular injectable suspensions/colloidal systems, intraocular in situ–forming depots and gels, punctal plug-based delivery systems, non-biodegradable drug release devices (e.g., drug-coated stents, drug-coated contact lenses), biodegradable and non-degradable ocular inserts/bioadhesives (for cul-de-sac or conjunctival-sac applications), and other such dosage forms. For products having a localized and immediate response when applied to the eye (e.g., topically applied dosage forms, including dispersed systems, having very short residence time for absorption), a dissolution/drug release test may have no practical value.

Application of a dissolution/drug release test to assess performance as a surrogate for in vivo testing should be considered only with appropriately validated in vivo–in vitro correlations (see *In Vitro and In Vivo Evaluation of Dosage Forms* ⟨1088⟩). Dissolution/drug release tests are used as a quality control tool for specific product attributes (e.g., burst release from matrix-type, biodegradable, polymeric systems). These tests may have the ability to distinguish between different lots of a drug product having one or more formulation and/or process changes.

Changes may be related to the drug substance(s) or excipients present in the formulation, physical and/or chemical attributes of the finished formulation, critical manufacturing variables, shipping and storage effects, aging effects, or other formulation and/or process factors critical to the performance of the ophthalmic product. Such changes may affect the performance characteristics of the dosage form when applied to the eye. Consideration should be given to whether processing or components are intended to provide for prolonged exposure to any part of the eye and whether a dissolution/drug release test could be used to demonstrate this effect.

## PERFORMANCE TESTS (DISSOLUTION/DRUG RELEASE)

Depending on the design and release mechanism of the dosage form, the dissolution/drug release test can be developed using any apparatus described in *Dissolution* ⟨711⟩ or *Drug Release* ⟨724⟩. Novel dosage forms may require the use of noncompendial equipment and/or conditions. Any dissolution/drug release test should be discriminative for the intended critical quality attributes of the product and should be properly validated (see *The Dissolution Procedure: Development and Validation* ⟨1092⟩). The test conditions should reasonably mimic the method of administration of the product and in vivo conditions to establish, if possible, an in vivo–in vitro correlation that can be used to predict in vivo performance of the product.

## 1. INTRODUCTION AND SCOPE

Image analysis is the qualitative or quantitative characterization of two- or three-dimensional digital images. In its simplest form, image analysis is the manual measurement of an image using a scaled ruler. This is a time-intensive way to generate data associated with an image, and it is not in the scope of this chapter (see *Optical Microscopy* ⟨776⟩). Image analysis is primarily a size and shape analysis and yields data that are complementary to many other techniques such as laser diffraction and sieve analysis.

Digital image processing and analysis started in the late 1970s, and technology and automation have advanced to enable more routine use of image analysis. Therefore, its applications and use in the pharmaceutical industry are expanding rapidly. Currently, the use of automated image analysis has been expanded to be a valuable research and quality-control tool. For example, where monitoring of particle-size-related parameters was predominant historically, image analysis is increasingly being adopted to complement size with numerous shape measurements and images that offer additional insight into the materials in question.

The purpose of this chapter is to provide general considerations regarding the use of images for particle and material characterization (size and shape analysis, identity, etc.) as well as a standardized approach for the use of the technique in pharmaceutical applications. The chapter also describes the principles of the science that supports the measurement tool.

### 1.1 Image

An image is an array of pixels where the pixel position represents the spatial arrangement of the imaged objects within the field of view. Pixel values represent a measured property such as intensity (gray scale), color (intensities for multiple colors), and spectra (absorbance versus wavelength). This chapter concentrates on two-dimensional images, however, it should be noted that the third dimension may also be employed in tomographic methods [nanotomography, atomic force microscopy (AFM), microtomography, etc.] and 3D shape characterization, for example.

Image resolution is important and is defined by the number of pixels per unit area. More pixels improve shape definition and detection of smaller features. This is illustrated in *Figure 1*, where we can see better resolution for sizing accuracy and shape discrimination. However, system resolution is also impacted by other optical components such as optics and lighting.

https://pharmacopeia.cn/v29240/

Official

Figure 1. An example of pixel arrays with increasing resolution.

Images may be obtained in several ways:

- Macroscopic imaging (e.g., photography)
- Microscopy [optical microscopy, scanning electron microscopy (SEM), confocal scanning microscopy (CSM), transmission electron microscopy (TEM), and AFM]
- Electromagnetic reflection, illumination, and detection [terahertz, infrared, visible, ultraviolet, X-ray, micro-computed tomography (micro-CT), neutron]

Images may also be generated in different environmental conditions (e.g., different temperatures) or during processing, enabling the analysis of transformations.

## 1.2 Image Analysis

Image analysis is the derivation of information from the numerical processing of the pixel array. Images are processed using algorithms to differentiate the component parts (often particles) from the background. The data are then analyzed to provide quantitative information such as:

- Size (dimensions, separations, etc.)
- Shape (curvature, aspect ratio, etc.)
- Surface texture and/or roughness
- Number density of features with particular characteristics
- Chemical nature (*Mid-Infrared Spectroscopy—Theory and Practice* ⟨1854⟩, *Near-Infrared Spectroscopy—Theory and Practice* ⟨1856⟩, and *Raman Spectroscopy—Theory and Practice* ⟨1858⟩)
- Classification of different types of features within a sample; this could be done to quantify components of the same species with different morphological profiles (in its simplest form, those that are larger/smaller) or it could be to differentiate between components of the image

Image analysis is employed in many fields with applications as diverse as astronomy, medicine/biology, meteorology, satellite imaging, facial recognition, geology, agriculture, materials science, pharmaceuticals, and other industrial applications. The content of this chapter is limited to pharmaceutically relevant applications of image analysis, including the following:

- Characterization of particle size, shape, and texture
- Mixture composition and uniformity

- Orthogonal technique complementary to other physical analyses
- Bulk materials characteristics and processability
- Foreign particulate matter detection, quantification, and/or identification in the visible and subvisible ranges

Within pharmaceutical, medical, and biological applications there are other examples not covered in this chapter, including the following:

- Defect detection and identification (e.g., vials, tablets, packaging, printing) using machine vision systems
- Fill level detection and verification
- Biological tissue characterization such as microscopic and macroscopic imaging in pathology and radiology [e.g., X-ray, CT, magnetic resonance imaging (MRI)]
- Clinical applications such as pathology and diagnostics

## 2. APPLICATIONS OF IMAGE ANALYSIS OF PARTICLES

### 2.1 Characterization of Raw Materials in Development

Image analysis is a useful tool in characterization of the active pharmaceutical ingredients (APIs) throughout the development process. One of the advantages at the early development stage is that a multiparameter, full description of particles is possible from a small quantity of material (e.g., milligrams). At the early stages, physical characteristics may vary between different lots of raw materials. Aspects of particle morphology can be monitored and optimized for drug delivery, formulation, and processing. This also enables the optimization of the API synthesis process. Examples include assessing particle roughness for respiratory formulations, particle size and shape distribution for solid dosage formulations, and particle morphology for suspension formulations. Use of early phase image analysis can support formulation and process development in the later phases.

In the later stages of development, a broader understanding of the particle morphology of the API and its impact on the formulation process can be obtained by image analysis than by the more traditional techniques (e.g., laser diffraction, optical and scanning microscopy, and specific surface area). Image analysis may also be a key technique in characterization of excipients, intermediates, and the formulated drug product. For example, image analysis may show that a well-defined range of size distribution of raw materials is needed to avoid segregation during powder-blending steps or that the granule size distribution can be optimized for compression.

### 2.2 Image Analysis through Life Cycle/Late Stage Manufacturing

Image analysis is also employed throughout the product life cycle in such areas as the investigation of process changes and quality by design (QbD). This enables predictive trending for raw material changes (API and excipients) and tracking of crystallization/crystal growth, thereby allowing the definition of in-process specifications.

Quality control is another area where image analysis can serve as a useful tool. Raw materials can be tested for size as well as for aspects of shape, such as smoothness, which impact both flowability and mixing (*1*). Ensuring consistency in overall size and shape as well as identifying an overpopulation of fine particles or larger agglomerates is an advantage of image analysis over size-only methods. In API manufacturing, image analysis systems also allow for number-based assessment of crystal growth and concentration as well as crystal milling to ensure proper size and shape of API material.

Raw materials and finished product may also be assessed for the presence and quantity of intrinsic or foreign particles.

### 2.3 Assessing the Contribution of Particle Size and Shape to Bulk Powder Properties Such as Flow and Behavior

Particle morphology may have a significant impact on a powder's suitability for different pharmaceutical applications (*2*). Even relatively minor variations in these physical properties can affect interparticulate forces, which in turn influence powder flow, packing, and in-process/application behavior. Image analysis enables quantification of particle size and shape properties of the bulk powder. In addition, as it is fundamentally a number-based technique (see *4.2.3 Data Reporting*), it provides insight into the presence of low quantities of particles with a specific morphology compared to the bulk, such as the presence of fine particles, information that may not be obvious when measuring by volume-based techniques alone.

Clear relationships have been observed between particle size, shape, and flow properties under a range of different process conditions (*3*) such as:

- The presence of fine particles may cause sticking
- Particle shape may determine the extent of particle interlocking, entrained air, and bed permeability
- Fine particles and/or irregular particle shape can lead to bridging and blockages
- Morphology may influence particle–particle friction, determining the ease with which particles shear against each other whether as APIs, excipients, or blends
- Particle shape may influence particle interactions with equipment surfaces and other media

Process operations where particle parameters are important for considering powder behavior include:

- Flow out of hoppers and intermediate bulk containers (IBCs) and flow into tablet dies (*4*)
- Use of dry powder inhalers (DPIs), as particles entrained in an air flow during conveying or dispersion will experience different drag forces and therefore different terminal velocities

@2024 USPC

- Variation in aerodynamic behavior contributes to the complex interactions between the carrier and drug particles within an assembly during aerosolization and affects impact energies during collisions, which are recognized as important factors contributing to DPI efficacy (*5*)

## 2.4 Particle Quantitation and Identification of "Foreign Particulate Matter"

It is possible to generate information on the quantity, size, and shape of particles including contaminants. Contaminants may be identified through a combination of size, shape, opacity, and/or color differentiation or identified from the particle images themselves. In some cases, staining the sample may help identify and separate contaminants. If a suitable combination technology is used, such as electron microscopy coupled with energy dispersive X-ray (EDX) or optical microscopy coupled with Raman spectroscopy, the chemical composition of contaminants can also be determined.

The maximum number of particles that are permissible in a specific mass or volume of sample is addressed in *Particulate Matter in Injections* ⟨788⟩, *Visible Particulates in Injections* ⟨790⟩, *Methods for the Determination of Subvisible Particulate Matter* ⟨1788⟩, and *Visual Inspection of Injections* ⟨1790⟩.

## 2.5 Assessing Crystal Growth, Milling, and Dissolution

Crystallization is a key step in almost every process in the manufacturing of pharmaceutical compounds. Crystallization is often used as a purification step. Image analysis of crystal growth can be used to detect the starting point (when nucleation begins) and then used to record event data. As the crystallization process advances, image analysis systems can capture in real time the size, shape, and concentration data as well as thumbnail images that serve as objective evidence of the process. This is all captured in a series of sequential analyses and compared over time. These data can then be used to study the rate of crystallization and how the crystal shapes form over time under different conditions. In some cases, instrumentation can be used to notify the end user when select shape and size conditions are met. The different shapes can help identify how these crystals can impact bioavailability, solubility, and dissolution rates.

The images in *Figure 2* were taken from a crystallization process where sequential analyses were taken. Each analysis captures the size, shape, concentration, and thumbnails of the crystal particles. As the subsequent runs are taken, the crystal particles are growing in size, changing in shape, and increasing in concentration. Thumbnail images are used as objective evidence to backup the large amount of particle data saved for each analysis.

Figure 2. Monitoring crystal growth using image analysis. The measuring abilities of image analysis make it possible to capture quantitative information. The stored images themselves enable qualitative review of the samples. Monitoring the dissolution of the particles exhibits the opposite trend. Note that different magnifications were used in these images; measurement values are in micrometers.

## 2.6 Studying Particle Properties as a Function of Environmental Conditions

Another example of using image analysis as a tool to study particles while environmental conditions are applied is dissolution testing. This method is the reverse of the process described above. Image analysis can be used to sample small aliquots of the representative sample from a starting point to an end point. Because image analysis can classify particles based on shape, it is possible to monitor the size and concentration of multiple components being released by therapeutics over time, with images captured to serve as objective evidence.

Time-lapse image analysis can be used to monitor particle size and shape as a result of being subjected to changes in process parameters and environmental conditions (e.g., heat, humidity, physical stress, and time), typically achieved by using an environmentally controlled chamber. An image analysis system can capture images of the samples as the conditions are adjusted, or it can record images at set intervals. The added value that image analysis provides over size-only systems for monitoring particle properties over time is the ability to classify particles based on shape, to quantify particles per unit volume (concentration of the particles of interest), and to provide objective evidence of the particles as they change over time with thumbnail images. Analysis intervals can be established using the starting point of interest and the point at which the ending condition occurs based on the environmental condition applied. Particle data results can then be compared in a sequence over time to study how the environmental conditions to which the particles were subjected caused physical changes in shape and concentration.

Another example is hot-stage microscopy (HSM), which can be utilized to analyze particle properties as a function of temperature. This microscopy technique monitors both particle size and shape as materials are heated on a "hot stage" from which the technique gets its name (*6*). In pharmaceutical applications, this technique is typically used to investigate API crystal

https://pharmacopeia.cn/v-download/

growth and polymorphism. A lack of understanding and control over the different polymorphs formed by an API can lead to significant changes in particle morphology, influencing tableting performance and dissolution rates.

## 2.7 In-Process Monitoring of Particle Properties

In-process monitoring of particle properties can have many advantages over the more conventional off-line analyses. For example, process downtime can be minimized as it is not necessary for aliquots to be removed from process equipment for off-line analysis and results. In addition, materials are measured under their processing conditions, and the data is likely to be representative of a greater proportion of processed material.

The increased use of in-process techniques for particle imaging is consistent with guidance from the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use (ICH) and the US Food and Drug Administration (FDA) for better process understanding and monitoring (*7*).

## 2.8 Evaluating the Chemical Composition of Materials

Image analysis combined with spectral information may provide chemical insight into materials. The area of chemical imaging is growing with an ever-expanding range of combination techniques, and instrumentation. Such techniques may use vibrational, fluorescence, physical, or other responses to probe the chemical composition of a species. These techniques include: SEM with EDX, optical image analysis with Fourier-transform infrared (FTIR) or Raman microscopy (*8*), confocal fluorescence microscopy, atomic force microscopy, nanotomography, and MRI. With X-ray microcomputed tomography (XMT) (*9*), it may even be possible to image the packed product, for example within a blister or a tube.

These techniques may be applied to particles, granules, and certain formulated products, which are DPIs (*10*), oral solid drug products, nasal sprays (*11*), and semisolid formulations, to gain insights into the chemical distribution of materials within a sample (*12*). These techniques may also be useful for understanding the chemical changes in a formulation over time, and in investigations of possible contamination.

# 3. THEORY AND INSTRUMENTATION

The following discussion is limited to optical systems as these cover the majority of applications.

## 3.1 Basics of Image Acquisition

Image acquisition systems consist of several instruments: an illumination source, a sample presentation unit, an optical system that magnifies the sample, an image capture device, and data processing software to perform the image analysis that provides the particle data.

Image analysis systems typically come in two broad types, static and dynamic, which differ on the basis of sample presentation method (*Figure 3*). With static systems, the particles (dispersed as dry powder or as wet suspension, or captured on a filter) remain static on a presentation cell within an automated stage that moves under the optics. With dynamic systems, particles dispersed as a suspension (either dry in air or wet in a liquid medium) travel through a flow cell and images are taken as the particles are in motion.

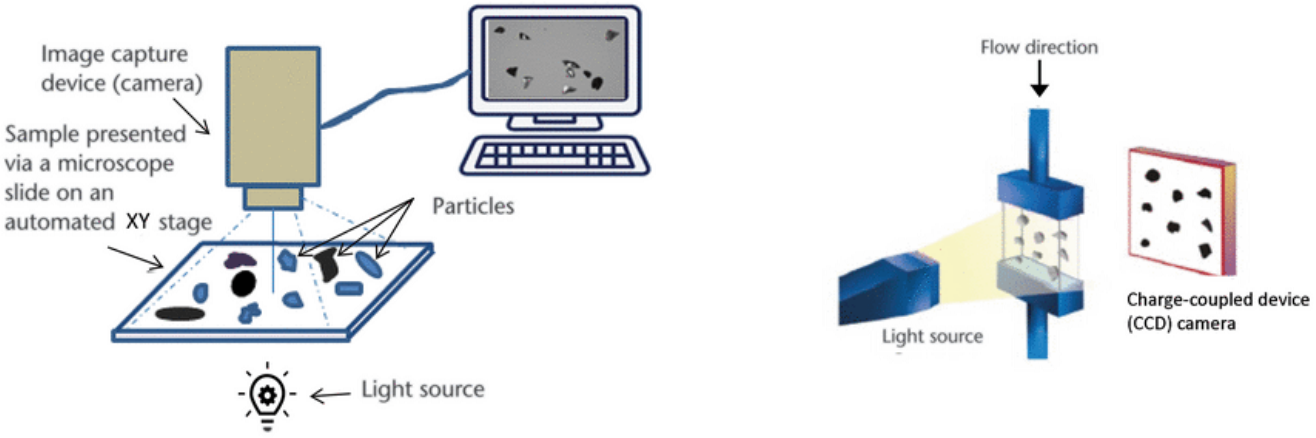

Figure 3. Example diagram of static and dynamic image analyses.

### 3.1.1 ILLUMINATION

Illumination techniques are either stroboscopic or fixed, and the goal is to obtain a clear image with as much edge definition as possible to enable suitable detection and measurement. Depending on the system configuration, illumination options may

include diascopic (transmitted) or episcopic (reflected) and brightfield or darkfield (*Figure 4*). In addition to proper illumination, optical filters and polarizers may be used to further improve the edge definition of particles being analyzed.

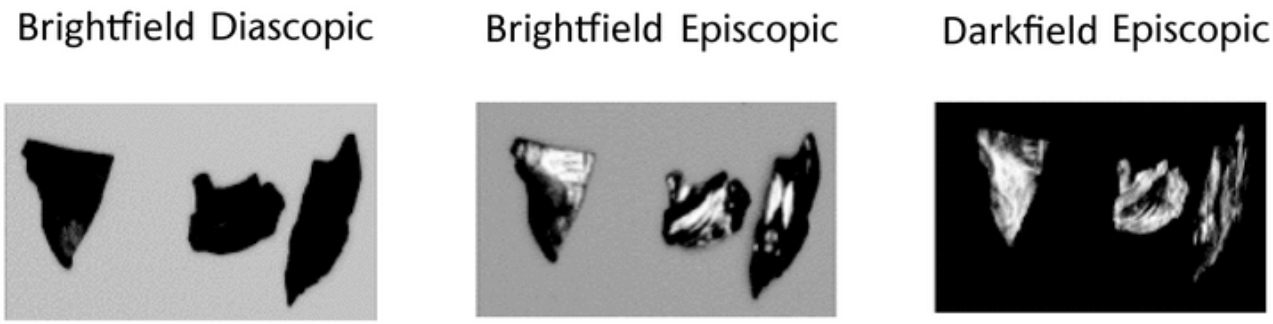

Figure 4. Examples of different types of illumination.

### 3.1.2 SAMPLE PRESENTATION

For successful image analysis, it is critical that the sample presentation be appropriate for the measurement technique. When measuring bulk properties, specific components, or foreign particulate matter, it is important to ensure that the aliquot measured is representative of the bulk material (see *Bulk Powder Sampling Procedures* ⟨1097⟩).

Factors that affect results include the sample volume or concentration and the conditions used to disperse the sample. Adequate particle separation is required without particle breakage. Particles should be appropriately dispersed to ensure that there are clear boundaries between distinct particles and agglomerates, thereby avoiding coincidence or unwanted agglomeration/flocculation, as these could be misrepresented as larger particles. Equally important, particle damage can result if dispersion aids such as pressure or ultrasound are used, which would also misrepresent the sample results. For wet or dry dispersions, it is important to optimize the appropriate dispersion methods and conditions.

Specific applications discussed above may have different sample preparation considerations.

Dynamic image analysis systems may include wet and/or dry dispersion units. Wet dispersion is usually achieved by controlled stirring, and the use of ultrasound may also be an option. Dry dispersion is usually achieved via gravity fall or with the aid of differential air pressure. Many static image analysis systems utilize dry powder dispersion units, which control differential air pressure for dispersing the sample. Wet samples are presented in specific cells or are filtered. The latter is typical for low-concentration foreign particulate matter applications. Some sample types such as topicals and viscous suspensions (e.g., nasal sprays) are prepared using classic microscope techniques with the sample sandwiched between a slide and coverslip.

### 3.1.3 OPTICAL SYSTEM

Once the sample is properly prepared to ensure statistical accuracy, the next step is to magnify the images to fit on the optical field of view. As larger magnifications are used, the field of view becomes smaller (see *Figure 5*).

When zooming into an image, the detection zone becomes smaller (see *Figure 5*, far below). It is important to take this into consideration to ensure that proper sampling is performed. Use of excessive magnification may underrepresent larger particles because it becomes less likely that they will appear fully in the field of view. Statistically, this would skew the results toward the smaller sample population. Conversely, as magnification is decreased to see the larger particles properly, smaller particles may fall outside the detection ability of the instrument configuration, skewing the results toward the larger size particles. Due to inherent limitations for a given magnification, a compromise between these two factors may be needed, with consideration of the purpose of the application.

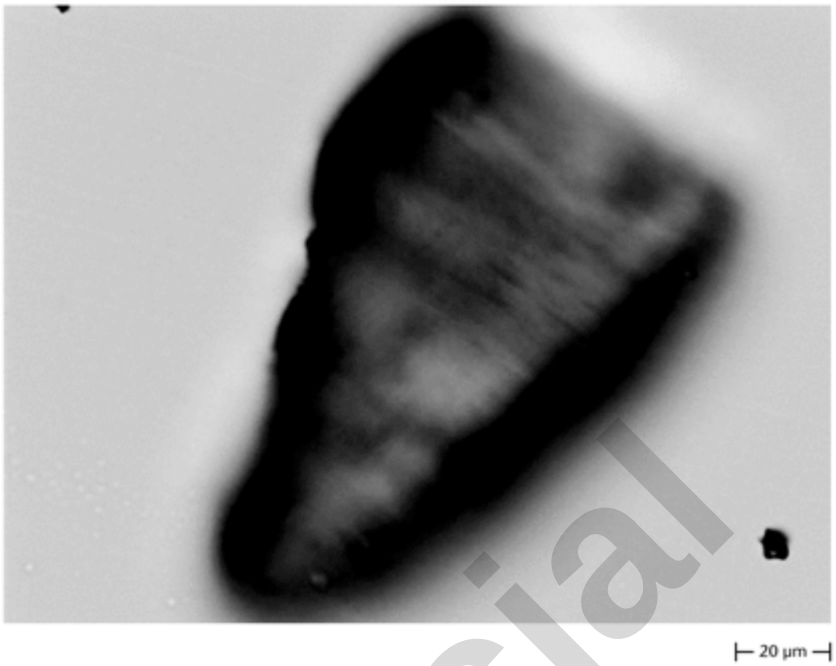

Figure 5. Images of the same particles taken at 2.5×, 10×, and 50×. As the magnification is increased the field of view is reduced and the resolution is increased. The third image shows that the depth of field of the magnification is not sufficient for the object. This could be overcome using *z*-stacking algorithms, but this would also increase the measurement time. For an image analysis measurement, a compromise may be needed; for this example the 10× magnification may be optimal.

*Figure 6* shows the field of view and depth of field of flow cell in a dynamic image analysis system.

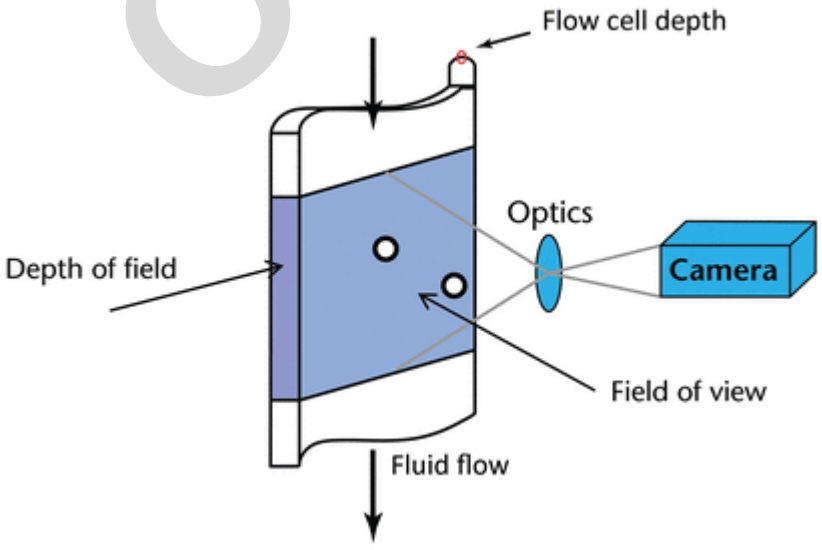

Figure 6. A diagram (shaded area) of the field of view and depth of field of an image.

Depth of field (DoF) will also be a factor; it is the distance between the nearest and farthest objects (particles) that are in an acceptably sharp focus within an image (see *Figure 7*). DoF is generally controlled by the optical components of the imaging system, which includes the aperture or f-stop. Generally, as the aperture is smaller, the DoF is larger. The degree to which a user has DoF control will depend on the instrumentation; many manufacturers provide the largest DoF possible in order to minimize out-of-focus particles for analysis.

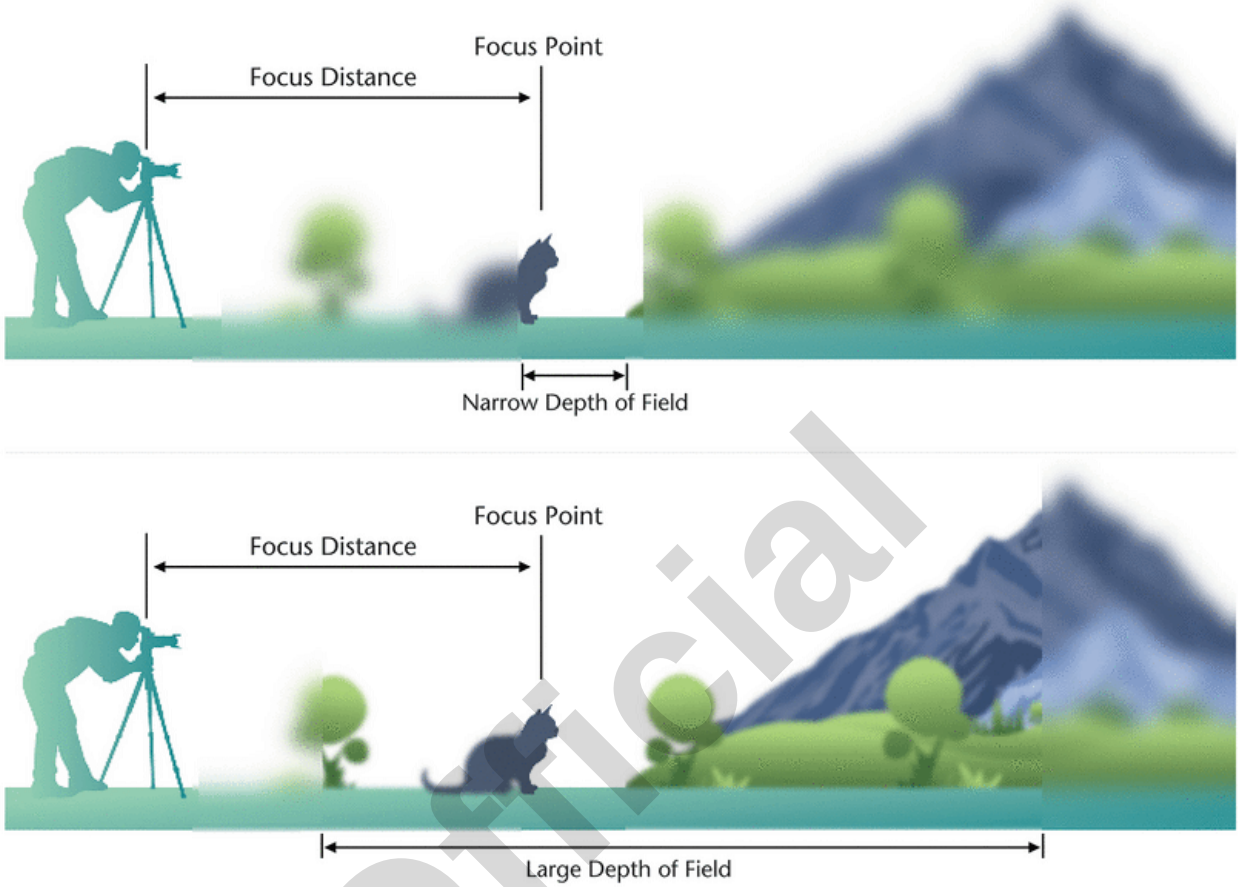

Figure 7. Images captured at different depths of field.

## 4. DATA PROCESSING, INTERPRETATION, AND REPORTING

### 4.1 Data Processing

Software processing is the next step after image capture. Once images have been captured and are available for processing on a computer, image analysis systems perform a series of functions to identify particles on every image.

Operations may be applied to the gray level images to enhance further processing, for example adjustments to brightness and contrast.

For the scope of this chapter, the majority of applications being considered involve measurements of individual particles, often a large number of them, within a given image. It is necessary to identify and define the boundaries of the individual particles. This is often done by defining a threshold gray level value and defining the desired objects as above or below that level (light, dark, color, or other appropriate value). However alternative edge detection and combined algorithms are used by some systems.

Once the desired objects have been identified, further processing is necessary for accurate measurements (e.g., separation of closely spaced or touching objects). The required criterion for an analyzable discrete object will be a minimum number of associated pixels, which will depend on the application (see *Figure 1*).

The gray-scale images are converted to a binary format for the purposes of size and shape calculations. The size and the number of pixels are used to accurately characterize images and calculate the particle size and shape parameters. Some systems report the binarized particle images, whereas others retain the gray-scale images, which may provide additional information about the samples, such as texture. This is important if qualitative information about the objects is required.

### 4.2 Data Interpretation and Reporting

#### 4.2.1 SIZE PARAMETERS

Image analysis calculates a variety of particle size parameters derived from the size of the pixels, which relates to the magnification used and the number of pixels per unit area. Size parameters that are typically reported are described in *Table 1*.

Official

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M13956_02_01
@2024 USPC

There are a number of aspects used to describe the dimensions of a particle, such as various diameters or chords. Common measures include the Feret and Martin diameters or the dimensions of bounding circles, rectangles, or other polygons. Depending on the measure used, the definition of descriptors such as length or width may differ. One must be aware of the definitions used by specific instrument systems and software.

**Table 1. Most Common Size Parameters Used in Image Analysis**

| | | |
|---|---|---|
| **Area** | The area (1) is the visual projected area of the particle and is usually reported in both pixels and microns. | |
| **Circular equivalent diameter (CED)** | CED is the diameter of a circle with the same 2D image (area) as the particle. It can be calculated from either the area of the particle or the perimeter of the particle. [NOTE—CED is a very important parameter as it is often used to compare with other particle sizing techniques. Most other particle-size-only techniques perform indirect measurements. As a result, these size-only techniques report particle size under the assumption that particles are spherical in nature.] |  |
| **Length** | Length can be described in a number of ways. Lines from all points on the perimeter are projected onto the major axis (1) of the particle as shown. The longest distance between the points where two of these projections meet the axis is the length (2) of the particle. |  |
| **Width** | Lines from all points on the perimeter are projected onto the minor axis (1) of the particle as shown. The longest distance between the points where two of these projections meet the axis is the width (2) of the particle. |  |
| **Perimeter** | The length of the total distance around the shape under analysis, e.g., length of the green line in the image to the right. |  |

Official

### 4.2.2 SHAPE PARAMETERS

Shape measures are essentially combinations of the basic size measurements. Those typically reported are described in *Table 2*.

**Table 2. Most Common Shape Parameters Used in Image Analysis**

| | | |
|---|---|---|
| **Aspect ratio and elongation** | These parameters are used to describe the overall form of an object.<br>Aspect ratio = width/length<br>Elongation = 1 – (width/length)<br>[NOTE—Although the convention is to define aspect ratio such that the values range from 0–1, the inverse (length/width) is also commonly used.] | |
| **Convexity and solidity** | These parameters are edge roughness of an object.<br>Convexity = convex hull perimeter (in green)/actual perimeter (in blue)<br>Solidity = area (in green)/convex hull area (in blue) | |

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M13956_02_01
@2024 USPC

**Table 2. Most Common Shape Parameters Used in Image Analysis** *(continued)*

| | | |
|---|---|---|
| **Circularity** | Circularity is a measure of how close the object's shape is to a perfect circle. There are two definitions that are often used:<br>1. Circularity is the ratio of the circumference of a circle equal to the object's projected area to the perimeter of the object.<br>$$\text{Circularity} = \frac{2 \times \sqrt{\pi \times \text{area}}}{\text{perimeter}}$$<br>$$\text{Circularity} = \frac{\text{circular equivalent perimeter (in blue)}}{\text{perimeter (in green)}}$$<br>2. High-sensitivity (HS) circularity is equivalent to squaring the numerator and denominator of the circularity calculations to obtain a more sensitive measure; it is sometimes called compactness.<br>$$\text{HS Circularity} = \frac{4 \times \pi \times \text{area}}{\text{perimeter}^2}$$ |  |

Some applications may make use of gray level measurements. These could include gray level averages or gray level distributions in the image or specific regions of interest, determination of a gray level profile along a defined line, or other measurements. One common application for gray level processing is the differentiation of particles based on opacity where two particles can be identical in size and shape but one may be darker than the other when viewed as an image (see *Figure 8*).

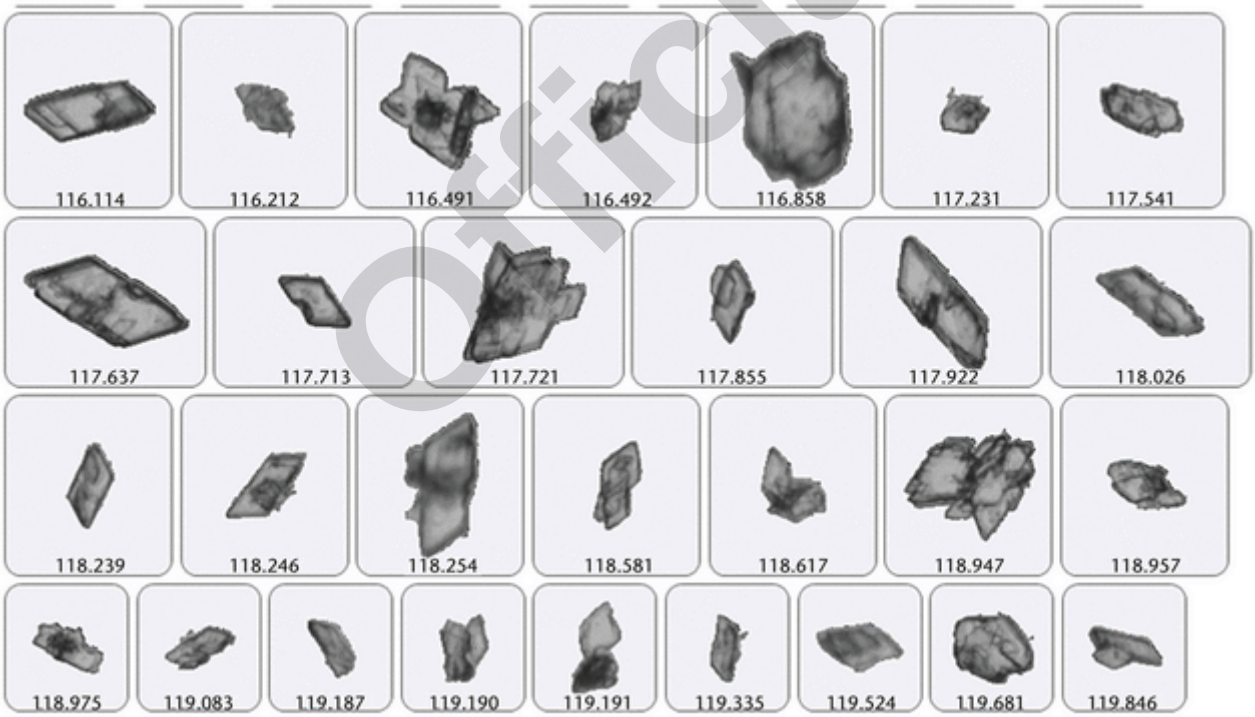

Figure 8. Differentiation of particles based on the opacity.

### 4.2.3 DATA REPORTING

Detailed individual particle data are typically reported along with the particle images providing key qualitative information as well as whole sample distributions and statistics.

For every parameter measured, statistical histograms are created (see *Figure 9*). The full distributions can be compared across samples, which may enable the detection of differences among samples when statistically relevant data are used to differentiate populations of particles from one another.

Imaging is a number-based technique but mathematical conversion to volume results is typically available to compare results with those of other techniques (*13*). However, care must be taken with such comparison because different techniques calculate sizes on the basis of different factors.

DOI: https://doi.org/10.31003/USPNF_M13956_02_01

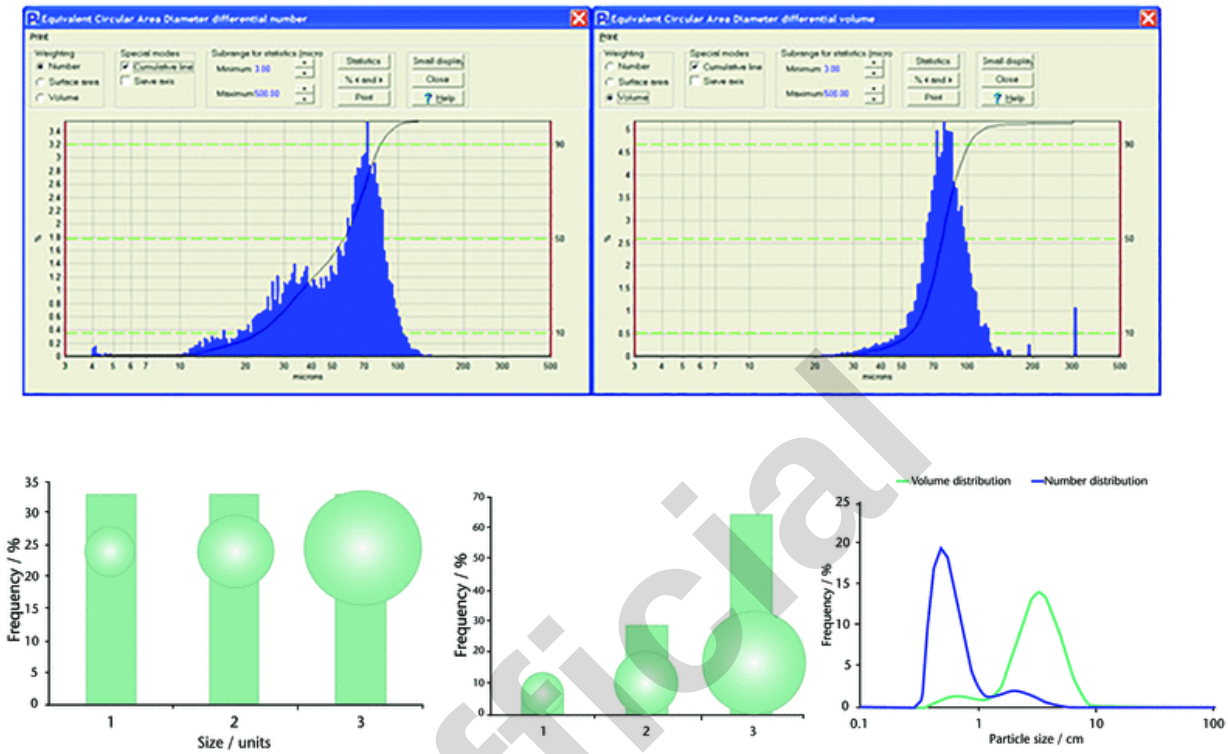

Figure 9. Illustration of number-weighted versus volume-weighted distributions. The first illustration shows a number-weighted distribution for three objects where each object contributes equally. The second illustration shows the volume-weighted distribution for the same three objects. The third illustration shows the number- and volume-weighted distributions for the same sample. This illustrates that the small number of particles that are bigger than 1 μm in size contain most of the volume in the sample. It is important to note that both of these distributions are correct; they are just different ways of representing the same particles.

The two histograms in *Figure 9* may look very different, but they represent the same sample. The histogram on the left is a number-weighted distribution, and the one on the right is a volume-weighted distribution. Because it is a number-based method, image analysis has the ability to identify and quantify fine particles, as is well shown with the number-weighted distribution. This enables end users to identify the presence of fine particles in their sample regardless of the amount. As discussed in this and other *USP* chapters, the presence of fine particles can significantly impact the powder flowability of the sample. This can also be used as a tool to assess the performance of milling processes. Volume-weighted distributions are also very useful for identifying and quantifying large, rare events such as agglomerates, bubbles, or contamination. It is important to keep in mind that with a number-based system, end users are able to view single particle events that appear on histograms as objective evidence.

Many systems also offer the ability to classify particles according to particle size and/or shape combinations, providing further insight into the samples. Systems combined with spectroscopic techniques allow further classification by elemental or chemical nature.

## 5. MEASUREMENT AND EXPERIMENTAL CONSIDERATIONS

### 5.1 Size Calibration

For accurate size measurements, the magnification of the system must be calibrated. A size standard of suitable quality must be used. For optical microscopy-based systems, this is most often a stage micrometer or reticle. The image of the standard should span as large a portion of the image field as possible to maximize the number of pixels used. This method is most suitable for static systems. For dynamic systems, although calibration with a reticle or micrometer may be possible, it is most commonly accomplished using well-characterized standard particles of known size. Once calibrated, a given optical arrangement (e.g., a

DOI: https://doi.org/10.31003/USPNF_M13956_02_01
@2024 USPC

set of lenses) will normally be maintained. However, it is good practice to check the sizing accuracy periodically, or prior to critical measurements. Shape factors are scale independent and should not be affected by the sizing accuracy.

## 5.2 Factors That Affect the Measurement

### 5.2.1 SPATIAL ACCURACY

In most applications, it is presumed that the pixel array accurately represents the geometry of the imaged object. However, there are potential sources of inaccuracy and asymmetry in the image.

Asymmetry may arise from both the optics used to acquire the image and the detector elements. To assess the potential for inherent asymmetry in the experimental arrangement, spatial calibration should be checked at multiple angles, both within a given image and in the arrangement of the dimensional standard.

Another source of geometric inaccuracy within an image is due to the DoF and focus. If objects are not in the same physical focal plane, their relative perceived sizes could be inaccurate due to perspective. Likewise, with a limited DoF, objects at different distances from the collecting optics will differ in focus. The measured size of objects not sharply focused will be dependent on the thresholding values used to discriminate boundaries (see *3.1.3 Optical System*).

### 5.2.2 GRAY LEVEL ACCURACY

For many applications, especially those dealing with the size and shape of individual particles, the accuracy of gray level values is not needed. When extracting quantitative information from gray levels, such as a concentration, it is necessary to consider factors affecting the accuracy of gray level values. Detector response to intensity may not be linear or may be affected by illumination wavelength. Software factors such as adjustments to brightness and contrast or the application of other image enhancement filters, such a gamma distribution, will affect the apparent response. Users should be aware of default software settings for such factors to avoid unintended effects.

# 6. METHOD DEVELOPMENT AND VALIDATION

The major consideration for method development is the purpose of the measurement (i.e., is the primary goal to measure size or shape?). Among the factors to be considered are:

- Sample characteristics (e.g., size range of the particles)
- Level of assurance needed for accuracy and precision
- Sample, equipment, or time limitations

Optimization of the conditions will apply to all phases of the image analysis process:

- Sampling and sample preparation
  - The sample must be representative
  - The sample preparation must disperse the particles as intended
  - There must be adequate numbers of particles in the image (i.e., images of a statistically representative number of particles are captured for analysis)
- Appropriate image acquisition parameters
  - Illumination should be uniform and suitable to aid discrimination of particles from background
  - Magnification must be appropriate for the purpose
    - Fine shape features will often require higher magnification
    - Magnification must balance accuracy of sizing of small particles while avoiding exclusion of larger particles
- Application of appropriate data processing and statistical analysis
- Sample orientation (fixed versus random orientation)

As with all analytical methods, consistency is key to ensuring accurate, representative results. Analysts must be familiar with the equipment and potential sources of error. Detailed method conditions will be equipment specific. For method validation, the normal considerations apply, namely precision, accuracy, and ruggedness.

## 1. INTRODUCTION

Chirality is a ubiquitous aspect of the world of three spatial dimensions. Molecules that possess sufficient structural complexity so that their mirror-image structures are non-superimposable are termed chiral. For chiral pharmaceutical molecules, two important structural measures critical to their physical characterization are absolute configuration (AC) and enantiomeric excess (EE), also termed enantiomeric purity. The AC of a chiral molecule specifies its three-dimensional structure in space and distinguishes it from its mirror-image structure. Structures related by mirror symmetry are known as "enantiomers". The AC of a particular enantiomer is critical to its action as a pharmaceutical agent because mirror-image structures, i.e., enantiomers, have different therapeutic effects, both desired and undesired. The EE of a sample specifies, usually as an excess percentage, the relative amounts of enantiomers. An EE of 100% is a pure enantiomer (100% enantiomeric purity), 0% is a racemic mixture with equal amounts of enantiomers and no excess, and –100% specifies a pure sample of the opposite enantiomer with respect to the EE definition.

The principal chapter that addresses molecular chirality in the *USP–NF* is *Optical Rotation* ⟨781⟩. The optical rotation (OR) of a sample is the measure of the angle of rotation of a plane of polarized light by a chiral sample at a particular wavelength, typically in the visible or near-UV region. The AC and EE of any sample are determined by a measure of its OR if the measurement has been previously calibrated using a sample of known AC and EE. The sign of the OR determines the larger enantiomer amount, and the magnitude of the OR determines the EE, where 100% EE corresponds to the maximum OR possible for the chiral molecule under consideration. Although OR is a simple, well-established method for determining AC and EE relative to their known calibrations, not all molecules have measurable OR, particularly with limited sample quantities in which the presence of chiral impurities cannot be determined by an OR measurement. The OR is simply a number with no structural information about the sample molecule.

In the past several decades, the AC of an unknown chiral molecule has been determined using the Bijvoet method of single-crystal X-ray crystallography. The Bijvoet method requires a single high-purity crystal of the molecule with a single chiral phase. Analysis by this method is not always possible, for example, for noncrystallizable liquids or insoluble solids, and in many cases analysis using the Bijvoet method requires lengthy efforts and time to achieve crystallization.

This chapter presents a technique for the determination of AC that relies on vibrational circular dichroism (VCD), a procedure that is now widely used throughout the pharmaceutical industry for chiral molecules for which the AC is unknown. The technique involves comparing the measured VCD spectrum for a chiral molecule to the quantum chemistry calculation for the same molecule. If the measured and calculated VCD spectra show agreement on the principal features and their signs, this means that the AC of the physical sample is the same as the AC of the structure used in the calculation. If the signs are opposite, the AC of the sample is the opposite of that used in the calculation.

As described below, statistical methods have been developed for assessing the degree of confidence that the AC has been correctly determined by the VCD method. Usually the AC of a chiral molecule is specified by connecting its structural chirality, labeled with *R* or *S* for chiral centers or *P* or *M* for chiral axes, to the sign of its measured OR as (+) or (–). Once the AC of a molecule has been determined by VCD, for example, (S)-(–)-α-pinene, its VCD spectrum can become a reference standard of the AC of this molecule, and the AC of any subsequent sample of this molecule can be determined by comparison to its VCD reference standard. An important advantage of determining AC by VCD is the spectral richness of a VCD spectrum that supports the simultaneous determination of the structural identity of the molecule and its absolute chirality. In contrast to OR, every chiral molecule has a VCD spectrum, because all molecules have infrared (IR) absorption bands, each one of which acts as a chromophore for a VCD spectrum. VCD also is sensitive to molecular conformations. As demonstrated below, information about the conformation of a chiral molecule is obtained as a bonus from the VCD determination of AC, but AC is the principal

informational content of chiral pharmaceutical molecules. An extensive body of literature describing the AC of biological molecules has been created during the past 30 years and can be used as a basis for determining secondary and higher-order structural states of biological drug substances. Stereospecific methods using VCD can be developed to characterize the production, formulation, and stability of biopharmaceutical products.

This chapter also presents a method for the determination of EE using VCD. EE determination with VCD takes advantage of the fact that the magnitude of a VCD spectrum, measured as the circular polarization absorbance difference for a constant parent IR absorbance spectrum, is directly proportional to EE with no offset. Thus, the maximum relative size of a VCD spectrum is obtained for an EE of 100%, is zero for an EE of 0% (racemic mixture), and is maximum with opposite signs (all positive VCD bands are negative and all negative VCD bands are positive) for an EE of –100%. The advantage of VCD EE determination is that the EE of any molecular sample can be determined by a single VCD measurement once the relative size of VCD for 100% EE (or any %EE value) is known for that molecule. Separation of enantiomers with chiral chromatography is not needed.

## 2. DEFINITION OF VIBRATIONAL CIRCULAR DICHROISM

VCD is defined as:

$$\Delta A = A_L - A_R$$

$\Delta A$ = the difference in the IR absorbance
$A_L$ = sample absorbance $A$ for left circularly polarized (LCP) radiation
$A_R$ = sample absorbance $A$ for right circularly polarized (RCP) radiation

Unpolarized IR absorbance intensity is defined as the average of LCP and RCP intensities:

$$A = (A_L + A_R)/2$$

The IR intensities of enantiomers are identical, whereas enantiomers have equal and opposite-signed VCD intensities.

## 3. VCD INSTRUMENTATION

The measurement of a VCD spectrum and its parent mid-IR spectrum is based on Fourier transform-IR (FT-IR) absorption spectroscopy. The optical–electronic layout for the measurement of VCD using an FT-VCD spectrometer is illustrated in *Figure 1*. The output beam of an FT-IR spectrometer is optically filtered and then linearly polarized before passage through a photoelastic modulator (PEM). The zinc selenide (ZnSe) PEM, typically used for VCD measurement, changes the polarization state of the beam between LCP and RCP at a frequency of 37 kHz. A sample solution in a standard IR cell is placed in the beam, and a liquid nitrogen-cooled detector of mercury–cadmium telluride (MCT) detects the transmitted beam. The detector produces signals in two frequency ranges: 1) $I_{DC}$, in the range of 1–2 kHz, represents the FT-IR interferogram; and 2) $I_{AC}$, centered at 37 kHz, represents the FT-VCD interferogram. The FT-IR interferogram may be directly Fourier-transformed to yield the IR spectrum. After synchronous demodulation (using a lock-in amplifier or purely numerical processing) with a reference at 37 kHz, the VCD interferogram can be Fourier-transformed to yield the VCD spectrum. Both the IR and VCD spectra are presented in dimensionless absorbance units, $A$, and hence the ratio of the VCD to the IR intensity for any band in the spectrum yields the dimensionless anisotropy ratio for that vibrational transition. *Figure 1* illustrates the minimum setup for VCD measurement, but technically advanced instruments use two PEMs to increase baseline stability and two sources to increase signal quality or reduce sample measurement time. Measurement of VCD in other spectral regions, for example the hydrogen-stretching or near-IR, can be carried out with appropriate changes in sources, polarizers, filters, PEM, cells, and detectors.

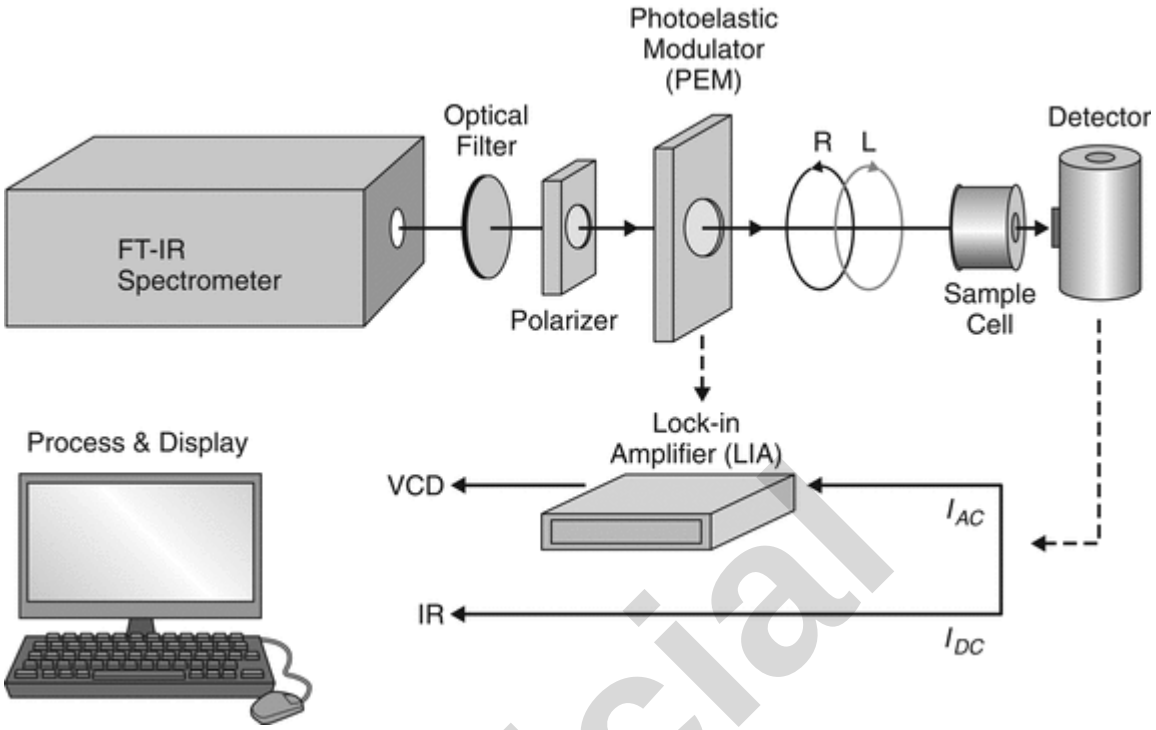

Figure 1. Diagram illustrating the typical features of an FT-VCD spectrometer for the measurement of the IR and VCD spectra of a chiral sample.

## 4. MEASUREMENT OF VCD SPECTRA

*Figure 2* shows the IR and VCD spectra for (+)-*R*- and (–)-*S*-α-pinene as a neat liquid measured at 4 $cm^{-1}$ spectral resolution for 1 h. Also shown are the stereostructures of the two opposite enantiomers (+)-*R*- and (–)-*S*-α-pinene. This figure shows that the IR spectra are nearly identical (superimposed dash and solid traces) for these enantiomers and that IR is therefore blind to chirality. By contrast, the corresponding VCD spectra have intensities that are equal in magnitude with opposite signs for each band in the spectrum. The two stereostructures for α-pinene are presented in a form that makes clear their mirror symmetry, and it follows that mirror-symmetric pairs of chiral molecules have mirror-symmetric VCD spectra about the zero baseline. The VCD baseline for these spectra is offset slightly above zero and can be baseline corrected as discussed below. Inspection of the intensity scales for the IR and VCD spectra reveals that the VCD intensities are approximately four orders of magnitude smaller than the corresponding IR intensities. Finally, each band in the IR spectrum has a corresponding VCD band. The richness of the resolved spectral bands in the VCD spectrum, each one representing what has traditionally been called a chromophore in electronic circular dichroism (ECD), gives VCD its exceptional combination of structural richness and stereochemical specificity.

Figure 2. IR (lower) and VCD (upper) of (1*S*)-(–)-α-pinene (dash) and (1*R*)-(+)-α-pinene (solid). To the left are presented the quantum chemistry-optimized stereostructures of (1*S*)-(–)-α-pinene (upper) and (1*R*)-(+)-α-pinene (lower). The IR and VCD spectra were measured at 4 $cm^{-1}$ spectral resolution, and the VCD spectra were averaged for 1 h.

Sampling requirements for VCD are similar to those needed to obtain a good IR spectrum. Ideally, as shown in *Figure 2*, analysts choose a combination of path length and sample concentration to obtain an average IR absorbance value *A* in the range between 0.2 and 0.8 and concentrations between 0.1 and 1.0 M, depending on the molecular weight of the sample. Typical path lengths for organic solvents are in the range of 50–100 µm, and sample quantities needed are typically 5–10 mg, although amounts as small as 2 mg are possible. Typical solvents for VCD measurement of organic molecules are deuterated solvents that have reduced solvent absorption in the mid-IR region. Besides hydrogen-free solvents, such as carbon tetrachloride ($CCl_4$), other commonly used solvents for VCD are deuterated chloroform ($CDCl_3$) and deuterated dimethyl sulfoxide (DMSO-$d_6$).

IR and VCD spectra can be plotted either in absorbance units, as *A* and $\Delta A$, that reflect the sampling conditions, or in molar absorption coefficients, ε and $\Delta\varepsilon$, that remove the concentration and path-length dependence of the intensity to give a molecular-level property that can be compared quantitatively to calculated IR and VCD intensities. The conversion between these two sets of quantities is given by:

$$A = \varepsilon C \times l$$

*A* = IR absorbance
ε = molar absorption coefficient
*C* = concentration (mol/L)
*l* = path length (cm)

and

$$\Delta A = \Delta\varepsilon C \times l$$

$\Delta A$ = difference in the IR absorbance
$\Delta\varepsilon$ = difference in molar absorption coefficient

A useful dimensionless measure of the intrinsic strength of a VCD band is the anisotropy ratio, defined as $g = \Delta A/A = \Delta\varepsilon/\varepsilon$. Including the spectral frequency dependence of IR and VCD, the measured spectra are expressed respectively either as $A(\nu)$ and $\Delta A(\nu)$ or as $\varepsilon(\nu)$ and $\Delta\varepsilon(\nu)$.

VCD spectra require baseline corrections for instrumentation and solvent intensity. Deviations from a perfectly flat baseline with zero offset must be removed before a final calibrated VCD spectrum is complete. Solvent baseline correction can be achieved for VCD spectra by subtraction of the VCD spectrum of the solvent in the same sample cell. If the opposite enantiomer or racemic mixture of the sample is available, baseline correction can be achieved as one-half the difference between these two equal and opposite VCD spectra in the case of enantiomers or as simple subtraction in the case of the racemic mixture. Baseline deviations are caused by the unavoidable presence of linear birefringence in the optical elements of the instrument and the sample cell that can become important for all but the largest VCD intensities. An example of a baseline-corrected VCD spectrum is presented in *Figure 3*, along with the corresponding IR and VCD noise spectrum. The spectrum of this sample of neat (–)-(*S*)-α-pinene was collected for a period of 1 h at 4 $cm^{-1}$ spectral resolution in barium fluoride ($BaF_2$) with a path length of 75 µm. The noise spectrum is less than $1 \times 10^{-5}$ absorbance (*A*) units across the spectrum. The IR, VCD, and noise spectra presented in *Figure 3* may be taken as a validation standard for the performance of a mid-IR FT-VCD instrument, as described in *Vibrational Circular Dichroism Spectroscopy* ⟨782⟩.

# 5. QUALITATIVE AND QUANTITATIVE ANALYSIS

## 5.1 Ensure That Signs and Intensities Are Correct

Qualitative analysis can be carried out with VCD by comparing the VCD spectrum of an unknown to a reference spectrum of that molecule to identify common features and to confirm that the VCD spectrum of the sample is a close match to the reference spectrum.

Quantitative analysis using VCD involves measuring the VCD intensity of the sample molecule and comparing it to a standard reference spectrum for that molecule. In this way, the concentration and the %EE of the sample can be determined as follows. The intensity of the IR spectrum relative to the IR standard of the sample determines the concentration for measurements with the same path length. After normalizing the IR intensity of the unknown sample to the standard, the relative intensities of the VCD determine the %EE of the sample. Such comparisons need to be carried out with all sampling conditions being the same, including the solvent and instrument spectral resolution.

To determine that the VCD intensities are correct, the uncalibrated VCD intensities must be calibrated. This is accomplished by placing a multiple-wave plate in the sample position, followed by a polarizer that is either parallel or perpendicular to the instrument polarizer in *Figure 1*. Measurement of the VCD spectrum of this multiple-wave plate set-up for two settings of the wave plate and polarizer that differ by 90° produces two sets of curves that have crossing points. The curve connecting the crossing points follows the shape of a first-order Bessel function and represents unit VCD intensity. Dividing this curve into the uncalibrated VCD spectrum produces a VCD spectrum with the correct calibrated intensities. The two calibration curves and their crossing-point curve are illustrated in *Figure 4*.

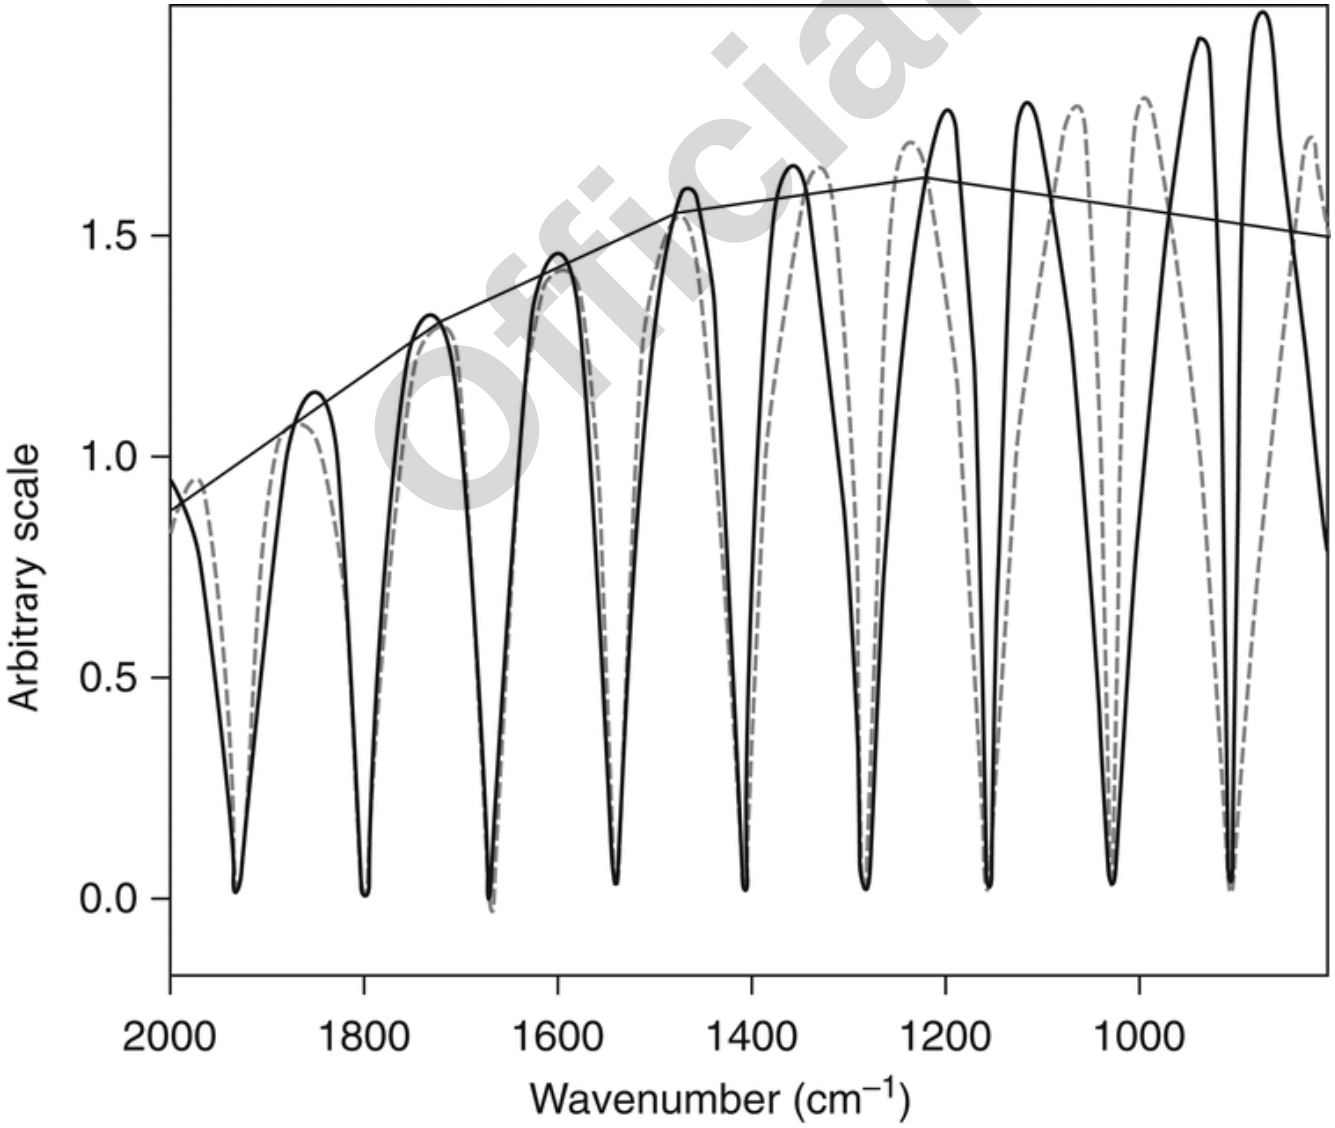

Figure 4. Calibration curves for VCD intensity generated by placing a multiple-wave plate and a polarizer in the IR beam and connecting the crossing points with a curve representing unit VCD intensity for maximum VCD intensity at 1200 cm$^{-1}$.

## 5.2 Determination of the Noise Level at Each Point in the Spectrum

A critical factor in quantitative analysis using VCD is the degree of accuracy of the spectrum as given by the VCD noise level and baseline stability of the measurement. The noise level depends on a number of factors such as the D* value of the detector, the amount of radiation passing through the sample from the source, and the amount of absorption of the sample. The noise level is obtained by dividing the VCD measurement into two halves. Addition of these halves gives the VCD spectrum, including noise, whereas subtraction eliminates the VCD features and leaves the equivalent noise spectrum. An example of a VCD noise spectrum is given in *Figure 3*, which shows, from bottom to top, the IR, VCD, and VCD noise spectra for a measurement of (–)-*S*-α-pinene. The VCD noise level can be reduced by increasing the measurement time through co-addition of the spectra, as desired.

## 5.3 VCD Baseline Accuracy

A second critical factor in the measurement of a VCD spectrum is the characteristics of the VCD baseline, namely its location, straightness, and stability. The VCD zero intensity line between positive and negative VCD intensities needs to lie as close as possible to the electronic zero of the measurement (zero of spectral display). Due to the sensitivity of the VCD intensity scale, some offset of the baseline from electronic zero almost always occurs, as discussed above in reference to the need for baseline correction of the VCD spectra of α-pinene in *Figure 2* and as carried out for *Figure 3*. Use of α-pinene as a validation standard is advantageous, because α-pinene has an unusually large intensity and thus, its spectrum is relatively easy to measure on a regular basis. α-Pinene can also be used as a measure of the baseline of a VCD measurement relative to the electronic zero of the measurement. This is illustrated in *Figure 5*, where the VCD spectra of (–)-α-pinene (*dash*) and (+)-α-pinene (*black*) are presented along with the VCD spectrum of a racemic mixture [equal quantities of (–)-α-pinene and (+)-α-pinene, hence cancelling the VCD intensity] of α-pinene (*gray*). The VCD spectrum of the racemic mixture of α-pinene is the VCD baseline for this measurement. A typical standard for baseline quality is deviations from electronic zero of <10% of the maximum separation of positive and negative VCD intensity of the neat α-pinene spectrum, or approximately $1 \times 10^{-4}$. The baseline illustrated in *Figure 5* satisfies this standard to within 5%. The baseline at 1350 $cm^{-1}$ is slightly above electronic zero and has maximum excursions away from electronic zero of <0.00005, or $5 \times 10^{-5}$ at 1170 $cm^{-1}$, which can be compared to the maximum positive and negative intensity values of (–)-α-pinene of $+5 \times 10^{-4}$ at 1220 $cm^{-1}$ and a negative peak value of $-4 \times 10^{-4}$ at 1130 $cm^{-1}$.

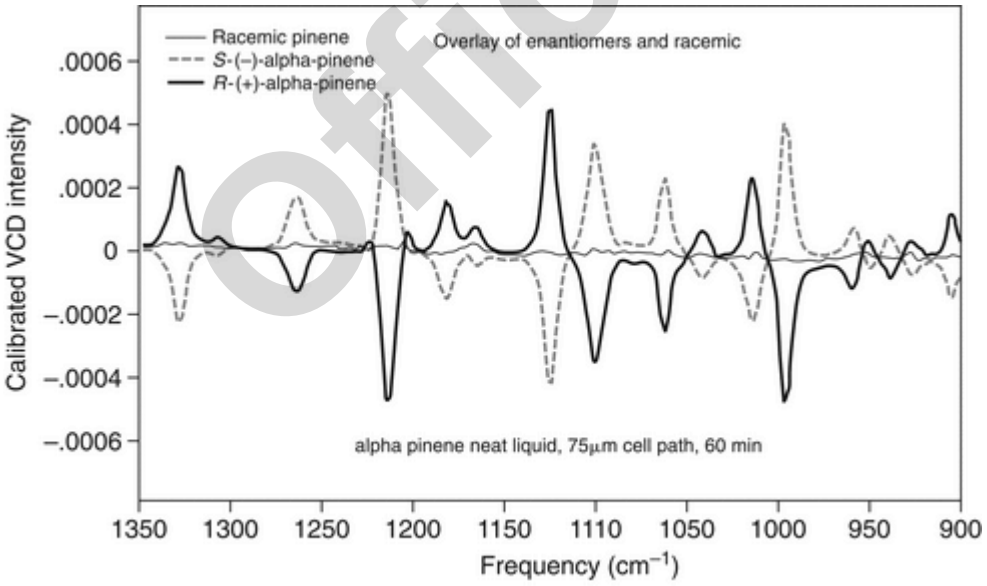

Figure 5. VCD spectrum of *R*-(+)-α-pinene (black), *S*-(–)-α-pinene (dash), and racemic (gray) α-pinene as a neat liquid for a 60-min measurement in a 75-µm path-length barium fluoride cell.

## 5.4 VCD Baseline Absorption Artifacts and Single-Enantiomer Measurement Capability

For tests of baseline accuracy and stability, the sample camphor in carbon tetrachloride solution is used as a qualification standard and provides a more stringent test than α-pinene, because the VCD spectrum of camphor is approximately one-fifth the magnitude, relative to the IR absorbance spectrum, of that of neat α-pinene. The VCD spectra of both enantiomers, as well as two measures of the VCD baseline, are provided in *Figure 6*. It is clear, as in *Figure 2* and *Figure 5*, that the VCD spectra of enantiomers, in this case (+)-camphor and (–)-camphor, are equal in intensity and opposite in sign relative to the VCD baseline to within the noise level of the measurement. The two VCD baselines provided are both zero VCD measurements. The VCD spectrum of racemic camphor [equal mixture of (+)-camphor and (–)-camphor] is the true VCD baseline for the individual (+)-camphor and (–)-camphor spectra, even if there are offsets (artifacts) due to absorption bands in the IR spectrum of camphor. The absence of such artifacts to within the noise level of the measurement is demonstrated by the congruence of the VCD spectrum of the racemic mixture and that of the solvent, carbon tetrachloride. Because carbon tetrachloride has no

@2024 USPC

significant level of absorbance in the region of the spectrum displayed, the agreement of these two baselines within the noise level demonstrates the absence of baseline artifacts in the VCD spectrum of racemic camphor, and therefore, for the VCD measurement of either of the two enantiomers of camphor.

Achieving a VCD baseline that is free of absorption artifacts is usually done by optical alignment of the VCD instrument such that the baseline is as close as possible to the true electronic zero of the instrument of the measurement. In *Figure 6*, the VCD baseline can be seen to wander above and below zero across the spectrum, but in this case, the deviations from the electronic zero are small (approximately $2 \times 10^{-5}$) and <20% of the positive and negative maximum VCD intensities of the spectrum (approximately $1 \times 10^{-4}$). This value of deviation is consistent with the maximum baseline magnitudes discussed above for α-pinene and displayed in *Figure 5*, because α-pinene has a much larger (approximately 5×) VCD spectrum, relative to its IR spectrum, than camphor. The baselines for camphor in *Figure 6* are noisier than that of α-pinene in *Figure 5*, because the VCD spectrum scale is smaller and the measurement time is 20 min instead of 1 h. As in *Figure 3*, the VCD baseline can be corrected by subtraction of an appropriate baseline spectrum, racemic or solvent. In *Figure 7*, the baseline-corrected VCD spectra for both enantiomers and the racemic mixture have been obtained by subtraction of the VCD spectrum of the solvent carbon tetrachloride. As a result the VCD zero baseline and the instrument electronic zero are the same to within the noise level, and the mirror symmetric properties of these spectra are even more apparent. This VCD test verifies that by subtracting the VCD spectrum of the solvent, an accurate VCD spectrum of camphor can be obtained using only one enantiomer, either the (+)- or (–)-enantiomer, and hence, the instrument possesses a single-enantiomer VCD measurement capability.

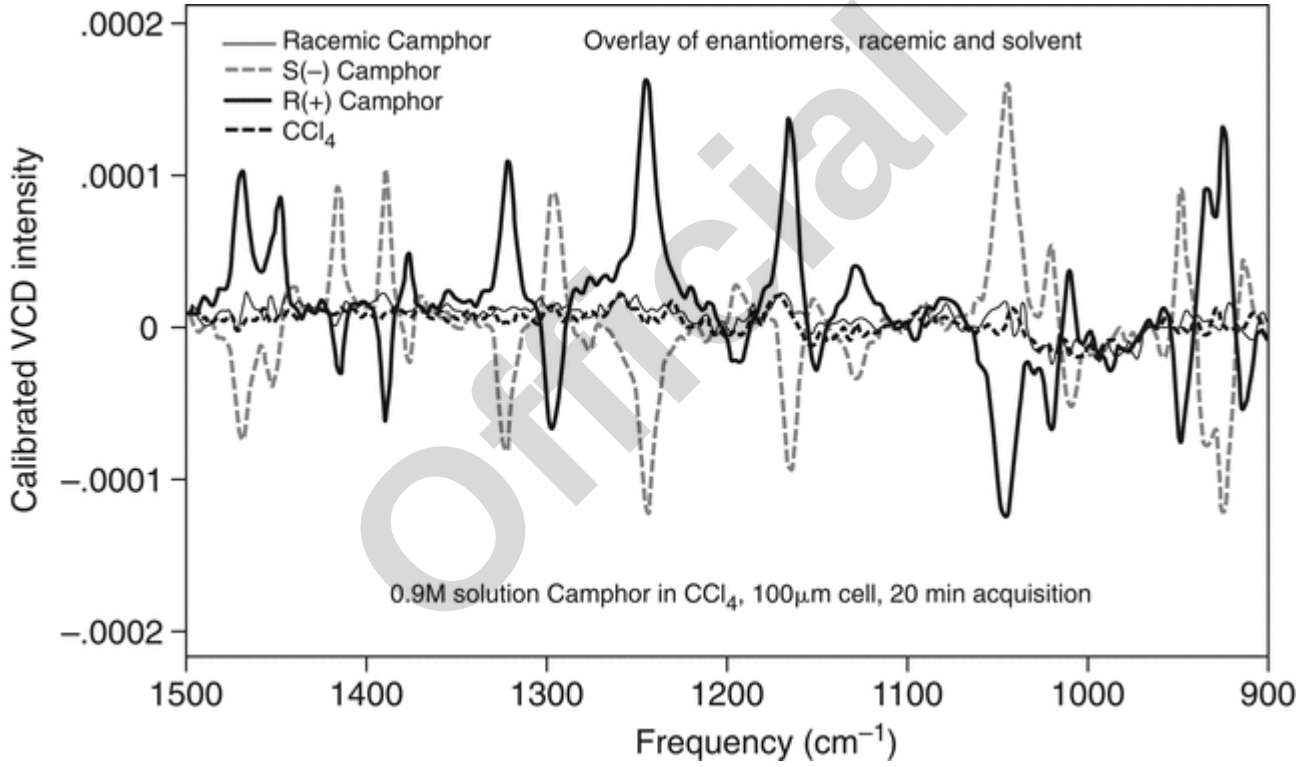

Figure 6. VCD spectrum of *R*-(+)-camphor (black), *S*-(–)-camphor (gray dash), and racemic camphor mixture (gray) as a 0.9 M solution in carbon tetrachloride. Also provided with the same cell and path length is the VCD spectrum of pure carbon tetrachloride (black dash). The sampling conditions were a spectral collection time of 20 min with a 100-μm path-length barium fluoride cell.

## 5.5 VCD Measurement Stability and Noise Level Reduction

Comparison of VCD measurements of camphor for 20 min to that measured over a period of 4 h in blocks of 20 min permits evaluation of instrument measurement stability as well as the reduction of noise level over time. In *Figure 8*, 12 such 20-min VCD spectra measured in 4 h are presented to show the stability of a VCD spectrum over time. It is clear that there are no deviations of VCD spectra outside the noise level of any one 20-min spectrum, and hence, there is no long-term drift in the VCD baseline over this time period.

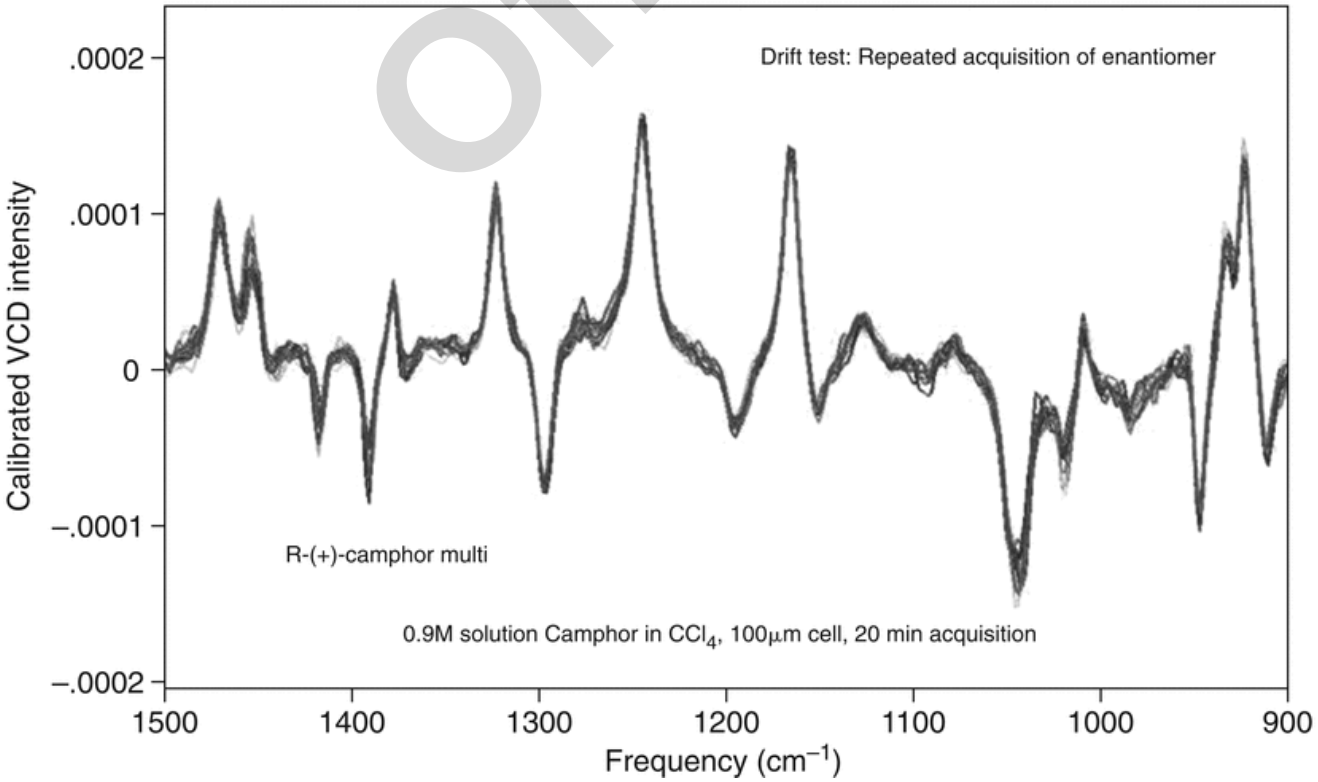

Figure 8. Superposition of 12 20-min VCD spectra of *R*-(+)-camphor under the conditions of *Figure 6* and *Figure 7*.

If the 12 blocks of 20-min VCD spectra in *Figure 8* are averaged, the resulting 4-h VCD spectrum can be compared to a 20-min VCD spectrum of the same sample to demonstrate the noise reduction that is achieved upon signal averaging, provided there are no other systematic noise sources in the VCD spectrometer. In this case, the noise reduction should be a factor of the square root of 12, or approximately 3.5. Thus, the signal-to-noise ratio should improve by a factor of 3.5. Such a comparison is provided in *Figure 9*.

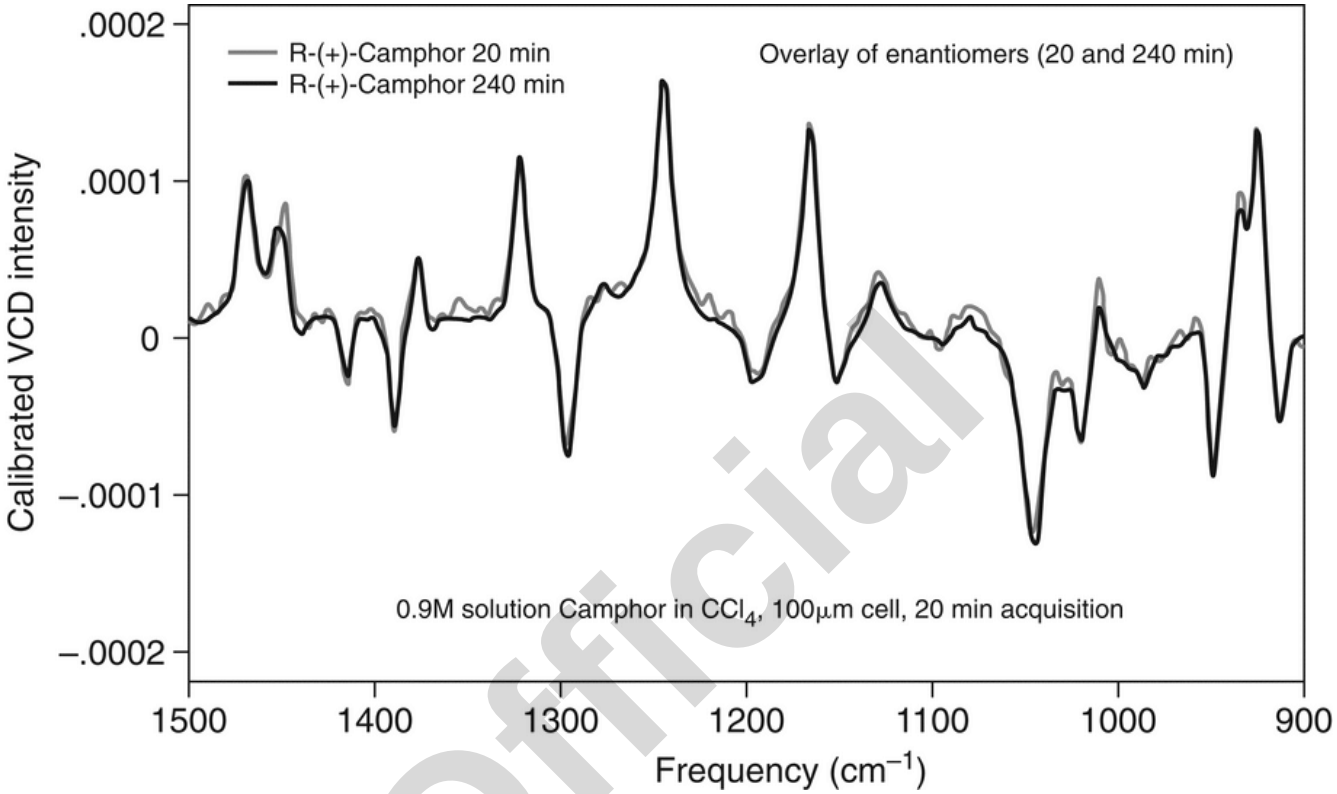

Figure 9. Comparison of the 4-h average of 12 20-min VCD spectra [*R*-(+)-camphor 240 min (gray)] to one 20-min measurement of camphor [*R*-(+)-camphor 20 min (black)], under the conditions of *Figures 6*, *7*, and *8*, showing improvement in signal-to-noise ratio with increased collection time.

The noise level can be visualized directly on a 5× more sensitive scale to better evaluate the noise levels by comparing the noise spectrums, as illustrated and described in *Figure 3*, for the 4-h and 20-min VCD measurements. This is presented in *Figure 10*.

## 6. DETERMINATION OF ABSOLUTE CONFIGURATION

The IR and VCD spectra of a sample are measured in solution in a matter of minutes to hours without the requirement of prior crystallization or high sample optical purity. The AC of an unknown sample is determined by comparison of its measured VCD spectrum to a VCD quantum chemistry calculation of the same molecule, where the AC used in the calculated VCD spectrum is chosen arbitrarily. If the signs of the bands in the measured VCD spectrum match those in the calculated VCD spectrum, the AC of the sample is identical to that used in the calculation. If the signs are opposite, then the sample has the opposite AC compared with that calculated. An example of the determination of the AC of a pharmaceutical molecule is shown in *Figure 11*. The AC of mirtazapine, which is sold in racemic form, is determined by comparison of the measured IR and VCD spectra of the (–)-enantiomer to the calculated IR and VCD spectra of the *R*-enantiomer. The close match in VCD signs—vibrational frequencies, intensities of the observed and calculated spectra, and IR frequencies and intensities—demonstrates clearly that the AC of mirtazapine is (–)-*R*. Also shown in *Figure 11* is the stereospecific quantum chemistry calculated structure of *R*-mirtazapine.

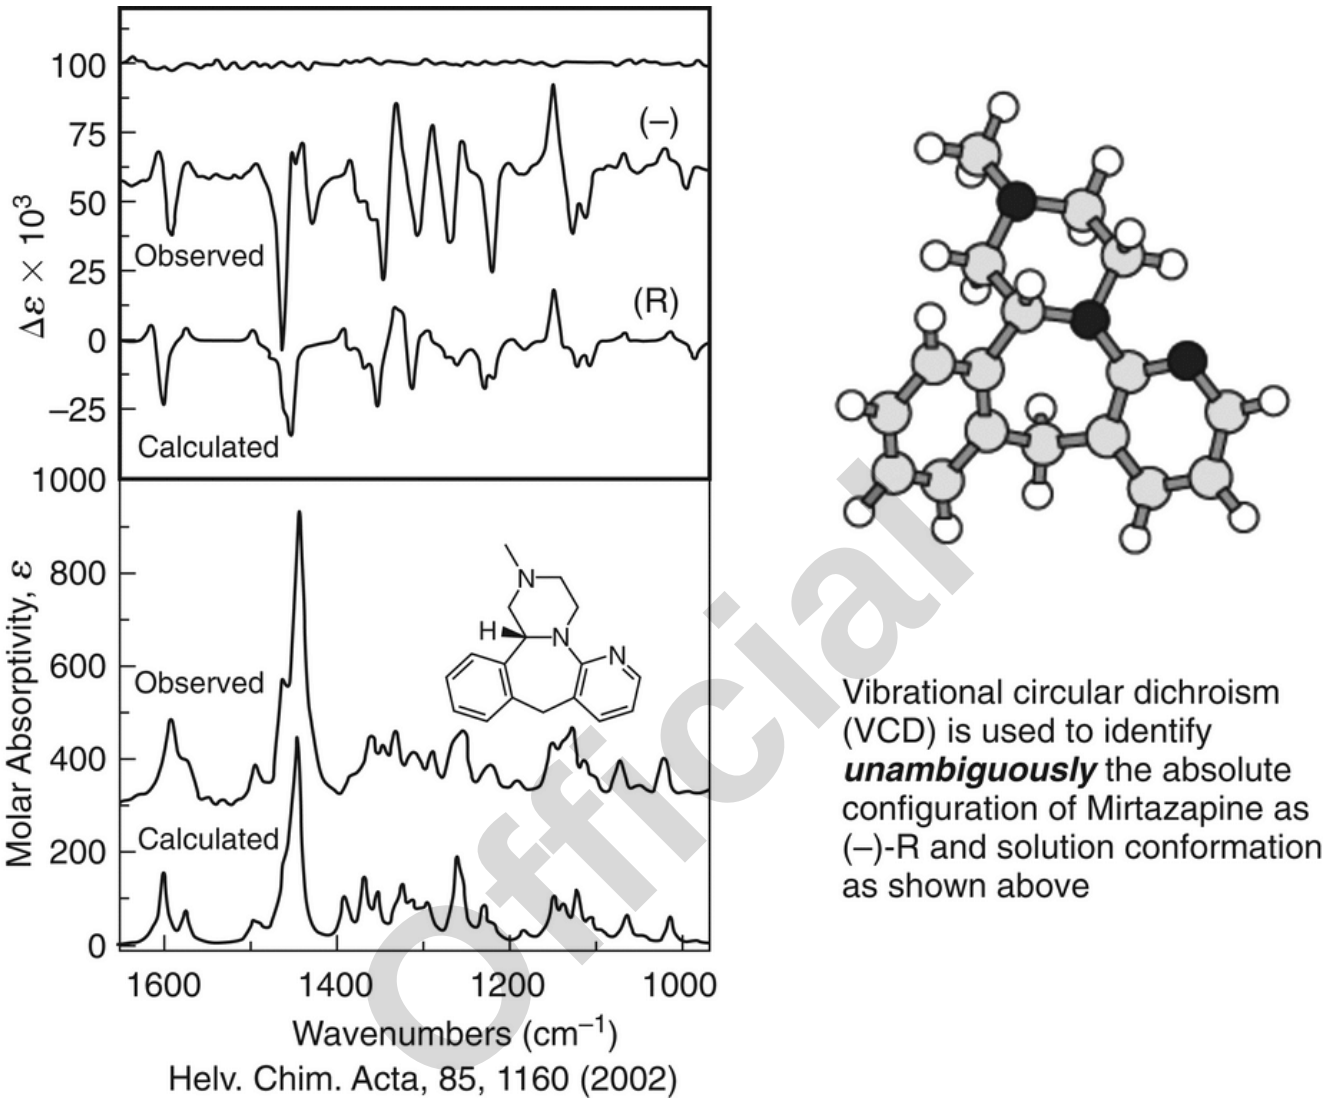

Figure 11. Comparison of the measured (observed) and calculated IR and VCD spectra of mirtazapine, allowing assignment of its AC to (–)-*R*. Reproduced in part with permission from John Wiley & Sons.

If the AC of a molecule has previously been established, for example, by X-ray crystallography, a VCD calculation of the molecule is not necessary (but could be performed as a check of the X-ray assignment), and the measured VCD spectrum of the molecule may be taken as a reference standard for the AC of the molecule, supported, for example, by USP. For a molecule with unknown structural chirality, the determination of its AC by VCD requires a comparison of the measured and calculated IR and VCD spectra, $\varepsilon(\nu)$ and $\Delta\varepsilon(\nu)$, as shown in *Figure 11*. The key point of the comparison is correlating the major VCD bands to determine whether they have the same or opposite signs. The IR spectrum is a guide in the process. Seeing a close correspondence between the calculated and measured IR spectra provides confidence that a good vibrational force field has been calculated and the most important vibrational bands are correlated. If a corresponding correlation of the signs of the major VCD bands can be made, as in *Figure 11*, then the AC has been determined.

When the measured and calculated VCD spectra are compared, the magnitudes of the corresponding intensities are not critical. What is important is the relative intensities of the bands in the two spectra, and in fact, that the comparison of measured and calculated spectra can be made using different sets of intensities for $\varepsilon(\nu)$ and $\Delta\varepsilon(\nu)$ for the calculated spectra and $A(\nu)$ and $\Delta A(\nu)$ for the measured spectra. In general, an exact match of the measured and calculated band frequencies is not expected because of several limitations of the calculations. Examples of these limitations include the assumption of the harmonic approximation when some anharmonicity is present in the measured spectra, the need to ignore the effects of solvent interactions with the chiral solute molecule, limitations in the size of the basis set used for the quantum calculation, and the choice of density functional required for the density functional theory (DFT) calculation.

## 7. CALCULATION OF VCD SPECTRA

To determine the AC of a molecule with unknown chirality using the VCD method as an alternative to, or supplement to, X-ray crystallography, analysts conduct a quantum chemistry calculation of the IR and VCD intensities of the molecule. Since

the late 1990s, commercial DFT software has been available and can be used effectively by a trained user because it does not require special expertise or extensive experience in quantum chemistry calculations. For example, VCD calculations are now part of some undergraduate chemistry curricula. The following steps are required to perform a DFT calculation of IR and VCD:

1. The stereospecific structure of the molecule is entered through a visual graphics interface.
2. The quantum chemistry program then automatically performs the following steps:
    A. The geometry is optimized to a minimum energy conformation.
    B. A force field is calculated that determines the vibrational modes of the molecule, with 3N-6 modes for a molecule with N atoms.
    C. Atomic polar tensors that yield the IR spectrum are calculated.
    D. Atomic axial tensors that yield the VCD spectrum are calculated.
3. The output of the calculation consists of a table where for each mode *i* there is a frequency, $\nu_i$, IR intensity (dipole strength), $D_i$, and VCD intensity (rotational strength), $R_i$.
4. Commercially available programs calculate the IR and VCD spectra for the molecule using the following steps:
    A. A line shape, $f(\nu)$, is applied to each dipole and rotational strength value, $D_i$ and $R_i$, centered at each vibrational frequency, $\nu_i$.
    B. Summation of these normal mode line-shaped intensities automatically produces the final calculated IR and VCD spectra $\varepsilon(\nu)$ and $\Delta\varepsilon(\nu)$ that can be compared directly to the corresponding measured IR and VCD spectra.

Another important factor that often is encountered in the assignment of the AC of pharmaceutical molecules and natural products (because of the structural complexity of these types of molecules) is the presence of more than one important conformer under the measurement conditions. The fractional populations of different conformers can be predicted by using their relative calculated energies in the Boltzmann distribution. The lowest-energy conformer has the highest fractional population and so on, to increasingly less-populated conformers with higher relative energies. To calculate the VCD, one must calculate the IR and VCD of each important conformer and then add these spectra together, weighted by the fractional Boltzmann population. Usually, one can ignore the spectral contributions of conformers that account for less than a few percent of the total population.

Programs for calculating VCD and IR spectra to the level of accuracy sufficient for comparison to measured IR and VCD are available commercially from a variety of sources. First, one needs a program for evaluating and finding the geometry of all the lowest-energy conformations of a chiral molecule. A variety of programs using molecular mechanics are available for this purpose. Second, one needs a full quantum chemistry software program for calculating the ab initio force fields, vibrational frequencies, and VCD and IR intensities for each of the lowest-energy conformers. A common chemical model of sufficient accuracy for AC determination is DFT, using a basis set minimum of 6-31G(d), and a choice of hybrid functionals, such as B3LYP or B3PW91. Higher-level basis sets and alternative choices of hybrid functionals may be made. Finally, one needs a software method for comparing measured and calculated VCD and IR spectra to assess the degree of spectral agreement between the measured and calculated spectra, and hence the level of confidence that the correct assignment of AC has been predicted. Additional details are described below.

In *Figure 12*, the AC of the bioactive enantiomer of the analgesic (*S*)-(+)-ibuprofen is determined by comparing the measured and calculated IR and VCD spectra. The calculated IR and VCD are the sums of the IR and VCD conformer spectra, one for each conformer, weighted by the fractional populations 0.37, 0.36, 0.12, and 0.07, plus smaller contributions from another eight conformers that have a total contribution of 0.08. Clearly, there are two important conformers that are nearly equally populated, and the basic features of the final IR and VCD spectra are determined by these spectra. As a result of this analysis, not only has VCD been able to confirm the AC of (+)-ibuprofen as *S*, but two dominant solution-state conformers have been identified, along with two additional less-populated conformers.

## 8. COMPARISON OF MEASURED AND CALCULATED SPECTRA

To provide an unbiased statistical measure of the degree of similarity between measured and calculated IR and VCD spectra, an analytical method based on a convolution algorithm has been developed. The degree of similarity, or congruence, between a measured and a calculated spectrum can be calculated and used to determine a degree of confidence that the AC determined by visual inspection is correct.

### 8.1 Degree of Confidence of Correct Assignment

The results of the use of such statistical measures are shown in *Figure 13*. The degree of similarity (the total neighborhood similarity, TNS) of the measured and calculated IR is 92.5, where 100 is a perfect match. The same TNS measure for the VCD is 82.2. Because VCD bands can be either positive or negative, a more refined analysis is carried out for VCD, and only regions of sign agreement are compared for each enantiomer. In this case, the value of the signed neighborhood similarity (SNS) for the *S*-enantiomer is 92.8, and for the *R*-enantiomer it is only 12.1. Clearly, the analysis confirms the visual agreement of the measured VCD spectrum (*upper solid line*) and the calculated VCD spectra (*lower solid line*) for the *S*-enantiomer versus the *R*-enantiomer (*dashed line*). An additional numerical comparison is calculated as the enantiomeric similarity index (ESI), which equals SNS(*S*)– SNS(*R*). The result (*black dot*) is then plotted against a database of 89 prior correct VCD assignments, where the axes are SNS (*vertical*) and ESI (*horizontal*). The closer a statistical point is to the *upper right-hand corner* of the plot, the higher the similarity of the comparison and the higher the degree of confidence. The upper right-hand corner of the plot is defined as 100% spectral similarity. The degree of confidence is a statistical measure that is set to be 100% confidence for points

## 9. DETERMINATION OF ENANTIOMERIC EXCESS

After AC, the next most important property of a chiral sample is the EE, as described in *1. Introduction*. For enantiomers labeled *R* and *S*, the EE for the *R* enantiomer is defined as EE = $(N_R - N_S)/(N_R + N_S)$ and %EE = EE × 100%. Here, $N_R$ represents the number of moles of the *R* enantiomer present in the sample; for a solution, $N_R$ can represent the concentration of the *R* enantiomer. Thus, %EE for the *R* enantiomer can vary from +100% to –100%.

Official

https://pharmacopeia.cn/v-download/

VCD spectra also can be used to determine the EE of a sample once the sample has been calibrated by a single IR and VCD measurement of a sample with a known EE. VCD scales linearly with EE with a maximum VCD intensity for a given IR intensity at 100% EE, one-half VCD intensity for the same IR intensity at 50% EE, and zero VCD for the racemic mixture of 0% EE. These points are illustrated in *Figure 14* for 11 measurements of *R*-(+)-α-pinene for which the %EE decreases from 100% to 6.7%. The IR spectra are identical, but the VCD spectra grow smaller linearly as EE is reduced by the addition of measured amounts of the opposite enantiomer to the sample cell. The degree of accuracy of this determination of %EE was slightly >1%, as indicated in the plot of actual prepared EE versus VCD predicted EE, using a partial least-squares chemometric analysis as presented in *Figure 15*.

## 10. CONCURRENT USE OF VCD FOR ABSOLUTE CONFIGURATION AND EE

### 10.1 Chiral Raw Material Identification

Currently, there is no routine, real-time chiral measurement for material identification (ID). Chiral drug substances must comply with the *USP–NF* monograph tests that typically rely upon nonchiral test procedures such as mid-IR spectroscopy (*Mid-Infrared Spectroscopy* ⟨854⟩ and *Mid-Infrared Spectroscopy—Theory and Practice* ⟨1854⟩). In practice, near-IR (for additional information, see ▲*Near-Infrared Spectroscopy—Theory and Practice* ⟨1856⟩▲ (CN 1-May-2020)) is used in many manufacturing facilities. For near-IR analysis of solids, analysts commonly use fiber-optic probes and then confirm the raw material by comparison of the measured spectrum against that of the USP Reference Standard. To determine the AC and EE of a chiral material, analysts must make a separate optical rotation measurement, which requires large amounts of sample in a 10-cm path-length cell, where uncertainty errors are possible for materials with small OR values.

A single measurement of the VCD spectrum and its associated IR spectrum in the mid-IR or near-IR region of a raw material, either as a crystalline solid or in solution, simultaneously contains information for the three critical measures: ID, AC, and EE. By comparison to a USP Reference Standard, the simultaneous measurement of IR and VCD spectra of a test material identifies the sample and the presence of impurities and separates impurities into achiral (IR only) or chiral (IR and VCD). The signs of the VCD identify the AC of the dominant enantiomer, and the ratio of the VCD to the IR gives the EE, as described above. Typical VCD accuracy for EE determinations is in the range of 0.1%–1%.

### 10.2 Chiral Quality Control

VCD can be used as a chiral measure for characterization of raw materials for process analytical technology (PAT) during development, synthesis, formulation, and final production of drug substances and drug products. VCD also can be used to test the interaction between formulated chiral drug substances and excipients. Currently, there are no protocols for monitoring EE as a quality control measure in the pharmaceutical industry. Because of the importance of chirality as a critical measure of sample integrity, there is a need for the incorporation of a new technology, such as VCD, to ensure the desired level of chiral quality of pharmaceutical products from discovery through to final formulation.

# ⟨1787⟩ MEASUREMENT OF SUBVISIBLE PARTICULATE MATTER IN THERAPEUTIC PROTEIN INJECTIONS

## INTRODUCTION

Parenteral products are designed and manufactured to minimize particulate matter, which is differentiated into two broad categories: visible and subvisible. The absolute limit of visibility, or detectability, depends on the test conditions and the nature of the particulate matter. This general information chapter covers subvisible particles in the range of 2–100 µm. Particles larger than 100 µm are generally considered visible particles (see *Visible Particulates in Injections* ⟨790⟩).

Foreign and particulate matter are undesirable in the final product. These undesired particles arise from two sources: extrinsic or foreign matter and intrinsic or product-related matter. Extrinsic matter cannot be associated with product or process. Intrinsic particles may be a byproduct of the assembly of the product or result from change over time. A third category, inherent matter, describes a physical state or particles that are an expected attribute of the product. The aim of this chapter is to provide additional information to support *Subvisible Particulate Matter in Therapeutic Protein Injections* ⟨787⟩, which has limits for ≤10-µm and ≤25-µm particle content. Because the monitoring of the sub-10-µm population may be an important product quality parameter, collection of data in the 2–10-µm range (e.g. 2–5 µm and 5–10 µm) is recommended. This chapter will focus on enumeration, characterization, and when possible, identification of inherent particles, distinguishing them from extrinsic and intrinsic particles. The chapter does not cover formulations that are suspensions or emulsions, or those that contain adjuvants or similar intended particle components. However, foreign and particulate matter should be minimized in the final drug product, and the strategy and methods utilized are ultimately determined by the manufacturer.

### Extrinsic Particles

Materials that are not part of the formulation, package, or assembly process, but rather are foreign and unexpected. Examples of extrinsic particles include materials from biological sources (e.g., fibers, insect parts, pollens, and vegetative matter), from process and building materials (e.g., cellulose, lint, minerals, glass, plastics, rubber, metal, and paint), and from personnel (e.g., epithelial cells, clothing fragments, and hairs).

### Intrinsic Particles

Materials occurring in the final product that arise from sources within the formulation ingredients, assembly process, or packaging. Their association with the production process and/or package-related sources can be indicative of systemic problems. For example, silicone oil is an important manufacturing and product component that may affect particle counts and, in excess, is considered intrinsic. The incidence of silicone oil-related particles may correlate with processing sequences or formulation component sources. Detection, identification, and measurement of silicone oil-related particles are discussed further in another section of this chapter. Intrinsic particles can be similar in some ways to extrinsic particles such as rubber, metal, plastic, and glass, but may arise because of insufficient cleaning of processing equipment. Intrinsic particles can also arise from changes in the product over time. These changes may be related to ionic or organic extracts, instability of the active pharmaceutical ingredient (API), formulation degradation, or product–package interaction. Intrinsic particles may promote protein, and one should be aware of this possibility.

### Inherent Particles

Materials that are expected from the drug substance and other formulation components, and thus represent a potentially acceptable characteristic of the product. In the context of therapeutic protein injections, the primary source of inherent particles is proteinaceous aggregates formed either solely by interactions of the protein with itself or in combination with other formulation ingredients. The presence of proteinaceous particles should be assessed for process consistency and product quality. Identification and characterization of the aggregates are critical for distinguishing them from extrinsic and intrinsic particles. The tools and techniques discussed in this chapter are applicable to all sources but are especially useful for the characterization of protein aggregates.

Heterogeneous particles consist of more than one chemical entity. They are classified as either extrinsic or intrinsic based on the nonproteinaceous component that presents the greatest risk.

Historically, test methods contained in *Particulate Matter in Injections* ⟨788⟩ were developed for detection and control of extrinsic and intrinsic particle content and rely on light obscuration (LO) and/or microscopic determination of particles that are between 10- and 25-µm thresholds. These sizes were selected to allow consistent measurement of subvisible particle content and allow determination of product acceptability from the perspective of patient safety and process consistency. The membrane microscopic method was developed first and was used only for large-volume (>100 mL) products. Later, improvements in the microscopic method and development of an automated light extinction (obscuration) method provided an efficient and robust means of tracking particulate content in a variety of products with different fill volumes. Evolution of analytical application is typical of the compendial standard-setting process, where methods are updated to reflect technological advances, patient safety considerations, and regulatory requirements.

Since ⟨788⟩ became official, the varieties of dosage forms and the numbers of therapeutic protein products have increased markedly. The LO method described in ⟨788⟩ has some technical limitations when used for analyzing certain particle types (e.g., those that have low contrast in the product medium and/or may change shape/size during analysis, as is typical for inherent particles in therapeutic protein injections). Other ⟨788⟩ limitations for therapeutic protein products relate to sample handling

and low product volumes. These considerations have led to the development of *Subvisible Particulate Matter in Therapeutic Protein Injections* ⟨787⟩.

## OBJECTIVE

This chapter was written to describe strategies for identifying and characterizing extrinsic and intrinsic particle populations, compared with inherent proteinaceous particle population(s), in therapeutic protein injections. Information about specific methods that can be used for these purposes, as well as their advantages and limitations, is discussed; the information applies to therapeutic protein injection products and their dilution or infusion solutions. The overarching goal is to provide comprehensive guidance on use of a broad array of analytical methods, one or more of which may be used beyond the methods described in ⟨787⟩ and ⟨788⟩. This is expected to achieve enhanced or orthogonal characterization of therapeutic protein products during development and support, root cause analysis for nonconformance investigations, stability studies, and others. This includes methods that allow assessment of a variety of characteristics of the inherent protein aggregates including morphology, conformation, reversibility/dissociation, and covalent modification. Guidance on sample handling and preparation is discussed in general terms.

## BACKGROUND

Extrinsic and intrinsic particles should be minimized in all parenteral products. However, protein-related particles may be inherent to therapeutic protein products. Inherent particles should be understood and controlled. These inherent particles are known and expected, arising from the association of protein molecules that can be present in a continuum of sizes, ranging from nanometers (dimers) to hundreds of micrometers (multimers and visible particles). The distribution of particle size is affected by amino acid sequence, solution conditions, sample handling history, and other factors. The specific phenomenon of protein association that gives rise to particles is called aggregation. The terms “proteinaceous particles” and “aggregates” are used interchangeably in this chapter.

Because multiple potential sources of particles exist, it is important to identify the particles and determine whether they are extrinsic, intrinsic, or inherent. Once this has been accomplished, it is possible to develop and apply appropriate control strategies. If deviations occur, particle identity will guide the root cause analysis, risk assessment, corrective actions, and control strategy.

Protein aggregates inherent in therapeutic protein products may consist of a heterogeneous population, and therefore size alone does not adequately describe them. When aggregate populations are being compared across products, labs, etc., it is important to consider other characteristics such as morphology, the ability to dissociate, the protein conformations (or higher-order structures) within the aggregates, and the chemical modifications present (*1*). These are summarized in *Table 1* [adapted from (*1*)]. It is important to realize that the results obtained depend on the technique and methodology used, and this information must be included in any description of protein aggregate characterization. The tools available for aggregate characterization are described later in this chapter. The tools used and the characteristics analyzed should be thoughtfully chosen based on the protein being studied. A more detailed description of attributes that should be considered during aggregate characterization follows.

Size is the particle attribute that has been monitored historically and remains a primary descriptor. When measurements are reported, they should include the size range measured and technique used. Thus, subvisible particles could also be described as aggregates/particles between 1 and 100 µm based on: the equivalent circular diameter, determined using LO; the longest chord, using light microscopy; the equivalent spherical volume, using electrical zone sensing; or other relevant dimensions obtained using other available technologies. The sample preparation, determination method, and algorithms applied are all important factors to include when presenting the results.

The ability of any aggregate species to dissociate (i.e., revert to the monomeric state) and the conditions required to accomplish this are also important characteristics to consider. Sample preparation could affect the results obtained if the aggregates are dissociable; therefore, understanding this aspect of the aggregates is critical when selecting techniques for counting, measuring, and characterizing them. The dissociability of protein aggregates can be assessed by diluting the aggregates into the formulation buffer or other solutions and then re-analyzing them with the original technique. This can also include simply returning the sample to the original conditions and assessing how much of the aggregate has dissociated. Ability to dissociate is thus a characteristic of protein aggregates that can inform sample handling and preparation (e.g., dilution conditions) for particle counting. The ability to dissociate may also apply to intrinsic and, to a lesser extent, extrinsic particles species.

The structure and conformation of protein molecules in the aggregates can be investigated by using several biophysical techniques. The findings may help in investigations and troubleshooting. It is also useful to know about the presence of chemical modifications such as oxidation, deamidation, cross-links, or fragments in the aggregate. Conformation of protein molecules within protein aggregates, as well as their state of covalent modification, may help explain the potential biological impact of the inherent particle.

Morphology of the particles can serve as another descriptor and also help identify their source. More specifically, characterization of morphology may allow one to distinguish between particles that are inherent to the therapeutic protein product and those that are extrinsic or intrinsic. Proteinaceous as well as many intrinsic and extrinsic particles are generally of irregular shape, whereas silicone oil and air bubbles tend to be spherical. The morphology of protein aggregates also constitutes important data that can facilitate comparisons across studies and over time.

*Table 1* provides an overview of protein aggregate characteristics to consider, which can be used to classify them.

### Silicone Oil

A standard lubricant in pharmaceutical products and packaging. In excess, it may contribute to elevated particle counts in products. Assessing the effect of silicone oil on particle counts in therapeutic protein injections, where relevant, is critical to the overall particle control strategy. In parenteral manufacturing, silicone oil is used primarily to facilitate packaging component handling, alleviate adherence of rubber parts, allow free stopper flow in the bowl/hopper, and promote tracking onto the waiting, filled container. Silicone oil is also used as a lubricant to decrease glide force and allow plunger stopper movement in glass, pre-filled syringe presentations. For parenteral container preparation, controlled stages of washing, rinsing, siliconization, and sterilization are routine. The tumbling of closures (e.g., vial stoppers) with a measured amount of silicone has been a routine process for uniformly coating surfaces before use. Application of a known amount of an accepted lubricant, rendered sterile, is common.

Even when applied judiciously, silicone oil can migrate from the product-contact surface to the fill-over time during product transport, storage, and use. Silicone oil droplets can contribute significantly to the subvisible particle counts of the product, specifically, particles in the <10-µm range in the case of therapeutic protein injections. The particle count depends on the amount of silicone oil, and in some cases small amounts of silicone oil can have a significant effect on particle counts (*2*).

Within therapeutic protein products, protein may become adsorbed to silicone oil droplets. Agitation resuspends and rearranges the oily matrix into different particle forms and sizes. The size range of the silicone oil droplets in protein formulations may be similar to inherent protein particles, but the morphology and optical properties of the two substances differ. Silicone oil in aqueous solution is typically spherical, with a higher refractive index than that of protein aggregates and a regular decrease in contrast from the outside to the center of the particle. This is unlike protein aggregates, which are typically amorphous and translucent and have a refractive index very similar to the protein monomer background of the drug formulation. These distinctions can be used to develop algorithms for differentiating silicone oil particles from protein particles. It is also possible to monitor changes in one population and distinguish them from changes in the other.

Because silicone oil serves a function in the product, particle counts arising from the oil are considered intrinsic and generally will vary over time. However, poorly controlled application processes can lead to excessive amounts of silicone oil. Careful design, control, and application of the silicone oil are recommended to obtain proper functionality with the minimum amount needed for the shelf life of the product.

## PARTICLE STANDARDS

Analysis of particle size distribution depends on the instrument used and its method of calibration. Some available particle standards (count and size) are polystyrene latex beads, mono-disperse silica or polymethylmethacrylate (PMMA) beads, and polydisperse glass beads. All of these standards are spheres, with a refractive index and density that are distinctly different from those of therapeutic protein products. Because typical protein particles have irregular morphology and low optical contrast, there are currently no standards available to consistently mimic the morphology and parameters of protein particles.

@2024 USPC

Protein particles have a refractive index that is quite close to that of the matrix solution. This difference in refractive index is a critical parameter for detection of protein particles by methods that rely on light interaction to measure size distribution. It is important to establish standard reference materials that mimic the properties of protein particles (*3*). The development of standards that better resemble protein particles is currently an active area of research. These standards should serve as surrogates for the actual protein particles in that the surrogate's properties mimic those of actual proteins for the detection method of choice. This approach is necessary because standards using proteins are limited by the following factors: (a) storage and transport should be at temperatures close to –80° to achieve acceptable stability; (b) any non-ambient technique may affect the standard; and (c) protein particles are themselves quite variable, making it difficult to have a single protein that would match all applications.

## SUBVISIBLE PARTICLE MEASUREMENT AND CHARACTERIZATION TECHNOLOGIES

The following sections review the advantages, limitations, and appropriate uses of each methodology (see *Table 2*) that allow assessment of a variety of characteristics of all particles, especially for the inherent protein aggregates, including size and distribution, size and morphology, and characterization. The methodology selected will affect reported particle size because of instrumental measurement principles, mode of measurement, particle characteristics, preparation, and handling. It can also be affected by the algorithms applied to estimate size, volume, and count. Thus with any size measurement, the method used should be specified. Also, the units should be clearly stated, because size can be provided using various parameters, usually hydrodynamic diameter, equivalent circular diameter (ECD), longest chord, equivalent spherical diameter (ESC), Feret's diameter, or molecular weight. The list in *Table 2* is not meant to be all inclusive.

**Table 2. Methodologies Useful in Measuring Properties of Subvisible Particles**

| Section I: Size and Distribution | | |
|---|---|---|
| **Technique** | **Principle of Operation** | **Range** |
| Light obscuration | The size of the particle in the product fluid is determined by the amount of light that it blocks when passing between the source and the detector. | 1–300 µm |
| Electrical sensing zone (Coulter) | The size of the particle in the product fluid or selected electrolyte is measured in terms of the change in resistance as the particle passes through a microchannel (orifice). | 0.4–1600 µm |
| Laser diffraction | The size of the particles in product fluid or dilution is determined by measuring the angle of the scattered light. | 0.1–3500 µm |
| | | |
| **Section II: Size and Morphology** | | |
| **Technique** | **Principle of Operation** | **Range** |
| Light microscopy | Photon imaging of substances directly in product fluids or mounts, or of isolated specimens on substrates | 0.3 µm to 1 mm |
| Flow imaging analysis | Digital image capture of the particles' magnified image in streaming product fluid, revealing size, shape, and optical properties | 0.7–100 µm for size distribution; 4–100 µm for morphology |
| Electron microscopy (EM): Scanning EM, scanning transmission EM, and transmission EM | Electron imaging of specimen isolates on substrates. High vacuum or near-ambient pressures is required. | Å to mm |
| | | |
| **Section III: Characterization** | | |
| **Technique** | **Principle of Operation** | **Range** |
| Fourier Transform Infrared (FTIR) microspectroscopy | Photon imaging of isolated specimens on substrates | 10 µm to 1 mm |
| Dispersive-Raman microspectroscopy | Photon imaging of isolated specimens on substrates, or in product fluids or fluid mounts | 0.5 µm to 1 mm |
| Electron microscopy (EM) with energy-dispersive X-ray spectrometry (EDS) | X-ray photon emission from specimens energized by a focused electron beam | Å to mm for imaging; 1 µm to 1 mm for elemental composition |
| Electron microscopy (EM) with electron energy loss spectroscopy (EELS) | Inelastic scattering from specimens energized by a focused e-beam; e-loss is characteristic of the source element; complementary to EDS | Å to mm for imaging; 0.5 µm to 1 mm for elemental composition |
| Time-of-Flight Secondary Ion Mass Spectrometer (TOF-SIMS) | Identification of particles according to their mass spectra profile | µm to near mm |
| Staining assay | Visible staining to gain qualitative confirmation of unknown materials | 0.3 µm to 1 mm |

The accuracy of equipment used to determine particle size distribution is verified by calibration with reference particles of known concentration and size traceable to the International System of Units.

The concept of three-dimensional particle size is critical to understanding how particle standards interact with the various types of measurement equipment and how to compare the results across methodologies. Different techniques use different measurements and algorithms to determine size (e.g., volume equivalent diameter, surface equivalent diameter, and drag or Stokes diameter).

***Change to read:***

## SIZE AND COUNT DISTRIBUTION

### Light Obscuration (working range 1–300 µm)

PRINCIPLE OF OPERATION

The sample is passed between a light source and a sensor. Counts are generated when individual particles pass between the two, disrupting the light, which yields a voltage spike. The height of each voltage spike depends on the size of the particle causing it. The particle size to be recorded is generated from a size–voltage response calibration curve constructed using monosphere, certified reference size standards (typically polystyrene beads). LO tabulates particle size as the diameter of a circle having an equivalent cross-section. The product may be sampled directly from the container, pooled from several containers, or prepared as a dilution (see general chapters *Globule Size Distribution in Lipid Injectable Emulsions* ⟨729⟩, ⟨788⟩, *Particulate Matter in Ophthalmic Solutions* ⟨789⟩, and ▲*Methods for the Determination of Subvisible Particulate Matter* ⟨1788⟩▲ (CN 1-May-2021)).

ADVANTAGES

- Primary *USP–NF* method with large archive of historical data
- Particles directly observed in solution
- Measurements are straightforward and quick
- Capable of unit–unit sampling; analyzes almost entire sample
- Easily implemented
- Medium-to-high sample throughput.

LIMITATIONS

- One sensor head cannot cover the full working range
- Tabulates particle size as the diameter of a circle having an equivalent cross-section
- Dilution of the sample may be required and may change sample properties
- Upper limits for particle load that can be measured depend on sensor used and potential for coincidence counting
- May underestimate subvisible protein particles formed in formulation because of low contrast
- Medium should be transparent for laser light
- Sensitive to air bubbles, and some degassing techniques can change sample properties
- Destructive, i.e., sample cannot be reused.

### Electrical Sensing Zone (Coulter Principle) (working range 0.4–1600 µm)

PRINCIPLE OF OPERATION

The sample is diluted into an electrolyte solution and drawn through a small aperture, passing between active electrodes, interrupting an electric field. Response is based on the displacement volume of the electrolyte, and thus size is reported as the equivalent spherical diameter (the diameter of a calibration standard sphere of the same volume as the particle). The response is unaffected by particle type (e.g., variations in color, hardness, opacity, refractive index).

ADVANTAGES

- Determines particle size in terms of equivalent spherical volume
- Not affected by optical properties of the solution
- Orthogonal technique to light-based methods, i.e., LO
- Medium-to-high sample throughput for a single orifice.

LIMITATIONS

- Low particle concentration required
- Each orifice has limited measuring range (2%–60% of orifice diameter)
- Near the lower end of the working range, electrical noise may be hard to distinguish from true particle counts
- For broad particle size distribution, more than one orifice may be necessary, which will involve reduced sample throughput
- Sample must be diluted in electrolyte solution if the formulation buffer does not have sufficient conductivity; the dilution may alter sample properties

@2024 USPC

- Smaller orifices require higher conductivity of medium and can require significantly increased buffer concentration
- Destructive, i.e., sample cannot be reused.

### Laser Diffraction (working range 0.1–3500 µm)

PRINCIPLE OF OPERATION

Laser diffraction detects particles passing through a laser beam as they scatter light at an angular distribution of intensity that depends on the size of the particles. Therefore, it is possible to calculate particle size distributions if the intensity of light scattered from a sample is measured as a function of angle. This angular information needs to be compared with a scattering model (Mie theory) to calculate the size distribution.

ADVANTAGES

- Brief analysis time (up to 30 s)
- Analytical samples can be retrieved
- Limited sample preparation
- Scattering pattern allows molecular mass calculation
- High sample throughput
- Large dynamic range.

LIMITATIONS

- Intensity is directly proportional to size, which can lead to misinterpretation of the population
- Analysis relies on a theoretical fit that requires refractive index and other optical factors
- Medium should be transparent for laser light
- Assumes particles are spherical and not interacting with each other
- Low concentration of particles required; dilution may be necessary and may change sample properties
- Complications can occur when comparing data from one instrument vendor to another
- Particle–particle interactions and occasionally multiple scattering may yield apparent size results that differ significantly from actual particle size
- Poor results for polydispersions when small and large particles are presented simultaneously
- For exact molecular weight calculation, monodisperse particles are required.

## SIZE AND MORPHOLOGY

### Light Microscopy (LM) (working range 0.3 µm to 1 mm)

PRINCIPLE OF OPERATION

Optical or light microscopy involves passing light through a series of lenses after it is transmitted through or reflected from the prepared sample. The light is detected directly by the eye, imaged on a photographic plate, or captured digitally. Samples can be analyzed directly or after filter capture. Light microscopy can be combined with static imaging analysis, thereby allowing digital images to be captured and further deconvolved using the software systems in image analysis. When using image analysis, one may select certain parameters to screen out unwanted artifacts or particle populations (circularity, aspect ratio, and others) and then begin studying the selected population set (see *Optical Microscopy* ⟨776⟩, ⟨788⟩, ⟨789⟩, and ⟨1788⟩).

ADVANTAGES

- Direct observation of particles in product fluid and filter capture
- Visualization, counting, sizing, and morphological characterization of particles are readily obtained
- Direct observation of particle may provide immediate recognition and identification
- Can be coupled with spectroscopic analyses (infrared, Raman) to identify chemical composition
- Particle identification can be enhanced via image database search and comparison
- Only small sample volume is needed for direct observation
- Membrane filtration is secondary to the ⟨788⟩ LO method.

LIMITATIONS

- Time consuming
- Low sample throughput
- Limited depth of field at high magnification can affect sizing accuracy
- Only a small sample volume is analyzed, so sampling must be done carefully
- For filter-captured samples, protein particles can pass through membranes and may present as amorphous background

- For filter-captured samples, potential exists for sample preparation artifacts
- Difficult to visualize particles with low optical contrast; must use phase, differential interference contrast microscopy, polarized light microscopy, and other methods
- Destructive, i.e., sample cannot be reused for filter-captured samples.

## Flow Imaging Analysis [working range 0.7–100 µm (size) and 4–100 µm (morphology)]

### PRINCIPLE OF OPERATION

This method captures digital images of materials within a flowing sample stream and uses post-collection analyses of the stored images. As in optical microscopy, which is essentially a static image analysis system, dynamic image analysis or flow microscopy captures multiple separate images, in this case using a dynamic, flowing system. Dynamic image analysis uses the components of illumination, objective lens, and focusing lens of a microscope, and adds a closed fluid pathway within a defined dimensional flow cell, plus camera and processor for acquisition and analysis. Thus, the method provides in situ conditions with realistic views of the particles. Visualization of the particles of gas, liquid, semisolids, or solids with this technique aids the interpretation of other in-suspension measurements that cannot visualize the particles being studied. The particles are moving and are likely tumbling, and this must be accounted for in the system design or data consideration. Increasing the system magnification and pixel resolution and reducing the flow cell depth will augment the quality of the captured image. An additional advantage of dynamic flow microscopy is the ability to apply size and feature analyses to the particle image. Also, any number of additional algorithms may be applied to study the collected image set as necessary. Particle image clarity, contrast, and shape may indicate possible source or type of particle, and with sufficient comparator data, mathematical filters can be applied to analyze and quantify different populations in a sample. This approach has been used to help distinguish silicone oil from protein aggregates.

### ADVANTAGES

- Direct observation of particles in product fluid (in situ)
- Analysis of captured digital images allows visualization, counting, sizing, and characterization of particles
- Retained images may be further analyzed by different algorithms
- Actual particle images facilitate understanding of contamination sources and product nature
- Compared to LO or membrane microscopy (MM), increased sample volume and reduced analysis time
- Morphology and relative refractive index of particles apparent, easily calibrated
- Technique can be used with image databases to identify some particles
- High repeatability, high resolution, and good selectivity
- Medium-to-high sample throughput.

### LIMITATIONS

- Minimum particle size necessary
- Results dependent on algorithm used to select, classify, and size particles
- Difficult to visualize and appropriately quantify number and size of particles with low optical contrast, such as translucent proteins
- Dilution of sample may be required and may change sample properties
- Destructive, i.e., sample cannot be reused.

## Electron Microscopy (working range Angstroms to mm)

### PRINCIPLE OF OPERATION

In EM, a beam of electrons is used to illuminate the samples and produce a magnified image. The practical spatial resolution limit of EM for biological samples is approximately 1 nm, which greatly exceeds resolution requirements for typical >0.1-µm particles in protein solutions. For EM analysis, subvisible particles should be either individually isolated or captured on a suitable filter and then mounted onto special grids or stabs for observation in the microscope. Traditional EM operates in high vacuum (about $10^{-6}$ Torr). Sample drying and coating is a required preparation step. Newer technologies allow examination of uncoated, as-is samples (environmental or wet EM). Detection techniques are divided as follows: (a) scanning electron microscopy (SEM), which may use secondary electron or back-scattering signals; (b) transmission electron microscopy (TEM), which visualizes electrons penetrated through sample; and (c) scanning tunneling electron microscopy (STEM), which combine SEM and TEM principles (see also *Scanning Electron Microscopy* ⟨1181⟩).

### ADVANTAGES

- Visualization, counting, sizing, and morphological characterization of particles are readily obtained
- Direct observation of particle may provide immediate recognition and identification
- High repeatability, high resolution, and good selectivity
- Information about chemical composition of object can be obtained using energy-dispersive spectroscopy (EDS) or electron energy loss spectroscopy (EELS) (see below)

@2024 USPC

- Enhanced depth of field compared with photon methods
- Image analysis and building permits quasi-3D imaging of particles.

LIMITATIONS

- Time-consuming preparation and analysis
- Low sample throughput
- Possible changes in structure and size may arise from sample preparation and high-vacuum operation
- Specialized sample preparation requirements may exist, depending on the nature of the sample
- Contrast staining with heavy metals salts may be required for enhancing protein samples
- Protein particles are flexible and can pass through membranes
- Destructive, i.e., sample cannot be reused.

## CHARACTERIZATION

Characterization of the protein active ingredient includes not only size distribution assessment but also determination of the chemical nature of the primary protein as well as conformation, aggregation, and self-associated species (see *Table 1*). The size of the fundamental particle–aggregate is important; however, the nature of the solids and the association with other species are similarly important.

### Fourier-Transform Infrared (FTIR) Microspectroscopy (working range 10 µm to 1 mm or greater)

PRINCIPLE OF OPERATION

When light interacts with a substance, the light can be reflected, absorbed, or scattered. Infrared spectroscopy determines the vibrational properties of matter, typically in the 200–4000 $cm^{-1}$ range, by analyzing the interaction with light while detecting the absorption of photons. In addition, the use of microscopy-based instruments, thus microspectroscopy, allows selection of individual particles or domains of interest, with the benefit of filters and polarizers for microscopes and the ability to capture an image, along with vibrational or other imaging data. Vibrational spectroscopy techniques are particularly useful for analysis of particles in protein solutions.

Particles can be isolated individually or captured on a membrane filter and then analyzed using FTIR microscopy. Because the infrared signal from water interferes strongly with protein bands, these samples usually require thorough drying before analysis. Typically, FTIR microscopes can operate in either image mode or spot mode. In image mode, the infrared signals are collected from individual pixels in the pre-defined area. However, spot mode usually provides higher signal-to-noise ratio, because the combined infrared signal is collected from the area defined by the aperture size. Many organic compounds have unique infrared signatures. Spectra collected for an individual particle can be analyzed by performing an infrared spectra library search or by comparing the particle's spectra results with those of suspected materials.

ADVANTAGES

- Microspectroscopy has the same sample advantages as LM
- FT instruments excel compared with dispersive spectrometers (grating monochromator) for particle analysis
- Provides rapid chemical identification and classification of particles, manually or automatically, in comparison with spectral databases
- Identification, structure, and composition can be derived from spectral data
- Provides some information on protein structure
- Nondestructive; samples can be reused.

LIMITATIONS

- May have the same limitations as LM
- FTIR provides strong absorption for common materials, such as silicones, water, and glass, which may interfere with or hinder sample analysis
- Identification depends on availability of information on possible components in spectral libraries
- Particle size limit is dependent on instrument resolution (~10 µm for FTIR)
- Process of particle identification becomes time consuming, if not available in a database
- FTIR is not sensitive to many inorganic materials or other molecules that do not possess a dipole moment
- Certain detectors are not sensitive to inorganic materials.

### Dispersive-Raman Microspectroscopy (working range 0.5 µm and greater)

PRINCIPLE OF OPERATION

As with infrared spectroscopy, Raman spectroscopy is the study of how light interacts with a substance. A defined, monochromatic photon source (laser) is focused on the sample, thereby producing reflectance, absorption, and scatter, probing

@2024 USPC

the same vibrational states probed by infrared microspectroscopy. Specifically, Raman spectroscopy is the study of the inelastically scattered photons (Raman scattering). Photons are also scattered elastically (Rayleigh scattered) with no change in wavelength, but are of use only to mark the laser excitation energy. A virtual excitation state is attained, which then relaxes to a base vibrational or rotational state, emitting energy characteristic of a functional group such as molecular and related atoms. Lower (Stokes) and higher (anti-Stokes) shifts are recorded due to interaction with the electron cloud of the functional group bonds. Lasers are used because only a very small proportion of Raman-scattered photons (only about 1 in $10^6$–$10^8$) exhibit wavelength shift. Raman microspectroscopy combines a light microscope with a coincident laser and white light pathway. The microscope, with the benefit of filters and polarizers, aids in selection of individual particles or domains of interest to allow capturing of an image, along with vibrational spectra.

Fourier-Transform Raman is generally complementary to dispersive Raman, and in using longer wavelength excitation yields little sample fluorescence. One important advantage of Raman microscopy compared with infrared is the ability to analyze aqueous samples directly, often in glass sample holders. Individual particles can be analyzed in situ, and in some cases directly in the container, if it does not interfere with the Raman signal. Similar to the infrared analysis, unknown spectra can be analyzed either by a spectral library search or by matching the spectra of individual reference compounds.

Raman spectroscopy theory and techniques are further described in *Raman Spectroscopy—Theory and Practice* ⟨1858⟩.

#### ADVANTAGES

- Same sample advantages as LM
- Dispersive instruments excel over Fourier-Transform spectrometers for particle analysis
- Rapid chemical identification and classification of particles, manually or automatically by comparison with spectral databases
- Identification, structure, and composition can be derived from spectral data
- Provides some information on protein structure
- Good lower size limit; instrument resolution is ~0.5 µm for dispersive-Raman technique
- Raman analysis viable for many organic and most inorganic compounds
- Identification uses Raman shift data, known for molecular categories and functional groups
- Nondestructive; samples can be reused
- Glass and plastic packaging have weak Raman spectra, thus interference from packaging is minimized.

#### LIMITATIONS

- Same limitations as with LM
- Specimen fluorescence may hinder data collection
- With sensitive samples, there can be laser-induced changes (heat, light)
- Many organic species yield no Raman shift; that is, there is no molecular polarization
- Identification may depend on the information available in proprietary and public spectral libraries.

### Electron Microscopy (EM) with Energy-Dispersive X-Ray Spectrometry (EDS or EDX) (working range for qualitative analysis, 0.1- to 3-µm particles; for semiquantitative analysis, >3-µm particles)

#### PRINCIPLE OF OPERATION

Energy-dispersive X-ray spectrometry (EDS or EDX) is based on characteristic X-ray photon emission generated from a specimen through interaction with a high-energy source, such as an electron beam. Typically, an elemental intensity is plotted against X-ray emission energy, which correlates with the content of atomic valence shell transition energies. Current instrument technology uses thin-window and windowless detectors positioned near the sample in EM systems, which improves detection and signal-to-noise ratio for all elements, especially lighter elements, e.g., $Z < 11$ (sodium). Immediate, qualitative elemental composition is attained for solid specimens (see also ⟨1181⟩ for general EM and related EDS background information).

#### ADVANTAGES

- Complementary to EM and available for most commercial electron microscopes
- Determines elemental composition of the sample
  - Rapid qualitative collection for small particles
  - Semiquantitative analysis (1% LDL and ±20% RSD) possible in controlled experiments
- Most useful during survey investigation of particle origin
- Involves manual elemental screening and/or search of databases
- Elemental mapping can assist in protein particle visualization.

#### LIMITATIONS

- Not all instruments are equipped for determination of light elements (e.g., $Z < 11$)

Official

https://pharmacopeia.cn/

- Quantitative analysis entails measuring line intensities for each element in the sample and for the same elements in calibration standards of known composition
- Strong background may be contributed by filter membrane material and sample coating.

## Electron Microscopy (EM) with Electron Energy Loss Spectroscopy (EELS) (working range 0.5 µm to 1 mm)

OPERATION PRINCIPLE

Electron energy loss spectroscopy (EELS) measures the vibrational motion of atoms and molecules on and near the surface by analyzing the energy spectrum of low-energy electrons back-scattered from it.

ADVANTAGES

- Used in conjunction with transmission electron microscopy
- Determines elemental composition of the sample, especially light elements (e.g., $Z < 11$)
- Can provide information about chemical bonding
- Qualitative and quantitative analyses are possible
- Has lower detection limits than in EDS.

LIMITATIONS

- Difficult to interpret
- Strong background
- Quantitative analysis entails measuring line intensities for each element in the sample and for the same elements in calibration standards of known composition.

## Time-of-Flight Secondary Ion Mass Spectrometer (TOF-SIMS) (working range µm to near mm)

OPERATION PRINCIPLE

Time-of-Flight Secondary Ion Mass Spectrometer (TOF-SIMS) is a surface-sensitive analytical method that uses a pulsed ion beam [microfocused cesium (Cs) or gallium (Ga)] to remove molecules from the very outermost surface of the sample. The particles are removed from atomic monolayers on the surface (secondary ions). These particles are then accelerated into a "flight tube", and their mass is determined by measuring the exact time at which they reach the detector (i.e., time-of-flight).

ADVANTAGES

- Surveys of all masses on material surfaces; these may include single ions (positive or negative), individual isotopes, and molecular compounds
- Elemental and chemical mapping on a submicron scale
- High mass resolution, to distinguish species of similar nominal mass
- High sensitivity for trace elements or compounds, on the order of ppm to ppb for most species
- Surface analysis of insulating and conducting samples
- Depth profiling (in the near surface environment, on the order of individual atomic layers to 10 s of nanometers)
- Nondestructive analysis
- Retrospective analysis, for post-data acquisition analysis and interpretation of stored images and spectra

LIMITATIONS

- Generally does not produce quantitative analyses (semi-quantitative at best)
- Optical capabilities typically limited, making it difficult to find grains or specific regions of interest for analysis
- Charging may be a problem in some samples, although charge compensation routines are generally sufficient to overcome these problems
- There is commonly an image shift when changing from positive to negative ion data collection mode, making it difficult to collect positive and negative ion data on exactly the same spot.

## Staining Assay (working range 0.3 µm to 1 mm)

OPERATION PRINCIPLE

Staining methods utilize reagents to provide specific reactions, such as visible staining or fluorescence, which provide qualitative confirmation of an unknown materials category or identity. Generally conducted via microscopical methods; microscopy advantages and limitations apply.

Official

https://pharmacopeia.cn/

ADVANTAGES

- Direct observation of staining effects upon particles in product fluid and by filter capture
- Visualization, counting, sizing, and morphological characterization of particles are readily obtained
- Direct observation of particle may provide immediate recognition and identification
- Can be coupled with spectroscopic analyses (infrared, Raman) to identify chemical composition
- Surface analysis of insulating and conducting samples
- Particle identification can be enhanced via image database search and comparison
- Only small sample volume is needed for direct observation

LIMITATIONS

- Low sample throughput
- Limited depth of field at high magnification
- Only a small sample volume is analyzed, so sampling must be done carefully
- For filter-captured samples, protein particles can pass through membranes and may present as amorphous background
- For filter-captured samples, potential exists for sample preparation artifacts
- Difficult to visualize particles with low optical contrast; must use phase, differential interference contract microscopy, polarized light microscopy, and other methods
- Destructive; that is, sample cannot be reused for filter-captured samples

## STRATEGY

Particles in therapeutic protein products generally have continuous size distributions with exponentially higher numbers of the smaller (<10 µm) particles. Information generated from analysis of inherent protein particles can be used for guiding development efforts and to facilitate communication and understanding of this important quality attribute of therapeutic protein products. A rational strategy should be developed for characterizing protein aggregates or particles. The categories in *Table 1* provide a guideline for differences observed between types of protein aggregates, recognizing that size distribution analysis of these species is important, but it is not the only informative characteristic. Describing the characteristics of the protein aggregates in the manner shown in *Table 1* can help define the population and/or characteristics that may be the most important for assessment of the effect on product quality.

To obtain a comprehensive characterization of the particle distribution, a variety of analytical techniques must be applied. There are a number of techniques available to measure and characterize particles, each with its advantages and limitations. Multiple methods are needed because they differ in their ability to analyze specific attributes of the particle. By using orthogonal methods, one can better ascertain the nature of the particles (extrinsic, intrinsic, or inherent), the size distribution, and other aspects that may allow differentiation between particles. Information about the particle characteristics can be used to perform a risk assessment around the presence of aggregates and to help identify potential mechanisms of formation. This knowledge about the particles' characteristics can also be used during formulation and process development to inform choices of the formulation and process steps, which can help in reducing the overall particle content of the drug product.

A comprehensive strategy for assessing subvisible particles involves multiple phases from development through commercialization and during marketing. Particle measurement/characterization may begin as early as candidate selection, with the use of high-throughput techniques to predict particulate-forming tendencies of the molecules under consideration. This involves using small amounts of material and providing a relative ranking of aggregation propensity.

### Early Development

At this stage, the focus is on understanding the typical particle profile for the product, including the size distribution and the characteristics of the aggregates most commonly seen in the drug product. The particle size and count in the 1- to 100-µm range should be monitored at the time of manufacture and during stability.

### Late Development

At this stage, the focus is on understanding the drug product and comparability between lots, as well as the linkage between particle size analysis and formulation, manufacturing, and use. Particle size and count in the 1- to 100-µm range should be monitored in clinical batches. Enhanced characterization of aggregates and particles, including pivotal product batches, should be performed. Quantitative and qualitative data about the subvisible particles formed under storage, use, and stress conditions should be collected, and risk mitigation strategies created. When the final method for monitoring the product's particle size and count is chosen, control strategies for inherent and intrinsic particles should be established. The overall control strategy developed may include action limits beyond which an investigation may be warranted.

### Marketing

At this stage, one should collect data over commercial batches to align with the overall control strategy, which may include the sub-10-µm (1- to 10-µm) range. Use quantitative as well as qualitative analysis during the management changes for the

@2024 USPC

post-marketing life cycle. When an investigation occurs, the knowledge obtained during development can be used to design mitigation strategies. Stability studies are also part of life cycle management, and are addressed later in the *Application* section.

### Overall Perspective

In-depth characterization of aggregates during development, coupled with correlation of results from these tests to those used for product release (such as LO), may provide the basis for a rational, overall control strategy. Aggregates are usually present in a continuum of size from oligomers to particles that are hundreds of micrometers. If a correlation (or mathematical relationship) can be demonstrated in the counts of particles from oligomers through the >25-µm sizes assessed as part of the compendial method, it might be possible to rely on the LO determination of the >10- and >25-µm particle content to reveal the effect of changes and trends in manufacturing on 1- to 10-µm particles. In this situation, the overall control strategy would be used to establish action limits for particles >10 µm, which when exceeded would trigger an investigation, including the characterization methods discussed in this chapter.

## SAMPLE CONSIDERATIONS

Certain aspects of sample handling and volume require special consideration. Handling and degassing procedures need to be developed and applied to avoid artifacts such as false positives attributable to bubbles, or aggregates generated during the sample preparation steps. Under certain circumstances, dilution of samples may be necessary to obtain reliable results. Aspects of sample handling are described in ⟨787⟩.

## APPLICATION

A key focus during development of a protein drug product is to gain knowledge about the nature, source, and number of inherent particles/aggregates present in the therapeutic formula, as well as their stability and overall effects on product quality, safety, and efficacy.

Protein aggregates in the 1- to 10-µm size range may also carry a risk of potentiating immunogenicity against the therapeutic activity (*4,5*). From a product-development perspective, changes in the concentrations of proteinaceous subvisible particles, particularly in the 1- to 10-µm range, can be an early and sensitive indicator of potential issues with product stability (*6,7*). Apart from stability, particles in these size ranges should also be measured as part of the risk assessment exercise to improve understanding of how various stressors and conditions of use affect the product. These conditions could include thermal, freeze/thaw, light, transport, dilution/admixture, and use characteristics. Particle counts in the 1- to 10-µm range tend to be significantly (orders of magnitude) greater than those in the ≥10-µm range. This makes the 1- to 10-µm range useful for the purpose described above, because changes can be easier to observe. However, the counts also tend to be quite variable, and thus the ability to discern trends requires proper controls, adequate sampling, and good technique.

Detailed characterization of subvisible particles, especially inherent particles, provides information that can support the formulation and product development program, leading to a robust process and commercial control strategy. On the other hand, although characterization alone may not reveal possible correlations between an immune response and aggregates/particles, the use of multiple methods applied to multiple drug product lots helps inform the definition of product quality, which can be linked to safety and efficacy data obtained from clinical trials. This knowledge is also useful in life cycle management, such as movement of product between manufacturing sites, changes in presentation (liquid to lyophilized; vial to prefilled syringe), and changes in strength.

To illustrate these points, two examples are presented below; they show ways that complementary techniques can be used to gain product knowledge.

### Example 1: Comparison of Drug Product Configurations

Not all drug products are formulated as liquids. In one case of a lyophilized drug product filled in glass vials, a liquid formulation in a prefilled syringe configuration was developed to facilitate patient administration. A comparison of subvisible particle counts by LO was expected to show that the particle count of the reconstituted lyophilized formulation was higher than in the liquid formulation, but the opposite results were observed, with the liquid formulation containing significantly higher levels of particles >2 µm [~130,000 particles per container (ppc) compared to ~30,000 ppc]. These samples were then assessed by the MM method, and the results were more consistent with the expected outcome: for particle sizes >5 µm, the lyophilized formulation contained ~70 ppc compared to ~14 ppc for the liquid formulation. Analysis was then performed using flow microscopy to understand the discrepancy in results between the MM and LO methods. Flow microscopy supported the LO results, with the liquid formulation showing higher numbers of particles >2 µm (~600,000 ppc) compared to the lyophilized formulation (~150,000 ppc). Examination of the structure of the particles revealed a different morphology in the liquid formulation, with a predominant number of the particles exhibiting a spherical shape, consistent with the presence of silicone oil droplets from the prefilled syringe container. These results were confirmed by testing a sample of the liquid formulation that had not been exposed to the prefilled syringe (the source of the silicone oil), which showed <20,000 ppc. Once the silicone oil droplets were accounted for, the number of remaining particles in the liquid formulation in the prefilled syringe was lower than in the lyophilized formulation, consistent with the MM results.

## Example 2: Selection of Filling Technology

Filling processes can affect product quality by introducing physical stresses such as adsorption, shear, friction, and cavitation, which may lead to protein aggregation. Certain drug product filling pumps may shed extrinsic particles that can lead to heterogeneous nucleation-induced aggregation.

The effect of using a stainless steel displacement piston pump on the subvisible particulate content of solutions was investigated using multiple techniques to analyze the particulates in solution (*8*). Coulter counter analysis of a buffer solution passed through the pump revealed that the pump shed particles in solution, with the pumped solution containing >13,000 particles per mL in the 1.5- to 6-µm range. Elemental analysis confirmed that the particles were stainless steel. Analysis of the particle size distribution in this solution, performed using a laser diffraction particle sizer, showed that most of the particles were between 0.25 and 0.95 µm. Incubation of stainless steel nanoparticles with a solution of MAb-Y led to increases in both the number of particles and the particle size distribution over time. Characterization of the particles by FTIR spectroscopy showed that the protein adsorbed onto the metal particles contained a slightly perturbed secondary structure compared to the protein in solution. It was concluded that the metal particles served as nucleation sites for protein aggregation. In this case, selection of a different type of filler may be warranted to mitigate protein aggregation.

A comparison of the effect of different pump types on subvisible particulate formation in a solution of MAb-Z was performed (*9*). Flow microscopy showed that piston pumps, made of either stainless steel or ceramic, produced particles in the size range of 1–100 µm at levels approximately 100-fold higher than the control samples. Examination of the microscopic images of these particles revealed that the particles were translucent, suggesting they were protein based. Incubation of the protein solution with shed particles from the piston pumps did not lead to a significant increase in either the particle size distribution or particle counts for these solutions, indicating that extrinsic particles did not serve as nucleation sites for the protein. In this case, the formation of particles in the solution was considered to be from shear stress caused during the pumping operation. These results were supported by examination of other filler types (peristaltic, time-pressure, and rolling diaphragm), which produced solutions with significantly lower particle load.

## SUMMARY

This chapter provides strategies for describing, characterizing, and identifying the particle content in therapeutic protein injections, including extrinsic and intrinsic particle population. Information regarding specific methods that can be used for these purposes, as well as their advantages and limitations, is discussed. A rational, comprehensive control strategy can be developed on the basis of an in-depth characterization of aggregates during development, coupled with correlation of results from these tests to those used for release. Aggregates are usually present in a continuum of sizes, from oligomers to particles that are hundreds of micrometers. Correlation in the counts of particles from oligomers through the >25-µm size, assessed as part of the compendial method, may make it possible to rely on the LO determination alone to reveal changes and trends in manufacturing. In this situation, the overall control strategy would be used to establish action limits for particles >10 µm, which when exceeded would trigger an investigation, including the characterization methods discussed in this chapter.

## 1. INTRODUCTION

Light obscuration (LO) is useful for an approximate particle range from 1 to 300 μm, depending on the instrument and configuration (see *Measurement of Subvisible Particulate Matter in Therapeutic Protein Injections* ⟨1787⟩ and *Methods for the Determination of Subvisible Particulate Matter* ⟨1788⟩). Certain solution formulations may not be easily analyzed by LO. The LO method may encounter problems with products that do not have the clarity and viscosity approximating that of water. Further, formulation characteristics such as color and high viscosity, or inherent formulation properties such as shear-induced changes, may generate erroneous LO data. Similarly, products that produce air or gas bubbles when drawn into the LO sensor, such as bicarbonate-buffered formulations, may generate erroneous data. For these product types, the membrane microscope (MM) method may be more appropriate.

LO is based on light blockage/light extinction on a photodiode detector induced by particles passing a flow cell illuminated by a laser beam. The degree of obscuration is converted into electronic pulses, which can be related back to the equivalent circular diameter of the particles, based on a calibration curve generated with polystyrene standard beads. Because of the nature of the detection and counting system, air bubbles and immiscible liquids may block sufficient light to be recorded along with the target suspended particles. These artifacts must be diminished through proper preparation techniques. Solutions with excessive immiscible liquids may not be amenable to LO analysis. A variety of suitable devices of this type are commercially available. It is the responsibility of those performing the test to ensure that the operating parameters of the instrumentation are appropriate for the required accuracy and precision of the test results, and that the artifacts and interferences inherent in certain products and with certain methods of preparation are eliminated or accommodated.

## 2. PRINCIPLES OF OPERATION

The apparatus is a liquid-borne particle counting system that uses a LO sensor with a suitable sample-feeding device to deliver controlled aliquots of sample for analysis. Suspended particles in the sample fluid flow between a light source and sensor to obscure the transmitted light by either scattering or absorbing light. The corresponding signal reduction correlates to the area of each particle. In other words, larger particles cause a larger reduction in transmitted light, and the extent of the reduction represents the projected area of the particle passing through. LO instruments report the equivalent circular diameter of a polystyrene (PS) microsphere that attenuates the light beam by the same magnitude as the particle in the test sample. Because of the nature of the detection and counting system, air bubbles and immiscible liquids may diffract or block sufficient light and be recorded as particles. These artifacts must be diminished through proper sample preparation. Solutions with excessive immiscible liquids may not be amenable to LO analysis.

LO instruments detect, size, and count particles that are opaque or have a refractive index that is significantly different from the surrounding liquid. This includes not only ordinary (extrinsic) dirt particles but also gels, immiscible liquid droplets such as silicone oil droplets, air bubbles, and refractive index anomalies such as Schlieren effects. Semitransparent particles allow some laser light to pass through the particle, potentially resulting in the assignment of a smaller than actual size. All of the considerations for quantification, calibration, etc., discussed in ⟨1788⟩, *Verification of Compendial Procedures* ⟨1226⟩, *Particulate Matter in Injections* ⟨788⟩, *Subvisible Particulate Matter in Therapeutic Protein Injections* ⟨787⟩, and ⟨1787⟩ apply here. When performing the LO test on new drug products that have not been tested using this method, orthogonal methods should be

@2024 USPC

considered as well. Ideally, subvisible particle analysis should be included during product development such that product history can be used to inform analysis and data interpretation or the product's release and commercial use.

A variety of suitable LO devices are commercially available. It is the responsibility of those performing the test to ensure that 1) the operating parameters of the instrumentation are appropriate to the required accuracy and precision of the test result and 2) the artifacts and interferences inherent in certain products and with certain methods of preparation are eliminated or accommodated. Because LO does not distinguish between air bubbles and particles, sample handling is critical (see ⟨1788⟩ and ⟨1787⟩). Adequate training must be provided for individuals responsible for the technical performance of the test.

It is important to note that for pharmacopeial applications, the ultimate goal is that the particle counter can reproducibly size and count particles present in the material under investigation. The instruments available range from those systems where calibration and other components of standardization must be carried out by manual procedures to more sophisticated systems that incorporate hardware- and software-based functions for the standardization procedures. Thus, it is not possible to specify exact methods to be followed for standardization of the instrument, and it is necessary to emphasize the required result of a standardization procedure rather than a specific method for obtaining this result. This section is intended to emphasize the criteria that must be met by a system rather than specific methods to be used. It is the responsibility of the user to apply the various methods of standardization applicable to a specific instrument. Critical operational criteria include the following two considerations.

### 2.1 Sensor Concentration Limits

Use an instrument that has a concentration limit (the maximum number of particles per milliliter) identified by the manufacturer that is greater than the concentration of particles in the test specimen to be counted. The vendor-certified concentration limit for a sensor is specified as the count level at which the coincidence error caused by the simultaneous presence of two or more particles in the sensor view volume comprises less than 10% of the counts collected for 10-µm particles. The coincidence error at sizes below 10 µm also should be known or evaluated.

### 2.2 Sensor Dynamic Range

The dynamic range of the instrument used (range of sizes of particles that can be accurately sized and counted) must include the smallest particle size to be enumerated in the products.

## 3. INSTRUMENT STANDARDIZATION TESTS

Because different brands of instruments may be used in the test, the user is responsible for ensuring that the counter used is always operated according to the manufacturer's specific instructions. For LO, the instrument standardization tests described in this section are consistent with installation qualification (IQ) and operational qualification (OQ) principles described in *Analytical Instrument Qualification* ⟨1058⟩.

The following discussion of instrument standardization emphasizes performance criteria rather than specific methods for calibrating or standardizing a given instrument system. A wide variety of approaches can be taken to achieve this, and the underlying principle and final results should be the focus. Appropriate instrument standardization (calibration and routine qualification) is essential to performance of the test according to requirements.

The following information for instrument calibration helps ensure that the sample volume accuracy, sample flow rate, particle size response curve, sensor resolution, and count accuracy are appropriate to the performance of the test. Routine performance qualification should be carried out prior to use of the instrument or with sufficient frequency to verify that the instrument provides accurate and consistent results within the manufacturer's specifications and for the intended use. The following sections focus on the instruments most commonly in use. For those older instruments without built-in routines to define particle size directly or those that do not incorporate computer-based software routines, see *Appendix*.

### 3.1 Sample Volume Accuracy

Because the particle count from a sample aliquot varies directly with the volume of fluid sampled, it is important that the sampling accuracy is known to be within a certain range. To accomplish this, transfer a volume of particle-free water that is greater than the sample volume to a container and weigh the container. Using the sample feeding device, withdraw a volume that is appropriate for the specific sampler and equal to the volume to be run during testing, and again weigh the container. Determine the sample volume by subtracting the tare volume from the combined sample plus tare volumes. Verify that the value obtained for the sample volume is within 5% of the appropriate sample volume for the test. Alternatively, the sample volume may be determined using a suitable Class A graduated cylinder (see *Volumetric Apparatus* ⟨31⟩). [NOTE—Instruments of this type require a variable tare volume. This is the amount of sample withdrawn before counting. This volume may be determined for syringe-operated samplers by setting the sample volume to zero and initiating sampling so that the only volume of solution drawn is the tare. Subtract the tare volume from the total volume of solution drawn in the sampling cycle to determine the sample volume.]

The choice of syringe has a significant effect on both the volume accuracy required to provide small volumes, as noted in ⟨787⟩, and the associated flow rate required.

### 3.2 Sample Flow Rate

Verify that the flow rate is within the manufacturer's specifications for the sensor used. This can be accomplished by using a calibrated stopwatch to measure the time required for the instrument to withdraw and count a specific sample volume (i.e.,

https://pharmacopeia.com/

the time between beginning and end of the count cycle as denoted by instrument indicator lights or other means). Sensors can be operated accurately over a range of flow rates.

## 3.3 Diameter Calibration

Refer to ⟨1788⟩ for general guidance on diameter calibration. Laser LO instruments should be calibrated using spherical PS particles with an approximate refractive index of 1.59. Diameter readings are sensitive to the particle refractive index in two cases: 1) particle diameters below approximately 5 µm and 2) particles of all diameters with a refractive index within approximately 0.2 of the refractive index of the liquid. In these cases, instrument calibration ensures that the LO instrument is functioning properly and gives reproducible results, but it does not ensure that the reported diameters match the actual physical size of the test particles. Prior to conducting the calibration procedure, it is recommended that a system suitability test be performed to determine the "as found" performance of the instrument.

Two options for conducting diameter calibration are the automated method and the electronic method. With the automated method, the calibration (size response) curve can be determined for the instrument–sensor system using validated software routines offered by instrument vendors. These routines may be included as part of the instrument software or may be used in conjunction with a microcomputer interfaced with the counter. The use of these automated methods is appropriate if the vendor supplies written certification that the software provides a response curve equivalent to that attained by the manual half-count method or the electronic method and if the automated calibration is validated as necessary by the user.

The electronic method uses a multichannel peak height analyzer to determine the center channel of the particle counter pulse response for each standard suspension. This peak voltage setting becomes the threshold used for calculation of the voltage response curve for the instrument. The standard suspensions used for the calibration are run in order, and median pulse voltages for each are determined. These thresholds are used to generate the size response curve manually or via software routines. The thresholds determined from the multichannel analyzer data are then transferred to the counter to complete the calibration. Instrument indications other than a direct voltage reading may be used to construct the response curve.

## 3.4 Sensor Size Resolution

The particle size resolution test determines the amount of peak broadening due to instrument response. Determine the resolution of the particle counter for 10-µm particles using the 10-µm calibrator spheres. The relative standard deviation of the size distribution of the standard particles used, as reported by the manufacturer, must be NMT 5%. Acceptable methods of determining particle size resolution are 1) an electronic method of measuring and sorting particle sensor voltage output with a multichannel analyzer or direct reporting of the particle size distribution and 2) automated methods. Refer to *Appendix* for details on the electronic method.

### AUTOMATED METHODS

Software that allows for the automated determination of sensor resolution is available for some counters. This software may be included in the instrument or used in conjunction with a microcomputer interfaced with the counter. The use of these automated methods is appropriate if the vendor supplies written certification that the software provides a resolution determination equivalent to the electronic method and if the automated resolution determination is validated as necessary by the user. LO resolution can degrade due to contaminated flow-cell walls; routine checks of resolution are useful since the flow-cell wall cannot be inspected otherwise.

Perform a system suitability test upon completion of the instrument calibration to ensure that diameters are accurately reported and that the count accuracy is verified using any of the three methods described in *7. Particle Counting Accuracy (System Suitability)*.

## 3.5 Qualification Considerations

### DIAMETER BIASED

For particles of nonspherical shape and low refractive index, the reported diameter may differ substantially from the actual diameter (*1*).

The reported diameter of a particle is affected most by the following:

- The refractive index of the particle
- The orientation of nonspherical particles
- The degree of particle elongation, especially for long fibers (*2*)

If the diameter is reported incorrectly, the particle size distribution will be affected and the particle concentration for affected size channels (bins) will be incorrect. Concentration errors are most prevalent for particles that have a low refractive index (e.g., protein aggregates).

### OPALESCENCE

Particle detection may be hindered in samples that are highly opalescent. To assess the visibility of particles, spike microspheres of known diameter and concentration into a test sample, measure the microsphere diameter and concentration, and then compare to the diameter and concentration expected. The microsphere chosen for this analysis should have a refractive index similar to that of the particles of interest in the test sample (e.g., silica microspheres could be used to mimic lower-contrast protein aggregates; polystyrene could be used to mimic higher-contrast particles).

@2024 USPC

VISCOSITY

For some samples, especially highly concentrated biologics such as antibody therapeutics, the drug product can be highly viscous. This can complicate the measurement by affecting instrument performance as well as the amount of material actually sampled and measured by the instrument. This measurement process should be tested during method development. It might be necessary to dilute the sample in order to get reliable measurements. If so, the effect of dilution on the particle distribution obtained should be determined, and appropriate procedures should be used to minimize differences due to this sample handling.

## 4. SYSTEM SUITABILITY

First, measure the particle concentration of nominally particle-free water. The measured particle concentrations obtained must in all cases be sufficiently small as to be insignificant relative to any acceptance limits for the tests to be run. The actual background level obtained will be dependent on the size range, the instrument used, and the type of samples routinely run in the instrument. Records of past blank runs are useful to document the level of performance expected of particular instruments and to identify deviations from acceptable performance (or unacceptable levels of particles in the water used).

### 4.1 Mixing

For Reference Standards, such as the USP Particle Count Set RS (used for particle count accuracy, recovery studies, or calibration), homogenization of the mixture may be attained by agitating the preparation for 20 s and sonicating for NMT 30 s. Mixing of most product samples will require different handling than that for the standard. Please note that this sample handling is not appropriate for many samples themselves, especially for the biologics.

The instrument should be checked for the correct size and concentration readings using at least one size of PS microspheres; bead sizes from 5 to 15 µm are typical for this test. Size and concentration should agree within the combined uncertainty of the manufacturer's specifications and the tolerances listed on the size and concentration standard. Bead concentration standards should have a concentration three times lower than the manufacturer's stated upper concentration limit for 10% coincidence error. Size and concentration tests may be conducted with a single bead suspension, or size and concentration may be tested independently.

If reduced particle count is observed, instrument fouling is suspected. Back-flushing the sensor to remove the clog may be helpful, followed by reconfirming the count accuracy using larger PS microspheres (e.g., 25 µm). When flushing sensors to change samples or to clean the sensor, alternate liquid and air in the fluid line to achieve the best flush of the sensor.

Refer to ⟨1788⟩, *11.1 Guidelines for the Use of Calibrator Spheres* if the instrument fails a system suitability test. If failure of the standard is ruled out, then follow the manufacturer's directions for thoroughly cleaning all fluid lines and the sensor head. The instrument is deemed suitable for use if it passes the system suitability tests after cleaning. Flush the system to remove traces of the particle standard prior to routine use.

## 5. TEST ENVIRONMENT

Refer to ⟨1788⟩, *12. Test Environment and Preparation* for general guidance.

## 6. BLANK AND SAMPLE HANDLING

Refer to ⟨1788⟩, *12. Test Environment and Preparation* for general guidance.

## 7. PARTICLE COUNTING ACCURACY (SYSTEM SUITABILITY)

Determine the particle counting accuracy of the instrument using *Method 1* [for sensors requiring the moving window half-count (MWHC) method for calibration], *Method 2* (for multichannel sensors), or *Method 3* for any instrument (manual comparison to MM method). Prepare the standard as described in *6. Blank and Sample Handling*, including continuous stirring throughout the analysis. Perform five counts on 5-mL volumes of the suspension using the particle counter's 10-µm size threshold. Obtain the mean cumulative particle count per milliliter.

Note that the three methods in this section verify particle counts. Only *Method 1* verifies particle size as well as the count for MWHC instruments. *Method 2* and *Method 3* verify counts (>10 µm) but not size for instruments with fewer than 15 size channels, which means the instrument size accuracy can be off by more than 10% and still provide the correct counts (>10 µm) when using these two methods. Automated instruments with 512 or more size-channels (bins) and validated software routines provide accurate mean size and concentration for each standard peak as well as other statistical parameters for each peak. The user needs to understand the limits and capabilities of the instrument being used and proceed accordingly.

### 7.1 Method 1 (Manual Method for MWHC Instruments)

## 7.2 Method 2 (Multichannel Instruments)

PROCEDURE

Use one of three standards: 1) USP Particle Count Set RS (a dilution may be used if deemed necessary); 2) a commercial preparation of standard calibrator spheres with a nominal diameter of 10–30 µm, certified by the manufacturer; or 3) a laboratory-prepared suspension of standard calibrator spheres with a nominal diameter of 10–30 µm. The use of non-*USP* standards for options 2 or 3 is acceptable when they are compliant with *USP* standardization criteria: five successive counts are NMT ±10% of the stated count.

Stir continuously throughout the analysis and perform five counts on 5-mL volumes of the suspension using the particle counter's 10-µm size threshold. Stirring should be sufficiently thorough that the set of five counts does not show an obvious trend. Obtain the mean cumulative particle count per milliliter. Note that multichannel instruments provide a mean size and other statistical information as well as the particle counts within the size range selected by the user, i.e., the region that contains the peak.

INTERPRETATION

The instrument meets the requirements for *7. Particle Counting Accuracy (System Suitability)* if the count obtained at ≥10 µm conforms to the values obtained for the USP Particle Count Set RS, or the expected particle number if other acceptable standards were used. If the instrument does not meet the requirements, repeat the procedure. If the results of the second test are within the limits given above, the instrument meets the requirements of the test for *7. Particle Counting Accuracy (System Suitability)*. If the system does not meet the requirements of the test on the second attempt, identify and correct the source of the failures and retest the instrument.

## 7.3 Method 3 (Alternate Manual Method)

PROCEDURE

Prepare a suspension of standard calibrator spheres with a nominal diameter of 10–30 µm that contains 50–200 particles/mL, and determine the particle concentration as described in *Membrane Microscope Method for the Determination of Subvisible Particulate Matter* ⟨1788.2⟩. Stir continuously throughout the analysis and perform five counts on 5-mL volumes of the suspension using the particle counter's 10-µm size threshold. Stirring should be sufficiently thorough that the set of five counts does not show an obvious trend. Obtain the mean cumulative particle count per milliliter. This mean count should be within 20% of the count per milliliter for the suspension.

# APPENDIX

## Instrument Standardization Tests

These sections describe the development and use of methods to accommodate the few remaining older LO instruments still in use and for instrument manufacturers to refer to for development and verification of automated methods. In modern instruments, these methods or their equivalents have been incorporated into instrument software, and users will generally not need to execute the tests as described below.

## Diameter Calibration Methods

MANUAL METHOD FOR DEVELOPING THE CALIBRATION CURVE

In this method, the diameter indications of an LO instrument are obtained by finding the LO instrument voltage corresponding to the midpoint of the particle size distribution (PSD) for nominally monodisperse PS spheres of known size. Refer to *3.3 Diameter Calibration*, which describes the requirements for standards to be utilized in the calibration. When using the manual method, ensure that the total number of spheres counted is within the sensor's concentration limit. Prepare suspensions of the calibrator spheres in water at a concentration of 1000–5000 particles/mL, and determine the channel setting that corresponds to the highest count setting for the sphere distribution. This is determined by using the setting for the highest count threshold to split the distribution into two bins containing equal numbers of particles, with the instrument set in the differential count mode (MWHC). Use only the central portion of the distribution in this calculation to avoid including asymmetrical portions of the peak.

The portion of the distribution that must be divided equally is the count window. The window is bound by threshold settings that will define a threshold voltage window of ±20% around the mean diameter of the test spheres. The window is intended to include all single spheres, taking into account the standard deviation of the spheres and the sensor resolution while excluding noise and aggregates of spheres. The value of 20% was chosen on the basis of the worst-case sensor resolution of 10% and the worst-case standard deviation of the spheres of 10%. Because the thresholds are proportional to the cross-sectional area of the spheres (and all particles) rather than the diameter, the lower and upper voltage settings are determined by the following equations:

@2024 USPC

$$V_L = 0.64\ V_S$$

in which $V_L$ is the lower voltage setting and $V_S$ is the voltage at the peak center, and

$$V_U = 1.44\ V_S$$

in which $V_U$ is the upper voltage setting. Once the center peak thresholds are determined, use these thresholds for the standards to create a regression of log voltage versus log particle size from which the instrument settings for the 10- and 25-µm sizes can be determined.

### SENSOR SIZE-RESOLUTION METHODS

The test for sensor size resolution calculates the standard deviation of reported sizes from the measured PSD for monodisperse PS spheres. The instrument resolution is obtained by correcting the observed standard deviation of the reported sizes for the standard deviation of the PS sphere size standard, as reported by the manufacturer.

**Manual method:** The manual method applies to instruments with size bins that have adjustable voltage thresholds. When using the manual method, adjust the particle counter to operate in the cumulative mode or total count mode. Refer to the calibration curve obtained earlier, and determine the threshold voltage for the 10-µm spheres. Adjust three channels of the counter to be used in the calibration procedure as follows:

- *Channel 1*—set for 90% of the threshold voltage
- *Channel 2*—set for 100% of the threshold voltage
- *Channel 3*—set for 110% of the threshold voltage

Draw a sample through the sensor, observing the count in *Channel 2*. When the particle count in that channel has reached approximately 1000, stop counting and observe the counts in *Channels 1* and *3*. Check to see if the *Channel 1* count and *Channel 3* count are 1.68 ± 10% and 0.32 ± 10%, respectively, of the count in *Channel 2*. If not, adjust the *Channel 1* and *Channel 3* thresholds to meet these criteria. When these criteria have been satisfied, draw a sample of suspension through the counter until the counts in *Channel 2* have reached approximately 10,000, or until an appropriate volume (e.g., 10 mL) of the sphere suspension has been counted. Verify that the *Channel 1* and *Channel 3* counts are 1.68 ± 3% and 0.32 ± 3%, respectively, of the count in *Channel 2*. Record the particle size for the thresholds just determined for *Channels 1, 2,* and *3*. Subtract the particle size for *Channel 2* from the size for *Channel 3*. Subtract the particle size for *Channel 1* from the size for *Channel 2*. The values so determined are the observed standard deviations on the positive side and negative side of the mean count for the 10-µm standard. One commonly used method for calculating the percentage resolution of the sensor is the following:

$$\% \text{ Resolution} = (100/d) \times [(s_{observed})^2 - (s_{standard})^2]^{1/2}$$

in which $d$ is the diameter of the spheres, in µm, as specified by the supplier; $s_{observed}$ is the highest observed standard deviation determined for the sphere standard; $s_{standard}$ is the supplier's reported standard deviation for the spheres. The resolution is NMT 10%.

**Electronic method:** Either record the voltage output distribution of the particle sensor using a multichannel analyzer while sampling a suspension of the 10-µm particle size standard or record the reported particle size distribution of an LO system that reports counts within adjustable diameter bins directly. (Other sizes ranging from 5 to 25 µm may be used provided the resolution is initially compared to the results for 10-µm microspheres and the subsequent measurements all use the same-size microsphere.) Particle size bins must each have a diameter range ±0.5 of the standard deviation of the main singlet bead peak, and the number of bins used for determination of the standard deviation must cover a minimum size range from ($d_{observed} - 2s_{observed}$) to ($d_{observed} + 2s_{observed}$). From the recorded particle size distribution, first identify the range of size bins that bracket the main singlet bead peak. From these identified bins, calculate the standard deviation ($s_{observed}$) of the readings:

$$s_{observed}^2 = \frac{1}{N-1} \sum_{i=1}^{M} n_i \left(d_i - d_{average}\right)^2$$

where $N$ is the total number of particulates; $M$ is the number of bins; $n_i$ is the number of particles in the $i$th bin; $d_i$ is the mean diameter of the $i$th bin; and $d_{average}$ is the average diameter of all the particles in the bins calculated as follows:

$$d_{average} = \frac{1}{N-1} \sum_{i=1}^{M} n_i d_i$$

The resolution is obtained using the formula given above for the manual method.

## Particle Count Accuracy Manual Method Test for MWHC Instruments

### OVERVIEW

The USP Particle Count Set RS contains PS spheres of approximately 15 µm in diameter. Counting with a size threshold ≥10 µm gives a measure of all the PS spheres. On setting the threshold to ≥15 µm, however, only approximately half the spheres will be counted. Comparison of the counts at these two size thresholds with values on the USP certificate provides a test of count accuracy. The test is also sensitive to size accuracy at 15 µm, since small errors in size will translate into large errors in count at the midpoint of the ▲particle size▲ (ERR 1-Oct-2021) distribution.

## PROCEDURE

Prepare the suspension and blank using the USP Particle Count Set RS. With the instrument set to count in the cumulative (total) mode, collect counts at settings of ≥10 µm and ≥15 µm. Withdraw three consecutive volumes directly from the container. Historically, these have been volumes of NLT 5 mL each, due to instrument limitations and the desire to maximize sample volume. However, where desired, volumes that meet the standardization criteria and address the sensitivities of the formulation may be utilized. Obtain the particle counts and discard the data from the first portion. Complete the procedure within 5 min. Repeat the procedure using the suspension in place of the blank. From the averages of the counts resulting from the analysis of the two portions of the suspension at ≥10 µm and from the analysis of the two portions of the blank at ≥10 µm, calculate the number of particles in each milliliter:

$$(P_S - P_B)/V$$

in which $P_S$ is the average particle count obtained from the suspension; $P_B$ is the average particle count obtained from the blank; and $V$ is the average volume, in mL, of the four portions tested. Repeat the calculations using the results obtained at the setting of NLT 15 µm.

## INTERPRETATION

The MWHC instrument meets the requirements for *7. Particle Counting Accuracy (System Suitability)* if both the count obtained at ≥10 µm and the ratio of the counts obtained at ≥10 µm to those obtained at ≥15 µm conform to the values that accompany the USP Particle Count Set RS. If the instrument does not meet the requirements for *7. Particle Counting Accuracy (System Suitability)*, and adequate test volumes remain, repeat the procedure; if insufficient volumes remain, prepare new a suspension and blank and then repeat the procedure. If the results of the second test are within the limits given above, the instrument meets the requirements of the test for *7. Particle Counting Accuracy (System Suitability)*. On the second attempt, if the system does not meet the requirements of the test, determine and correct the source of the failures and retest the instrument. When using this ratio method, it is recommended to check the instrument size accuracy at both 10 µm and 15 µm prior to measurement of the count ratio, since a size error at 15 µm can translate into a large count error.

## 1. INTRODUCTION

The membrane microscope method (MM) may be applied to samples of both large-volume and small-volume parenteral injections, as well as ophthalmic solutions. This test enumerates solid[1] particulate matter that is ≥10 µm after collecting, rinsing, and drying on a microporous membrane filter. Semisolid substances may also be isolated, although all liquid and sub-micrometer material will pass through the membrane. Because a wide range of test aliquots may be utilized, particle counts may be determined on a per-volume or a per-container basis without dilution or extrapolation.

Contrary to the light obscuration (LO) or flow imaging (FI) methods, particles are not measured using the MM method in their in-situ state. Particles are isolated from the formulation and examined on an air-dried substrate, and thus they may have changed from their wetted state in the final product. MM is not a reliable method for analyzing particles <10 µm; however, these particles can be analyzed using LO and FI. Because of their deformable shape and low contrast, protein particles can be difficult to detect or pass through the filter. For these reasons, this technology is best-suited for the analysis of foreign particles, which is useful in root cause analysis.

To perform the MM assay, the analyst estimates the size of retained materials viewed at 100× magnification, tabulating them into two (or more) size categories. In this process, materials on the membrane surface that do not appear solid may be encountered, showing little or no surface relief like a "stain" on the membrane. *Particulate Matter in Injections* ⟨788⟩ advises not to size or enumerate such semisolid particles due to comments in the past from large-volume injectable manufacturers that encountered brown stain-like residues after heat sterilization of dextrose solutions using terminal sterilization. However, if a carbohydrate solution or similar formulation is not being tested, recognizing the presence of such material may help to determine changes that would increase formulation robustness. Consistent evidence of such materials may be an indication that further product development is necessary to understand their content. The nature of these materials and the subsequent decision to count or investigate must be based upon product formulation experience. Interpretation of microscopical enumeration may be aided by testing a sample by the LO method or a validated alternative method and characterizing by Fourier transform infrared spectroscopy (FTIR) or another spectral microscopy method (see *Measurement of Subvisible Particulate Matter in Therapeutic Protein Injections* ⟨1787⟩). Information is provided in this chapter to aid the analyst in using the MM method.

## 2. TEST APPARATUS

### 2.1 Principles of Operation

Sample packages are mixed and opened, and product fluid is drained or transferred into a clean filtration barrel. Free particles from the product are captured on a membrane surface. The membrane-retained material is rinsed and dried for subsequent microscopic examination. Sizing and counting of particles is conducted at 100× using two size thresholds: ≥10 µm and ≥25 µm. Particle content is reported as the total count in each category.

[1] Soft particles and semisolid substances may also be retained.

## 2.2 Basic Configuration

Elements of the filtration and microscopic equipment are described in ⟨788⟩. Additional considerations are discussed here.

### FILTRATION APPARATUS

Use a filter funnel suitable for the volume to be tested, such as a 25-mm 50 mL or 47-mm 300 mL barrel. Larger barrels are also available. However, the barrel inner diameter will determine the final counting surface; for example, an inner diameter of about 16 mm for 25-mm membranes or about 37 mm for 47-mm membranes. The funnel may be made of plastic, glass, or stainless steel. Use a filter support made of stainless steel or sintered glass as the filtration base. The goal is a flat, dry, even-colored, and unmarked membrane background.

Cleaning and rinsing the apparatus is facilitated with a pressurized solvent dispenser capable of delivering fluids passed through a terminal membrane filter at a range of pressures from 10 to 80 psi.

### MEMBRANES

Chapter ⟨788⟩ recommends a black or dark gray membrane with a pore size of <1 µm; however, finer pore size membranes will have smoother surfaces, enhancing the resolution of particles in the microscope. Smaller pore sizes may impede the filtration of more viscous sample fluids during the assay. The black or dark gray membrane is recommended to provide good contrast for the array of particle colors, shapes, and transparencies. Other colored membrane types may be suitable depending on the product.

Alternative membrane choices may also be used to improve or alleviate incompatibility during product filtration. Product compatibility is an issue for mixed cellulose ester membranes or for the isolated materials used for further compositional analysis. Gold-coated or metallic silver filters may be used for these applications, especially spectroscopic analysis or particle type identification.

The test apparatus is described in ⟨788⟩. Additional comments are the following:

- A compound binocular microscope that corrects for changes in interpupillary distance by maintaining a constant tube length must be used.
- The objective must be of 10× nominal magnification with flatness correction and color correction, such as a planar achromat or better in quality, with a minimum 0.25 numerical aperture (NA).
- The objective must be compatible with an episcopic illuminator attachment.
- The eyepieces must be matched. In addition, one eyepiece must be designed to accept and focus an eyepiece graticule.
- The microscope must have a mechanical stage capable of holding and traversing the entire filtration area of a 25-mm or 47-mm membrane filter in order to completely scan the isolate surface.
- One episcopic and one oblique illuminator are required. Both illuminators must be of sufficient output to provide a bright and even source of illumination and may be equipped with blue daylight filters to decrease operator fatigue during use.
- The *USP* graticule as described in ⟨788⟩ is used.

### STAGE MICROMETER

Used for calibrating the microscope configuration and graduated in 10-µm increments, the stage micrometer is preferably utilized each day of use. For initial calibration, utilize a stage micrometer that is traceable to the National Institute of Standards and Technology (NIST) to verify the *USP* graticule dimension features. A commercial stage micrometer graduated in 10-µm increments to verify proper setup may be used for daily calibration/verification.

## 2.3 Instrument Dynamic Range

The following considerations apply to both human operator and machine vision. Although the instrument has a wide dynamic range and this technique may be used for visible particles at the upper end, the focus in this section is at the lower end, a subvisible range.

### SIZE ACCURACY

The microscopical assay uses 100× observation by reflected illumination in an air mount that produces optical diffraction effects, e.g., blurriness. Thus, the practical resolution at the specified size thresholds is about 1 µm. At a nominal 100× magnification, the smallest particles (10 µm) are easily discriminated from the background. Particles <10 µm can be observed via the MM method, but differentiation of particles close to the thresholds is important in the sizing process.

Because there is a diffraction limit of about 1 µm, it may be difficult to discriminate 9 µm from 10 µm or 24 µm from 25 µm due to suboptimal illumination, interfering background, particle features, et cetera. As a best practice, if there is doubt in determining whether an object is a particle, it should be counted. The operator should note the predominant particle morphologies descriptively and may perform further analysis if appropriate.

### PARTICLE CONCENTRATION

The filtration operation will capture any solid material that is suspended within the sample fluid. For a blank (e.g., filtered water), there may be several particles ≥10 µm. The particle load is typically higher for samples.

Considering the ⟨788⟩ small-volume injection limit of 3000 particles that are ≥10 µm per container, several thousand particles may be isolated from a 10-container pool. That particle load is atypical, but when encountered, must be processed. Full counting

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M12536_02_01
@2024 USPC

of a high particle load membrane is possible but time consuming and fatiguing when thousands of particles are present. Partial or statistical counting is recommended and is described later in this chapter in *Partial Count Procedure*. The partial counting approach extrapolates the count of a high particle load membrane from a defined portion of the filtration area. A practical upper limit for counting is around ≥3000 particles per membrane. The ≥3000 particle load typically takes a trained analyst an hour or more to count. Consider reducing the sample volume (e.g., fewer product samples) to reduce the total load of isolated particles. Finally, when a high particle load sample cannot be adequately processed, pursue an alternative analytical strategy.

THRESHOLDING/SENSITIVITY

Training is essential because the assay requires the operator's judgment of particle size by comparison to the calibrated reticle. Calibration of the microscope after optimization of the illumination allows the operator to make the best judgment on whether a particle should or should not be included in the particle count.

For automated systems, the same rules for image analysis apply. Because the 10-µm and 25-µm thresholds are used, the sensitivity at these sizes is essential. The *General Notices* require that accuracy be within 10%; therefore the system must be able to recognize 10 ± 1 µm. Thresholding implies the definition of actual particle boundaries versus background, which can be difficult for the human operator and even more so for the instrumental logic applied for feature recognition.

## 3. BLANK AND SAMPLE HANDLING

A blank determination is necessary at the beginning of each test sequence to verify minimal contribution from the background, equipment, or personnel. Test sequence can be defined as per shift, product family, series of filtrations (manifold), or sample. The suitability of the selected test sequence is dependent upon the operational needs of the laboratory system; the ability to clean glassware between samples, the number of different products, and the volume of sample tested. However, the blank should be considered as a system suitability check. Failure of the blank would suggest that all samples that were run after the previous blank are questionable.

To determine the blank count, duplicate the sample preparation process regarding the apparatus and membrane types. Assemble a clean filtration apparatus with a fresh membrane, rinse the interior with filtered water to drain, and then deliver 50 mL or more volume of filtered water to the filtration funnel while applying vacuum, drawing the entire volume of water through the membrane filter. Remove the membrane from the filter funnel base and place it onto a holding device, typically, on a strip of double-sided tape on a microscope slide or in a commercial membrane holder or Petri dish. After allowing the membrane to dry (it must be counted dry), examine the entire filtration area microscopically at 100× magnification. If NMT 20 particles ≥10 µm and NMT 5 particles ≥25 µm or larger are present within the filtration area, the background particle level is sufficiently low to meet the criteria in ⟨788⟩, *Method 2 Microscope Particle Count Test*. If particle load exceeds these limits, repeat the procedure.

There is value in further limiting the background counts for both ⟨788⟩ and *Particulate Matter in Ophthalmic Solutions* ⟨789⟩ testing in regard to good laboratory practice, and more specifically in regard to the ≥25-µm and ≥50-µm particle limits in ⟨789⟩, which may be more restrictive than injectable limits considering the total particle content allowed for the (usually) small unit volumes.

## 4. TEST ENVIRONMENT

The recommended operational detail to enhance the successful performance of the MM assay is given in this section. It is ideal to use two unidirectional airflow hoods (UAFH) or other unidirectional airflow (UAF) enclosures, one for "wet" sample preparations and the other an enclosure for the microscope counting phase. The UAFH should have a capacity sufficient to envelop the area in which the analysis is prepared. The UAFH provides high-efficiency particulate air (HEPA) filtered air that meets the International Organization for Standardization ISO 14644-1 standard (*1*).

Throughout the operational procedure (in the HEPA environment), it is preferable to use powder-free gloves and low-shedding clothing. Before conducting the test, clean the work surfaces of the UAF enclosure with an appropriate filtered solvent. Glassware and equipment should be rinsed successively with a warm, residue-free solution of detergent, hot water, and filtered distilled or deionized water. [NOTE—Prior to use, pass the distilled or deionized water through membrane filters of at least 0.2-µm nominal pore size.] If an alternate solvent must be used, use proper safety precautions. Perform the rinse in the UAF enclosure. Allow the glassware and filtration apparatus to dry in the enclosure, upstream of all other operations. The enclosure is preferably located in a separate room that is supplied with filtered cool, conditioned air and maintained under positive pressure with respect to the surrounding areas.

### 4.1 Microscope Preparation

The microscope optical alignment and illumination are critical for the success of this method. Although it is not difficult to differentiate a 10-µm particle from a 25-µm particle at 100× with reflected light, the decision regarding the boundary at each size category is difficult with inadequate equipment, maintenance, or optical alignment. Also, operator fatigue is caused by poor microscope alignment. The operator will have to determine if a particle is above or below the limit (e.g., the particle size is 9 µm or 11 µm). Optimized system resolution (i.e., the ability to discern discrete points of minimal separation) relies upon good and well-aligned optical systems. Factors including instrument cleanliness, resolution (e.g., objective NA[2]), and focus of both eyepieces, and the graticule will all play significant roles in attaining the best images. In consideration of optimizing the use of the binocular compound microscope, it is best to utilize operators familiar with the instrument and comfortable with its

[2] NA is an indicator of optical light-gathering capability and, thus, resolution. High NA correlates to high resolution.

alignment. The operator conducting the method should align the optics and illumination for his/her use with supervisory/trainer approval.

It is recommended to start with the alignment of the microscope for a typical transmitted illumination observation using a known sample. Any specimen familiar to the operator will suffice; however, a common particle count reference standard suspension, such as the USP Particle Count Set RS, is a good selection because it is also utilized in method system suitability evaluation. A drop of USP Particle Count Set RS is placed between a glass microscope slide and coverslip and viewed microscopically[3] With appropriate interpupillary distance and a comfortable sitting position at the microscope, the operator examines the fields of suspended spheres. One should observe (with ease) the small standard spheres, crisp on a combined field for both eyes. One attains crisp focus and ease of view after the focal adjustment of each eyepiece on a single point on the specimen.

Rotate the graticule in the right microscope eyepiece so that the linear scale is located at the bottom of the field of view, bringing the graticule into sharp focus by adjusting the right eyepiece diopter ring while viewing an out-of-focus specimen. Focus the microscope on a specimen, looking through the right eyepiece only. Then, looking through the left eyepiece, adjust the left eyepiece diopter to bring the specimen into sharp focus.

When the operator is not comfortable using the microscope or does not attain an equivalent crisp focus for each eye in a merged field of view, counting will become a difficult experience and will result in fatigue and flawed size comparison.

Nothing is better for preparing the operator for counting particles than to examine a test membrane as a positive control. Seasoned microscopists may not require this step, but for new operators or individuals conducting many different types of methods in the modern laboratory, familiarization is a prudent exercise. A filter membrane of the type being used for the method —such as a 25-mm, color-contrast, plain, membrane filter of 0.45-µm nominal pore size, containing particles—is a good choice. This may be a sample from a previous method that contains a variety of particle types or one prepared for familiarization. This positive test control will contain natural particles (e.g., flakes, threads, equant particles, and particles of various colors/opacity in a range of sizes) to effectively refresh the operator's sensitivity and facilitate microscope and illumination alignment for optimal viewing.

To examine the membrane preparation, locate a typical array of particles and first bring the illumination into good alignment:

1. Adjust the external, incident illumination at an oblique angle (10°–20° inclined to the stage) so that an even ellipse of reflected light is visible on the membrane and even illumination is evident through the eyepiece field of view (even across the full field). Shadows will be evident from larger particles, such as those with *z*-axis dimension >5 µm (*z*-axis is the microscope's vertical axis).
2. Now adjust the internal episcopic brightfield illuminator to yield an even illumination at a high setting on the transformer control. More importantly, when dialing down the illumination, one observes the evident shadow from the larger particles. In this manner, the high reflectivity of flat, glassy particles and the distinct shadows of more equant (*x*:*y*:*z* ~ 1:1:1) particles are evident.

## 4.2 Using the Circular Diameter Graticule

In order to properly focus the ocular lenses and attain a balanced single-field view, each operator must bring the *USP* graticule lines into sharp focus by adjusting the eyepiece diopter ring. Next, focus the microscope on a specimen through this same eyepiece, and then, looking only through the other eyepiece, adjust its diopter ring to bring the specimen into sharp focus. The *USP* graticule and specimen particles are now in focus on a well-balanced illumination field.

The *USP* graticule is specifically fabricated for each microscope. The relative error of the graticule used must be ±2% and is initially measured with an NIST traceable stage micrometer. To accomplish this, align the graticule micrometer scale with the stage micrometer so that they are parallel. Compare the scales, using as large a number of graduations on each as possible. Read the number of graticule scale divisions (*GSD*), compared to stage micrometer divisions (*SMD*). Calculate the relative error:

$$\% \text{ Relative error} = 100[(GSD - SMD)/SMD]$$

A relative error of ±2% is acceptable and verifies good alignment, focus, and proper magnification. Thereafter, a day-of-use verification by the microscope operator with the NIST traceable stage micrometer is sufficient to demonstrate proper setup.

The basic technique of measurement, applied with the use of the circular diameter graticule, is to count all particles 10 µm and larger, further categorizing in sizes ranging from 10 to 24 µm and 25 µm or greater. The circular zone or graticule field of view (GFOV) is a useful zone for active sizing and counting. Particles are compared to the linear scale and/or circles to determine their size against the circular diameter design. This is conducted by mentally transforming the image of each particle onto the 10- and 25-µm graticule reference circles. The sizing process is carried out without having to physically superimpose the particle on the reference circles; particles are not moved from their locations within the GFOV (the large circle) for comparison to the reference circles. Compare the longest chord of the particle being sized to the diameter of the black or transparent circles. The circles allow comparison of the particles regardless of their orientation. The linear scale may also be used for size comparison. Use the clear graticule reference circles to size white or transparent particles. Use the black reference circles to size dark particles.

The intent of comparing particles to an equivalent circular diameter is correlation to the LO particle sizing methodology, for which many manufacturers have extensive databases. In practice, particles with nearly circular areas will correlate well with the graticule circle diameters. For particles with one long axis, such as rods and needles, the conversion to circular area will produce more significant bias to smaller estimated sizes. It is simpler, and most conservative, to count particles in longest chord. To use an extreme example, the total count of monodispersions of fine needle crystals would vary greatly dependent upon the size determination utilized.

[3] The microscope objective requires a defined cover slip thickness, nominally 170 µm, or No. 1½.

### 4.3 Particle Counting Accuracy (System Suitability)

- It is valuable to use a reference count preparation for verifying illumination and as a means to discuss counting and sizing criteria.
- Calibration of the graticule/linear scale should be done as needed to verify proper setup (ocular, objective, and intermediate lenses are easily removed and changed).
- Particle counting accuracy is an important training operation and a reasonable annual check. A monodisperse sphere standard, such as a membrane deposit of the USP Particle Count Set RS, is useful for comparative counts between the trainer and the operators.
- Blank samples are an effective means of confirming the cleaning preparations for the method.

## 5. TEST PROCEDURE

### 5.1 Sample Preparation

Preparation of the filtration apparatus and test preparations are discussed in ⟨788⟩ and *Methods for the Determination of Subvisible Particulate Matter* ⟨1788⟩.

Filter large-volume injection (LVI) units individually. Small-volume injection (SVI) units having a volume of 25 mL or more may be filtered individually.

Transfer to the filtration funnel the total volume of a solution pool or of a single unit, and apply vacuum. If the volume of solution to be filtered exceeds the volume of the filtration funnel, add a portion of the solution, stepwise, until the entire volume is filtered. It is prudent to maintain more than half of the funnel volume of liquid in the filtration funnel between refills, especially if the partial count procedure is to be used (see *Partial Count Procedure*). [NOTE—This step is necessary in order to ensure even distribution of particles on the analytical membrane.] After the last addition of solution, begin rinsing the walls of the funnel by directing a low-pressure stream of filtered water in a circular pattern along the walls of the funnel, and stop rinsing the funnel before the volume falls below about one-fourth of the fill level. Maintain the vacuum until all the liquid in the funnel is gone.

Remove the filtration funnel from the filtration base while maintaining vacuum, then turn the vacuum off, and remove the filter membrane with nonserrated forceps. Place the filter in the prepared holder and label with sample identification. Allow the filter to air-dry in the UAF enclosure with the cover ajar.

### 5.2. Particle Enumeration

The MM test described in this section is flexible in that typical artifacts such as air and immiscible liquids do not interfere with the final count. The method has a broad size-detection and counting range if applying the partial count procedure. This method may be used where all particles on an analysis membrane surface are counted or where only those particles on some fractional area of a membrane surface are counted.

TOTAL COUNT PROCEDURE

The microscope method is a slower process than the LO or FI methods, but they all have their value. Because the results rely upon the training and experience of human operators (e.g., visual inspection), insufficient training and lack of diligence can result in imprecision (e.g., poor agreement within and among labs) and inaccuracy (e.g., particle size estimates that are inaccurate for nonspherical particle shapes). Operator fatigue can be a problem and is promoted by poor ergonomic fit (chair height), poor or imbalanced ocular focus, and inattention to detail due to interruptions and lack of mental focus. Restricting the eye movement to a field-defining graticule, such as the *USP* counting graticule, restricts eye movement to the central one-third of the field of view. This significantly limits eye movement and may induce fatigue.

Sample size is an important consideration in counting precision. Care must be taken to sample many containers within a batch for a good representation of the particle distribution. Accordingly, the portion of the individual package sampled is critical. Particles may float or settle. Sampling only the first 25 mL of a large volume parenteral or sampling without adequate and recent mixing will lead to serious undercounting. Sampling whole, well-mixed containers with the particles in suspension is the best approach.

Counting the isolated particles is an important parameter. Counting all of the particles retained on the membrane is certainly the best approach, and then the simple problem is determining the correct size for placement into the threshold bins, 10 µm and 25 µm. This will be increasingly important for methods utilizing additional bins for population determination, such as 5-, 50-, and 100-µm. Note that the particle limits for ⟨788⟩ and ⟨789⟩ must be reported as all particles ≥10 µm and all particles ≥25 µm (and all particles ≥50 µm). If the lab method has been configured to count in several bins, such as 10–24 µm, 25–49 µm, and ≥50 µm, et cetera, all bins ≥10 µm must be added to yield the total ≥10-µm count; all bins ≥25 µm need to be added to yield the total ≥25-µm count. Using a number of narrow size bins may be beneficial in product improvement efforts to separate particle groups.

In performing a total count, the graticule GFOV is defined by the large circle of the graticule, and the vertical crosshair is used as a counting target. Count and size particles as they pass across the full diameter line of the GFOV, keeping mental track of the path over the membrane. Scan the membrane in paths that cover the effective filtration area (EFA) adjoining but not overlapping previous scan paths. Repeat this procedure; tabulate particle counts minimally in the 10–24-µm and ≥25-µm thresholds, moving across the membrane until all particles on the membrane within the EFA are counted. Record the total number of particles that are 10–24 µm and the number that are ≥25 µm.

For large-volume products, calculate the particle count, in particles per milliliter, for each unit tested:

@2024 USPC

$$P_{\Sigma\geq10}/V$$
$$P_{\Sigma\geq25}/V$$
$$P_{\Sigma\geq50}/V$$

in which $P_{\Sigma\geq10}$ is the total particle count obtained from all portions ≥10 µm analyzed; $P_{\Sigma\geq25}$ is the total particle count obtained from all portions ≥25 µm analyzed; $P_{\Sigma\geq50}$ is the total particle count obtained from all portions ≥50 µm analyzed; and $V$ is the volume, in milliliters, of the solution tested.

For example, the analyst has counted the test samples in four bins: a) 10–24 µm, b) 25–49 µm, c) 50–99 µm, and d) ≥100 µm. This would then be calculated as:

$$P_{\Sigma\geq10} = P_{10–24\ \mu m} + P_{25–49\ \mu m} + P_{50–99\ \mu m} + P_{\geq100\ \mu m}$$

For small-volume products, calculate the particle count, in particles per container:

$$P_{\Sigma\geq10}/\eta$$
$$P_{\Sigma\geq25}/\eta$$
$$P_{\Sigma\geq50}/\eta$$

in which $P_{\Sigma\geq10}$ is the total particle count obtained from all portions ≥10 µm analyzed; $P_{\Sigma\geq25}$ is the total particle count obtained from all portions ≥25 µm analyzed; $P_{\Sigma\geq50}$ is the total particle count obtained from all portions ≥50 µm analyzed; and $n$ is the number of units pooled (1 in the case of an individual unit).

## PARTIAL COUNT PROCEDURE

When encountering a membrane full of particles, the task of adequately counting all of them is daunting. Consider that an small volume parenteral with an at-limit content of small particles, sampled in a 10-vial pool would have 30,000 10-µm particles on the membrane. Partial or statistical counting of the membrane's EFA may be the only means to attain consistent results. Partial counting should be used not to reduce count times but to estimate the total load on a high-count isolate. Field-defining devices, such as grids on the membrane surface or an ocular GFOV, have been used reliably. An ocular graticule provides a sharp boundary for area definition. Gridded membrane lines are rather broad and have ink-spatter that may be mistaken for particulate matter.

For 25-mm membranes, the EFA is 16-mm in diameter using typical commercial filtration funnels; therefore the EFA ($\pi \times r^2$) = 201 mm$^2$. Based upon earlier proposals from the Health Industry Manufacturers Association (HIMA) and discussion by Draftz (*2*), acceptable confidence intervals (Poisson distribution, two standard deviations) dictate that for samples with <1000 particles, the imprecision of statistical counting is objectionable. Full count is recommended for such samples. For samples with >1000 particles on a 25-mm isolate membrane, a reasonable estimate of particle population is attained using 20 GFOVs. If a smaller confidence interval for the result is desired, a larger number of fields and particles may be counted.

For 47-mm membranes the EFA has a 37-mm diameter. These larger-diameter membranes may be selected for formulations needing more membrane surface area (i.e., formulations that have slow flow characteristics through 25-mm membranes); in which case, the EFA ($\pi \times r^2$) is ($\pi \times 18.5$ mm$^2$) = 1075 mm$^2$. Thus, for 47-mm membrane EFAs, many more GFOVs must be counted to attain similar confidence levels. Using 100 GFOVs for partial counting of 47-mm membranes provides similar statistical confidence to the 20-GFOV/25-mm approach. Accordingly, when a particle load of 1000 or less is present, a full count is recommended.

When a partial count of particles on a membrane is to be performed, the analyst must first ensure that an even distribution of particles is present on the membrane. This is assessed by rapid scanning at 50× to qualitatively scan for clumps of particles. If heterogeneity is observed, one should perform a full count on the membrane. Next, count the 10-µm or larger particles in one GFOV at the edge of the filtration area as well as one GFOV in the center of the membrane. The number of 10-µm or larger particles in the GFOV with the highest total particle count must not be more than twice that of the GFOV with the lowest total particle count. If this criterion is not met, perform a full count of the membrane.

To perform a partial count of the particles on a membrane, include all particles 10–24 µm and ≥25 µm within the GFOV and those that are in contact with the right side of the GFOV circle. Do not count particles outside of the GFOV. Ignore those that touch the left side of the GFOV circle. The dividing line between right and left sides of the GFOV circle is the vertical crosshair and is a useful counting line.

[NOTE—Make the best possible judgment on particle size without changing the membrane position, microscope magnification, or illumination.]

Start at the center edge of the filtration area and begin counting adjacent GFOVs. When the other edge of the filtration area is reached, move one GFOV toward the top of the filter and continue counting GFOVs by moving in the opposite direction. This can be accomplished by one of two methods: define a landmark (particle or surface irregularity in the filter) and move over one GFOV in relation to the landmark, or use the Vernier scale on the microscope method to move 1 mm between GFOVs. To facilitate the latter, adjust the microscope *x*- and *y*-method positioning controls to a whole number at the starting position at the center right edge of the filtration area so each GFOV will be one whole division of movement of the *x*-method positioning control. If the top of the filtration area is reached before the desired number of GFOVs is reached, begin again at the right center edge of the filtration area one GFOV lower than the first time. This time, move downward on the membrane when the end of a row of GFOVs is reached. Continue as before until the number of GFOVs is complete.

For large-volume products, extrapolate the total count of particles per milliliter:

$$P_{\Sigma\geq10}\,A_T/A_P V$$
$$P_{\Sigma\geq25}\,A_T/A_P V$$

@2024 USPC

in which $P_{\Sigma \geq 10}$ is the total particle count obtained from all fields of view and all size thresholds; $A_T$ is the filtration area of the membrane in millimeters$^2$ (inner filtration barrel diameter); $A_P$ is the partial area counted in millimeters$^2$, based on the number of graticule fields counted (GFOV area × number of GFOV counted); $V$ is the volume of solution filtered in milliliters; and $P_{\Sigma \geq 25}$ is the total particle count obtained from all fields of view and all size thresholds ≥25 µm.

For a solution pool (for small-volume product units containing less than 25 mL) or for a single unit of a small-volume product, extrapolate the total count of particles per unit:

$$P_{\Sigma \geq 10} A_T / A_P n$$
$$P_{\Sigma \geq 25} A_T / A_P n$$

in which $P_{\Sigma \geq 10}$ is the total particle count obtained from all fields of view and all size thresholds; $P_{\Sigma \geq 25}$ is the total particle count obtained from all fields of view and all size thresholds ≥25 µm; and $n$ is the number of units counted (one, in the case of an individual unit). For all types of product, if the tested material has been diluted to decrease viscosity, the dilution factor must be accounted for in the calculation of the final test result.

# 6. AUTOMATED APPROACHES

## 6.1 Background

The original MM method was designed as an operator-intensive operation, from preparation to filtration to counting. The judgment of the operator regarding the presence and "countability" of isolates is paramount to effective detection, sizing, and counting of the retained particles. There may be alternative approaches. Static image analysis systems offer automated tracking and detection of particles based on contrast against the background. There is increased potential for objective accuracy and precision versus subjective human decision and tabulation. Primary considerations for the qualification of image systems are: recognition of thin or indistinct particles, "acceptance" of background features, discrimination of particles from background, and counting of artifacts. Use of these systems is supported with proper qualification using typical particle types as challenge sets.

To provide a more comprehensive guidance for human or machine vision, this chapter includes qualification recommendations for operators running the membrane assay for demonstrating the applicability of an automated method.

Qualification is a quality or accomplishment that makes someone suitable for a particular job or activity. Discussion points to address this simple goal are as follows:

- Microscope selection, preparation, and use are critical in detecting, sizing, and counting particles in the collected isolate. See *2. Test Apparatus* for background on the type of microscope and illumination used in daily counting.
- Familiarization of the operator is essential in particle recognition and size/count decision making. The following are elements of a proper training program:
  - It is imperative to fully scan the EFA for countable particles:
    - The membrane is tracked under the 10× objective with an *x-y* stage control
    - The lateral tracks must be parallel and not underpassed (gaps) or overpassed (recounted)
    - The edge of the EFA must be recognized and taken as the limit for tracking
  - Real particles ≥10 µm must be tabulated and discerned from the background
  - Blank samples familiarize the operator with the characteristics of the membrane texture, color, and reflectivity
  - Differentiation of 10–24 µm and ≥25 µm (additionally ≥50 µm for ⟨789⟩) particles is imperative

## 6.2 Qualification

A bimodal suspension of standard spheres is a reasonable means to verify operator recognition of ≥10 µm and ≥25 µm standards to satisfy the above criteria. Use two sphere standards just above the two size thresholds, such as 12–15 µm and 30–35 µm. Prepare a suspension of equal portions of the standard spheres in particle-free water, limiting the total content to ≤1000 in the volume tested. Training operators are charged with preparing and counting the preparations to verify acceptability.

The trainer counts the preparation, once acceptable, three times within a workday. This is the reference count. To promote stability, the membrane standard preparation may be sprayed with a fixative, such as a clear photoprotectant aerosol spray or a hand-pumped clear hairspray to fix the particles to the membrane surface. These applications may be used for months but should always be verified by trainers.

Trainees count the preparation three times in the same workday. The relative standard deviation (RSD)[4] for each threshold for one operator should be small, such as ≤5%. The RSD for each threshold between operator and trainer must be ≤10%.

In addition to manual microscopy, advances in technology have provided for automated testing of membrane-filtered samples. These techniques replace the human eye with a charge-coupled device (CCD) camera for image collection and the human decision-making process with advanced image processing software. While these techniques may seem to be simple, human-error free substitutes, careful consideration of the experimental variables, much like those for manual microscopy, is required for proper method qualification.

System particle size accuracy and count may be determined using traceable etched slides available from national standards organizations. These suffice to provide a calibrated measure of particle size, typically using chromed circular spots on a rigidly controlled sample. This approach also offers the user a self-contained system check with limited overhead once method qualification is complete (i.e., internal verification of system performance).

[4] The relative standard deviation (RSD), also known as the coefficient of variation (CV), is a standardized measure of dispersion of a probability distribution or frequency distribution. It is often expressed as a percentage and is defined as the ratio of the standard deviation to the mean (or its absolute value).

@2024 USPC

Beyond the initial system verification, it is necessary to directly compare the results of operator-conducted MM to automated methods. Although the mixed-sphere samples suggested for operator familiarization/training are excellent for comparing data collection methods, they represent optimal samples that may not highlight differences between manual and automated approaches. Instead, it is imperative that manual and automated methods be compared in a vein similar to that expressed for manual operator training.

- Using a minimum of three real samples, have the manual operator conduct the assessment of particulates ≥10, ≥25, and ≥50 µm
- Using the automated method for the same samples, have the system conduct three replicates of each sample for assessment of particulates ≥10 and ≥25 µm
- The RSD for the automated method replicates should be ≤3%
- The RSD between the manual and automated methods should be ≤10%
- The manual operator should review automated results to ensure that the automated system accurately captures particle populations observed manually

In general, repeatability of automated methods should be reasonably high (≤1%), and that of a single human observer slightly lower (≤5%). However, differences in method variables between manual and automated methods can lead to large changes in the apparent count and/or size results when comparing techniques. This variance can be far outside that expected for a human operator versus an automated method, which typically points to a shortcoming of the automated method. Such a situation warrants an understanding of why the method results diverge and a question of whether automation of the method is reasonable.

These considerations are usually related to either the microscope illumination or the thresholding mechanism defined in the automated method. Illumination varies among automated systems and can include diascopic (transmitted), episcopic (axial reflected), or oblique lighting. Manual methods have evolved to utilize oblique lighting exclusively, while automated methods may utilize alternate illumination, depending on the substrate selection. This can lead to automated methods with considerably different contrast quality from corresponding manual methods, so care should be taken to closely match the lighting conditions when comparing size/count results. Single-value thresholding schemes, which are quite common for automated systems, may produce fragmented images or miss particles entirely, whereas a human operator can clearly resolve the particle projection and accurately size/count the particles. It is critical to ensure that the qualification of an automated method includes a review of detected particles.

A final topic of consideration involves the selection of membrane type. Not all product forms are amenable to using cellulosic membranes, so alternatives to the standard cellulose-based membrane substrate may be appropriate. Novel membranes are now available that feature superior homogeneity, compatibility with organic solvents, and spectroscopic compatibility. These membrane choices may be used to develop manual or automated methods that meet ⟨788⟩ requirements, with an appropriate qualification of the method.

## 1. INTRODUCTION

Flow imaging (FI) is useful for an approximate particle range from 2 to 100 µm, depending on the instrument and its configuration, covering particle sizes from the accepted subvisible size range to hundreds of micrometers (see *Measurement of Subvisible Particulate Matter in Therapeutic Protein Injections* ⟨1787⟩ and *Methods for the Determination of Subvisible Particulate Matter* ⟨1788⟩). Specialized instruments or configurations can cover expanded size ranges. FI instruments provides both individual microscopic images of observed particles and reports of particle size distribution (PSD) and particle concentration at selected size thresholds. Values of morphological parameters and sample images corresponding to the stated size bins or thresholds may be added to the report. Particle size can be reported as an equivalent circular diameter [similar to light obscuration (LO)] or based on Feret's diameter, which captures some information about the shape. Algorithms categorizing particles are usually based on optical density and morphological parameters such as circularity, allowing them to differentiate to some degree between elongated fibers, dense symmetrical air bubbles, circular silicone oil droplets, and amorphous protein particles, etc.

This is an essential characterization method that is often used as an orthogonal method to the compendial LO and membrane microscope (MM) methods, especially during development. This method is described, along with other orthogonal techniques, in ⟨1787⟩. Because of its increasing use and importance as a technique to size, count, and bin by morphology, more details on how to optimize the application of this technology are provided here.

## 2. TEST APPARATUS

### 2.1 Principles of Operation

The principles of operation and the strengths and weaknesses of FI are discussed in ⟨1787⟩. Briefly, the apparatus is a liquid-borne particle counting and imaging system using a sample-feeding device to deliver controlled aliquots of liquid for analysis. The samples flow through an optical cell positioned between a light source and camera, allowing the capture of a digital stream of particle images present in the sample.

Image analysis of the captured image frames can provide necessary information. Fundamentally, information may be obtained about particle size and number within a size range from about 2 to 100 µm (exact size range and larger size ranges will depend on the instrument, cell size, and magnification). Other parameters such as shape, contrast, and transparency of the particles allow for the evaluation of the particle population.

FI combines the benefits of in situ observation, as in LO, with the ability to qualitatively evaluate some characteristics of the particles, as in MM. Air bubbles and immiscible liquids are detected because imaging is performed on flowing liquid samples. With software algorithms, these common artifacts may be discriminated from "real" particles. The effectiveness of particle discrimination is a function of magnification, resolution, software algorithms, and particle properties.

Therefore, product fluids with air bubbles and immiscible liquid droplets (e.g., silicone oil), which are not discriminated from other types of particles when using LO analysis, are imaged by FI and can be discriminated through software processing. It is the responsibility of those performing the test to ensure that the operating parameters of the instrumentation meet the required

@2024 USPC

accuracy and precision, that artifacts and interferences observed in certain products and preparation methods are eliminated or accommodated, and that the algorithm is assigning particle type correctly.

High-resolution optics have a small depth of field relative to optical configurations with lower resolution. Thus, for typical instruments where the particle suspension travels through a flow cell of approximately 100-µm thickness, there is a tradeoff between ensuring that all particles remain in focus versus obtaining high-resolution images. It may be appropriate to obtain high-quality images with different hardware settings than typically required to obtain an accurate particle count.

FI instruments vary in the flexibility and range of adjustment of instrument hardware. Some instruments will have user-selectable flow cells, objectives, and illumination. Other instruments will have predominantly fixed settings. It is the user's responsibility to determine if the optical configuration of a particular instrument, whether fixed or variable, serves the stated purpose of the measurement.

It is important to note that for compendial applications, the ultimate goal is that the imaging instrument accurately size and count the particles present. FI enables classification of particles according to particle image properties (e.g., aspect ratio, brightness, transparency, and circularity), which can assist the user in understanding the nature of particle subpopulations and in diagnosing possible particle count interferences (e.g., as air bubbles). Establishing an image library will aid in the categorization of particulate unknowns and could be part of risk assessment. The instruments that are available range from manual calibration and standardization systems to sophisticated hardware- and software-based standardization systems. Thus, it is not possible to specify the exact methods to be followed for instrument standardization, and it is necessary to emphasize the required end result of a standardization procedure rather than a specific method for obtaining this result. This chapter is intended to emphasize the criteria that must be met by a system rather than specific methods to be used in their determination. It is the responsibility of the user to apply the various methods of standardization applicable to a specific instrument. Indeed, no single method will apply to all experiments. Factors such as the desired range of detection, formulation characteristics, available sample volumes, and nature of the particulate matter are typical considerations for the method used. Validation concepts for a limits test in *Validation of Compendial Procedures* ⟨1225⟩ provide sufficient guidance for these purposes.

## 3. INSTRUMENTATION STANDARDIZATION TEST

### 3.1 Concentration Calibration

The particle concentration reported by a FI instrument is based on the total number of particles measured, within a specified range of diameters, divided by the total volume of fluid that has been imaged. Each camera image records particles within a volume equal to the imaged area multiplied by the interior thickness of the flow cell. Consequently, the imaged sample volume requires accurate knowledge of the flow cell thickness but does not depend directly on the liquid flow rate through the cell. Because direct measurement of flow cell inner dimension is difficult for some types of flow cell, the thickness is often inferred by measuring the particle concentration of a suspension of microspheres of certified concentration. Calibration procedures are given in the *Appendix*.

### 3.2 Sample Flow Rate

The flow rate through the cell should be consistent with the manufacturer's recommendations in order to ensure that the instrument is functioning properly. This may be accomplished by weighing the amount of liquid passed through the system at a specified rate, using a calibrated stopwatch to measure the elapsed time. Instruments may be operated accurately over a range of flow rates. Perform *7. Test Procedure* at the same flow rate as that selected for calibration of the instrument.

### 3.3 Diameter Calibration

Refer to ⟨1788⟩ for general guidance on diameter calibration. A microscopic particle image depicts the projected area of a particle. From this area, a variety of effective diameters may be obtained, depending on the instrument model and software settings. Instruments should be calibrated so that the reported effective diameter for polystyrene (PS) microspheres equals the actual microsphere diameter. Calibration procedures are given in the *Appendix*. Calibration of an instrument with PS microspheres may result in incorrect reported diameters for particles with low optical contrast. Refer to *Diameter Bias* for guidance in this circumstance.

### 3.4 Sensor Performance or Resolution

The particle size resolution of the instrumental particle counter is dependent upon the instrument model, flow cell, and hardware and software settings. Poor particle size resolution will lead to broadening of the PSD, which can lead to errors in reported particle concentrations. A procedure for determining instrument resolution is given in the *Appendix*.

### 3.5 Qualification Considerations

Qualification of the instrument should be based on frequency of use, maintenance schedule and accuracy requirements. Specific qualification considerations are similar to those for LO. Critical operational criteria consist of the following:

- *Integrated microscopy and fluid handling*—The fluidics system, microscope, and instrument control should be designed to provide repeatable imaging of particles, in a known fluid volume for each frame, at a controlled sample flow rate.
- *Instrument dynamic range*—The dynamic range of the instrument used (i.e., the range of particle sizes that can be accurately sized and counted) must include the smallest particle size to be enumerated in the product.

https://pharmacopeia.com/

- *Automated particle identification*—Particles should be identified with image threshold settings suitable for the detection of protein aggregates or other species of interest. The system should support classification of particles by size, morphology, and image intensity parameters. Agreement with visual analysis of the images should be verified by a skilled operator.

Reliable and accurate measurements require attention to several stages in the measurement process. Key quality activities include:

- Initial instrument qualification
- Method development
- Periodic operational checks
- Routine running of blanks and inspection of data
- Instrument maintenance

## INITIAL QUALIFICATION

All methods should be qualified for performance, considering the guidance in ⟨1225⟩. Specifically, volume accuracy, standards for particle size, particle count accuracy, and a determination of image resolution should be included in qualification.

## METHOD DEVELOPMENT

**Adsorption:** Compared to PS microspheres and other inert particles, some drug substances (e.g., proteins) are much more likely to adsorb onto the walls of the fluidic system. The degree of adsorption can vary with the nature of the formulation, the nature of the particulate matter, and the active pharmaceutical ingredient (API). To assess adsorption, run different prime or rinse volumes and check for variations in particle concentration. Run buffer blanks after the completion of a run and observe the particle counts in the blanks as a function of blank volume.

**Diameter bias:** Estimates of diameter bias may be corrected by adding an appropriate correction (which may be positive or negative) to the measured diameter of each particle, then recalculating the PSD. Diameter bias may be assessed by measuring monodisperse particles of a known size or polydisperse particles of known PSD provided that the chosen particles have optical properties similar to those in the test sample. Refer to ⟨1788⟩, *11.3 Validation Considerations for All Techniques* for further guidance. Consult manufacturer's recommendations for additional information and specific guidance.

The apparent diameter of a particle is affected by the following:

- The choice of threshold
- The degree to which the particle is out of focus
- Diffraction effects
- The ability of the instrument software to identify adjacent, low-contrast regions as a single particle
- Alignment of elongated or platelike particles in the flowing fluid

If the incorrect diameter is reported, PSD and particle concentration for affected size bins will be inaccurate. Concentration errors are most prevalent for small particles near the lower limit of the instrument's resolution and those that are difficult for the instrument to resolve (e.g., glass lamellae or protein aggregates in high-concentration formulations).

**Opalescence:** Particles may be obscured in samples that are highly opalescent. To assess the visibility of particles, spike microspheres of known diameter and concentration into a test sample, measure the microsphere diameter and concentration, and compare to the diameter and concentration expected. The choice of microsphere for this analysis should have a similar refractive index as the particles of interest in the test sample (e.g., silica microspheres could be used to mimic lower-contrast protein aggregates; PS could be used to mimic higher-contrast particles).

**Viscosity:** The low volumetric flow rate of FI instruments makes them generally insensitive to typical fluid viscosities. Confirm that no bubbles are introduced on priming or running at standard speed. For systems that use a peristaltic pump, confirm that the delivered volume is correct if the sample viscosity differs substantially from the viscosity of water. Reduce volumetric flow rates if necessary.

**Stuck particles:** Stuck particles may be observed during the actual data collection or in post-collection analysis. If particles or air bubbles become temporarily affixed in the detection zone of the sample cell, the data around the affixed particle should be eliminated using software recognition to avoid overcounting particles; if this is not possible, the entire data set should be discarded and the sample cell should be changed.

**Schlieren effects:** Inhomogeneities in solvent refractive index due to mixing (typically when water or buffer is mixed with a high-concentration protein suspension or cold solvent) lead to localized variance in the background intensity, which can impact analysis. Schlieren effects are often more pronounced when the sample viscosity is high relative to buffer or water. These inhomogeneities should be removed from the flow channel before the system background is recorded or data is collected. Priming with a sufficient volume of the sample to be measured, or with an equivalent solution, to reach the equivalent refractive index and viscosity of the test samples prior to its injection can remove such artifacts.

**Particle classification:** After data has been acquired, many FI systems enable the sorting of images by size, image intensity attributes, and morphological image attributes. This type of classification can be very useful in distinguishing silicone oil or air bubbles from other types of particles. However, care must be taken to ensure that the classification algorithms work as intended. Studies of different types of particles can be used to generate reference libraries, and additional measurements combining known populations of particles can be used to confirm the performance of the algorithms. As mentioned above, the "binning" should be verified by a subject matter expert to ensure the algorithm differentiates populations as expected.

**Software settings:** Instruments will differ in the degree to which software settings can be altered. The manufacturer should be consulted for recommended instrument settings for the type of samples being investigated. Common settings may include:

- Prime and sample volumes
- Flow rate through the cell
- Illumination intensity

- Particle identification threshold
- Image processing settings (e.g., closing holes in the binary image)

**Hardware setup:** Instruments will differ in the degree to which hardware settings can be altered. The manufacturer should be consulted for recommended instrument settings for the type of samples being investigated. Common settings may include:

- Magnification
- Collimating lens
- Cell inner dimensions
- Sample delivery and mixing

There is a tradeoff between high optical resolution (obtained using high-magnification objectives with a high-numerical aperture) and large depth of field (obtained using objectives with low-numerical aperture). Large depth of field is necessary for accurate particle counts, but high resolution may be necessary for detection of low-contrast particles and accurate classification. Care must be taken that the choice of magnification and cell is compatible with the desired purpose of the test. For an instrument where sheath flow is used, throughput is less, but all of the particles are within the depth of field.

**Fouling:** Test samples with high particle loads or with particle sizes approaching the flow cell thickness may cause fouling of the cell entrance. Often, the flow path will only be partially clogged such that the liquid will continue to flow through the cell and small-size particles will still be observed. Evidence of partial fouling is typically a reduction in the observed concentration of larger size particles, a variation in count rate during a run, or visual observation of contaminants near the entrance of the flow cell. If fouling is observed, it may be helpful to backflush the flow cell to remove the clog, and then reconfirm the count accuracy using larger-size PS microspheres (e.g., 25 µm). For the best result, alternate liquid and air in the fluid line when flushing to change samples or to clean the flow cell.

### SYSTEM SUITABILITY

**Instrument configuration:** Verify appropriate instrument hardware and software settings and record them as appropriate (see *Analytical Instrument Qualification* ⟨1058⟩).

**Blanks:** Run filtered water as needed throughout the day to ensure cleanliness of the system. The measured concentration for a well-cleaned system is typically <60 particles ≥5 µm per milliliter. Some debris inside the instrument may be loosened and introduced into the count when exposed to surfactant solutions. Additional runs with filtered buffer or filtered test sample may be useful to confirm that carryover from the previous sample is acceptably low.

Prior to testing blanks, degas according to the guidance in ⟨1788⟩.

**Size and concentration standards:** It is prudent to verify system performance often according to the guidance in ⟨1788⟩. Failure to reproduce the size and/or count reference values can often be traced to a clogged or dirty flow cell, compromised tubing or pump, or other hardware problems. Errors in measured concentration may be due to partial clogs of the flow cell, especially for particles near the upper size limit. Refer to *Fouling* in the previous section for guidance. If counts are below the certified value or deviate statistically from prior readings, backflush, clean the cell, and repeat the concentration measurement.

### PRACTICAL MAINTENANCE

**Routine flushing:** Maintain system cleanliness by flushing with water or filtered formulation buffer between samples. Users may wish to introduce small slugs of air to assist in removing any trapped particulates from the flow channel between samples. Samples with particles that adhere preferentially to the flow cell may require rinsing with 70% isopropanol and/or surfactant solution to remove. The system should be flushed between samples to ensure background levels do not significantly affect the counts.

**Short- and long-term storage:** For short-term storage, the system should be cleaned as recommended by the manufacturer, rinsed with copious amounts of purified water, and kept filled with water to limit the accumulation of material or growth of organisms between routine uses. Long-term storage may necessitate the removal of all solvent from the FI system, possibly with the use of dry nitrogen to drive all water from the flow path.

## 4. TEST ENVIRONMENT

Specimens, sampling and specimen-preparation equipment (e.g., pipet tips, vials), and the FI instrument itself must be cleaned to the extent that the level of particles added by testing has a negligible effect on the outcome of the test. For FI instruments, the predominant sources of contaminating particles are often the fluidics components that come into direct contact with the test specimen. When cleaning these components, it may be necessary to disconnect tubing lines, etc., to permit cleaning of tubing joints or other crevices that can harbor particles.

See ⟨1788⟩, *12. Test Environment and Preparation*.

## 5. PARTICLE COUNTING ACCURACY (SYSTEM SUITABILITY)

The particle counting accuracy (system suitability) should follow the process described in ⟨1788⟩, *13. Instrument Standardization Tests*, using one of three standards: 1) USP Particle Count Set RS (a dilution may be used if deemed necessary); 2) commercial preparation of standard calibrator spheres of nominal diameter 5–30 µm, certified by the manufacturer; or 3) a laboratory-prepared suspension of standard calibrator spheres having a nominal diameter of 5–30 µm. (Refer to *3.1 Concentration Calibration* for additional information.) Spheres with diameters <5 µm are harder to distinguish from environmental or sample-bottle debris. Spheres with diameters >30 µm are more prone to measurement errors due to sedimentation.

Official

https://pharmacopeia.cn/

Stir continuously throughout the analysis, if possible. In systems without continuous stirring, the use of standards with a nominal diameter of 5–10 µm is recommended. Perform five counts on samples of the suspension. Obtain the mean cumulative particle count per milliliter for the main singlet particle peak, excluding the first run. The lower and upper diameter limits for delineation of the peak may be set by consulting the FI instrument vendor and any available information from the standard manufacturer.

Thorough mixing is imperative. Analysis must be conducted in a timely manner to avoid count bias due to the settling of dense species but in a careful manner to avoid generating new particles or breaking existing ones.

### 5.1 Interpretation

The instrument meets the requirements for *5. Particle Counting Accuracy (System Suitability)* if the count obtained within the specified diameter limits conforms to the values that accompany the USP Particle Count Set RS or other certificate of particle concentration. If the instrument does not meet the requirements for *5. Particle Counting Accuracy (System Suitability)*, repeat the procedure. If the results of the second test are within the limits given above, the instrument meets the requirements of the test. If on the second attempt the system does not meet the requirements of the test, determine and correct the source of the failures, and retest the instrument.

## 6. BLANK TEST

Refer to ⟨1788⟩ for guidance on blank handling.

Conduct a blank test (perform after the *5. Particle Counting Accuracy (System Suitability)* test to ensure that any microspheres have been cleared from the system). The blank test for the FI method ensures that the instrument, diluent, glassware, and environment are suitable. Failure of a blank consisting of nominally particle-free water is most often a reflection of contamination in the flow cell or in the fluidics upstream of the flow cell. The acceptance criteria of the blank may be set using the desired statistical precision based on the expected sample counts and the historical background levels observed with clean instruments. Obtain the mean cumulative particle concentration. The concentration obtained should be below a predetermined cutoff specified by the method developed in *3. Instrumentation Standardization Test*.

## 7. TEST PROCEDURE

### 7.1 Product Determination

Because the volumes for FI are small, the nominal volume of the product is not important. The analysis will reveal the nature of the particles present in the product and will be used to support the counts from the other techniques.

Deliver the aliquot into the sampler and count particles according to the developed method. Commercial FI instruments will generate reports of the PSD or of the number of particles above stated diameters, as determined by software settings and the specified method. On the basis of the volume of fluid imaged, the software will normalize the particle counts so that results are reported as particle concentrations as well as particle counts.

## 8. FLOW IMAGING CALCULATIONS

FI instruments typically report particle load as a number concentration of particles per milliliter. For determination of the particles per container, multiply the average particle concentration (in units of particles per milliliter) by the liquid volume of the full container (in milliliters):

Particles per container = average particles/mL × nominal product volume (mL).

## 9. CONSIDERATIONS OF CONCENTRATION LIMITS BY FLOW IMAGING

For properly conducted measurements, particle concentrations as obtained by FI will be more accurate than those obtained by LO for particles with low optical contrast (such as aggregated proteins). However, LO remains an important tool for assessment of particle load because:

- LO instruments are highly reliable and repeatable
- Regulatory requirements for non-US markets may require the use of LO
- There is a long history and significant accumulated experience with LO testing of pharmaceutical products, and the historical values of measured particle concentration are readily compared to contemporary LO measurements

The correlation between FI and LO results will be repeatable if the measured particles have relatively high optical contrast (i.e., a refractive index difference between the particle and the matrix liquid >0.15), or if the nature of the particles in the test samples is similar to that of the samples used to establish the correlation in the drug-characterization phase of development. PS particle standards give equivalent PSD profiles with FI and LO. However, very different particle counts may be obtained with natural particle populations, especially those with protein or other semisolid particles.

Official

https://pharmacopeia.cn/

# APPENDIX

## Methods for FI Instrument Verification

### CONCENTRATION CALIBRATION

The particle concentration reported by an FI instrument may be checked by measurement of commercial PS concentration standards. The particle suspensions should have a nominal microsphere concentration between 3,000 and 10,000 $mL^{-1}$, with a stated uncertainty of the certified value of 10% or better in an aqueous media. The PSD should be largely monodisperse with a mean diameter of either 5 or 10 µm. Microsphere suspensions should be thoroughly mixed prior to use by following the manufacturer's instructions. Perform a preliminary measurement of the PSD to identify the measured diameter of the main peak. Adjust the measurement protocol to establish diameter limits corresponding to the lower and upper bounds of the main peak. Manufacturer's guidance on the diameter limits corresponding to the certified value may be useful for this purpose.

Instrument hardware should be adjusted so that each run records at least 1100 counts in the main peak (to obtain a relative standard deviation from Poisson count variance of ≤3%). If the instrument cannot be so adjusted to achieve this count, the results of multiple runs may be combined to obtain sufficient counts.

### DIAMETER CALIBRATION

**Background:** Calibration and adjustment of FI instruments to give correct diameter readings are typically performed at the manufacturer's factory or by field technicians, using proprietary methods. The tests below give recommendations for instrument verification suitable for implementation by manufacturers or field technicians.

Users, in general, will implement the less complex system suitability tests discussed in *5. Particle Counting Accuracy*, which suffice to demonstrate continued reliability of instrument performance.

**Manual method:** Calibrate the instrument with a minimum of three calibrators, such as near-monosize PS microspheres having diameters of approximately 2, 5, 10, 15, and 25 µm, in an aqueous, particle-free vehicle.[1] The calibrator spheres must have a mean diameter within 5% of the nominal diameters and be standardized against materials traceable to National Institute of Standards and Technology (NIST) standard reference materials. The microsphere suspensions should have a nominal microsphere concentration between 3,000 and 10,000 $mL^{-1}$, in an aqueous media. The PSD should be largely monodisperse. Microsphere suspensions should be thoroughly mixed prior to use by following the manufacturer's instructions. Perform a preliminary measurement of the PSD to identify the measured diameter of the main peak. Adjust the measurement protocol to establish diameter limits corresponding to the lower and upper bounds of the main microsphere peak. Manufacturer's guidance on the diameter limits corresponding to the certified value may be useful for this purpose. The range between lower and upper bounds is intended to include all single spheres, taking into account the standard deviation of the spheres and the instrument resolution while excluding noise and aggregates of spheres. Determine the mean of the measured particle diameters, and compare it to the stated mean diameter of the calibrator spheres.

**Automated method:** The calibration (size response) curve may be determined for the instrument by the use of validated software routines offered by instrument vendors; these may be included as part of the instrument software or used in conjunction with a microcomputer interfaced with the counter. The use of these automated methods is appropriate if the vendor supplies written certification that the software provides an appropriate response curve and if the automated calibration is validated as necessary (see also ⟨1058⟩.

### METHOD FOR DETERMINING INSTRUMENT RESOLUTION

Determine the resolution of the particle counter for 10-µm particles, using the 10-µm calibrator spheres. Other particle diameters can be used when justified. The relative standard deviation of the size distribution of the standard particles used should be NMT 5%. Run the microsphere suspension through the system to obtain at least 1000 counts in the main microsphere peak. Filter the data to remove any particles with circularity <0.85. the data to obtain the PSD with bin sizes NMT 0.25 µm. Identify a range of particle bins that are symmetric about the bin that has the maximum count and a sufficiently broad range of diameters such that the lowest- and highest-diameter bin have <1% of the count of the bin with the maximum count. Compute the standard deviation of the diameters of the filtered data corresponding to the range identified by data binning. The instrument resolution may be calculated from the observed deviation using the formula for percent resolution given in *Light Obscuration Method for the Determination of Subvisible Particulate Matter* ⟨1788.1⟩, *Appendix.*▲ (USP 1-May-2021)

[1] ASTM standard F658-00a provides useful discussions pertaining to calibration procedures applying near-monosize latex spheres.

## ▲1. INTRODUCTION

It is the intent of *USP* general test chapters *Injections and Implanted Drug Products* ⟨1⟩ and *Particulate Matter in Injections* ⟨788⟩ that systems, packaging, and formulation be selected and developed with regard to commercial product cleanliness and stability. Monitoring and limiting particulate levels are an important effort in ensuring product quality and controlling the risk of adverse effects or loss of drug efficacy.

A related chapter, *Measurement of Subvisible Particulate Matter in Therapeutic Protein Injections* ⟨1787⟩, categorizes particulate matter as intrinsic, extrinsic, or inherent. Process streams, equipment, and other factors related to the manufacturing process may contribute intrinsic particulate matter. Formula components and container/closure systems may contribute to immediate and even long-term generation of intrinsic particles. Poor selection or cleaning of components and systems can exacerbate these problems. The production environment, including personnel gowning and behavior, may contribute extrinsic particulate matter to the filled product. Finally, some products may have a small level of unintended particulate matter that is inherent to the product, even after careful formulation. All of these contributors to particulate matter and final product quality may be evaluated by the methods in ⟨788⟩ or variations thereof.

Historically, the first USP requirements for determination of subvisible particulate matter used the microscopic membrane (MM) method. Membrane filtration has the advantage of collecting a wide size range of particles and retaining these for later analysis, but MM is labor intensive and requires special facilities and operator training. Because it is automated and robust, the

light obscuration (LO) method was introduced in USP standards in 1985. By 1995, both methods had been optimized and applied in ⟨788⟩ to both large and small volume products. *Appendix 1* contains further information on the historical development of ⟨788⟩.

Several *USP* chapters are related to subvisible particles, including three compendial chapters, *Subvisible Particulate Matter in Therapeutic Protein Injections* ⟨787⟩, ⟨788⟩, *Particulate Matter in Ophthalmic Solutions* ⟨789⟩, and the aforementioned informational chapter ⟨1787⟩. This informational chapter is meant to complement the others and focuses on the description of the LO, MM, and flow imaging (FI) methods. All methods should address the specific analytical life-cycle requirements for the individual methodologies (*1*).

Chapters ⟨788⟩ (a harmonized chapter) and ⟨789⟩ provide an LO test (*Method 1*) for sizing and counting of subvisible particles (generally 2–100 µm) for nearly transparent, low viscosity ("waterlike") product samples, and an MM particle count test (*Method 2*) for manual particle sizing and counting as an alternate method. ⟨787⟩ also includes LO and is especially pertinent to protein therapeutics. FI is recommended as a third method to complement LO and MM, especially for particle characterization, and during product development. Although FI is not included in ⟨788⟩, FI can provide useful information on the types of particles in a test sample, aiding interpretation of LO and MM results, particularly for protein therapeutics.

In the LO method, a laser beam shines through the liquid sample as it is drawn through an optical flow cell. Any particles, air bubbles, or liquid droplets will scatter or absorb light to some degree, briefly reducing the total transmitted light. Each transient drop in detected light is counted as one particle. The MM method consists of filtering the liquid sample, inspecting the dried filter through a microscope, and manually counting particles above stated size thresholds. Soft objects, such as liquid droplets or aggregated proteins, can pass through or absorb onto the filter and are not reliably counted by this method For the FI method, the sample is drawn through a flow cell and a sequence of photographic images obtained of particles in the sample. Subsequent automated analysis gives image parameters such as size, morphology, and image intensity, which are useful to categorize particle images and provide improved understanding of the different particle types observed.

Product packaging, formulation, administration, and sourcing have become much more diverse since the 1980s. Improvements in manufacturing and filling arena design and control and the evolving quality of packaging components have steadily reduced the total particle load from adventitious contamination. This particle reduction has come through particle remediation efforts and improvements in product process control. (See *Visual Inspection of Injections* ⟨1790⟩*, 4. Inspection Life-Cycle*.)

The complexity of products has expanded to include smaller delivery volumes, specialized dosing and devices, the advent of therapeutic proteins and other biologics, and issues of product and package physical instability. This has led to increased scrutiny of particle load, with an emphasis on particles resulting from formulation-related changes (intrinsic) and product characteristics (inherent), especially for the subvisible particles (defined here as particles between 1 and 100 µm).

## 2. SCOPE

This chapter is meant to expand upon the information in ⟨787⟩, ⟨788⟩, and *Particulate Matter in Ophthalmic Solutions* ⟨789⟩ by including FI techniques and by providing additional guidance on the recommended use of LO and MM.

The use of the FI method for particle sizing and enumeration in this chapter constitutes a substantial update to past approaches. FI has become a valuable orthogonal method that provides morphology data. These data contribute to a better understanding of the particle population, help resolve discrepancies between other methods, and provide insight into further definition of the sources of the particle load, supporting risk assessment and evaluation of acceptability. This technique is commonly used for characterization of product and process. FI is not currently planned for inclusion in ⟨788⟩ because: 1) ⟨788⟩ is a harmonized chapter, and addition of a new technique would require new discussions for acceptance; 2) this is an emerging technique and there is both a lack of historical data from products that have patient exposure and an undetermined relationship of the particle size distribution obtained with FI relevant to that determined by LO or MM, making the establishment of specifications difficult; and 3) specifications (if/when set in the future) should be set by the stakeholder/company and should be product specific, based on prior knowledge and risk assessment.

This chapter directly supports ⟨788⟩ and ⟨789⟩; however, the chapter is also useful for ⟨787⟩, which addresses particulate matter testing for therapeutic protein products. Therapeutic protein products require special care in terms of particle measurement, and ⟨787⟩ provides modifications to ⟨788⟩ methods that are suitable for protein and other large-molecule formulations. This chapter incorporates those improvements because these are applicable to small molecule formulations as well.

The informational chapter ⟨1787⟩ describes additional tools and instrumentation for analyzing subvisible particles and remains a solid resource for forensic methods. The recommendations in ⟨1787⟩ are applicable to ⟨788⟩ and ⟨789⟩ as well. The techniques included in ⟨1787⟩ are all commercially available and can be used during product and process characterization. However, more experience and development is often necessary before methods can be validated and qualified to the extent necessary for lot release, for use in quality control laboratories, and for application in all product forms.

Tracking and identifying particles allow identification of the sources of the particle load and provide a means to evaluate product acceptability and drive product improvement. USP subvisible particle concentration limits apply to particle sizes ≥10 µm. Note that ⟨788⟩ carries limits for 10- and 25-µm particles, and ⟨789⟩ carries limits for 10-, 25-, and 50-µm particles. These limits were based on historical clinical exposure, not necessarily the demonstrated impact on patient safety (*2*). The use of the LO and FI methods at smaller diameters can provide valuable insights into product quality, especially in the development of biotherapeutics, as described in ⟨1787⟩. The impetus for evaluation of the <10 µm particle population for protein formulas is addressed by Carpenter et al. (*3*), Singh et al. (*4*), and Cao et al. (*5–6*).

# 3. BACKGROUND

## 3.1 Testing Considerations

LO is the preferred first-pass method for ⟨787⟩, ⟨788⟩, and ⟨789⟩, although certain solution formulations may not be easily analyzed using this technique. The LO method may encounter problems with a product that does not have clarity or viscosity approximating that of water. Further, formulation characteristics (e.g., color or viscosity) or inherent formulation properties (e.g., shear-induced changes) may generate erroneous LO data. Similarly, products that produce air or gas bubbles when drawn through the LO sensor, such as bicarbonate-buffered formulations, may generate erroneous high-bias data. LO has an inherent bias for sizing larger or fibrous particles (Feret's diameter ≥50 µm). For fibers that are longer than the illumination zone, LO will report an equivalent circular diameter that is closer to the fiber width than the equivalent circular diameter based on the projected area of the fiber (*7*).

The LO method can also be applied to particle sizes considerably smaller than the ⟨788⟩ lower limit of 10 µm with good reproducibility (*5*) and to particles sizes much larger than the upper limit of 25 µm, with proper sensor selection. Thus, valuable information on the product for visible and subvisible particle content is enhanced by including a few more size categories in the subvisible methods such as ≥2 µm and ≥5 µm, the compendial thresholds ≥10 µm and ≥25 µm, and perhaps ≥50 µm and ≥100 µm. Chapter ⟨1787⟩ provides guidance and advice for many orthogonal approaches that can also cover expanded size ranges.

FI is also useful for long-axial-dimension particles, yet it may encounter flow restriction biases. During calibration, size thresholding for LO is determined against spherical calibration standards, thus the results are reported in terms of equivalent circular diameter. MM and FI utilize direct comparison to linear standards. For particles of low refractive index close to that of the solution (such as protein aggregates), the diameter reported by LO will be smaller than the physical diameter of the particle, especially at sizes ≤5 µm (*8*). Any particles of entrained air or immiscible liquids (primarily silicone oil) commonly encountered in liquid samples are counted and added to the total particle population. Immiscible liquids and air are not detected by MM and are observed directly as high-contrast images by FI.

The MM method is useful for testing formulations that are not amenable to LO, such as those with color and viscosity affecting optical detection and those that are emulsions. MM isolates particles as a filter retentate, which a trained and qualified operator then uses to determine the count and size population. The isolate may be used for characterization of the individual particles and forensic microscopic categorization. The filter isolate in the membrane assay can retain particles ranging in size from the nominal pore size to millimeters. The dried, retained solid may differ from its nature in the product liquid. While the operator counts particles on the membrane surface that meet counting criteria (≥10 µm and <25 µm or ≥25 µm), there is also a concurrent, streaming view of particle appearance that provides an impression of the particle types or categories that are present. MM methods will not be useful for evaluation of silicone oil droplets or protein aggregates, because these flexible, amorphous particles are difficult to detect on the membrane and can pass through the pores as well. However, MM often can more accurately measure the size of particles with unusual aspect ratio or physical/optical properties.

The FI method has the advantage that all particles, liquid droplets, and air bubbles are captured in microscopic images. The images can be classified by morphological and image-intensity parameters, as well as by particle size. The classification can be useful in determining the relative proportions of different particle types, such as silicone oil droplets and protein aggregates. The reliability of the classification must be carefully qualified, especially for sizes <5 µm. FI has the additional advantage that particles of low refractive-index difference from the matrix formulation are more accurately sized than in LO, although these particles can still be problematic. Selection of proper flow cells and optics configurations in FI can provide particle detection <10 µm or >50 µm. Chapter ⟨1787⟩ provides more detail on alternate techniques for protein particle characterization. See also ASTM E3060-2016 for additional guidance on FI methods (*9*).

With past development of ⟨787⟩, ⟨788⟩, and ⟨789⟩, the focus was always on extraneous or foreign matter present in the finished drug product. Concerns about safety related to capillary occlusion and sterility, as well as pharmaceutical elegance, primarily drove this focus. Safety concerns about large numbers of subvisible extraneous particles were expressed by Langille (*2*) and Bukofzer et al. (*10*). However, there is an increased understanding that additional particles may result from the manufacturing process, from product or container degradation, or from properties of the drug product such as self-association. The presence of particles from any of these sources is an important product quality factor. Accurate particle concentration measurements are critical for understanding the content and source of the particulate matter and for ensuring long-term product stability. A more comprehensive explanation of particle categories is provided in *3.2 The Nature of Particulate Matter*.

In the case of protein-based pharmaceutics, there is an additional source of particles and associated product safety concerns. Proteins self-associate based on the inherent molecular properties of the specific molecule and can form aggregates in a broad size range, including 1–100 µm and larger. Proteinaceous particles in this size range can be quantified using LO and FI. Aggregated proteins have the potential to be immunogenic, adding another level of complexity to the monitoring and control of subvisible particles in protein therapeutics. On the other hand, protein-based vaccines may consist of aggregates or organized complexes such as viruslike particles, as inherent components of the vaccine product. In vaccines, immunogenicity is a desirable attribute, and subvisible particle monitoring may be performed to monitor product quality and batch consistency. The strategy and practices described in this chapter provide approaches for the safety and quality evaluation of the drug product. Safety perspectives for proteinaceous subvisible particles were introduced (as counterpoints) by Carpenter et al. (*3*) and Singh et al. (*4*) and more recently addressed in commentaries by Corvari et al. (*11*) and Narhi et al. (*12*). This has resulted in a substantial body of work exploring the potential immunogenicity of protein particles, which was reviewed by Moussa et al. (*13*), among others.

## 3.2 The Nature of Particulate Matter

Particles arise from many different sources. Over time, with growing experience in manufacturing and administration of therapeutics, it has become apparent that not all particles are equivalent in terms of their effects on safety or indications for

https://pharmacopeia.cn/
Printed on: Fri Jan 05 2024 06:39:38 AM(EST)
Printed by: USP NF
Do Not Distribute

product stability. One way to capture this difference in the risk associated with particles is to classify them into three broad categories: extrinsic, intrinsic, and inherent (See ⟨1787⟩). However, within these categories, different particle types can pose different patient safety risks. Since particle counting instruments have limited ability to differentiate among particle types, no single technique may be adequate to delineate the categories and track the particulates of most concern for product quality.

*Ophthalmic Products—Quality Tests* ⟨771⟩, *Injections and Implanted Drug Products* ⟨1⟩, ⟨787⟩, and ⟨1787⟩ have all adopted a unified definition for particulate matter. Two categories, extrinsic and intrinsic, describe the traditionally held concept of particles as foreign matter. A third category, inherent, describes particles that represent the character of the drug formulation and typify acceptable product. For further details, refer to ⟨1787⟩. The *European Pharmacopoeia* and *Japanese Pharmacopoeia* use two categories, extrinsic, which is from outside the manufacturing process, and intrinsic, which includes anything from the manufacturing process or the active ingredient and formulation components (the latter two described as inherent in the *USP*).

Heterogeneous particle populations are common (e.g., more than one chemical entity with many variations of density, refractive index, color, and shape). Heterogeneous particles are classified as either extrinsic or intrinsic based on the non-proteinaceous component that presents the greatest risk. Orthogonal techniques must be used to fully understand this particle type. As with all quality attributes, the ultimate decision on what levels are allowed should be tied to risk assessment and the clinical history of the product.

## 4. DETECTION AND ENUMERATION OF PARTICLES IN DIFFERENT SIZE RANGES

Particle formation often occurs across a size continuum with the lower end of the visible range near the upper region of the detection methods described herein (see *Figure 1* and ⟨1790⟩). The size range detected depends on the particle type and method used, and care should be taken to choose the appropriate method for the population being tested.

The techniques reviewed in this chapter are applicable for the determination of unwanted particle content, such as contamination, solids from instability, and insufficient package cleaning, as well as particles that arise from lubricants, product contact, formulation components, and the active pharmaceutical ingredient (API) itself. These particles vary in size from tens of nanometers to hundreds of micrometers, and many particle types do not have a defined size. Instead, they occur as a broad distribution of sizes, often with many more particles in the smaller size portion of the distribution.

Pharmaceutical products come in various forms with large differences in particle size distributions and in concentrations of particle types. Drug forms may include nanoparticulate suspensions, solid drug suspensions, and emulsions. Extremes of drug concentration and factors such as color and transmission variability, along with a wide array of active ingredient sources that have small to very large molecular weights, may all play a role in particulate formation. Packaging varies in terms of fill volumes and materials, which include soft polymers, glass, and hard polymers. Medical devices, combination devices, and unique drug delivery systems are also on the market. Sampling many of these systems presents a challenge to existing conventional procedures.

For example, products formulated as non-solutions are inherently particulate in nature and can thus complicate the analysis of the unwanted subvisible particles within the overall product. For this reason, it may be necessary to monitor subvisible product at non-adjuvanted/intermediate product stages, where justified. One can also evaluate the particle load of a placebo or media fill on the same line to demonstrate quality. Whatever their nature, monitoring of subvisible particles is important to ensure consistency from lot to lot and between clinical and commercial products.

Evaluation, test method development, and control for particles in the formulation in the <10-µm range can be important for some of these products. For biologics and vaccines, detection below 10 µm is important to capture protein aggregate contents (see ⟨787⟩ and ⟨1787⟩). Ophthalmic solutions require particle determination at an additional 50-µm threshold, as specified by ⟨789⟩. Correlation of subvisible content with the visual inspection program (see ⟨1790⟩) promotes the use of higher-end instruments to probe the lower end of the visible size range. Certainly, there are other applications that may affect the system design and use. Calibration is described in ⟨788⟩ as "….apparatus is calibrated using dispersions of spherical particles of known sizes between 10 and 25 µm. These standard particles are dispersed in particle-free water." When detecting particles <10 µm and those ≥50 µm, as discussed in ⟨789⟩, calibration may be necessary far outside the conventional range set for in ⟨788⟩ in order to address the above considerations.

The sizes reported and the populations interrogated are quite dependent upon the technique, so it may be necessary to run orthogonal techniques plus qualitative particle identification to assess the particle population with confidence. Chapter ⟨1787⟩ provides an overview on the practical use of commercial instrumentation for the pharmaceutical subvisible range (2–100 µm). The difficult <2 µm domain, which is of interest for quantifying inherent protein-particle content of biotherapeutics, will require multiple techniques for full understanding (*14*). Note that ⟨787⟩ and ⟨1787⟩ focus on the inherent protein (or other formulation) particles, rather than contamination analysis.

No single method should be used during development, but rather orthogonal testing should be employed for full characterization and understanding of the expected particle population for that particular product. During production, if the LO lot release method fails, these methods can be deployed to determine root cause and other factors.

All three methods produce appropriate counts in size thresholds when used properly and applied to appropriate sample formulations and particle populations. But each can be misused, and each has inherent drawbacks to consider. Calibration and operator training are imperative. Instrument standardization and count accuracy demonstrate appropriate configuration. See *Table 1*.

The comparison in *Table 1* considers visible to subvisible techniques recommended for all particle sizes. It underscores that an orthogonal approach for particle evaluation and tabulation is important to obtain comprehensive information about the particle population and thus product fill integrity and product stability. The ⟨788⟩ guidance methods are used as a baseline and as prospective release methodology. The use of additional non-compendial techniques may be necessary to develop a full understanding of the particle population. An example of these techniques has been reviewed in ⟨1787⟩ and in a 2016 *Stimuli* article (*15*).

Final product quality regarding particulate matter must include both the visible and subvisible size ranges, which may be related for certain incidents involving contamination or product instability. Inherent particles resulting from protein

self-association often span a continuum from sub-micrometer to visible particles as well. Chapter ⟨1790⟩ provides a comprehensive discussion of visible particle detection systems and product development considerations.

## 5. APPLICABILITY OF METHODS

All sterile solutions for injection or parenteral infusion are included within the scope of these test regimens. However, some solutions are amenable to the methods while others are not. All will require qualification of the methods for specific product forms and formulation families.

Clear, aqueous-solution formulations with low to moderate concentrations of the active pharmaceutical ingredient (API), and simple vehicles, will be the most suitable (with minimal method development or changes) and amenable to all ⟨1787⟩ and ⟨1788⟩ methods. Of greatest concern for all techniques are formulations that have competing solids, suspensions (either as-is or after resuspension), emulsions, and nanodispersions. Many of these issues may be addressed by additional sample treatment. Informational chapter ⟨1790⟩ and *PDA Technical Report No. 79: Particulate Matter Control in Difficult to Inspect Parenterals* (*16*) discuss options for analyzing the visible particles in these products, which are also applicable to subvisible assays.

Certain products may exist as suspensions, i.e., containing insoluble components in the formulation. Examples include cellular therapeutics and adjuvanted vaccines. Such products may not be tested directly unless a phase separation of the product is feasible, allowing subsequent analysis. Other techniques described in ⟨1787⟩ may be useful.

**Table 1. Comparison of Visual Inspection, LO, MM, and FI**

| Technique | *USP* General Chapter(s) | Sample Volume | Compendial Method-Based Detection Ranges | Method Artifacts | Method Limitations |
|---|---|---|---|---|---|
| Visual | *Visible Particulates in Injections* ⟨790⟩, ⟨1790⟩ | Container volume in a defined cylinder of view | Probabilistic, nominally single particles >100 µm in reflected light; color, opacity, and refractive index (RI) difference aid detection | Subjective decisions, container seams and irregularities, air bubbles | Particulate matter (PM) of small size, transparency, or low contrast, dwell time and depth of field or container/formula limitations on detection |
| LO | ⟨787⟩, ⟨788⟩, ⟨789⟩, ⟨1787⟩, ⟨1788⟩ | 0.2–5 mL per draw of product or test fluid | PM >2 µm up to sensor limit; shadow on the detector from particles in confined cell between illuminator and sensor; upper limit depends on the sensor used; opacity, RI difference aid detection | Air, immiscible liquids, Schlieren effects, cell soiling, high PM concentration | Low contrast and large PM, >500 µm; floaters, sinkers, very thin flakes; size range determined by sensor choice |
| MM | ⟨788⟩, ⟨789⟩, ⟨1788⟩ | 0.1 to hundreds of milliliters per draw of product or test fluid | PM >5 µm, virtual optical image by reflection and shadowing on membrane substrate; particles are retained on the membrane for subsequent analysis, if desired | Membrane features, PM in rinse or glassware, deposition/drying effects on membrane | Air, immiscible liquids, soft or gelatinous semi-solids that may sink into surface; sample must be chemically compatible with membrane and also visually discernible |
| FI | ⟨1788⟩ | 0.5–1 mL per draw of product or test fluid | PM generally >2 µm to an upper limit depending on the flow cell, digital camera images captured; image and dimension may be evaluated post-collection | Particles adhering to cell walls, transient air gaps; cell contamination is effectively removed by background subtraction; changes in cell contamination are a bigger issue | Low-contrast PM, floaters, fibers; size range determined by flow cell |

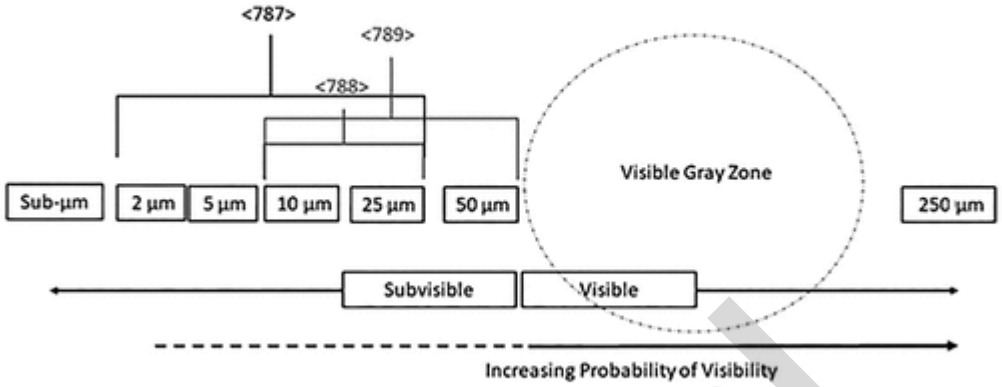

Figure 1. Continuum of particle sizes from subvisible through visible, indicating the scope of ⟨787⟩, ⟨788⟩, and ⟨789⟩.

*Figure 1* provides a schematic overview of the size ranges within the scope of ⟨787⟩, ⟨788⟩, and ⟨789⟩. Brackets indicate the range of lower size limits requiring particle concentration determinations for each of these chapters. The "Visible Gray Zone" refers to the size range where particle detection by visible inspection is probabilistic, with the probability of detection falling to zero near 50 µm.

## 6. PARTICULATE MATERIAL EVALUATION

For all particle determination efforts, and ultimately to reach a comprehensive control strategy, it is necessary to understand the category, if not the identity, of the particle population. As described in this chapter, extrinsic and intrinsic particles may be quantified (using LO), quantified and described (using MM and FI), and isolated (using MM) for further analysis.

For extrinsic and intrinsic particle varieties, it is recommended to use a database consisting of an internal particle library that provides particle references. The database is a key component of particle classification, risk assessment, and the ultimate identification. Some public domain and vendor databases are available, but the best database comes from compilation of particle species from your own operations.

Evaluation of the inherent particle-population baseline will utilize ⟨788⟩ techniques but also those described in ⟨1787⟩. For protein therapeutic drugs, establishment of the inherent baseline of proteinaceous particles is necessarily important and has been discussed in detail (*17*).

LO provides only particle concentration for specified size bins. Although these data are valuable for tracking product quality and manufacturing consistency, LO does not differentiate among particles based on particle types. Both MM and FI provide additional information on particle attributes other than size. FI reveals the images of all particles streaming by the camera system and thus allows classification according to morphology and image intensity. MM not only tabulates counts but also reveals the particle image and provides an isolate for analysis after counting.

However, much more can be done to fully characterize and possibly identify particulate matter with an integrated approach using light microscopy, vibrational spectroscopy, elemental analysis, and electron microscopy (*18–20*). These references describe a forensic pathway of identification, and ⟨1787⟩ provides a review of useful techniques with their advantages and disadvantages.

Applicability of any of these tests for specific products should be evaluated using appropriate qualification steps. Qualification of the instrument should be based on frequency of use, maintenance schedule, and accuracy requirements. General guidance on performing qualification is provided in *Validation of Compendial Procedures* ⟨1225⟩ and *Verification of Compendial Procedures* ⟨1226⟩.

### 6.1 Final Filter Exemption

General chapter ⟨788⟩ provides the following: "Parenteral products for which the labeling specifies use of a final filter prior to administration are exempt from the requirements of ⟨788⟩, provided that scientific data are available to justify this exemption." The purpose of this exemption is to offer a mechanism to reduce the subvisible particulate burden inherent in the final drug product when the amount would exceed acceptable limits and cannot otherwise be reduced through formulation adjustments or the manufacturing process prior to use. The utilization of an in-line filter should be driven by risk benefit evaluation of the potential clinical implication of subvisible particulates for the intended user population, but not be recommended to mitigate a Current Good Manufacturing Practices (cGMP)-related product quality issue (e.g., the presence

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M3023_02_01
@2024 USPC

of extrinsic particles). The application of this exemption should be supported by scientific evidence sufficient to justify its adoption and generally include the composition and mechanism of formation of the particles in addition to demonstrating that process-optimization strategies failed to reduce the particle load. Labeled recommendations of filter type and size should also be supported by appropriate drug product compatibility assessments, consistency in particle removal, and clinical data as necessary. Demonstration that drug potency is not significantly affected is essential. An associated risk assessment is strongly encouraged to evaluate the potential clinical implications to the intended user populations if a final in-line filter is not utilized.

## 7. USP SUBVISIBLE PARTICLE LIMITS

Current limits for ⟨787⟩ and harmonized ⟨788⟩ methods are set at maximum allowable particles per container or particles per unit volume at size thresholds ≥10 and ≥25 µm. These limits are historical and have changed over time based on method development and species of concern. Chapter ⟨789⟩ applies the 10- and 25-µm thresholds as well, plus a 50-µm threshold. In ⟨789⟩, the limits are provided only on a per milliliter basis. Chapter ⟨771⟩ provides the direction for the testing of ophthalmic products, using ⟨787⟩, ⟨788⟩ or ⟨789⟩ limits, based upon product application.

The calculation of allowable particle content is based on product volume (as determined by the manufacturer) for the SVI market, and on a particles-per-milliliter basis for the LVI market. However, these limits are generous, and actual particle loads are often an order of magnitude below them. All efforts to reduce particle load and maintain a consistent low-particle contribution are encouraged.

**Table 2.** ⟨788⟩ **Particle Content Limits**

| | Technique | | | |
|---|---|---|---|---|
| | LO | | MM | |
| Technique range | 2-500 µm | | 5 µm to several millimeters | |
| Particle size | ≥ 10 µm | ≥ 25 µm | ≥ 10 µm | ≥ 25 µm |
| SVI ≤100 mL | 6000/container | 600/container | 3000/container | 300/container |
| LVI >100 mL | 25/mL | 3/mL | 12/mL | 2/mL |

[NOTE—Chapter ⟨787⟩ limits the total content of particles in LVI products to 6000 particles ≥10 µm and 600 particles ≥25 µm.]
[NOTE—For ophthalmic products, please consult ⟨771⟩]

*Table 2* gives the particles per container or particles per volume requirements from ⟨788⟩. No limits have been established for the use of FI or for the collection of data with size thresholds <10 µm for ⟨787⟩, ⟨788⟩, and ⟨789⟩. As *Table 2* shows, the registration limits vary according to technique and injection product volume. Furthermore, as discussed previously, the technique capabilities are certainly not equivalent across a broad range of sizes.

Particle concentration should be monitored even for samples that give results below the *Table 2* limits. Although technically within USP specifications, particle content in a single container near the limit may be a concern and may indicate problems in product quality. Results that are out of trend with what is normal for a product, even if well below the specification limits, would be of concern as well and should also be investigated. The use of additional analytical methods and the imparting of controls specific to the medication and dose are important extensions of this guidance.

The *Table 2* particle concentration limits are often significantly higher than the particle concentrations observed with many commercial products. The limits apply both at time of release and at the end of shelf life, and they apply to a range of product types, from the simplest (e.g., sterile water in an ampule) to the most complex formulas with stability issues. As mentioned in *1. Introduction*, this is a limit based on historical experience; internal target choices, discussed in *8.1 Development*, allow for consideration of product histories, product types, therapeutic uses, and patient populations.

The intent of these tests is to provide a control strategy framework for designing the most stable formula, selecting the most stable and inert package, and employing an elegant fill/finish in a high-quality, state-of-the-market factory. The limits are imposed as a minimal standard of control, with the intent that the innovator, contract manufacturing operation, or generic producer will meet and exceed this standard across all injectable dosage forms, as appropriate to ensure high product quality. A strategy to achieve these goals is discussed in *8. Control of Particulate Matter*.

## 8. CONTROL OF PARTICULATE MATTER

It is the intent of ⟨1⟩ that in the design of formulations, selection of packages, and final assembly of packages, a stable final product is attained. Using the methods and limits in ⟨788⟩ and ⟨789⟩, high-quality commercial product cleanliness and stability are verified. This state can be described as "clean" (few particles) and "stable" (avoiding changes that promote particle growth). Process streams, equipment, filling lines, pumps, staging tanks, personnel gowning, packaging cleanliness, and environmental quality all may contribute particulate matter to the product. Insufficient cleaning of product components and inappropriate selection of both container–closure systems and formula components may contribute to immediate and long-term generation of particles. Intrinsic sources of detectable particulate matter may be present but not yet evident until particles form over time, sometimes long after lot release. This should be assessed by performing drug stability studies, and subsequently controlled in the commercial product.

Official

https://pharmacopeia.cn/v-cn/

## 8.1 Development

Due diligence using particle detection methods endorsed by USP or alternate method strategies (new methods, not in *USP–NF*) for the best product design is recommended during product and process development and may be continued in selected evaluations during commercial production. The use of many methods early in development is an important consideration for limiting the number of particles in the product and for full understanding and characterization of the particle population.

To accomplish this, start early and conduct analyses often, using methods appropriate to the product development phase (*11*). Analysis using only lot release methods will give a limited understanding of the particle population. As the development cycle progresses, the use of orthogonal techniques provides greater confidence in particle assessment. It is important to explore the incidence of change in the number of particles during early phases of development to provide the optimal selection of formulation, manufacturing process, and packaging. Also, prior to commercialization, the character of inherent solids must be fully explored to establish the range of its acceptability.

Particles may form during manufacturing or over time due to any one or more of the following factors:

- Formulation instability
- Package cleanliness
- Package selection (quality/stability)
  - Inorganic extracts
  - Organic extracts
  - Product-package interaction
- Process contributions
  - Stresses throughout the process (e.g., pH swings, surface exposures)
  - Inorganic extracts
  - Organic extracts
- Silicone content

When evaluating particle data, consider the basis for size and number generation as well as the types and sizes of particles that each technique can or cannot reliably detect. Also consider when a change of particulate amount and/or distribution is or is not significant. Likely it depends upon the basis of the technique and its demonstrated precision for quantification of the particle type of interest. Important considerations are matrix and particle character such as opacity, density, color, refractive index, shape/morphology, and true nature (e.g., liquid, matrix-aggregate, agglomerate). Results should be qualified by known standards matching the particle type(s) of interest to the extent feasible. In the case of interfering particle populations (e.g., silicone droplets interfering with counts of protein aggregates), qualification may include measurement of two single-component populations and mixtures of these.

The chosen target specifications unique to a product are an important extension of the USP limits in *Table 2*. In the implementation of a target-specification strategy, several tenets apply:

- Understand and minimize inherent particle load when appropriate
- Minimize intrinsic particle load
- Identify and characterize particles during development, and establish a particle database
- Correlate particle load to visible particle rejects
- Track the particle population within product families and across historical batches to reveal anomalous trends and initiate remediation
- Establish targets for particle content relevant to product family, including considerations of manufacturing arena, packaging, and formulation complexity

## 8.2 Statistical Sampling Plan

Chapter ⟨788⟩ provides the sampling plan according to product volume, while ⟨787⟩ emphasizes a statistically relevant sample plan independent of volume. For all products, regardless of volume, comprehensive experience regarding the integrity and consistency of the batch is gained throughout development by analyzing a number of samples throughout each batch. Experience obtained during product development indicates the proper sampling plans to be applied in commercial production to ensure that sample selection is representative of batch quality. All batches must have sampling plans that accommodate desired statistical measures of batch quality and facilitate process control. Earlier stages of drug development will require less statistical precision than late-stage development or release. The sampling plan should consider the statistical precision of the obtained counts, the likely heterogeneity within a vial or other vessel, the likely heterogeneity between vials or other vessels, and variations in particle concentration with time or other variables.

A combination of individual and pooled counting data should be considered in statistical evaluations to provide confidence in commercial release testing. For example, during development, primary consideration is given to formulation stability, because production is usually in smaller batches and not in the final at-volume commercial arena. Ideally, all containers contain the same low level of particulate matter; however, there are conditions that promote heterogeneity or, more specifically, produce containers with higher particle load than average. These conditions include the following:

1. Insufficient or inconsistent container washing
2. Particle load on the stoppers
3. Variations in silicone coater performance
4. Particles contributed by the filling equipment (particle load may vary from pump to pump)
5. Particles contributed by the drying/sterilization system
6. Failure of aseptic filling conditions

@2024 USPC

7. Self-association of active ingredient or formulation components
8. Particles generated over time, due to formulation instability or product-package interaction. Inherent particles have been observed to have highly non-repeatable growth kinetics such that one vial may have a single large particle while other vials of the same lot have multiple small particles.

Chapter ⟨788⟩ provides a sampling plan according to product volume. This plan is based solely upon the limitations of traditional optical counting instruments for adequate, multiple-sample aliquot draws. Originally, the sample volume for the LO method was set at 25 mL and maintained for years, primarily due to the limited capability of the then-primary instrument, the high-accuracy particle counter (HIAC), to draw 5-mL sample volumes. Collecting sample aliquots for averaging provided a single value for the batch. Accordingly, the same sample volume was maintained for MM, but this volume was not due to a method restriction. Due to the current capability of MM to process any liquid aliquot regardless of volume, a wide range of sampling volumes can now be accommodated.

In the current analytical instrument market, much smaller sample-volume draws are accurate and precise for optical particle counters and other techniques. Additionally, due to the expansion of dosage forms to include very small volumes of a highly concentrated drug, and the cost of certain pharmaceutical drug products, there is compelling stakeholder interest in allowing much smaller sample aliquots such as those described in ⟨787⟩.

Unit variability is an important quality parameter 1) during development of the formulation; 2) after process changes, such as container or stopper washing or fill-arena changes; and 3) when changing package vendors. Evaluation of the non-pooled vials can give a better measure of inter-vial variability and also can eliminate the introduction of particles in the pooling process. However, use of smaller sampling volumes must be balanced by batch sampling, which will provide adequate statistical power for evaluation of acceptability.

For all products, regardless of volume, comprehensive experience regarding the integrity and consistency of the batch is gained throughout development. This allows the proper batch sampling plans to be applied for commercial production to ensure that sample selection is representative of batch quality. All batches must have sampling plans that accommodate desired statistical measures of batch quality and facilitate process control, regardless of volume tested or method used (e.g., ⟨787⟩, ⟨788⟩, or ⟨789⟩). The FDA provides sampling plan guidance (*21–22*), and guidance is also available from ISO (*23*) and ANSI (*24*).

Final unit variability should be minimal. While 100% visual inspection is a comprehensive check for the entire batch, it is limited to fill color, fill haze, and larger particles in the fill. Subvisible particles are only visible when large numbers produce light blockage and scatter. There is low probability of visibly detecting particles <100 µm.

The above factors account for heterogeneity of the sampled particle load. Lack of repeatability in the particle measurement process introduces additional variability. Differences in sample preparation by different analysts can cause substantial variation in count, especially for samples sensitive to handling. Repeatability studies using samples similar to the samples of interest, rather than polystyrene microspheres, will give a more accurate assessment of measurement repeatability.

### 8.3 Risk-Based Approach

The USP limits in *Table 2* mirror the historical approach of obtaining particle concentrations above given size thresholds and treating all particles as equivalently deleterious to product quality. However, the increased variety of particle types in modern pharmaceuticals, each with different risk factors, suggests that a better approach would be to identify the particle concentrations of the component subtypes of the total particle load and to then assess the risk to product quality posed by each particle type.

For example, the presence of extrinsic particles could be evidence of a breach in sterility, with a high product risk. Increases in intrinsic particle load may be associated with the production process and/or package-related sources, which can be indicative of systemic problems. Conversely, the presence of air bubbles is not a concern.

Risk for elevated final product particulate levels will be reduced when there is deep product knowledge and when systems are utilized to control the process stream in the reduction of particle load (type). Consideration should also be given to the following:

- Package selection with regard to formulation (stability)
- Package source and preparation quality (removal and addition)
- Product-contact surfaces (particle load and extractable substances)
- Filling arena cleanliness and practices (addition)
- Formulation design (stability)

Successful risk analysis may require considerable particle characterization, beyond what can be achieved by LO, MM, and FI, and utilization of prior knowledge (*25*).

## 9. SILICONE DROPLETS AND AIR BUBBLES VERSUS NON-SILICONE PARTICLES

With the historical use of a single optical particle counting approach (LO), there was high reliability, reproducibility, and throughput for the quality control lab analysis of particle load. However, the technique does not provide differentiation between solid, liquid, and gaseous matter initiating the counting pulse. Both FI and MM can be useful adjuncts to LO in distinguishing air bubbles and silicone oil droplets from other particle types.

Certainly, the content of gas bubbles identified as counts by a particle counter may be considered an artifact of the formulation and/or sample preparation and may be alleviated or negated by sampling or preparation methodology or data manipulation. The counts by optical methods of immiscible liquids, which are largely composed of the ubiquitous silicone lubricants in pharmaceutical articles, must be considered. For some dosage forms such as cartridges, syringes, and some devices, lubrication (usually by silicone oil) is necessary.

There is a difference of opinion regarding the relative risk posed by silicone oil droplets. These opinions range from "no risk"—based on the droplet sterility and on the long history of medical use and patient exposure to silicone oil—to "potential concerns" about the increased immunogenicity of biologic drugs. Immunogenicity would arise from possible interactions between the

https://nhathuocngocanh.com/

droplets and the protein, resulting in an increase in protein aggregation or the silicone oil acting as an adjuvant. This is an active area of research. Regardless of the acceptability of the presence of high levels of silicone oil, an analytical strategy to accommodate and explain the presence of silicone droplets must be achieved by selection of the instrumental technique and methods applied during counting.

Historically, MM was used as a "referee" method to resolve the occurrence of elevated LO particle counts by verifying whether the counts were due to solid particles rather than gases and liquids. With the addition of FI, it is now possible in many cases to begin to resolve and differentiate gases and liquids counted as particles from the semisolid to solid particle fraction. Even in those cases where the differentiation of air bubbles and silicone oil from other particles is imperfect, the partial differentiation obtained with FI can provide useful guidance for optimization of sample handling and assessment of comparability of the protein particle population.

Air and immiscible liquids do not affect the membrane count. Membrane surface artifacts and semisolid particles can, however, complicate this analysis, while many protein samples spread out on the surface such that they are not detectable. This procedure is also time consuming and difficult to reproduce, requiring extensive operator training. It is usually only applied to biologics when identification of foreign particles is performed during development of nonconformance investigations.

## 10. CHALLENGING SAMPLES

Alternate methods may be necessary for dosage forms for which ⟨788⟩ cannot be directly applied. This includes some of the sample types described in *5. Applicability of Methods* (e.g., process streams, vehicles, or components). Alternate methods and/or evaluation should be considered for dosage forms and process samples for which optical detection is not practical.

For example, some products have inherent properties that affect or preclude particle counting so ⟨788⟩ methods cannot be used as written. For other products, development activity may be needed (see ⟨1787⟩). Direct evaluation of container–closure rinses and product vehicles may be used for these suspension systems by the ⟨788⟩ methods. When the product is not a solution or is viscous or will otherwise confound the ⟨788⟩ methods, it must be altered or accommodated to facilitate the assay. Examples of alternate methodologies are:

- Particle determination of product after treatment with solvent to dissolve all product solids
- Use of centrifugation to separate product solids from the vehicle
- Use of selected screens or sieves to separate product solids from the product vehicle to minimize interference
- Evaluation of the product filling system by using an alternate, clear fluid such as sterile media or saline

Use the methods that are best adapted to the particle type and volume of sample. Selected sampling requires careful statistical evaluation of the batch population when using small sample volumes to evaluate product acceptability; this applies to all methods. Regardless of the sample size, the number of samples tested should be determined statistically based on acceptable risk and development history.

## 11. FACTORS AFFECTING ALL METHODS

### 11.1 Guidelines for the Use of Calibrator Spheres

#### 11.1.1 GENERAL

Polystyrene spheres of stated diameter, or stated diameter and concentration, are commercially available for calibrating particle counting instruments. All such standards are only valid if the spheres are predominantly unaggregated. When measuring particle mean diameter, particle concentration, or instrument resolution, the user should inspect the particle size distribution to confirm the absence of microsphere aggregates. Aberrant calibration results may be due to instrument or method problems or calibrant quality. If there is evidence of aggregation, the bottle of calibrator spheres used should be discarded. Any results obtained from a vial that has demonstrated aggregation of spheres should be disregarded, as long as a satisfactory result with a new source of spheres is obtained. If the instrument is running properly but the calibration results deviate from the manufacturer's specifications, and the calibrator spheres show no indication of aggregation, the manufacturer of the instrument should be consulted.

#### 11.1.2 SPECIFIC STANDARDS

Chapter ⟨788⟩ specifies the use of mono-sized dispersions of traceable spherical particles with known diameters that include the 10- and 25-µm required sizes for particulate-matter testing. This must also include an expanded range of sizes to cover the calibrated range between 2 and 100 µm. The calibration curve should include additional sizes such as 2, 5, 10, 15, 25, and 50 µm, especially when particle load data are expected outside the traditional ⟨788⟩ thresholds. All particles are suspended in particle-free water (do not use *Water for Injection*), with small amounts of surfactant and preservative allowed.

Each calibrator sphere size should have a mean diameter within 5% of the nominal diameter and should be traceable to National Institute of Standards and Technology (NIST) standard reference materials or certified reference materials from other national metrology institutes.

The concentration of calibrator microspheres may be certified by the manufacturer or by the user via MM or other methods (*26*). For an MM determination of particle concentration, pipet a volume of the suspension containing 250–500 particles into a filter funnel. After drying the membrane, count the total number of standard spheres collected on the membrane filter. The size calibration should be done with the same standards. It is very important to calibrate for both size and number of particles, as the accuracy of one can influence the other.

## 11.2 Elements of Measurement Quality Control

Quality control of measurements is ensured by a hierarchy of activities. See *11.3 Validation Considerations for All Techniques*. This topic can be generally summarized as the following:

- Method validation ensures that the chosen method will reliably measure the quantity of interest at known levels of accuracy, precision, and specificity (see ⟨1225⟩)
- Instrument qualification verifies that a particular instrument is fit for purpose (see *Analytical Instrument Qualification* ⟨1058⟩)
- Instrument standardization tests (ISTs) are the historical parameters of control for LO and are described in this chapter
- System suitability tests (SSTs) are routine and usually single-pass measurements performed to demonstrate a high degree of confidence that the instrument is performing correctly in use. The SST contained in this chapter for LO is a series of tests that demonstrates that each parameter complies with the manufacturer requirements.

Elements of method validation will be discussed for each technique; however, each method should include an assessment of the following:

- Recovery
- Accuracy
- Precision
- Specificity
- Lower detection limit
- Upper detection limit
- Sampling volume
- Linearity/range

For all the methods, there are general laboratory and sample considerations. First, remember that the main objective is to determine the level of unwanted particulate matter in a final parenteral product. The handling of the article during setup, selection, preparation, and testing should not significantly affect the results. For articles with a higher resident particle load, the impact of handling and area cleanliness is not as pronounced; however, the same general, clean, systematic approach must apply for all samples. See *Appendix 2* for further details on cleaning procedures.

As described in ⟨788⟩, determine the particulate matter in 5 samples of filtered water, each with a volume of 5 mL (or a blank volume that is equivalent to the sample volume for your specific method). For the 5-mL blank volume, if the number of particles that are ≥10 µm in size exceeds 25 for the combined 25 mL (NMT 1/mL), then this indicates that the precautions taken for the tests were not sufficient. Achieving a low number in the blank verifies that the equipment, operations, and sample residuals are not contributing significant counts. This is most important for ⟨789⟩ operations, which have strict limits. This guidance provides a practical limit for all methods, as it demonstrates insignificant impact of the operations for article preparation, glassware, sample handling, and instrument/apparatus cleanliness. Having a low-traffic, designated area for particle counting operations is recommended but may not be necessary depending on the method and the sample condition. Finally, when utilizing any technique for ⟨789⟩, the blank test should be considered carefully, as the limits are more restrictive than for ⟨787⟩ and ⟨788⟩, and there is an additional size threshold, ≥50 µm, to consider. Blank counts for ⟨789⟩ should be consistently very low to zero within a properly configured lab and using clean equipment and glassware.

## 11.3 Validation Considerations for All Techniques

Although the ⟨788⟩ methods are deemed robust for most product forms, deviation from clear, noncolored, and waterlike formulations may need further study. At the very least, an alternative particle counting strategy and a recovery study with known particle size standards will demonstrate the performance of the method for a specific medium. As described in the rest of this chapter, orthogonal methods may be necessary to fully understand the properties of the product. The following guidance is useful for comprehensive evaluation.

Chapter ⟨1225⟩ and ICH Q2(R1) (*27*) provide comprehensive guidance for validation of analytical procedures, as do the IST routines endorsed by the vendors. The aspects of assay validation in these guidelines are as follows:

- Chapter ⟨1225⟩: Accuracy, Precision, Specificity, Detection limit, Quantitation limit, Linearity, Range, Robustness
- ICH Q2(R1): 1. Specificity, 2. Linearity, 3. Range, 4. Accuracy, 5. Precision, 6. Detection limit, 7. Quantitation limit, 8. Robustness, 9. System Suitability Testing
- IST for LO: *Light Obscuration Method for the Determination of Subvisible Particulate Matter* ⟨1788.1⟩*, 3. Instrument Standardization Tests, 3.1 Sample Volume Accuracy, 3.2 Sample Flow Rate, 3.3 Diameter Calibration, 3.4 Sensor Size Resolution*, and *3.5 Qualification Considerations*

Validation requirements are discussed in ⟨1225⟩. However, for a limits test such as the testing described in ⟨788⟩, it has been common and acceptable in the US to use the following for evaluation of performance:

- IST as described in *13. Instrument Standardization Tests*
- Particle count reference standard compliance for counts conducted daily, weekly, monthly, or quarterly
- Spiked recovery studies to verify optimal sample preparation, mixing, and presentation

Both LO and MM methods provide a robust and reproducible particle content determination. Many companies have collected these data over an extended history, and the data are appropriate for most product formulas as written. Clear, low-concentration formulations that mix easily often require no further method modifications for validation. However, verifying acceptability for specific product families is an important step. Interference of test-sample attributes with various particle counting methods is discussed in *4. Detection and Enumeration of Particles in Different Size Ranges*. Method development as discussed in this section is a critical aspect of method validation. The fewer samples that deviate from non-labile particles in waterlike formulations, the greater the need for careful method validation.

Official

https://pharmacopeia.cn/v-cn/

For those formulations that are highly concentrated, colored, or viscous, or that have specific gravity significantly different from water, the effects of the formulation character will require further consideration for method acceptability. Particle-recovery and -counting linearity should be standardized and verified for test methods that require sample mixing and pooling. When this is required, the test method should use the same procedure. MM samples the entire (drained) product fill and thus has no similar sampling issues.

Chapter ⟨1225⟩ indicates that specificity and detection limit are necessary elements for limit tests and, depending on the nature of the test, accuracy and range are as well.

For all techniques:

### 11.3.1 SPECIFICITY

As discussed previously, LO instruments will count air bubbles, immiscible liquid droplets, and semisolid and solid particles. Thus, LO has low specificity, and the specificity for detecting the particles of interest should be qualified by other methods. MM is insensitive to air bubbles and liquid droplets. FI will capture images of all bubbles, droplets, and particles. The specificity of FI can be assessed by measurement of mixtures of known particle concentrations followed by analysis with the algorithm that will also be used for the specific product.

### 11.3.2 RECOVERY

The use of microspheres of lower refractive index than polystyrene (such as polymethylmethacrylate or silica) or other particles of low refractive index may be appropriate to model particles of low refractive index difference for both LO and FI. In all cases, the ability of the method to accurately report the number of particles within the assigned sizing bins should be determined.

### 11.3.3 LINEARITY AND RANGE

Linearity and range can be assessed by the measurement of microsphere mixtures at different dilutions followed by comparison of the measurement result with the particle concentration expected from the known dilution factor. All three methods are subject to coincidence errors in which two particles appear as a single particle. LO method has typical coincidence errors of 10% at particle concentrations ranging from several thousand to a hundred thousand particles per milliliter, depending on the sensor choice. Typical FI instruments have much lower coincidence errors than MM or LO. For all methods, coincidence errors will depend on the nature of the particle size distribution, with larger errors for a size distribution with larger particles. The range extends from the level of background counts observed to the highest concentration with acceptable coincidence error.

### 11.3.4 ACCURACY

For particle counters, there are two types of accuracy that must be assessed: accuracy of reported diameter and accuracy of reported particle count. Both may be assessed at a basic instrumental level by measuring microsphere suspensions of known diameter and/or concentration. However, LO, FI, and MM will all report different diameters, even if the instruments have been properly calibrated to give accurate diameters with microspheres, because of the different dependencies of the instruments on particle morphology and refractive index. In every case, 2-dimensional images are being used to describe a 3-dimensional object.

While there is no consensus method for adjusting the reported diameter to a corrected diameter that addresses these effects, there are some methods that can be helpful in understanding them.

Silica and polymethylmethacrylate microspheres have lower refractive index than commonly used polystyrene microspheres.

Suspensions of these microspheres in glycerol/water solutions, or in other liquid mixtures of tunable refractive index, can be used to study the change in reported diameter with change in the refractive index difference between the particle and the matrix fluid.

Polydisperse suspensions of particles that optically mimic protein aggregates are in development. Use of these suspensions will be helpful for understanding the response of instruments to irregular particles of low optical contrast. Typical protein aggregates, for example, have an average refractive difference from the matrix fluid of only approximately 0.02 for sizes ≥2 µm.

Currently, there are two fundamental limitations on correcting errors of reported diameter. First, the refractive index of certain common particles such as protein aggregates is not yet established. Second, there is no accepted method for correcting diameter errors for heterogeneous mixtures of particles (e.g., silicone oil droplets and protein aggregates in a single test sample).

### 11.3.5 PRECISION

Precision may be assessed by considering the repeatability of multiple assays. Assays performed with microspheres or microsphere mixtures may be useful for assessing the fundamental precision limit of a method. Assays performed with samples representative of actual particles will provide a more accurate assessment of the precision that is possible in regular use.

### 11.3.6 DETECTION LIMIT

The detection limit is usually defined as the particle concentration corresponding to a 3:1 signal-to-noise (S/N) ratio. Particle counters may be theoretically capable of counting single particles without ambiguity, but noise is introduced in the form of background counts seen with blank or filtered buffer samples. The detection limit will vary with the size of the particle.

#### 11.3.7 ROBUSTNESS

Assay results for particle counts can be sensitive to sample preparation, sample variability, and instrument cleanliness for all methods. MM is especially dependent on operator judgment.

## 12. TEST ENVIRONMENT AND PREPARATION

The nature of the sample preparation and the analytical method used can substantially alter the environmental requirements. Especially for MM, the pooling of aliquots, and other procedures requiring sample manipulation or samples exposed to the environment, will require more attention to cleanliness than procedures that only require drawing samples out of a vial as for LO. In all cases, perform the test in an environment that minimizes background particulate matter. Glassware must be cleaned to the extent that the level of particles added by testing has a negligible effect on the outcome of the test. Methods are acceptable as long as blank samples or other negative controls provide good results.

### 12.1 Sample Handling

Best practices for minimizing particle contamination from packaging or the testing environment should be followed at every step. Remove tertiary and secondary packaging outside of the test area and ensure that the exterior of the product containers has been cleaned. Rinse the exterior of containers with filtered water after removing all retention hardware (e.g., ferrules, clips, bands) and as directed in *12.2 Sampling Practices* for each technique. Protect the containers from environmental contamination until analyzed.

#### 12.1.1 LIQUID PREPARATIONS

Prepare the container(s) as directed in ⟨788⟩*, Method 1 Light Obscuration Particle Count Test*, either pooling units to get the 25-mL test aliquot when using ⟨788⟩ or testing individual units if using ⟨787⟩. When using ⟨788⟩ for containers of 25 mL or more, simply open the container, insert the counter probe in the middle of the solution and measure. For all liquid samples, gently mix the samples by hand swirling, gentle inversion, or mechanical means. Care should be taken to avoid introduction of air bubbles or contaminants and to avoid disruption of particles in all cases.

#### 12.1.2 DRY OR LYOPHILIZED PREPARATIONS

Prepare the containers as directed under ⟨788⟩*, Method 1 Light Obscuration Particle Count Test*. Open each container, taking care not to contaminate the opening or cover. Reconstitute as directed by the product insert instructions, allowing time for the sample to stand if so directed. Alternatively, during product development, prior to the availability of the package insert, use conditions as close as possible to those expected at the point of administration or use.

Replace the closure and manually agitate the container sufficiently to ensure dissolution of the drug, being careful not to agitate too vigorously and cause particle formation. For some dry or lyophilized products, it may be necessary to let the containers stand for a suitable interval and then agitate again to achieve complete dissolution. After the drug in the constituted sample is completely dissolved, prepare the units as directed in *12.1.1 Liquid Preparations*. Gently stir the contents of the unit by hand swirling or by mechanical means to mix and suspend any particulate matter. Proceed as directed for the appropriate unit volume under the applicable *USP* chapter. When sampling, ensure that the sipping probe is inserted into the middle of the solution.

#### 12.1.3 PRODUCTS PACKAGED WITH DUAL COMPARTMENTS TO HOLD THE DRUG PRODUCT AND A SOLVENT IN SEPARATE COMPARTMENTS

Prepare the units to be tested as directed under ⟨788⟩*, Method 1 Light Obscuration Particle Count Test* and according to product insert directions. Mix each unit as directed in the labeling, activating and agitating it to ensure thorough mixing of the separate components and to ensure drug dissolution. Prepare as described in ⟨1788.1⟩*, 6. Blank and Sample Handling*, and proceed as appropriate.

#### 12.1.4 PRODUCTS LABELED AS "PHARMACY BULK PACKAGE NOT FOR DIRECT INFUSION"

Proceed as directed for *Liquid Preparations* where the volume is 25 mL or more. Calculate the test result on a portion that is equivalent to the maximum dose given in the labeling. For example, if the total bulk package volume is 100 mL and the maximum dose volume is 10 mL, then the average LO particle count per milliliter would be multiplied by 10 to obtain the test result based on the 10-mL maximum dose. [NOTE—For the calculations of test results, consider this maximum dose portion to be the equivalent of the contents of one full container.]

### 12.2 Sampling Practices

After proper mixing, open the container(s) and pour or withdraw by syringe the contents under test to transfer in a manner least likely to generate particles. The number of product samples is determined by the fill category (small volume or large volume) or the intent of the determination, such as container variation or batch matrix experiment (BME) or design of experiment (DOE).

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M3023_02_01
@2024 USPC

- *Direct sampling*—Contents of containers with removable stoppers may be poured out directly after removing the closures for MM. Products packaged in flexible plastic containers may be sampled by cutting the medication or administration port tube or a corner from the unit with a suitably cleaned razor blade or scissors. Sampling devices that have a needle to penetrate the unit closure may also be used for all three methods. With an appropriate instrument "sipper", the contents of the product package may be directly drawn for LO or FI analysis.
- *Pooling*—If there is insufficient volume for the test method, the contents of multiple containers may be pooled from freshly opened product into clean glassware (cleanliness verified by testing).
- *Reconstitution*—Dry or lyophilized products must be constituted using either their insert diluent or particle-free water (as desired). The closure is removed to add the fluid, which is injected via hypodermic syringe. If test specimens are to be pooled, allow each to constitute fully before sampling directly or pooling.
- *Dilution*—Some products will require dilution for LO or FI analysis due to insufficient volume or due to suboptimal fluid properties, such as color or viscosity. All MM procedures utilize particle-free water as a receiving and rinsing fluid, thus they are diluted by design. The diluent must be particle-free water (or filtered product vehicle) and dilution vessels must be scrupulously cleaned and verified. The impact of dilution must be evaluated for acceptability through feasibility studies. Feasibility is verified when it is demonstrated that the dilution does not dissolve resident particles and, more importantly, does not induce formulation change.

#### 12.2.1 MIXING

For reference standards, such as the USP Particle Count Set RS (used for system suitability particle count accuracy, recovery studies, or calibration), homogenization of the mixture may be attained by agitating the preparation for 20 s and sonicating for up to 30 s. Mixing of most product samples will require different handling than that for the standard.

Gently mix the contents of the sample just prior to analysis by hand-swirling, tipping of the vial, or mechanical means. Take care not to introduce air bubbles, or if open, contamination. Mixing of samples is necessary to resuspend settled particles; however, mixing must be done carefully, because agitation may alter fragile or shear-labile particles. Swirling is gentler than tipping the vial but may not resuspend all particles. To the extent feasible, confirm on the sample of interest that the mixing method produces an acceptably homogeneous sample and that multiple stirring operations do not introduce unacceptable shifts in the particle size distribution.

#### 12.2.2 DEGASSING

The handling of microspheres and some blanks is different from the handling of some test samples. Microspheres will not degrade under sonication; however, sonication will strongly affect some particle types and is never acceptable for protein-containing solutions.

Use a consistent degassing procedure appropriate for the samples. For protein-containing solutions, sonication must be avoided. Recommended degassing procedures include 1) sonication at 20–80 watts for about 30 s, 2) standing and equilibrating at room temperature for 10 min, or 3) applying a mild vacuum, e.g., 75 torr, for 10 min. The standing of the sample can result in particle stratification and/or settling; thus, a sufficient and gentle agitation should be applied before analysis to bring all particles into the sampling zone. For cases where procedure 2 is ineffective, such as viscous samples or gas-particle associations, gentle vacuum may remove these entrained bubbles without disrupting the inherent particle population.

There are caveats to sonication and standing. With sonication, much energy is dissipated as heat, resulting in denaturation of the biologics; this could also affect certain particles in the sample. Allowing the sample to stand to dissipate gas is effective, but stratification and settling of particulate matter occurs during standing. For this reason, use of the standing approach must be accompanied by sufficient gentle agitation to bring all particles into the sampling zone. Allowing the sample to stand also has the benefit of bringing the solution to room temperature, mitigating any thermal effects encountered when introducing the sample to the counting system. Sometimes, allowing the sample to stand is not sufficient to remove microbubbles (e.g., if the solution is viscous or if the air bubbles associate with the particles). Gentle vacuum can often remove these entrained bubbles without disrupting the inherent particle population.

#### 12.2.3 BLANK SAMPLES

For the ⟨788⟩ method, an environment blank verifies system cleanliness. To collect blank counts, use a cleaned vessel of the type and volume to be used in the test. Place a defined volume of filtered water consistent with the volume of sample to be counted in the vessel and agitate the water sample in the cleaned glassware by inversion or swirling. Using the same method as for product samples is recommended.

Best practice includes running additional blank samples, especially between product families. Measurement of additional blanks consisting of filtered formulation buffer may be useful for assessing the introduction of air bubbles or desorption of particles from wetted surfaces in surfactant-containing formulations.

## 13. INSTRUMENT STANDARDIZATION TESTS

ISTs are used to verify that the instrument performs in accordance with the manufacturer's specifications upon calibration and continues to provide accurate and consistent results between calibrations. ISTs, as described in *13. Instrument Standardization Tests*, are equivalent to the performance qualification (PQ) in ⟨1058⟩ and are intended to verify the acceptable performance of the instrument for its intended use. See ⟨1058⟩ for an in-depth description of PQ, operational qualification (OQ), and system suitability. These tests are also applicable for MM but in a much-simplified approach (see *Membrane Microscope Method for the Determination of Subvisible Particulate Matter* ⟨1788.2⟩).

ISTs for LO and FI include several tiers. Instrument calibration is the most comprehensive set of tests, and PQ tests provide assurance that the instrument meets all key performance requirements. Other verification tests provide daily assurance that the instrument performance is acceptable.

## 13.1 Diameter Calibration

Perform instrument calibration according to the instrument manufacturer's instructions. The count accuracy of an instrument can be significantly affected by the size accuracy of the instrumental particle counter. Count accuracy is also dependent upon the sensor used and may vary with individual sensors of the same model, as described previously.

Perform a system suitability test upon completion of the instrument calibration to ensure that the particle sizes of interest for the application (i.e., 10 and 25 µm) and other sizes (e.g., 5 and 15 µm), are accurately reported and that the count accuracy is verified. Count accuracy should be performed during or after the diameter accuracy is confirmed. Particle count accuracy may be assessed using commercial microsphere count standards. For LO and FI, corrections are incorporated into instrument software to give accurate particle diameters of the calibration microspheres.

## 13.2 System Suitability Tests

The key attributes of a particle counting system are that it counts particles accurately and that the level of background counts is acceptably low. Count accuracy may be assessed by routine measurement of microsphere count standards. Background counts may be assessed by routine measurement of blanks or filtered formulation. These two types of tests are the core system suitability tests.

A few factors influence how often a system suitability test should be run:

- Do the test samples tend to clog flow cells in the LO and FI methods?
- Do the particles in the test sample tend to adhere to wetted surfaces, thereby causing increased counts in subsequent blanks or test sample runs?
- What are the consequences if assay failure is detected at a date later than when the assay was run?

### 13.2.1 SYSTEM SUITABILITY FAILURE

Instruments that fail system suitability tests can often be remediated by thorough cleaning or by evaluating the particle standard used (these can aggregate over time). If failure of the standard is ruled out, the manufacturer's directions should be followed for thoroughly cleaning all fluid lines and the sensor head. Back-flushing to remove partial clogs may also be beneficial. The instrument is deemed to be suitable for use if it passes the system suitability tests after cleaning. Flush the system to remove traces of the particle standard prior to routine use.

Depending upon the dosage form being tested, proceed as directed under the appropriate category in *14. Calculations*.

# 14. CALCULATIONS

## 14.1 Pooled Samples

Average the counts from the aliquot portions analyzed. Calculate the number of particles in each container:

$$P_{\Sigma\geq 10} V_T / V_A n$$
$$P_{\Sigma\geq 25} V_T / V_A n$$
$$P_{\Sigma\geq 50} V_T / V_A n$$

in which $P_{\Sigma\geq 10}$ is the average particle count per threshold obtained from all portions analyzed and $P_{\Sigma\geq 25}$ is the average particle count per threshold obtained from all portions ≥25 µm analyzed. [NOTE—$P_{\Sigma\geq 50}$ is additionally used for ⟨789⟩. $V_T$ is the volume, in milliliters, of pooled sample; $V_A$ is the volume, in milliliters, of each portion analyzed; and $n$ is the number of containers pooled.] .

## 14.2 Individual Samples

Average the counts obtained for the aliquot portions from each separate unit analyzed and calculate the number of particles in each container:

$$P_{\Sigma\geq 10} V / V_A$$
$$P_{\Sigma\geq 25} V / V_A$$
$$P_{\Sigma\geq 50} V / V_A$$

in which $P_{\Sigma\geq 10}$ is the average particle count per threshold obtained from all portions analyzed and $P_{\Sigma\geq 25}$ is the average particle count per threshold obtained from all portions 25 µm analyzed. For ⟨789⟩, $P_{\Sigma\geq 50}$ is also reported and is the average particle count per threshold obtained from all portions ≥50 µm. $V$ is the volume, in mL, of the tested unit and $V_A$ is the volume, in mL, of each portion analyzed. For individual unit samples measured directly, the results are reported as $P_{\Sigma\geq 10}$ or $P_{\Sigma\geq 25}$ per unit volume, such as counts per milliliter.

@2024 USPC

## 14.3 Individual Unit Samples

Average the counts obtained for the aliquot portions taken from the solution unit. Calculate the number of particles in each milliliter of product solution taken:

$$P_{\Sigma\geq 10}/V$$
$$P_{\Sigma\geq 25}/V$$
$$P_{\Sigma\geq 50}/V$$

in which $P_{\Sigma\geq 10}$ is the average particle count per threshold obtained from all portions analyzed and $P_{\Sigma\geq 25}$ is the average particle count per threshold obtained from all portions 25 µm analyzed. For ⟨789⟩, $P_{\Sigma\geq 50}$ is also reported and is the average particle count per threshold obtained from all portions ≥50 µm. $V$ is the volume, in milliliters, of the portion taken.

For all types of product, if the tested material has been diluted to decrease the viscosity, the dilution factor must be accounted for in the calculation of the final test result.

[NOTE—For all methods, when reporting particle load the particle counts must be reported in cumulative mode. If the instrument has been configured to count in differential bins (e.g., ≥10–24 µm, >25–50 µm, >50 µm), all bins ≥10 µm must be added to yield a total ≥10-µm count and all bins ≥25 µm need to be added to yield a total 25-µm count. Reports should clearly state the diameter limits, the units of particle counts (e.g., counts per container or counts per milliliter), and that the particle loads are for all particles greater than or equal to the stated diameter limits.]

## Glossary

**Diameter bias:** Deviation of a derived particle diameter from the actual diameter due to technique parameters and limitations.

**Diascopic illumination:** Transmitted light illumination for transparent to translucent samples.

**Episcopic illumination:** An internal illumination path coincident with the optical path, providing top-reflected light for the detection of thin, flat particles and films.

**Equivalent circular diameter:** The diameter of a standard sphere that produces an equivalent electronic pulse or other signal to an analyte particle.

**Feret's diameter:** The dimension of an object along a specified direction, also known as caliper diameter.

**Flow imaging:** An instrumental system configured to collect digital images of solids in sample fluid flowing between a light source and a camera.

**Fouling:** Plugging or coating of a particle counting system sensor or flow cell; may be a full blockage, partial blockage, or an extraneous substance affecting the analysis.

**Image analysis, dynamic:** A software program used to collect images from a flowing display, store the images, and retrospectively analyze the collected data.

**Image analysis, static:** A software application used to collect images and discriminate the images from a live, unchanging image.

**Light obscuration:** An optical particle-sensing technique that records impulses on a photodetector from obscuration of a source illumination by analyte particles. Particle size correlates with the response curve of a known spherical standard.

**Longest chord:** The longest dimension that can be measured across the perimeter of an object.

**Membrane microscopy:** A particle determination method that isolates solids from product samples by filtration and then examines them with a light microscope to count the collected material in size thresholds.

**Operational qualification (OQ)/Performance qualification (PQ):** Essential elements of method validation: OQ specifies the principal operational elements of the device in both hardware and method controls; PQ verifies the acceptable performance characteristics for a specified instrument OQ.

**Optical particle counter:** An instrument that provides detection, sizing, and enumeration of substances in a fluid medium using visible spectrum illumination and an electronic detector.

**Particle concentration:** Number of particles (count) per unit volume.

**Particle count accuracy:** An evaluation of the capability of an instrumental system to collect particle counts for evaluation against a standard.

**Particle size:** *Visible*: In the context of pharmaceutical products, the size at which one can visualize a single particle within a final product package. USP has set a conservative threshold at 100 µm, which must be considered the size at which the optimal methods will reliably detect particles. The caveat for setting a size threshold is that detection by manual (human) methods is a probabilistic process. *Subvisible*: 2–100 µm. *Nanoparticles*: <2 µm. [NOTE—The <2 µm threshold is a cut-off based on the limitation of typical instrument capabilities.]

**Refractive index (RI):** The numerical ratio of the speed of light through a vacuum over the speed of light through a substance. The RI of water is 1.33, with fluid oils ranging to 1.50 and solids spanning a wide range upwards from 1.34. RI is wavelength specific.

**Relative standard deviation/Coefficient of variation:** A measure of dispersion of a probability distribution. It is the ratio of the standard deviation to the mean and is expressed as percentage.

**Schlieren effects:** These are regions of varying refraction in a transparent medium that are often caused by differences in temperature or pressure and are detectable by optical means, generally by the passage of a beam of light through the medium.

**Sheath flow:** A technique using a "wall" of higher-viscosity fluid encasing a lower-viscosity analyte sample flowing through it, thereby producing a limited focal plane due to hydrodynamic channels.

**System suitability:** A measurement of the system output with a known standard that demonstrates acceptable performance of the system, often the result of several operational parameters.

**Validation:** Validation of an analytical procedure is the process by which it is established, by laboratory studies, that the performance characteristics of the procedure meet the requirements for the intended analytical applications. This typically

includes measurement of method accuracy, precision, specificity, detection limit, linearity, range, and robustness. Described in ⟨1225⟩.

# APPENDICES

## Appendix 1: Historical Development of *USP* Chapters on Subvisible Particulate Matter

The determination of subvisible particulate matter in injections was initiated in 1975 as an MM method for large-volume injections (LVI) in *USP XV*. This one method was quite effective at revealing the content of unwanted solid particles ≥10 µm in the product, because filtration could accommodate a wide range of product volumes and the microscopist could evaluate the retained solids. However, the microscope method was much slower per sample than corollary instrumental techniques and required high-efficiency particulate air (HEPA) environmental hoods for isolation operations, with special microscope count training for the analysts.

Higher throughput with a robust electronic method was sought. Historically, the *British Pharmacopoeia* had utilized electrical sensing zone (Coulter counter) counting for all particles ≥2 µm; however, the method required dispersion of the product in an electrolyte solution, which did not work for certain products and formulations and could require extensive particle sampling prior to analysis.

The current USP subvisible particle determination methods were established in 1986 for determination of particulate matter in sterile injections, and in 1995, an improved version of this methodology was adopted (*28*) following extensive development by an expert volunteer group (*29*). The MM method was improved, and the combination of LO and MM was proposed for use as a two-stage test for both LVI and small-volume injection (SVI) products. In ⟨788⟩ and ⟨789⟩, "small-volume parenteral" is synonymous with SVI, and "large-volume parenteral" is synonymous with LVI. SVI and LVI are used throughout this chapter. The improved method for MM became official in 1995, and the first- and second-stage methods could be used for any sterile product amenable to testing by either method. Chapters ⟨788⟩ (a harmonized chapter) and ⟨789⟩ provide two methods: an LO test (*Method 1*) for sizing and counting of subvisible particles (generally 2–100 µm) for nearly transparent, low viscosity ("waterlike") product samples, and an MM particle count test (*Method 2*) for manual particle sizing and counting as an alternate method. The MM method also retains particles for further evaluation. Barber (*30*) has a good review of the limits history and instrument choices.

## Appendix 2: Cleaning Procedures to Limit Particle Contamination

Cleanse glassware, closures, and other required equipment, preferably by immersing and cleaning the items using warm, nonionic detergent solution. Rinse in flowing tap water, and then rinse again in flowing filtered water. Organic solvents may also be used to facilitate cleaning. [NOTE—These steps describe one way to clean equipment; alternatively, particle-free equipment may be obtained from a suitable vendor.] Preferably, the test specimen, glassware, closures, and other required equipment are then given a final rinse with filtered water using a hand-held pressure nozzle with final filter or other appropriate filtered water source within an environment protected by HEPA cabinets. While conducting the assay, non-shedding garments and powder-free gloves are worn within the HEPA environment.

For example, prepare the test specimens in the following sequence. Outside of the unidirectional airflow cabinet (UAFC) or HEPA filters to be used for the test, remove outer hardware or sealing bands. Labels typically don't need to be removed; however, if necessary, they may be removed or taped over before the next cleaning step. Rinse the exteriors of the containers with filtered water. Protect the containers from environmental contamination until analyzed.

Within the UAFC, open the containers and withdraw, pour, or otherwise sample the contents of the containers for testing in a manner least likely to generate particles that could enter the test specimen. Contents of containers with removable stoppers may be withdrawn directly by removing the closures. A sampling device with a needle to penetrate the unit closure may also be used. Products packaged in flexible plastic containers may be sampled by cutting the medication or administration port tube or a corner from the unit with a suitably cleaned razor blade or scissors.

## 1. SCOPE

### 1.1 Introduction

This chapter provides guidance on the inspection of injections for visible particles. The terms "particle," "particulates," and "particulate matter" are equivalent and do not have different meanings when used in this chapter. Particulate matter is defined in *Particulate Matter in Injections* ⟨788⟩ as "extraneous mobile undissolved particles, other than gas bubbles, unintentionally present in the solutions." Visual inspection is a probabilistic process, and the specific detection probability observed for a given product for visible particles will vary with differences in dosage form, particle characteristics (such as size, shape, color, and density), and container design. Some products and packages limit the ability to inspect for particles when compared to clear solutions in transparent containers. Additional guidance when inspecting these difficult-to-inspect products (DIP) are provided later within this chapter.

The requirement for injections to be "true solutions" appeared in *USP IX* in 1915, and the first appearance of "solution clarity" for parenteral products occurred in 1936 in *NF IV*. Since then, there have been numerous modifications to the compendia in this regard. A comprehensive history of compendial inspection standards is available in the *Pharmacopeial Forum* (*1*).

The practices discussed in this chapter are also applicable to the detection of other visible defects that are not the subject of *Visible Particulates in Injections* ⟨790⟩ but are critical to a qualified, comprehensive inspection process. These include, but are not limited to, container–closure integrity defects such as cracks, misplaced closures, or incomplete seals, any of which may compromise the sterility of the product. Additional container system defects (*2–3*), as well as other product characteristics such

@2024 USPC

as fill level, discoloration, or clarity, may also be detected during visual inspection, and nonconforming units should be rejected using the methods described in this chapter. Inspection for these container–closure quality attributes often occurs at the same time as the inspection for particles using a specifically designed and qualified inspection sequence.

The reference method described in this chapter and in ⟨*790*⟩ is a manual inspection of a single container for particulate matter. However, multiple-container manual inspection, semi-automated, and automated inspection methods are also discussed and permitted by the Pharmacopeia. These alternate inspection methods must be qualified to demonstrate equivalent or better defect detection when compared to the reference manual inspection described in ⟨*790*⟩.

### 1.2 Related Chapters

*Injections and Implanted Drug Products* ⟨1⟩ provides an overview of injectable dosage forms and the quality tests associated with them. Another chapter, ⟨*790*⟩, has been added to the *USP–NF* to provide a clear definition of routine inspection procedures for injectable products; the goal is to comply with the expectation that products be essentially free of visible particulate matter. Additionally, information on the detection of subvisible particulates and particulates in specific dosage forms is provided in *Ophthalmic Products—Quality Tests* ⟨771⟩, *Subvisible Particulate Matter in Therapeutic Protein Injections* ⟨787⟩, ⟨788⟩, and *Particulate Matter in Ophthalmic Solutions* ⟨789⟩. *Measurement of Subvisible Particulate Matter in Therapeutic Protein Injections* ⟨1787⟩ and *Methods for the Determination of Subvisible Particulate Matter* ⟨1788⟩ provide additional supporting information on measurement methods for subvisible particles.

### 1.3 Defect Prevention

Although this chapter focuses on the detection and removal of product units that show evidence of visible particles, the need for preventing such contamination should not be overlooked. No inspection process, manual or automated, can guarantee complete removal of all visible particulate matter or other visible defects; thus, prevention of such defects is an important consideration. Good process and product design, along with environmental control, are necessary to ensure the reliable production of products with a low particle burden. To ensure the control of defects throughout the process, manufacturers should consider an inspection life-cycle approach (*4*). This approach begins with developing quality attributes based on incoming component specifications, followed by component-level acceptance testing. It extends to component preparation and product-filling procedures, followed by 100% in-process inspection of filled product, and concluding with final acceptance sampling and testing of the finished product. The life-cycle approach must encompass purchased, ready-to-use (RTU) components such as primary containers or closures, where there is no opportunity for further particle removal before use. Single-use systems (SUS) and consumable cleanroom materials such as wipes, should also be considered as potential sources of particulates. Stability and retention sample inspection, customer complaint evaluation, and in-house investigative procedures support this integrated approach. The inspection life cycle is composed of and supported by sub-cycles involving defect detection method development, qualification of methods and personnel, maintenance, and personnel training. Categorization and identification of product-contact particles found during inspection are useful to support source identification. Forensic analytical methods and the use of libraries containing visual standards (e.g., photographs and/or drawings) and characterized defect samples further support these objectives. The final element of the life cycle is a feedback loop of trending and data review from each of these process areas, resulting in a quality system that supports continuous process improvement.

## 2. BACKGROUND

### 2.1 Inspection Process Capability

Visual inspection of injections is necessary to ensure articles for administration consistently exhibit a high-quality level and minimize the introduction of unintended particles to patients during the delivery of injectable medications. Such inspection also offers the opportunity to reject containers whose integrity has been compromised, such as those with cracks or incomplete seals, which pose a risk to the sterility of the product. The desire to detect these defects, despite their very low frequency and the randomness of their occurrence, has resulted in the longstanding expectation that each finished unit will be inspected (100% inspection). Although having zero defects is the goal and this should drive continuous process improvement, zero defects is not a feasible specification for visible particles given current packaging components, processing capability, and the probabilistic nature of the inspection process.

The visible particulate detection process is probabilistic: the likelihood of detection is a cumulative function of visible attributes such as particle quantity, size, shape, color, density, and reflectivity as well as optical characteristics of the surrounding product and package. Understanding human performance is therefore critical to establishing visual inspection criteria. Analysis of inspection results pooled from several studies (*5*–*7*) conducted with standards prepared with single spherical particles shows that the probability of detection (PoD) for a seeded sample with a single 50-µm particle in a clear solution contained in a clear 10-mL vial utilizing diffuse illumination between 2000 and 3000 lux is only slightly greater than 0%. The detection probability increases to approximately 40%-60% for a seeded standard with a 100-µm particle, and the threshold for routine, reliable detection (≥70% PoD) of individual visible particles is often near 150 µm in diameter. Particles 200 µm and larger are often necessary to achieve greater than 95% PoD (*5*). The PoD for fibers is often less than that discussed for similarly sized spherical particles above, with reliable detection often commencing at or above 500 µm (*7*). Thus, in a qualified visual inspection system, the vast majority of nonfibrous particles that might go undetected and be introduced into the pharmaceutical supply chain will be smaller than 200 µm. Some injectable products are more difficult to inspect due to the nature of the primary container (*8*) (e.g., increasing size, color, and opacity), as well as dosage form characteristics (e.g., fill level; solution color, clarity, or opalescence; and suspensions, lyophilized powders, emulsions, and implants). Particle characteristics beyond size (e.g., color, shape, and density) will also affect the PoD that can be achieved for a specific product and container system (*7*).

### 2.2 Patient Risk

A complete review of the medical literature is beyond the scope of this chapter, but the effect of particles on the patient must be considered. Several reviews on this subject are available (*9–15*). The clinical implications of particulate matter in injections are determined by many factors, including the size and number of particles, the composition of the material, the potential for microbiological contamination, the route of administration, the intended patient population, and the clinical condition of the patient. For example, an otherwise healthy individual receiving a subcutaneous or intramuscular injection containing sterile, inert particulates would likely experience no adverse effects, or at worst would develop a small granuloma. On the other hand, a critically ill premature infant receiving a particle-laden infusion directly through an umbilical catheter might suffer considerable pathophysiologic injury (*16–17*).

Numerous animal studies have been conducted to determine the fate of intravenous particles with different sizes and compositions (*18–21*). Most studies have focused on subvisible particles with a diameter <50 µm. In these studies, a massive infusion of particles has been accompanied by histologic evidence of injury to pulmonary capillary endothelial cells (*22*), microscopic thrombi in the pulmonary capillaries (*23*), pulmonary microscopic granulomata (*24*), and hepatic inflammatory effects (*25*). Although useful for understanding the pathophysiologic response to particulate matter, the large number of particles used in these studies (e.g., $10^9$ particles/kg per injection) provides little insight into the risk to humans posed by small numbers of visible particles.

Garvin and Gunner were among the first to report a concern about the effects of particles in human patients (*26–27*). For obvious ethical reasons, there is a lack of controlled clinical studies on the effects of particles purposely infused into human patients. Some anecdotal information about human patient safety may be obtained by examining case reports of intravenous drug abusers (*28–30*). In these cases, solid oral dosages are often ground up and injected as a slurry; pulmonary foreign-body emboli and granulomas were observed in these patients (*31*). Unfortunately, the clinical risks to human patients posed by small numbers of particles are difficult to infer from these observations due to the extreme number of insoluble particles and the uncontrolled conditions in which they were administered.

Arterial embolization using materials such as polyvinyl alcohol (PVA), collagen-coated acrylic microspheres, and gelatin spheres also provides some insight into the potential human pathophysiologic implications of non-target embolization of extraneous-particle intravenous infusions. In these cases, massive particle loads moving from the arterial injection site into the venous circulation were also reported (*32–36*). In addition, case reports have documented injury associated with the infusion of significant quantities of precipitated admixtures or therapeutic use of particles for embolization (*16–17,37*). Finally, recent studies evaluating the utility of in-line filtration (0.2- and 1.2-µm-rated filters) of intravenous fluids administered in a pediatric intensive care unit setting suggest that reducing the particulate burden associated with high volume infusions and multiple infused medications through bedside filtration may provide a reduction in morbidity in select patient populations (*38*).

Ultimately, the safety considerations related to particulate matter in injections must be assessed for each drug product, intended patient population, and method of administration. No single set of inspection criteria can adequately anticipate all potential risks to the patient. Despite the administration of an estimated 15 billion doses of injectable medicines each year (*39*), no reports of adverse events associated with the injection of individual visible particles have been found. The methods outlined in ⟨*790*⟩ should serve as essential requirements when assessing the adequacy of the visual inspection procedure, but alternative acceptance criteria (e.g., the use of tightened sampling plans) should be implemented when the patient population and intended use of the product warrant these additional measures.

## 3. TYPICAL INSPECTION PROCESS FLOW

### 3.1 100% Inspection

Chapter ⟨*790*⟩ establishes the expectation that each finished unit of injectable product will be inspected as part of the routine manufacturing process. This inspection should take place at a point when and where defects are most easily detected, for example, prior to labeling or insertion into a device or combination product. Each unit should be examined with the unaided eye under conditions appropriate for the container system (manual inspection) or by using a conveyor to transport and present the containers to a human inspector (semi-automated inspection), or by means of light obscuration or electronic image analysis (automated inspection). Manual and semi-automated inspection should be performed only by trained, qualified inspectors. Inspection may be conducted by means of a device that holds more than a single unit at one time for examination. This inspection may be performed at-line or in-line with filling or packaging or in a separate, off-line inspection. The intent of this inspection is the detection and removal of any observed defective unit. When in doubt, units should be removed. *Figure 1* shows a simplified process flow where solid boxes indicate required process operations, and those with dotted lines (supplemental testing) may be required for DIPs as discussed in *5.2 Unique Product and Container Considerations*. Alternative strategies, such as reinspection or two-stage inspection, may be required and are discussed in *3.3 Remediation and Alternative Practices*.

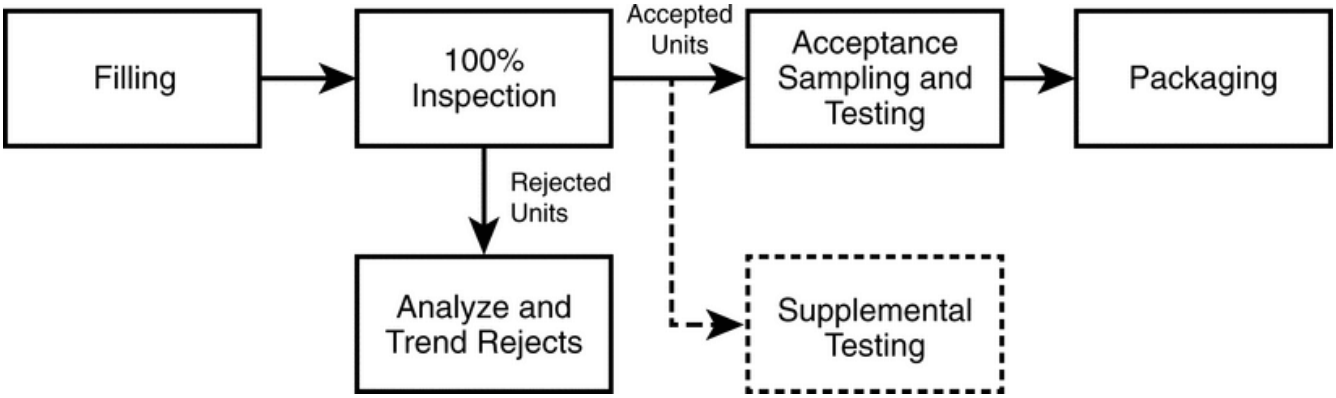

Figure 1. Typical process flow chart.

[NOTE—100% inspection refers to the complete non-destructive inspection of the container–closure system and its contents. Inspection may be accomplished in a single operation with specifically designed sequences for detecting visible particulate and/or container system defects or in multiple steps using a combination of technologies. See additional discussion in *3.3 Remediation and Alternative Practices* and *6. Inspection Methods and Technologies*.]

[NOTE—Supplemental destructive testing is required when the nature of the product or container limits visual inspection of the contents (e.g., with a lyophilized cake or powder, or with an amber glass or opaque container). See additional discussion in *5.2 Unique Product and Container Considerations*. Representative samples should be taken throughout the batch for supplemental testing from any point in the process after 100% inspection.]

During 100% inspection, limits on typical rejection rates should be established to identify atypical lots (*40*). These limits may be established for categories of defects (e.g., critical, major, and minor) or for specific types of defects (e.g., particles). A review of historical performance is useful in establishing these limits, and the review may include grouping products similar in appearance and manufacture. Periodic reassessment of these limits is recommended to account for expected process improvements and/or normal fluctuations in the process baseline (*41*). If a limit is exceeded, it should trigger an investigation. The investigation may include an additional inspection, or it may determine whether additional inspection is necessary.

## 3.2 Acceptance Sampling and Testing

After 100% inspection, a statistically valid sample is taken from the units accepted by the inspection process. These sampled units should be manually inspected under controlled conditions by trained inspectors. Chapter ⟨790⟩ provides reference inspection conditions for this purpose. The sample may be a random or a representative sample (e.g., at fixed time intervals or a fixed number per tray). Defects may not be distributed equally over the lot, and therefore a sampling process that represents the whole lot is required. Typical sampling plans used for this purpose can be found in ANSI/ASQ Z1.4 (*42*). Equivalent plans may also be found in ISO 2859 (*43*) or JIS Z9015 (*44*). These plans were historically developed for larger lot sizes and thus oversampled smaller batches (*45*). Alternative sampling plans may be justified for smaller batch sizes resulting in a smaller sample size. For batch release, the sampling plans listed as Normal II are typically used. Tightened sampling plans may be appropriate when an atypical result is observed, or reinspection is performed. All sampling plans specify a sample size for a range of batch sizes and require selection of an acceptable quality limit (AQL) to establish the sensitivity of the plan. The AQL is the defect rate at which 95% of the lots examined will be accepted and is a measure of falsely rejecting good batches. Critical defects (those that pose the greatest risk to the patient) should be assigned an AQL with a very low value. Often, the *accept number* (the number of defective units allowed in the sample) for a critical defect is zero. Major and minor defects, which pose less risk to the patient, will have increasing (less stringent) AQL values and accept numbers greater than zero. Further definition and discussion on defect categories are found in *5.1 Defect Classification*. *Table 1* shows the range of AQL values typically used for visual inspection processes (*46*).

**Table 1. Typical AQL Values for Visual Inspection Processes.**

| Defect Category | AQL Range (%) |
|---|---|
| Critical | 0.010–0.10 |
| Major | 0.10–0.65 |
| Minor | 1.0–4.0 |
| [NOTE—When selecting a sampling plan for AQL testing after 100% inspection using ANSI/ASQ Z1.4, ISO 2859, or JIS Z9015, choose the sample size to satisfy the AQL value for the most critical category (e.g., critical) of defects being evaluated. Then use the accept numbers for this sample size for the AQL values chosen for the other defect categories (e.g., major and minor). This assures that the sample size will produce a statistically valid result for all defect categories examined. The defect categories shown here represent a common basic approach to grouping defects by risk; however, additional categories may be added to these for more detailed analysis.] | |

While the standards referenced in the paragraph above are indexed by AQL, it is important to also know the unacceptable quality limit (UQL) for the sampling plan(s) used. These can be found in the operational characteristic (OC) curve data supplied for each plan found in these standards or calculated independently using qualified software. The UQL is the defect rate at which

DOI: https://doi.org/10.31003/USPNF_M7198_06_01

90% of the lots examined will be rejected and is a better measure of the customer or patient risk. The protection afforded by any sampling plan is represented by its OC curve. This is a plot of the probability of lot acceptance versus the defect rate in the lot. The AQL and UQL are two points on this curve. Sampled units should be manually inspected under controlled conditions by trained inspectors. Inspection conditions should be aligned with the 100% inspection process.

Manual acceptance sampling should be performed after any type of 100% inspection process, including manual, semi-automated, and automated inspection processes. It provides a measure of the performance of the overall inspection process and the quality of a specific lot, compared with predefined acceptance criteria. Although automated systems are validated before use and are routinely challenged to ensure acceptable performance, the use of manual acceptance sampling inspection detects unexpected defects that were not included in the development and training of the automated system by the manual inspection process.

Acceptance criteria are comprised of the product specifications and acceptance/rejection criteria, such as the AQL and UQL values, with an associated sampling plan that is necessary for deciding to accept or reject a lot or batch (or any other convenient subgroups of manufactured units) as described in 21 CFR 210.3 (*47*). If the acceptance criteria of the sampling plan are not met, an investigation should be conducted. Depending on the nature of the failure, this investigation should include forensic classification/identification of the particle(s), and examinations of the manufacturing process, the raw materials, and the packaging materials, as well as the inspection process. If, after investigation, the inspection process is deemed capable of detecting the defect(s) in question, the batch may be reinspected. An alternative inspection process better suited to detection of a specific defect may also be chosen for reinspection.

After reinspection (performing a second 100% inspection of the batch), a new statistically valid sample of the accepted units is taken and compared against established acceptance criteria. It is a good practice to use a tightened sampling plan and acceptance criteria under these circumstances because of the atypical nature of this process step.

Typical sampling plans for supplemental testing can be found in the special sampling plans S-3 and S-4 in ANSI/ASQ Z1.4 (*42*). These higher sensitivity S-plans offer a practical compromise between sample size and statistical power. For batch sizes between 200 and 100,000 they suggest a sample size of 20 with an accept number of 0 (based on an AQL of 0.65%). Sample sizes larger than 20, as found in these sampling plans, may be appropriate for larger batch sizes or when additional sensitivity to support reduced AQL values or a more conservative defect classification is desired. Refer to *Table 2*.

**Table 2. Typical 0.65% AQL sampling schemes for normal, single-pass inspection using S-3 and S-4 levels, dependent upon lot size.**

| Lot Size | (Sampling Letter Code) Accept Number, Reject Number/Sample Size | |
|---|---|---|
| | Inspection Level S-3 | Inspection Level S-4 |
| 200–10,000 | (F) 0,1/20 | (G) 0,1/20 |
| 10,001–500,000 | (G) 0,1/20 | (J) 1,2/80 |
| >500,000 | (H) 1,2/80 | (K) 2,3/125 |

Alternative plans are acceptable, but care should be taken to examine the UQL of such plans to assess their sensitivity.

## 3.3 Remediation and Alternative Practices

### REINSPECTION

As discussed in the preceding section, reinspection (repeating the 100% inspection followed by acceptance sampling inspection) may be appropriate if the initial 100% inspection is not successful in meeting in-process control levels or the initial acceptance sampling inspection criteria. This includes instances when the established 100% inspection failure rate(s) and/or the accept/reject number(s) associated with the chosen AQL values have been exceeded. Reinspection should only be conducted using a procedure that has been approved by the quality organization and addresses key parameters such as the inspection conditions (e.g., same as primary inspection or modified to enhance detection of a specific defect type), the number of times reinspection may be performed (this should be limited and justified), and the acceptance criteria (e.g., same as primary inspection or tightened). If reinspection is required often, consideration should be given to improving the sensitivity of the primary inspection process or of the manufacturing controls to prevent defects in the upstream process as determined by root cause analysis.

### TWO-STAGE INSPECTION

In cases where an assignable cause, such as the formation of air bubbles or specific container or closure variation, results in a high false-rejection rate (rejection of acceptable units), the use of a second inspection step may be considered. *Figure 2* shows a typical process flow for a two-stage inspection. Such an inspection strategy is more common with automated inspection systems, where there is less ability to tolerate normal variation in the product or container.

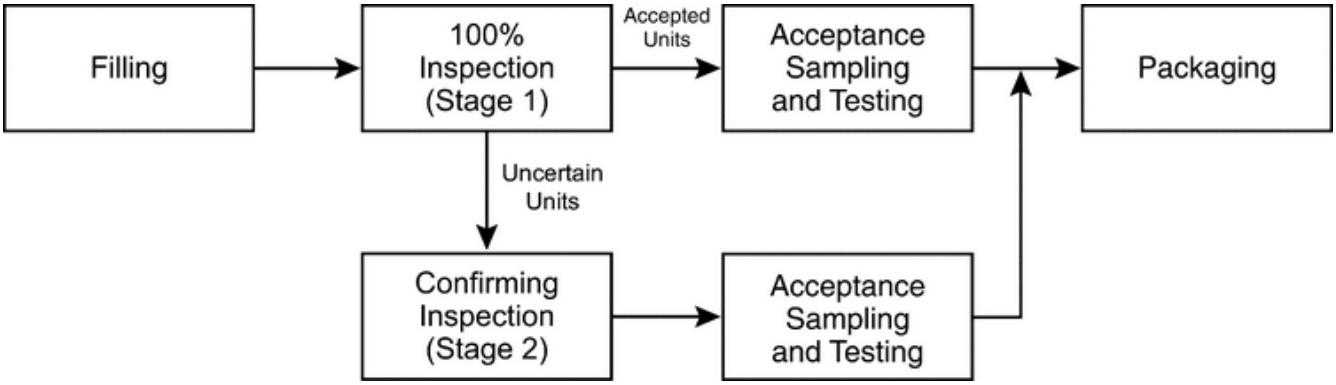

Figure 2. Two-stage inspection process flow chart.

Under these circumstances, the inspection system is adjusted to ensure acceptance of good units. Those not accepted during the primary inspection are considered of uncertain disposition until inspected by another means (e.g., enhanced manual inspection) to provide confirmation of acceptance or rejection. Inspection conditions may be adjusted to provide greater sensitivity in this second inspection step (e.g., additional inspection time) to ensure a higher probability that true defective units will be rejected. The limitations of the first inspection and the reason for conducting a second stage of inspection should be clearly defined and documented. The second inspection of these units by the same method and conditions (e.g., automated inspection with the same parameters after an initial automated inspection) is generally not recommended because the same limitation in inspection method is present for both inspections unless enhanced manual or more sensitive automated inspection parameters are employed for the second stage inspection. However, it may be suitable when the root cause is specifically related to air bubbles in the solution, and a study has been performed to establish an appropriate holding time to allow the bubbles to dissipate before performing the second inspection. It is recommended that each inspection stream (those accepted by the first stage and those accepted by the second stage) be sampled separately and evaluated against the sampling plan acceptance criteria before they are confirmed as accepted and recombined into a single batch. If a two-stage inspection strategy is used, it must be validated as intended for use. Defective containers with less than a 100% PoD will have the PoD reduced further with each stage of inspection; thus, the PoD should be determined after inspection through both stages to ensure that acceptable sensitivity is maintained.

## 4. INSPECTION LIFE CYCLE

### 4.1 Extrinsic, Intrinsic, or Inherent Particles

Particles may originate from many sources. These are discussed here, as well as in other chapters in the *USP* (e.g., ⟨1787⟩). Those that are foreign to the manufacturing process are exogenous or "extrinsic" in origin; these include hair, non-process-related fibers, starch, minerals, insect parts, and similar inorganic and organic materials. Extrinsic material is generally a one-time occurrence and should result in the rejection of the affected container in which it is seen; however, elevated levels in the lot may implicate a broader contribution from the same source. These particles may carry an increased risk of microbiological or extractable contamination because less is known about their path prior to deposition in the product container or their interaction with the product.

A second category of undesired particles is considered "intrinsic" or from within the process. The determination of whether the particulate is extrinsic or intrinsic to the process is based upon appropriate characterization of the particle's physicochemical properties. Process-related intrinsic particles may come from production equipment or primary packaging materials that were either added during processing or not removed during container or closure cleaning and preparation. These primary product-contact materials may include stainless steel, elastomers from seals and gaskets, container glass or plastic, fluid transport tubing, and silicone lubricant. Such particles still pose the risk of a foreign body, but they generally come from sterile or sanitized materials, and more is known about their interactions when in contact with the product. Any process-related intrinsic particles should have controls established based on the use of a life-cycle approach, as outlined in *1.3 Defect Prevention*. Another group of particles considered intrinsic is interrelated with the stability of the product. These product-stability-indicating particles arise from container or closure interaction (glass delamination, component erosion, and elemental extraction), changes to the drug preparation (insoluble degradation products), recrystallization, or temperature sensitivity over time. Stability-indicating intrinsic particles should be identified and addressed as early in the product development process as possible.

A third category is that of an inherent particle type that varies with dosage form and includes solutions, suspensions, emulsions, and other drug delivery systems that are designed as particle assemblies (agglomerates, aggregates). Such dosage-form-related particulates should be studied in the development phase and in samples placed on stability to determine the normal characteristics and time-based changes that can occur. Measurement of particle size distribution or characterization by image analysis in the subvisible (for particle sizes ≥2 µm) and visible ranges (≥100 µm) may be required to fully characterize inherent dosage-form-related particles. In biologics, protein particles are generally considered inherent and may be accepted when their presence is measured, characterized, and determined to be part of the clinical profile. Aggregation or agglomeration of proteins associated with a change in preparation constituents or other causative agents like excessive siliconization should be minimized. The manufacturer may allow inherent particles if the product appearance specification allows their presence or if the product is an emulsion, suspension, or implant.

@2024 USPC

An evaluation of the potential impact of particles identified from any of these sources may be enhanced by incorporating a clinical risk assessment (*15*). This assessment may include factors such as the intended patient population, route of administration, source and type of particles, and implications for product sterility. For intrinsic or inherent particulate matter sources, a risk assessment may be useful in developing product-specific control strategies. Given the probabilistic nature of particle detection, it is important to assess the possible implications of particles identified through the product life cycle to better ensure the product's safe use.

## 4.2 Prevention of Particulates

The manufacturing process is designed to keep the final container and its contents clean within the control parameters established for process-related particulates. Once the container is filled, the stability of the product needs to be maintained throughout its shelf life. Changes that occur as the product ages during its normal shelf life must be characterized. Avoidance of intrinsic particle sources that may affect final product stability depends on careful consideration of the entire product and packaging system. If these intrinsically sourced changes occur, and they affect stability, particles ranging from subvisible to visible may develop. Typically, these particles result from change mechanisms that slowly affect the on-shelf product.

### ROBUST DESIGN DURING DEVELOPMENT

To anticipate potential sources of instability that yield intrinsic particles, the product design should be evaluated from many perspectives, beginning with a literature review of similar preparations and packages. Points to consider include the reported sensitivities of the active ingredient, the dosage form type, and the final container–closure system needed for delivery. Knowledge of how glass containers are fabricated, controlled, sterilized, and tested is important as this may affect the tendency to form glass lamellae as discussed in *Evaluation of the Inner Surface Durability of Glass Containers* ⟨1660⟩ and by the FDA (*48*).

Obtaining further information on possible extracts and leachates, metals, or solubility limits is important as these factors may promote formation of solid material in the aging solution. Several additional factors for successful product design include the product concentration, solution pH, associated buffers, critical micelle concentration, oligomerization content/potential, package effects (large surface area, product volume, headspace, light/oxygen transmission), and compatibility of the specific preparation with the package. Furthermore, shock/vibration sensitivity at the air/liquid interface can be a significant contributor to particle formation that requires investigation during product development. Some key dosage form design factors include the formula components chosen and their purity, the solubilities of the active ingredient(s) and excipients, and consideration of potential salt forms. Finally, to maximize product stability, consider the final product preparation for delivery, product dilutions, and shelf stability of the commercial product or its therapeutic preparations.

To examine the appropriateness of the product design for maintaining product stability, there are two levels of evaluation. Both levels examine retained containers for visible changes using methods described in this chapter, but neither level dwells on low percentage defects.

For the first level of stability study, visual inspection and testing of trial containers will show general compatibility of the chosen components over time with regard to clarity, color, and both subvisible and visible particle formation. Careful product assembly in clean containers, with consideration of the container type, headspace, and sealing, will yield a beneficial first-pass trial of stability over several months' time. The nature of particles detected, and the investigation of type and frequency, is essential to differentiate additive types from instability or package interaction. Pursuit of extrinsic particles at this stage of development is generally not significant, as the particles do not reflect on the suitability of the specific preparation or expected manufacturing process under development but rather the way these study samples were prepared.

The second, more refined level of stability study involves conducting visual inspections of the injection in defined, International Council for Harmonisation (ICH)-relevant trials (*49*). This may include periodic inspection of the same containers over time if the product does not require reconstitution or is not affected by frequent temperature changes. Detection of minor or subtle differences in these containers is not the goal at this stage of development. Catastrophic change and the occurrence of intrinsic product-related visible particles should be the focus. Typically, a set of containers is carefully prepared to exclude extrinsic particles and is then inspected to cull out any units with visible defects. Next, a numbered set of containers appropriate for the batch size is placed on stability and visually inspected periodically for changes due to degradation or any sign of instability. It is important to be able to analyze the particulate matter or condition (change in color, turbidity, opalescence) to identify the cause of events due to instability. A typical sample size is 80–100 units. This quantity should be sufficient to assess package and preparation interaction. Additional sets of containers stored at selected extremes of ICH temperatures can be followed to aid discovery of solubility-edge phenomena. When unwanted changes are detected—such as particle formation, solution color change, solution haze, and package changes—the process of isolation, characterization, and identification can commence. Identification of the material comprising these changes aids in the determination of the cause of formation as well as development of improvements for future use.

### COMMON SOURCES OF PARTICULATES

Process-related intrinsic particles originating from product-contact materials tend to be stable and unchanging (e.g., glass, elastomers, or metal). In contrast, there may also be particles resulting from product-stability-related change mechanisms within the final product. It is very important to understand that these changes only need be slight in certain cases, far below the detection limit of most release or stability assays, to result in visible changes to the product. The threshold levels for the formation of visible change for certain substances may be as low as 10–100 ppm (0.001%–0.01%) based on the ability to detect a single 100-µm particle or many sub-10-µm particles creating a hazy or cloudy appearance. However, if all this insoluble material were contained in a single particle, it likely would not cause rejection of the container.

DOSAGE FORM COMPONENTS

The active ingredient may also contribute to the presence of stability-indicating intrinsic particles. For example, significant haze and particles have been observed in aqueous dosage forms due to extraction of plasticizers from filtration media during bulk drug production (*6*). Metal content in the active ingredient has contributed to organometallic salt formation and has also been observed as precipitated inorganic salts, blooming long after product release. The active ingredient and related degradation products may also be relatively insoluble and may grow to form visible particles. Isolated particulate material must be analyzed to determine its chemical nature and possible source.

Monomers or single molecules may join through chemical processes to form dimers, trimers, and oligomers (a limited assemblage of monomers, short of polymerization). Such changes are not unexpected (*50*). In high-concentration and/or saturated preparations, and especially for micellar drug associations, the solubility of related forms is significant when the aging preparations contain progressively higher concentrations of these substances. Larger molecules may have a greater effect on solution integrity due to their inherent insolubility, especially if the active drug is in a micellar preparation.

Polymorphs are unique crystalline forms of identical chemical entities. Although uncommon in solutions that have been mixed homogeneously and filtered, small seed crystals of a relatively stable polymorph may form over time, especially at nucleation sites such as container-surface defects. More common than formation of polymorphs is the formation of a modified crystal lattice containing an integral liquid, typically water or a solvent. The lattice may form slowly, promoted by evaporation, nucleation, and temperature extremes (*51*–*52*).

PACKAGING COMPONENTS

"Extractables" and "leachables" are terms commonly used to describe the potential for primary packaging materials to contribute unwanted agents to the product. Extractables represent all the materials that could be contributed, and leachables represent the practical contribution upon contact between packaging components and drug preparation as discussed in *Assessment of Extractables Associated with Pharmaceutical Packaging/Delivery Systems* ⟨1663⟩ and *Assessment of Drug Product Leachables Associated with Pharmaceutical Packaging/Delivery Systems* ⟨1664⟩ as well as in other references (*53*). These substances can also contribute to the formation of subvisible and visible particles. All product contact materials should be evaluated for extractables and leachables or product reactivity.

Product preparation attack of the container is a dramatic change and most often occurs in glass container systems. Glass containers undergo corrosion that is 25 times greater at pH 8 than at pH 4 (*54*, ⟨1660⟩). A preparation with a pH above 7, especially with high-ionic strength solutions, promotes attack of the inner glass surface, resulting in glass delamination and/or siliceous particle generation.

Silicone oil is added to stoppers and prefilled syringe systems to enhance lubricity for stopper or plunger insertion and its movement within the syringe barrel. Silicone may also come from tubing used for fluid transfer and a variety of polymeric fittings and seals that are used in the processing equipment. All these components must be compatible with the preparation to minimize leachates. Although silicones are processed to be sterile and are widely used, their use must still be strictly controlled, in other words, minimized. Silicone can cause container sidewall droplets and a variety of visible semisolid forms. No more than the minimum quantity should be used during processing to achieve acceptable machineability. Silicone and other hydrophobic substances have the capacity to coalesce and agglomerate with proteinaceous drug substances (*55*) or other particles, eventually reaching a visible size over time.

Residual tungsten from the manufacture of syringes has been known to increase protein aggregation (*56*).

## 4.3 Recommendations for Specific Components and Processes

GLASS CONTAINERS

Each step of the glass-container washing and rinsing process performed internally or by an external supplier, should be evaluated for particle-reduction capability. Incoming glassware may have significant particle load. The washer validation studies should demonstrate a reduction in naturally occurring particles (particle burden) or should use seeded containers to demonstrate such reduction capability. The use of statistical sampling plans with light obscuration (LO) for subvisible particle levels and membrane-microscope particle-counting method for the enumeration of visible particles can provide a means to demonstrate reduction of both subvisible and visible particles during washing cycle development and validation. The membrane filtration microscopic method is superior to the LO method for capturing and characterizing larger foreign particles in the visible range (>100 µm) during validation or monitoring activities. During process development, validation, and routine use, container-washing procedures should include periodic visual operational checks. This routine verification ensures that effective draining of all containers is occurring during all washing and rinsing steps. Review the wash-water recirculating filter maintenance procedures to ensure that particle overloading or breakthrough is being prevented.

Glass breakage that occurs during the component washing process could affect surrounding containers, and the washing cycle should be evaluated for possible glass particle generation and distribution. Written procedures describing container-clearance following glass breakage in the washer, in the depyrogenation tunnel, or on the filling line should specify the number of containers to be removed from the affected portion of the line. Removing units around the immediate area where the breakage occurred aids in minimizing particle transfer to the downstream process.

Processes that use racks or trays for transporting and holding samples, as are typically used in batch ovens, should be monitored for metal particle generation. The racks or trays should have a formal maintenance program associated with their routine use. Trays should be inspected for wear and scoring, which can be sources of particulates. Periodic cleaning, polishing, and/or resurfacing may be warranted to control particles effectively. Tunnels used for depyrogenation should also have a routine maintenance program for periodic cleaning, inspection, and replacement of parts that may wear and generate particles. Glass-to-glass and glass-to-metal contact should be minimized where possible to reduce weakening of the glass surface resulting

Official

https://mathdocs.org/doi/10.31003/USPNF_M7198_06_01/

in increased risk of subsequent fracture. The use of polymeric facing on guides can help to reduce such damage; however, coatings on metal surfaces must be monitored for degradation or particle generation by frictional wearing over time.

### ELASTOMERIC CLOSURES

Each step of the elastomeric-component washing and rinsing process should be evaluated for particle-reduction opportunities. Utilize statistically valid sampling plans to collect meaningful test units. The use of LO (for subvisible particles) or other automated particle counting or membrane-microscopic particle-counting methods may be used to demonstrate reduction of both subvisible and visible particles during washing validation. As stated above for glass containers, the membrane filtration microscopic method is superior to LO methods for capturing and characterizing larger foreign particles in the visible range (>100 µm) during validation or monitoring activities with elastomeric closures. During process development and validation and in routine use, container-washing procedures should include visual checks to ensure that stoppers are not routinely sticking together. Such sticking surfaces reduce cleaning efficacy and entrap particles or cause reduced sterilization and depyrogenation effectiveness. Periodic assessment of component cleanliness and supplier washing capabilities should be included as part of the supplier qualification program when using ready-to-sterilize (RTS) or RTU components.

Evaluate siliconization processes, whether in-house or by the supplier, to minimize excess silicone levels while maintaining machinability of the stoppers. LO or other automated particle-counting methods may be used to compare overall particle level reduction (subvisible background silicone oil droplets) during process development or validation. The level of residual silicone oil will affect the particulate quality of the final filled product, observed as dispersed droplets and particle-forming matrices.

### EQUIPMENT PREPARATION

It is important to minimize redeposition of particles on product contact surfaces after cleaning. Cleaned and sterilized equipment should be protected by HEPA-filtered, unidirectional airflow until transferred to, and installed on, the filling line. For cleaned equipment that needs to be wrapped or bagged prior to sterilization, utilize low-shedding, noncellulosic (synthetic) wrapping materials. Cellulose fibers are one of the most common particles found in the injections-manufacturing environment, and injectable products and their source will be a prime concern (*46*).

Personnel are a concern for the introduction of extrinsic particle types such as facial hair and skin cells. The equipment preparation staff should be adequately gowned with hair covers, facial hair covers, and goggles to prevent contaminating cleaned process equipment. During validation and monitoring activities of clean- and/or steam-in-place (CIP-SIP) systems (vessels, filters, tubing, and other product contact equipment), foreign particle burden should be evaluated after cleaning. Membrane filtration/microscopic-particle-capture and -counting methods provide a useful tool to assess and document performance.

### FILLING LINE

The transfer of open containers should be evaluated and reviewed to mitigate particle contamination. For example, for aseptically filled products, the transfer should be conducted in Grade A (ISO 5, Class 100), unidirectional airflow to minimize particle contamination. The air in critical zones should be monitored continuously during operation to confirm compliance. Routine checks to detect particles and potential particle-generation locations should be explained in the procedures. Effective, written container-clearance procedures to be used after glass breakage should specify the number of containers to remove from the affected portion of the line. Note that improper setup and adjustment of the filler can lead to “needle strikes,” where the filling needles contact the container being filled. This can generate either stainless steel or glass particles.

Filling pump design and the pump’s compatibility with the product are important considerations. Metal-on-metal piston pumps have the potential for generating metal particles. Pump maintenance is essential and includes a requirement to resurface the cylinders and pistons periodically. Peristaltic-action pumps must be monitored for generation of silicone tubing particles, especially with aggressive, near-saturated solutions or suspensions. Friction in the peristaltic roller area can break down the tubing, resulting in the generation of particles (spallation). Diaphragm pumps must have specific maintenance cycles to replace the pump lining.

Stopper bowl surfaces should have a formal maintenance program, and stopper handling or replenishment by operators should be specifically designed to minimize particle transfer to the stoppers. Proper operator positioning and avoidance of open containers is important in good aseptic-filling practices to avoid microbial contamination. These same principles help reduce particle transfer to the open containers and exposed elastomeric closures.

Careful selection of cleaning and gowning materials will help reduce contamination from extrinsic particles and fibers. These clean-room materials (typically polyester or Tyvek) should be selected for their superior non-shedding and low-particle properties.

## 4.4 Trending

Data obtained from the in-process 100% inspection followed by AQL inspection are used for batch release. Both 100% and AQL inspection data should also be analyzed for adverse trends on a periodic basis, typically at least annually. Data from the 100% inspection provides the best source of typical defect types and rates during normal production. High-volume products may generate enough data to allow quarterly analysis, whereas a longer period may be necessary to accumulate data for products that are produced infrequently. Data from component inspection, production 100% inspection, and the AQL inspections should be evaluated based upon sound statistical principles to determine whether the current action levels accurately reflect current process capability. Alert and/or action levels may be established and/or adjusted if the statistical analyses indicate that lower defect levels are being observed consistently. When establishing new action or alert levels, a preliminary target value may be used until enough production experience is obtained. Consideration should be given to planned improvements in the

manufacturing and inspection processes. If significant improvements are planned, the reduction of the action/alert level should not be instituted until the impact of the improvement is measured over enough time to establish the validity of the new value.

# 5. INTERPRETATION OF INSPECTION RESULTS

## 5.1 Defect Classification

Defects are commonly grouped into classifications based on patient and compliance risk (*2*). The most common system uses three groups: critical, major, and minor. Critical defects are those that may cause serious adverse reactions or death of the patient if the product is used. This classification includes any nonconformity that compromises the integrity of the container and thereby risks microbiological contamination of the sterile product. It may also include anomalous extrinsic particle types such as insects or other filth or adulteration. Major defects carry the risk of temporary impairment or medically reversible reactions or involve a remote probability of a serious adverse reaction. Visible intrinsic particulate matter typically falls into the major defect category. This classification is also assigned to any defect that impairs or makes the product unusable. Minor defects do not impact product performance or compliance; they are often cosmetic in nature, affecting only product appearance or pharmaceutical elegance.

Upon 100% inspection, visible extrinsic and intrinsic particles should be reliably removed. Particle motion aids in detection, and stationary particles (due to neutral buoyancy or fill viscosity) are difficult to detect, exhibiting a significantly reduced PoD. The test method allows inherent particles to be accepted if the product appearance specification allows inherent particle types. PoD for all particles is dependent on the container characteristics (e.g., size, fill level, shape, and transparency), inspection conditions (lighting and duration), preparation characteristics (color and clarity), and particle characteristics (size, shape, color, and density). The PoD at 70% or greater is known as the "reject zone" described in Knapp's methodology (*57–58*), which is used worldwide as a common industry practice for rejecting particle defects. Test sets characterized by repeated inspections, as described in *7.4 Rejection Probability Determination*, are used to "calibrate" the inspection method's PoD, inspector performance, or automated inspection systems, and to demonstrate the sensitivity to threshold particle size at the reject zone of >70% PoD. The limitation of the reject zone at 70% detection is that threshold particles at this size may routinely be missed or go undetected up to 30% of the time. These undetected units may contain some level of threshold-sized particles or subvisible particles at a lower PoD. Therefore, it is important to characterize and size any particles recovered from AQL testing, retention sample inspection, and product returned from distribution to understand how they could have gone undetected during the initial 100% in-process inspection.

## 5.2 Unique Product and Container Considerations

### DIFFICULT TO INSPECT PRODUCTS (DOSAGE FORMS, CONTAINERS, AND DELIVERY SYSTEMS)

As discussed throughout this chapter, 100% visual inspection is required as a final control mechanism for particulate and other container and closure defects in injectable products. This unit-level inspection allows for the final removal of any visually detectable and undesirable nonconforming units to ensure that batch-quality acceptance criteria are met. There are dosage forms for which the sensitivity of direct examination is significantly reduced. Often referred to as DIPs, the products hinder or block the inspectors' ability to reliably detect visible particulate matter. This is attributable to interference from the characteristics of the dosage form and/or the container or delivery system. A DIP, unlike a clear solution in a transparent container, is not as amenable to defect reduction even by an optimized 100% inspection process. Thus, there is a higher probability after the 100% inspection of such products, that undetected visible particulates may remain in the batch. Supplemental testing, as briefly described in *3.1 100% Inspection*, is required to better assess residual defects in the DIP. Because fewer particles can be detected and removed during 100% inspection, there is an increased risk that the statistical sampling for the supplemental destructive testing may not reliably meet the acceptance criteria stated in ⟨790⟩. Increased preventative measures can help to compensate for the reduced detectability in DIPs. Such measures should be part of a life-cycle approach to trend and identify sources of particulate matter and use this information to reduce or eliminate their entry into finished product.

Examples of DIPs include those having opaque or deeply colored solutions, lyophilized cakes, powders, concentrated suspensions, emulsions, and ointments. Examples of DIP container types include translucent and opaque plastic; blow-fill-seal and flexible bags; foiled containers; plastic syringes; and specialty containers such as cartridges and combination products. The following sections provide additional recommendations for visual inspection and supplemental testing of DIP examples. Test methods for DIP products are discussed in *5.3 Alternate Inspection Strategies for Supplemental Testing*. Expanded information on these and additional test methods for DIP products have been published separately (*8*).

### LYOPHILIZED PRODUCTS

Lyophilized products should receive 100% inspection after the freeze-drying and sealing of each unit. However, the solid, lyophilized cake can mask the presence of visible particles because they cannot be seen within the solid matrix. The cake surfaces (top, bottom, side) are visible during inspection but account for only a small fraction of the cake volume. Because of these challenges in evaluating acceptability, a small sample of units is reconstituted and inspected for visible particles in addition to the 100% inspection of the cakes for visible particles. When reconstituted, the sample has a particle detection probability like that of solutions. Care must be taken during reconstitution to avoid contamination that can lead to false-positive results. Sample preparation should be done in a clean environment with appropriate particle-control measures. Reconstituted samples should be inspected using the same qualified methods as those for routine detection of visible particles. The destructive nature of this test limits the size of the test sample.

Once inspection of these reconstituted samples has been performed, they may be used for other required testing, such as that for subvisible particles, potency, impurities, or other specified tests. If particles are detected in this relatively small sample,

DOI: https://doi.org/10.31003/USPNF_M7198_06_01
@2024 USPC

additional units may be reconstituted as part of an investigation to assess the compliance of the entire batch. The size of the additional sample should be based on the total combined sample size (initial plus additional sample) required to have an accept number greater than 0 for a sampling plan with an AQL of 0.65% or less. This will be based on the batch size. The results from the initial and second sample must be combined, rather than resampling and repeating the test and basing the accept decision on the results of the second sample only. The following is an example of a two-stage test plan as described above: Using an S-3 plan for a batch size of 100,000 units, the initial sample size is 20, with accept on 0 and reject on 1. If 1 unit is found with one or more visible particles, the S-4 (stricter) plan may be selected, and the new sample size of 80 may be used. An additional 60 samples are then tested and, if no further evidence of visible particles is detected, the batch meets the acceptance criterion.

Alternatives to reconstitution testing can be considered, such as collection of liquid samples from the filling line after stopper insertion and prior to the lyophilization process. Such samples represent the majority of particle exposure risk. This is a typical evaluation during development activity to provide a system check for unwanted particulate matter. These risks should be assessed and documented to justify this approach. Additional process information may be supported by inspection of media fill or water fill trials for visible particle types and frequencies.

## POWDER PRODUCTS

Sterile powders are difficult to inspect for particles due to powder flow and the occlusion of white or light-colored particles by the drug product itself. Sterile powders should be reconstituted and inspected for visible foreign particles using an approach like that for lyophilized products, as discussed above.

## EMULSION AND SUSPENSION PRODUCTS

The manufacturer may not be able to detect all extrinsic and intrinsic particle types due to the inherent characteristics of an emulsion or suspension. A test dissolving the suspension or disrupting the emulsion to provide for extrinsic and intrinsic particle detection, either by visual inspection or by filtration/microscopic exam, is also recommended as part of destructive supplemental testing of a small sample, as described above for lyophilized products.

## CELL AND GENE THERAPY PRODUCTS

Cell and gene therapies present unique challenges to the normal inspection strategies employed for particulate control and assessment. Particles may be introduced from the external environment, during the manufacturing process or because of cellular or protein degradation. As cell therapies do not undergo final filtration steps, particulates must be controlled and assessed during production with visual inspection at release and prior to administration. Because the cells are the intended final product, there is an inherent limitation to the product's purification, limiting particulate removal from the ultimate formulated material. Testing is often further complicated by the small batch sizes, thus making more extensive destructive testing undesirable. Establishing acceptance limits should be based on process and inspection capability along with clinical risk assessment following similar exposure in pivotal clinical trial materials.

## AMBER CONTAINERS

Inspecting amber containers is challenging because selected glass component elements have been added to mask UV light penetration into the Type I glass container. Light transmission is blocked below 500 nm, thus increased light intensity (e.g., 8000–10,000 lux or higher) may be required to observe visible particles during inspection. Directional lighting from below or behind the container may also be beneficial. At the extreme, solutions filled in practically opaque containers may be audited via sampling and transferred to clear, clean containers. The membrane filtration microscopic method is also suitable for capturing and characterizing larger foreign particles in the visible range (>100 µm).

## PLASTIC CONTAINERS

Transparent plastic containers (e.g., vials, syringes, and larger containers) should be inspected by procedures similar to those for products in clear glass, as described throughout this chapter. The only differences may be specific consideration for the unique properties of plastic molding and physical design.

Translucent plastic containers (e.g., plastic syringes, blow-fill-seal [BFS]) are chosen for break resistance or other properties that glass cannot offer, such as the ability to be injection molded into shapes that minimize hold-up volume or that can be used in a combination product. Plastic containers may have optical properties that require significantly increased light (e.g., 8000–10,000 lux) to illuminate any visible particles against black and white backgrounds. Directional lighting from behind the container or from the bottom (Tyndall light) may also be beneficial.

Opaque plastic containers are utilized for break resistance or other properties such as metered dispensing commonly used in topical ophthalmic container systems. The expectation for 100% inspection in process for particulates during manufacture is not feasible and necessitates alternate inspection strategies (*8*). The acceptance limits for visible particles should be based on process capability as established during product development. The expectation is that this capability is judged according to industry standards and product benchmarking. The risk profile for topical ophthalmic products is reduced relative to parenteral injectable products; therefore, application of an AQL value of <0.65% for particulate matter may not be appropriate for these topical dosage forms. The recommendation is to study and trend the particle burden of the product solution and the container–closure contribution, develop a reasonable life-cycle control strategy, and establish limits based on risk assessment.

## LARGE-VOLUME CONTAINERS

Large-volume containers (>100 mL) may require additional time for a thorough inspection to be completed. For flexible containers, in addition to solution opacity, container material choices may range from clear to semitransparent with potential

@2024 USPC

changes to container clarity following sterilization. Opportunities to inspect the empty container prior to printing or labeling, or the filled container prior to pouching or overwrapping, may be preferred to finished-package inspection. The point of inspection may be determined based upon the last opportunity for the introduction of the defect of concern and where the probability of detection is greatest. The use of higher illumination intensities along with directional lighting combinations (e.g., from behind the container), as discussed above for translucent plastic containers, should be considered to enhance the visibility of particles. The manipulation sequence for inspection should be established and may differ from traditional small-volume containers. Increased inspection time may be considered for larger fill-volume container systems.

#### COMBINATION PRODUCTS

When inspecting the unlabeled primary drug container for a combination product, the inspection considerations should be the same as those specified for a conventional drug product in a conventional package such as a vial or syringe. Sensitivity may be improved by performing inspection before assembly into the device. Where there are critical attributes that are only visible after assembly (such as alignment with a fill-level window), a second inspection after assembly may also be required.

### 5.3 Alternate Inspection Strategies for Supplemental Testing

#### TRANSFER

When the container limits thorough inspection, transfer to a clear and readily inspectable container is recommended. Using verified clean and clear containers, the sample is opened, transferred to the receiving container, stoppered, and then visually inspected.

#### FILTRATION

Membrane filtration methods, such as in ⟨788⟩, *Method 2 Microscopic Particle Count Test* focusing on particles >100 um, collect all solid particles from the filled unit(s) onto a membrane. Samples may be individual or pooled for analysis. This method will reveal all solid particles (visible and subvisible), which may be sized microscopically, and permits qualitative categorization of these retained solids.

#### CLARIFICATION

In the case of suspensions, there is a wide range of active ingredient particle sizes, from submicron (<1 µm) to tens of micrometers. In many cases, the solids may be clarified/dissolved in the original container with an appropriate filtered solvent to allow subsequent visual inspection or membrane filtration/microscopic exam. Dissolution solvent compatibility with the formula or package and filtration membrane, if used, must be demonstrated.

#### SIEVING

As above, if the solid particle suspension is small enough to allow selective sieving, this may be used as an alternative to membrane filtration. The very small solids pass through the sieve, and larger particles (>100 µm) are retained, counted, and categorized.

## 6. INSPECTION METHODS AND TECHNOLOGIES

### 6.1 Manual Visual Inspection

Manual visual inspection (MVI) is the reference inspection method described in all major pharmacopeias (*59*–*60*). It consists of viewing filled and sealed containers under controlled conditions. This process may be aided using a tool to allow consistent examination of more than one container at a time.

The quality decision, to either accept or reject the container, is made by a trained person. Inspection is a probabilistic process, and detection rates less than 100% are to be expected, especially for smaller or low-contrast defects.

#### CRITICAL PROCESS PARAMETERS IN MVI

**Light intensity:** The results of the manual inspection process are influenced by the intensity of the light in the inspection zone. In general, increasing the intensity of the light that illuminates the container being inspected will improve inspection performance; chapter ⟨790⟩ recommends that the minimum light levels be not less than 2000–3750 lux at the point of inspection for routine inspection of clear glass containers. This range was chosen to harmonize with current *European Pharmacopoeia* requirements (*59*) and is further supported by recent studies performed in Japan (*61*) as part of a review of the current *Japanese Pharmacopoeia* requirements (*60*). Special attention should be given to ensure that inspection is not performed below the lower limit of 2000 lux. Increased light levels are recommended for translucent plastic containers or those made from amber glass. Under these circumstances, light levels as high as 10,000 lux may prove beneficial. Care should be taken to avoid glare and direct viewing of the light source at these high intensities, as this may result in eye strain and fatigue. The final qualified inspection conditions of minimum light level will depend on measured performance using visual standards to ensure appropriate particle size detection sensitivity.

Light should be diffuse and even across the inspection zone, and it is a good practice to clearly identify this zone within the inspection station where the intensity meets the required levels. Fluorescent lamps have often been used as the light source for

Official

https://pharmacopeia.cn/
Printed on: Fri Jan 05 2024 06:39:21 AM(EST)
Printed by: USP NF
Do Not Distribute

inspection. When fluorescent lamps are used, high-frequency ballasts are recommended to reduce visible flicker (and associated inspector fatigue). Incandescent lamps have also been used successfully for this purpose, but they generate significant heat during use. Light-emitting diodes (LED) offer an energy-efficient, stable source of light without the added heat of incandescent lamps.

Light intensity in each inspection station should be measured periodically to ensure continued compliance within the specified range. The frequency of monitoring should be based on historical experience with the type of light source in use. A lower light-intensity action limit should be established to trigger corrective action before inspection is performed below the lower limit of the range.

**Background and contrast:** Contrast between the defect of interest and the surrounding background is required for detection. Increased contrast improves detection. The use of both black and white backgrounds is described in ⟨*790*⟩, as well as other global pharmacopeias. Matte/nonglossy backgrounds are recommended to avoid interference from reflection. The use of both backgrounds provides good contrast for a wide range of particulate and container defects, which can be light or dark in appearance.

**Inspection rate:** Enough time must be provided to allow for thorough inspection of each container; ⟨*790*⟩ specifies a reference time of 10 s/container (5 s each against both black and white backgrounds). Larger or more complex containers may require additional time for inspecting all attributes. Increased time may facilitate detection of defects near the threshold of detection, but studies by Wolfe et al. (*62–63*) suggest that there are diminishing or limited gains with increasing inspection time. Time spent per container is typically a function of the inspector training or may be controlled using an inspector-triggered pacing device (proximity switch) using an indicator light or tone. Timing devices that automatically repeat the timing cycle can be distracting to other inspectors; these devices may be used during training, much as a musician uses a metronome during practice to learn the tempo of a musical piece for later performance. Recording the time spent inspecting each batch and then calculating a nominal inspection rate is a good way to confirm that the rate of inspection was within established limits. Correction can be made for non-inspection activities performed by the inspectors during this time to better document the nominal inspection rate.

**Container handling and movement:** When observing objects, the human eye is very sensitive to movement. Good techniques for manual inspection include a careful swirl or inversion of the liquid product within the container. This displaces any particles from the upper inner surfaces of the container and the closure and puts them into motion. A technique that minimizes the introduction of air bubbles is important, as air bubbles can appear as particles and interfere with detection of offending particles. If multiple containers are qualified to be equivalent to the single-container inspection method per ⟨*790*⟩, they may be held during the particle detection sequence using a tool that holds these containers for consistent presentation. Holding many containers by hand at once should be avoided, as it is difficult to obtain a complete view of all container surfaces and contents. Full rotation (360°) of the container during the container–closure defect inspection sequence is recommended for identifying small container defects such as cracks or chips.

**Magnification:** Some inspection processes use a large magnifier to increase image size and thus increase the probability of detecting and rejecting containers with defects near the threshold of detection. Although magnification can be useful for critical examination of a portion of the container, it does not often lead to increased overall detection rates for defects of interest. This may be due, in part, to the added eye strain that often results from the use of magnification. As such, it is not recommended as part of the reference inspection method described in ⟨*790*⟩ or in other global pharmacopeias (*59–60*). Although not recommended for use during routine inspections, magnification can be helpful for critical examination of a small number of units, as may be needed during an investigation.

### INSPECTOR FATIGUE AND ERGONOMIC CONSIDERATIONS

Inspecting for extended periods of time can cause inspector fatigue and a decrease in inspection performance. On the basis of industry experience (*46*), it is recommended that inspectors be given a documented break from performing inspection at least every hour. This break should allow time to rest the eyes and mind and may be achieved with a short rest (e.g., 5 min) or a longer meal break. This need for regular breaks may also be met through rotation to a non-inspection function, such as material handling or documentation.

Inspection stations should be designed and operated in a manner that minimizes the inspector's risk of repetitive-motion injury. Adjustable chairs and careful positioning of light sources as well as incoming and inspected product can reduce the risk of such injury. These adjustments can also reduce inspector fatigue and discomfort, both of which can be distracting and thus can decrease performance.

The inspection room environment should also be considered. Temperature and humidity should be controlled for inspector comfort. Reduced ambient lighting is recommended to focus the inspection process and to reduce distraction from extraneous reflections. Special care should be given to inspection rooms with exterior windows that allow daylight into the room, thereby changing ambient lighting throughout the day and with the seasons.

## 6.2 Semi-Automated Visual Inspection

Semi-automated visual inspection combines automated material handling of the containers to be inspected with human vision and judgment to make the decision to accept or reject. These systems often use a conveyor equipped with rollers to transport the containers in front of the inspector inside an inspection booth or station. For inspection of liquids, the booth can be equipped with a high-speed spin station to set particles in motion. The rollers can also be used to slowly rotate the containers in front of the inspector as they traverse the inspection zone. These systems offer a means to control the presentation of the vials and can offer additional lighting options, such as Tyndall lighting, which may enhance the appearance of some defects such as cracks or small particles. Mirrors may also be used to provide a clear view of the top and bottom of each container. Rejected units may be removed from the rollers by hand, whereas some systems are equipped with a remote rejection system that can be triggered by the inspector. Care should be taken in the qualification and operation of these systems to ensure full rotation of vials in the inspection zone to assure examination of all surfaces. In addition, studies should be conducted to ensure

DOI: https://doi.org/10.31003/USPNF_M7198_06_01
@2024 USPC

the detection of heavy particles, which may not be lifted from the bottom of the container, and to ensure that the rate of inspection produces an acceptable detection rate for defects of interest.

With semi-automated visual inspection, performance should be demonstrated to be equivalent or better than that of MVI. Some increase in throughput may be achieved because the inspector spends all the available time viewing the containers rather than splitting the time between inspection and material handling.

#### CRITICAL PROCESS PARAMETERS FOR SEMI-AUTOMATED INSPECTION

Light intensity must be controlled, as with MVI. The rate of inspection is controlled by the speed of the roller/conveyor or some equipment that allows the inspector to call for a group of containers each time. Spin speed for liquid products and rotation rate for all containers should be established during validation/qualification and maintained within the validated range for routine inspection. The background color is controlled by the color of the rollers selected and the color of the background seen through the spaces between the rollers. Qualification of inspectors and validation of the inspection equipment should be based on comparison with the compendial single-container manual-inspection process with an expectation that alternative methods such as semi-automated inspection demonstrate equivalent or better performance.

### 6.3 Automated Visual Inspection

Automated visual inspection (AVI) combines automated material handling of the containers with electronic sensing of product appearance. Containers that do not meet preprogrammed acceptance criteria are automatically rejected by the machine. Early machines performed inspection for particles and fill level, but manual or semi-automated inspection was still required for the container and closure system. Newer models have the capability to inspect all attributes of the containers, along with the contents. As with MVI, machines often spin the containers to set particles in motion and make them easier to detect. Multiple cameras are used to image various regions on the container in detail. Each camera is coupled with unique lighting to highlight specific defects in the region of interest. Light- and dark-field lighting techniques offer the same benefits as white and black backgrounds as discussed above, offering contrast for a full range of light- and dark-colored defects. A defect found by any camera is tracked through the machine to allow accurate ejection by the reject system. These machines also offer detailed reporting of defects observed in a specific production lot.

AVI offers advantages in the areas of throughput and consistency, compared with MVI (*5*). AVI may also offer enhanced sensitivity for some defects, compared with MVI, but may suffer from higher false rejection rates due to the inability to tolerate normal variation in containers or product. This is especially true for molded glass containers and flexible bags.

Validation of the automated inspection equipment should be based on comparison with the compendial manual inspection process with an expectation that alternative inspection methods demonstrate equivalent or better performance. Significant effort is required to program these systems and to test their performance against a range of known defects, as well as acceptable containers. Recent experimentation with artificial intelligence (AI) or deep learning (DL) has shown promise in improving the discrimination ability of the AVI system (*64*). Early studies show both reduced false reject rates and improved detection performance (*65*). The use of these tools may also reduce the time to develop a recipe for a new product or container.

#### LIGHT-OBSCURATION METHODS

Some systems use an optical sensor to detect the shadow of particles in solution products. This LO technique has been used successfully for detection of both subvisible and visible particles. For the detection of visible particles, it requires particles to be in motion, typically using a high-speed spin and rapid braking of the container to achieve this motion. Spin conditions must be optimized to provide sensitivity for heavier particles while minimizing false rejections due to bubbles. Some biological products experience shear-induced agglomeration, so care should be taken to avoid excessive agitation and flow rates with these products.

LO methods are optimized for sensitivity to moving particles and can thus be made less sensitive to minor container imperfections. These methods can be used with both tubing and molded containers. Results are generally robust in detecting single particles that are 100 µm in diameter and larger, though detection of smaller particles at or below the visible threshold is improved when multiple particles are present.

These systems can also detect fill height by detecting the shadow of the solution meniscus. Generally, this process is not sensitive enough to ensure compliance with dose- or fill-weight specifications, but it can provide a secondary check of gross fill. Sensitivity is a function of the container shape, with greater sensitivity achieved in small-diameter containers.

#### IMAGING METHODS

Continuing advances in camera technology now allow the rapid capture of high-resolution images for inspection. When coupled with high-speed processors that have ever-increasing computational capability, a powerful inspection tool can result. Images are divided into inspection windows, and an array of tools such as image subtraction, pixel counting, intensity analysis, and others are used to assess the images against programmed quality attributes.

Imaging systems can detect particles and fill level, as well as other container and closure attributes. Inspection in this manner can provide a comprehensive inspection of visual attributes. These systems can offer high sensitivity but may also have high false-rejection rates if container and product attributes are not tightly controlled.

X-ray imaging has also been explored to detect particles within freeze-dried cakes, powders, or suspensions (*66*).

These technologies may be used alone or in combination with other inspection methods (e.g., leak detection or container integrity) to provide a comprehensive assessment of product quality before labeling and packaging.

# 7. QUALIFICATION AND VALIDATION OF INSPECTION PROCESSES

## 7.1 Standards

The use of standards for visual inspection has been described by Melchore and Berdovich (*67*). Development of inspection standards begins with a description of the defect types that will be represented in the test set(s). This information typically comes from observations made during product development and the manufacturing area, where naturally occurring defective units can be identified from rejected product. The defects are categorized as critical, major, or minor. These defects must be further characterized to allow for the selection of naturally occurring particulates and physical or cosmetic production rejects removed from the product lots. Characterization information on defects should include, where appropriate, the range of sizes typically observed and the specific location on the container. If feasible, a photograph of the defect should be included. All information that could support consistent re-creation of the defect standards should be included in the characterization description.

## 7.2 Preparing Defect Standards

Visual-inspection particulate standards should include particles identified during product development, acquired from known production rejects, or created manually with well-characterized particulate material. A single particle seeded into each container should be used when fabricating sets to determine detection thresholds. The focus should be to demonstrate single-particle detection sensitivity, especially at the edge of the reject and "gray" zones. The use of multiple particles in a container is not recommended in order to avoid skewing the data by increasing the PoD.

## 7.3 Particle Types

The primary packaging materials that directly contact the product and the potential environmental contaminants can be divided into specific particle groups such as glass, stainless steel, elastomeric closure, plastic, and fibers (synthetic or natural). Naturally occurring visible particles from production rejects containing these materials may be used for training and to assess inspection performance. Physically prepared particles can be sieved initially to target a specific size, and then the individual particles are measured using optical microscopy prior to seeding into a prepared container. The use of characterized production defects or physically prepared standards is preferred over standard spherical particles for inspector training and qualification, as well as machine validation as they better represent actual inspection challenges and performance.

Spherical standard particles may be utilized as surrogates for naturally occurring particulates; however, these are best used for routine machine calibration rather than validation or inspector qualification, as they do not move or look like actual production defects.

## 7.4 Rejection Probability Determination

Once a well-defined defect standard is available, it is assigned a detection frequency or PoD by conducting a documented, human-inspection qualification that is accomplished by repeated manual inspection. This repeated inspection is the basis for qualifying the defect standard. This approach has been described by Knapp and Kushner (*57–58*). The Knapp methodology recognizes that the detection of particles is probabilistic, and repeated inspections with strict controls on lighting and inspection pacing/sequencing generate the statistical confidence to assign a reject probability to each standard unit. A manual, visual inspection PoD of 0.7, or 70% or greater is required to assign the container to the reject zone for subsequent calculation of the reject zone efficiency (RZE). The RZE is simply a measure of the probability or percentage of containers assigned to the reject zone that are detected during inspection. Additional discussion on the calculation and use of RZE is provided in *7.8 Inspector Qualification Requirements*. Secure probabilistic data for particulate standards can be achieved with 30–50 inspections of each container. This is best achieved with multiple inspectors. Inspection reject probability is calculated for the defect as follows:

$$\text{PoD} = (\text{Number of times rejected})/(\text{Number of times inspected})$$

## 7.5 Test Sets

These qualified defect standard units are then assembled into test sets, which may be used to specifically challenge the particle detection technique of human inspectors, used as part of a defect test set (including container–closure defects) for human qualification, or used for comparison of PoD results during automated equipment qualification and validation. Acceptance criteria should reflect the different risk categories (i.e., critical, major, and minor) of these defects when combined into a single test set, and a single acceptance criterion should not be used with a set with multiple defect risk categories. When possible, the test set should be prepared with duplicate product units per particle type and size to ensure that backup units are available if a standard container is broken, or the particle is trapped or lost within the container. Particle standard units of the same type or size may not have identical performance due to subtle differences in morphology leading to different inspection (PoD) results. Therefore, each unit (including duplicates) must be calibrated to determine its average PoD by manual inspection, see *7.4 Rejection Probability Determination*. When using test sets, it is a good practice to verify the presence of particles before and after use, as particles may become lodged between the container and the closure. A stereomicroscope with top and bottom illumination is very helpful for this. When a freely moving particle cannot be verified in liquid preparations, the unit should not be used, and the data should be excluded from subsequent calculations. When this happens, it may be possible to free the particle with the use of an ultrasonic bath. If this is not possible, the unit should be replaced. For dry solid preparations, such as powders or lyophilized cakes, the appearance of the standards may degrade with repeated handling, requiring frequent

replacement and adding to the difficulty in performing these types of studies. The number of defective units in each test set should be limited to approximately 10% to prevent rejection bias (*62*). The accept containers will be identified as having a predetermined manual visual inspection PoD of <0.3 or 30%. The accept zone containers are used as blank units or may be used to study the false reject rate of the inspection method. Any particle standards found to fall within the acceptable gray zone, indicating a manual inspection rejection probability ≥30% and <70%, may be included as an "acceptable unit" in a test set, if desired. The true utility of the gray zone units is to study the units from ≥50% and <70% PoD and demonstrate manual detection frequency of subvisible particles just below the reject zone threshold. These data can be used for illustrating the subtle differences between the manual inspection and alternate inspection methods (semi-automatic or fully automatic) during comparison studies. The human efficiency in detecting gray zone containers should be used for information only; formal acceptance criteria is not typically applied to gray zone containers (*68*).

It is important to prepare a written procedure for the creation and maintenance of standards. This procedure should define the qualification criteria, appropriate storage conditions, periodic examination and requalification, expiration, and sample custody during use. Test sets should be approved by the quality unit. The container in which the specific particle set is stored must be clearly labeled with the test set identification information.

## 7.6 Types of Test Sets

The particle detection threshold can be determined for a specific inspection method and product/package combination. For example, it can be displayed as a standard curve of detection probabilities at various particle types and sizes in an approximate range of 100–500 µm (with recommended increments of 100 µm). Fibers are typically observed in sizes greater than 500 µm. The typical size range of particles used in threshold studies incorporates a variety of particle types and densities that are typically found in the manufacturing environment.

Threshold studies are conducted to determine the sensitivity of manual inspection methods, using a range of particle sizes, in a blinded study that yields the particle-size detection capabilities of a defined group or of an individual inspector. The threshold studies indicate that the method of inspection is valid and has appropriate detection sensitivity. For example, for clear solutions in 10-mL tubing glass vials, past threshold studies indicate that particles within the range of 150–250 µm (500–2000 µm for fibers) can be detected with a PoD of 70% or greater. Results can differ due to differences in dosage forms as well as container type and size. Particulate threshold studies are also useful as an assessment tool when evaluating or qualifying visual inspection staff on a specific method with fixed testing parameters. Container and closure defects should also be evaluated for detection performance (PoD) with prepared test sets using the assigned risk categories (e.g., critical, major, and minor) in a manner similar to that for particles. Detection threshold studies are typically the first step in evaluating the performance of any new inspection method.

Depending on the product and/or presentation, rejects in the test set should represent all defect types anticipated for a given container type or product family. For particles, use a bracketed range of types (densities) and sizes, from near the lower limit of the visible range (>100 µm in clear solutions) to the largest sizes routinely observed or expected in the pool of rejects. Separate test sets should be designed to represent that the unique visual characteristics of DIPs (*8*), such as lyophilized powders, suspensions, or emulsions or containers such as those made from amber glass, are inspected. Threshold studies should be used to determine the size and type of particles that can be routinely detected (≥70% PoD) in this DIP. These data can be used to support risk assessment for an optimized inspection program and help identify when and where additional upstream controls may be needed.

For an individual manual test set, it is important that all containers and closures are of the same type, and the samples are blinded. UV ink (invisible to the inspectors) may be used to mark containers. Alternatively, bar codes or other coded labels may be used. Manual test sets can be used initially to qualify, or periodically to requalify, human inspectors. These test sets may also be used for direct comparison of manual inspection to semi-automated or automated inspection methods during initial qualification or for periodic requalification.

A bracketing approach may be used to represent a range of different container sizes when other visual characteristics are similar. Other specialized test set types may be prepared as needed to be used for daily challenge or suitability checks for automated inspection systems.

## 7.7 Training and Qualification of Human Inspectors

Before training, potential inspectors should be tested for visual acuity (*69*) and color perception. Near-vision performance should be the equivalent of 6/6 m (20/20 ft), but not conducted at this distance, and with no impairment of color vision. Both the Snellen and Jaeger charts are useful for verifying visual acuity; they test far and near vision, respectively. The use of corrective lenses to achieve the desired visual acuity is permitted. Training should include a phased approach with a specified number of training hours expected for each segment. Initially, train the potential inspectors with defect photographs or a video library and clear, written descriptions. Utilize subject matter experts to mentor and provide hands-on training with defect standards for the specified method. Reinforce mental or silent counting and follow the paced sequence to achieve consistent inspection timing. Stress the importance of strict adherence to the inspection process (procedure, sequence, and timing). Inspector fatigue may be addressed in the qualification process by testing under worst-case conditions (e.g., at the end of a typical inspection shift).

Train all inspectors (QC, QA, and production) with common procedures used for 100% inspection and AQL inspection. All inspection practices should be standardized and consistently executed by all inspection groups.

Qualification should be performed for each product type and package that the inspector will encounter. A bracketed or matrix approach can be used to simplify qualification of products with similar physical or visual characteristics such as container type and size, dosage form, product viscosity, color, and others (product families or groups). It is common to initially train and qualify personnel on clear solutions in clear containers (if produced at the facility) and then expand their expertise to the inspection of more difficult dosage forms or presentations.

## 7.8 Inspector Qualification Requirements

The qualification of all inspection personnel utilizes a manual test set to be inspected under normal operating conditions and inspection critical parameters, including inspection timing and sequence, physical environment, and inspection duration. Three successful inspections of the test set are recommended to demonstrate consistent performance for initial qualification of new inspectors. Acceptance criteria for each defect class should be based on the PoD, or RZE observed during test set qualification for the package.

There are generally two basic approaches to establishing qualification acceptance criteria for the particulate matter detection sequence. Other qualification criteria may be used with sound rationale.

PERCENT RECOVERY QUALIFICATION METHOD: A test set is prepared with bracketing of each particle type with a one-seeded unit being near-threshold (just above 70% PoD) and the other larger with a higher PoD. Typically, not less than 80% or 90% of the units containing visible particles are expected to be detected from the qualification test set.

RZE QUALIFICATION METHOD: The previously determined test set RZE is used to assess the results obtained by the inspector to be qualified. Each inspector to be qualified would then inspect the blinded set, and the RZE (the average PoD for all units containing particles >70% PoD) is calculated for each trial. The acceptance criterion is to achieve an RZE during the qualification that is equal to or better than the RZE originally determined during the threshold study.

$$\%PoD = (\text{Number of times rejected})/(\text{Number of times inspected}) \times 100$$

RZE = the average of all PoD values for all units in the test set with an individual %PoD >70%

When assessing inspector performance, a limit is also needed for false rejection. A target of <5% falsely rejected good units in the test set is recommended.

## 7.9 Requalification

Inspectors should be requalified at least annually. Requalification includes a test of visual acuity and testing with at least one product/test set configuration. A single successful inspection of the test set is sufficient for requalification. Requalification may also be necessary if poor performance is observed during routine inspection or if the inspector has been away from the inspection operation for an extended period (e.g., more than 3 months).

If an inspector fails the requalification test, a retraining process should be initiated to identify the root cause and allow the inspector to receive additional instruction. After this process has been completed, the inspector may attempt to meet the acceptance criteria one additional time. If the inspector fails, he or she may attempt to qualify again after a specified time period.

# 8. PRODUCTS IN DISTRIBUTION

Chapter ⟨790⟩ states, "If it becomes necessary to evaluate product that has been shipped to customers (e.g., because of a complaint or regulatory concern), sample and inspect 20 units. If no particles are observed in the sample, the batch is considered essentially free of visible particulates. If available, additional units may be inspected to gain further information on the risk of particulates in the batch."

For products in distribution, questions regarding batch quality will occasionally arise from customer complaints, observations in the field, customer use questions, and from the use of nonstandard (sensitive) conditions of inspection. As discussed in this chapter, the detection process is probabilistic, and the likelihood of detection is a cumulative function of the particle's visible attributes, drug product and container characteristics, and the inspection method used. In an appropriately qualified manufacturing process, the batch is presumed to have been prepared according to robust processes and all containers with package defects and visible particles (nonconforming units) removed prior to labeling. In that regard, the evaluation outlined in ⟨790⟩, *Inspection Procedure, Sampling at Batch Release (After 100% Manufacturing Inspection)* and *Product in Distribution* is only permissible if both sampling at batch release and a 100% manufacturing inspection has been successfully completed.

The particle detection threshold should be determined for a specific inspection method and product/package combination incorporating a variety of particle types and densities that are typically found in the manufacturing environment. For example, the detection threshold for routine, reliable detection (≥70% probability) of a single spherical particle in a clear solution contained in a 10-mL vial utilizing diffuse illumination between 2000 and 3000 lux is often near 150 µm in diameter (*5*). Units returned from distribution may be false positive, may contain particle(s) larger than the acceptance threshold that were missed, may contain particle(s) in the gray zone (i.e., less than the detection threshold), or may have suffered a physicochemical change that resulted in a visible change. Ideally, there will be no visible particles in the containers released to market; however, there is always a low probability that this may occur.

Upon receipt, suspect containers should be subjected to the same inspection conditions and methodology used in the release inspection. Particle(s) verified in the returned or re-evaluated supply must be carefully characterized by an analytical forensic process to determine their source and likely cause. Single particles of typical product-contact materials are unlikely to present a concern. Multiple particles, large particle sizes, and any particles indicative of physical or chemical change are significant events and should be subject to further investigation. Rare instances of particulate material falling into the gray zone should be expected given the probabilistic nature of the inspection process and should not routinely trigger further evaluation of retention samples. Chapter ⟨790⟩ provides that zero particles found in the sampling and inspection of 20 units signify that the batch is "essentially free of visible particulates." If multiple suspect containers from the same batch are detected, additional units should be inspected, and an appropriate rationale provided to support the batch's conformance to the registered specifications.

Overall batch quality using internal systems to control particulate matter and the means to investigate these occurrences is key to the life cycle approach for modern pharmaceutical production. Evaluation of retention and stability samples provides insight to batch quality, as do the field-use effects for any medication. While the presence of particles or product or container

defects discovered in retained or returned product do not necessarily incriminate the quality of the batch, a careful investigation should be conducted to exclude systemic risks.

## 9. CONCLUSIONS AND RECOMMENDATIONS

Visual inspection for particles and other visible defects continues to be an important part of the manufacturing process for injections. Chapter ⟨790⟩ provides a useful reference method and acceptance criteria for visible particulates in injections. Successful execution of visual inspection requires an understanding of the inspection process and careful control of inspection conditions. Both visual inspection procedures and investigative processes for elevated rejects consist of comprehensive and well-documented systems relevant for the products being manufactured. Inspectors must be trained to ensure consistent, high-quality performance. Alternative inspection methods, either semi-automated or fully automated, may be used in place of manual inspection methods. Where machine methods are used, the equipment must be validated to demonstrate equivalent or better performance when compared to manual inspection. The use of test sets that contain standard defects is an important element in inspector training and qualification as well as machine validation. Good product development will lead to a stable product with a lower risk of particle formation. Identification of the type or types of particles found during product development and routine manufacturing is critical to reducing their occurrence. Inspection results should be trended to further aid in continuous process improvement with the ultimate goal of defect prevention.

## 1. INTRODUCTION

Radioactive drugs and devices require specialized techniques in their production, testing, handling, dispensing, and administration to ensure optimal effectiveness and maintain safety for workers, patients, and the public. All operations involving these articles should be carried out by or under the supervision of personnel who have been appropriately trained in the handling of radioactive materials.

The facilities for the production, storage, and use of radioactive drugs and devices are generally subject to licensing by the U.S. Nuclear Regulatory Commission, an appropriate state agency, or similar governmental agencies outside of the United States. Most radioactive drugs and devices, although not identified as hazardous drugs, are classified as hazardous materials and are therefore subject to other regulations relating to transportation, environmental release, and workplace safety.

The purpose of this chapter is to provide information regarding radioactivity—including definitions, types of decay, and general considerations relating to radioactive decay, counting, radionuclide production, purity, and labeling—as well as instrumentation for detection and measurement of radioactive emissions.

Specific information on standards for radionuclide identification and assay, including instrument qualification, performance checks, identification of radionuclides and radionuclidic impurities, and assay of radionuclides are provided in *Radioactivity* ⟨821⟩.

## 2. TYPES OF DECAY

"Radioactive decay" is the process by which an unstable nuclide transitions to a lower energy configuration. Depending on the particular starting radionuclide, the result of the transition may be either a stable nuclide or a different radionuclide. Typically, these transitions are accompanied by the emission of radiation from the nucleus, which is broadly classified as either particulate or nonparticulate. Some radionuclides emit multiple types of radiation in this process, whereas others emit only a single type. The main types of particulate radiation commonly seen in nuclear medicine are alpha, beta, and positron. Nonparticulate types of radiation include gamma rays and X-rays. Nuclear medicine imaging is accomplished through detection and localization of nonparticulate radiation, whereas therapeutic effects arise from the energy deposited in the target organ by particulate radiation.

### 2.1 Alpha Decay

"Alpha decay" is radioactive decay with the emission of alpha particles, or helium nuclei, and is generally limited to elements with an atomic number >83. In some cases, beta particles and gamma rays may also be emitted during alpha decay. An example of a radionuclide that decays by alpha decay is:

Radium-226 → Radon-222

### 2.2 Beta Decay

"Beta decay" is radioactive decay with the emission of an electron. This type of decay typically occurs in neutron-excessive radionuclides wherein a neutron is transformed into a proton. In some cases, the emission of a positively charged electron, or positron, may occur. This type of decay typically occurs in neutron-deficient radionuclides with a lower atomic number wherein a proton is transformed into a neutron. In some cases, gamma rays may also be emitted during beta decay. An example of beta decay through emission of an electron is:

Iodine-131 → Xenon-131

An example of beta decay through emission of a positron ($\beta^+$) is:

Fluorine-18 → Oxygen-18

Because a positron is an anti-electron, when it interacts with an electron, the two particles annihilate, and their combined mass is transformed into energy in the form of two 511 kiloelectron volt (keV) gamma rays. These gamma rays are produced simultaneously and travel away from the point of interaction in nearly opposite directions. These two characteristics form the basis for positron emission tomography (PET) imaging techniques.

### 2.3 Electron Capture Decay

"Electron capture" is radioactive decay that involves nuclear capture of an inner orbital electron, nuclear transformation of a proton into a neutron, and emission of one or more gamma rays. Electron capture generally occurs in higher atomic number radionuclides that are neutron deficient. An example of a radionuclide that decays by electron capture decay is:

Iodine-123 → Tellurium-123

### 2.4 Isomeric Transition

An "isomeric transition" is radioactive decay that involves a transition between nuclear isomers with the emission of one or more gamma rays. In contrast to other types of decay, the number of protons and neutrons remains the same in an isomeric transition. Isomeric transition generally occurs in radionuclides that are metastable. An example of a radionuclide that decays by isomeric transition is:

Technetium-99m → Technetium-99

## 3. GENERAL CONSIDERATIONS

### 3.1 Radioactivity

Radioactive decay is a first-order process (i.e., a fraction of atoms decay per unit time). The rate of decay for each radionuclide is a unique and constant value, which gives rise to the term "decay constant".

Each radionuclide's rate of decay is a unique and constant value (its decay constant) and can be described by the following equation:

$$A = \lambda N$$

$A$ = amount of radioactivity in a source at a given time
$\lambda$ = rate of decay of the radionuclide
$N$ = number of radioactive atoms

The traditional unit for radioactivity is the curie (Ci), which is equal to $3.7 \times 10^{10}$ atoms undergoing radioactive decay, or disintegrations per second (dps). Commonly used prefixes associated with the Ci include the millicurie (mCi) and the microcurie (μCi). The SI unit for radioactivity is the becquerel (Bq), which is equal to 1 dps. Commonly, prefixes associated with the Bq include the megabecquerel (MBq) and the gigabecquerel (GBq). Hence, 1 Ci = 37 GBq.

### 3.2 Fundamental Decay Law

The decay of a radioactive source is described by the equation:

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M9778_01_01
@2024 USPC

$$N_t = N_0 e^{-\lambda t}$$

$N_t$ = number of radioactive atoms remaining at elapsed time $t$
$t$ = time elapsed (time unit, such as seconds, minutes, or hours)
$N_0$ = number of radioactive atoms when $t = 0$
$\lambda$ = decay constant of the specific radionuclide

The above equation can be rewritten in terms of radioactivity:

$$A_t = A_0 e^{-\lambda t}$$

$A_t$ = amount of radioactivity at elapsed time ($t$)
$t$ = time elapsed (time unit, such as seconds, minutes, or hours)
$A_0$ = amount of radioactivity when $t = 0$
$\lambda$ = decay constant of the specific radionuclide

"Decay tables" that provide radionuclide-specific decay factors (i.e., fraction remaining) calculated from $A_0 e^{-\lambda t}$ at various elapsed times ($t$) are commonly available.

The half-life is defined as the time interval required for a quantity of radioactivity to decay to one-half of its initial value and is related to the decay constant $\lambda$ by the equation:

$$T_{1/2} = 0.69315/\lambda$$

$T_{1/2}$ = half-life of the radionuclide
$\lambda$ = decay constant of the specific radionuclide

The activity of a pure radioactive substance as a function of time can be obtained from the exponential equation, from decay tables, or by graphical means based on the half-life (*Figure 1*).

## 3.3 Counting Efficiency

The validity of any radionuclide measurement is dependent upon the reproducibility of the relationship between the source, the detector, and its surroundings. Appropriate allowances should be made for source configuration. Measurements of radioactivity require calculation of a calibration factor, or efficiency, and are dependent on the type of detector, the container in which the radioactivity is placed, and the source–detector geometry. The basic efficiency equation for detectors designed to count discrete decay events over a period of time is given as:

$$\text{disintegrations/s} = (\text{counts/s})/\varepsilon$$

$\varepsilon$ = efficiency or calibration factor

Because 1 dps is defined as 1 Bq, the above equation gives radioactivity in units of Bq. Through the application of the appropriate unit conversion, Bq can be transformed into µCi or any other unit of radioactivity. Detectors should be calibrated with a source of known radioactivity and in a fixed geometry.

## 3.4 Background

Cosmic rays, radioactivity present in the detector or shielding materials, and radiation from improperly shielded sources contribute to the background radiation. All radioactivity measurements should be corrected by subtracting the background count rate from the gross count rate in the test sample.

## 3.5 Statistics of Counting

Modern radiation detection systems often incorporate statistical analysis into their software. The user should understand the use and limitations of these programs to ensure accurate results.

Because the process of radioactive decay is a random phenomenon, the events being counted form a random sequence in time. Therefore, counting for any finite time can yield only an estimate of the true counting rate. The precision of this estimate, being subject to statistical fluctuations, is dependent upon the number of counts accumulated in a given measurement and can be expressed as:

$$\sigma = \sqrt{n}$$

$\sigma$ = standard deviation
$n$ = number of counts accumulated in a given measurement

The probability of a single measurement falling within $\pm 100/\sqrt{n}\%$ of the mean of a great many measurements is 0.68, which means that if each count were to lie within $\pm 100/\sqrt{n}\%$ of the mean for approximately two-thirds of the observations, then approximately one-third of the observations would lie outside of this interval.

Because of the statistical nature of radioactive decay, repeated counting of an undisturbed source will yield count-rate values in accordance with the frequency of a normal distribution. Any deviations in these values from the normal distribution conform to the chi-square ($\chi^2$) statistical test. For this reason, the $\chi^2$ test is frequently applied to determine the performance and correct operation of a counting assembly. The term "figure of merit" of a radioactive counting instrument is expressed as:

$$\text{Figure of merit} = \varepsilon^2/B$$

$\varepsilon$ = counter efficiency
$B$ = background count rate (cps)

In the selection of instruments and conditions for assay of radioactive sources, the figure of merit should be maximized.

## 3.6 Minimum Detectable Activity

In situations where only very small quantities of radioactivity are to be measured, the lower limit of the ability of the instrument to detect that particular radionuclide should be known. The "minimum sensitivity", also referred to as "limit of detection", is defined as the net count rate above background that must be exceeded before a sample is deemed to contain detectable radioactivity with a specified level of confidence. The minimum sensitivity is generally considered to be 3 standard deviations above the mean background count rate and is calculated as:

$$\text{Minimum sensitivity} = (3 \times \sqrt{B})/t$$

$B$ = background count rate (cps)
$t$ = count time

The minimum detectable activity is defined as the smallest quantity of radioactivity that can be measured under the specific conditions of minimum sensitivity and counting efficiency of the instrument. It is calculated as:

$$\text{Minimum detectable activity} = (\text{Minimum sensitivity})/(\varepsilon \times F)$$

Official

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-May-2017
DOI Ref: 0g32c
DocId: GUID-657CAE90-7432-4BCA-9290-3B9D05320DF5_1_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M9778_01_01
@2024 USPC

$\varepsilon$ = counting efficiency
$F$ = unit conversion factor

For example, if minimum sensitivity is in units of dpm and minimum detectable activity is desired to be in units of Bq, then $F$ = 60 dpm/Bq. If minimum sensitivity is in units of cpm and minimum detectable activity is desired to be in units of µCi, then $F = 2.2 \times 10^6$ cpm/µCi.

## 3.7 Limit of Quantification

The limit of quantification is the smallest quantity of radioactivity that can be quantitatively determined with suitable precision and accuracy. The limit of quantification is used particularly for the determination of impurities and degradation products. In practical terms, the limit of quantification is usually considered to be 10 standard deviations above the mean background count rate.

## 3.8 Counting Losses

The minimum time interval that is required for the counter to resolve two consecutive signal pulses is known as the dead time. The dead time is typically on the order of microseconds for proportional and scintillation counters and to hundreds of microseconds for Geiger counters. Nuclear events occurring within the dead time of the counter will not be registered. The corrected count rate, $R$, can be calculated using the formula:

$$R = r/(1 - r \times \tau)$$

$r$ = observed count rate
$\tau$ = dead time

The correction formula assumes a nonextendable dead time. The observed count rate, $r$, refers to the gross sample count rate and is not to be corrected for background before use in this equation. For general validity, the value of $r \times \tau$ should not exceed 0.1. Most modern counting systems have the ability to account for dead time, but dead time may still be a factor to consider in some circumstances.

## 3.9 Linearity and Range

When a radiation detection instrument is used in a quantitative measurement, the instrument should be suitable for the type(s) of radiation to be measured, and the instrument response should be linear over the range of measurements or a correction factor should be applied. Normally, a minimum of five different quantities of radioactivity are used to establish linearity. These quantities should bracket the range of radioactivity levels that are routinely measured in a particular application.

## 3.10 Calibration Standards

All radioactivity assays should be performed using measurement systems that have been calibrated with appropriately certified radioactivity standards. Such calibration standards may be purchased either directly from an appropriate National Metrology Institute (NMI) or from other sources that have established traceability to the NMI, through participation in a program of inter-comparative measurements. Where such calibration standards are unavailable, nuclear decay data required for calibration can be obtained from the Evaluated Nuclear Structure Data File maintained at the Brookhaven National Laboratory.[1]

## 3.11 Production of Radionuclides

The various radionuclides found in nature generally have undesirable properties for nuclear medicine applications, including very long half-lives (e.g., thousands or millions of years), decay with emissions of alpha or beta particles, and low isotopic purity because of the presence of other isotopes of that element. Because of these properties, naturally occurring radionuclides are rarely used for radiopharmaceuticals, except for some alpha-emitting members of the actinide decay series, which are used for certain therapeutic radiopharmaceuticals (e.g., radium-223).

There are four common production routes for artificially produced radionuclides: fission, neutron activation, charged-particle-induced reactions (cyclotron), and radionuclide generators.

"Fission byproducts" refer to radionuclides that are obtained as byproducts of the fission of uranium (uranium-235). These radionuclides, whether directly produced fission fragments or subsequent members in a decay chain originating from a fission fragment, can be chemically separated into individual forms from the mixture of fission products. Desirable properties of fission byproducts include high isotopic purity and moderate cost. Undesirable properties may include beta-particle emissions, low specific activity of certain radionuclides, and the limited selection of radionuclides produced. Examples of fission byproducts used in nuclear medicine applications include iodine-131 and xenon-133. Currently, the most widely used fission byproduct is molybdenum-99, which is used in technetium-99m generators.

"Neutron activation" refers to the production of radionuclides in a nuclear reactor by bombarding target atoms with thermal neutrons. Nuclear transformations, induced by neutron capture, result in isotopes possessing one additional neutron, and thus an atomic mass increased by one. The excess energy of the newly formed isotope is emitted as a gamma ray. These reactions

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M9778_01_01
@2024 USPC

are often termed ($n,\gamma$) reactions. Desirable properties of neutron-activated radionuclides include a wide variety of isotopes that can be produced and the moderate cost to produce them. Undesirable properties may include decay with beta-particle emissions and relatively low isotopic purity (i.e., unreacted stable target atoms are mixed with their radioisotope products). Because of their beta emissions, however, several of these radionuclides have been used in therapeutic radiopharmaceuticals. Examples of neutron-activated radionuclides used in therapeutic radiopharmaceuticals include strontium-89, yttrium-90, iodine-131, samarium-153, and lutetium-177.

Cyclotron production of radionuclides occurs by bombarding stable atoms with charged particles (e.g., protons or deuterons) that have been accelerated in the cyclotron's oscillating electromagnetic field. Nuclear transformations induced by particle capture usually result in a radioisotope of a different element with the emission of one or more neutrons or protons. For example, if a proton is captured and a neutron is emitted, the reaction is often termed a ($p,n$) reaction. Desirable properties of cyclotron-produced radionuclides include the wide variety of isotopes that can be produced, the availability of alternate production schemes, radionuclide decay by electron capture or positron decay rather than by beta decay, and high isotopic purity. Undesirable properties may include contaminating radioisotopes from side reactions and the relatively high cost of radionuclide product. Examples of cyclotron-produced radionuclides used in nuclear medicine applications include carbon-11, fluorine-18, gallium-67, indium-111, iodine-123, and thallium-201.

Generators refer to a special method of radionuclide production whereby a short-lived radionuclide results or is generated from the decay of a longer-lived radionuclide. The longer-lived parent radionuclide is generally bound to a column, and the short-lived radionuclide daughter product is then extracted (eluted) from the column. After elution, subsequent decay of the long-lived parent radionuclide generates more of the short-lived radionuclide daughter product, which can then be extracted. A generator provides a specific radionuclide in sequential elutions over a prolonged period of time. Desirable properties of generator-produced radionuclides include ready availability, portability, low-to-moderate cost, variety of radionuclides and type of decay, and relatively high isotopic purity. Undesirable properties may include the limited number of parent-daughter pairs and the potential for generator breakthrough of the parent radionuclide in the eluate. Examples of generator-produced radionuclides used in nuclear medicine applications include technetium-99m (daughter of molybdenum-99), rubidium-82 (daughter of strontium-82), and gallium-68 (daughter of germanium-68). The characteristics of all four production methods are summarized in *Table 1*.

**Table 1. Production Methods of Radionuclides**

| Production Method | Nuclear Reactor (fission byproduct) | Nuclear Reactor (neutron activation) | Cyclotron | Radionuclide Generator |
|---|---|---|---|---|
| Bombarding particle | Neutron | Neutron | Proton, deuteron, triton, alpha | Production by decay of parent |
| Product | Neutron excess | Neutron excess | Neutron poor | Neutron poor or excess |
| Typical decay pathway | $\beta^-$ | $\beta^-$ | Positron emission, electron capture | Several modes |
| Typically carrier free | Yes | No | Yes | Yes |
| High specific activity | Yes | No | Yes | Yes |
| Relative cost | Moderate | Moderate | High | Low to moderate |
| Radionuclides for nuclear medicine applications | Molybdenum-99, iodine-131, xenon-133 | Iodine-131, strontium-89 yttrium-90, samarium-153, lutetium-177 | Thallium-201, iodine-123, gallium-67, indium-111, fluorine-18, carbon-11 | Technetium-99m, krypton-81m, gallium-68, rubidium-82 |

Other methods of radionuclide production have been developed but currently are not used to produce radionuclides used in radiopharmaceuticals.

## 3.12 Carrier

The total mass of radioactive atoms or molecules in a radiopharmaceutical is directly proportional to the amount of radioactivity and is usually too small to be measured by ordinary chemical or physical methods. For example, 37 MBq (1 mCi) of iodine-131 has a mass of $8 \times 10^{-9}$ g. Because such small quantities behave in an anomalous manner, such as nonspecific adsorption to container walls, a carrier may be added during processing to permit ready handling. Amounts of the carrier, however, should be sufficiently small so that undesirable physiological, pharmacological, or toxicological effects are not produced. Also, because the carrier is chemically identical to the radionuclide, the amount of carrier should be limited to avoid competitive interference with the desired chemical reactions and overall radiochemical yield.

The term "carrier free" refers only to radioactive preparations in which other isotopes of the radionuclide are absent (i.e., free from the presence of carrier). In practice, a true carrier-free state may be difficult or impossible to achieve because of the ubiquity of certain elements or molecules. Hence, the term "no carrier added" may more appropriately describe a preparation that may contain a trivial amount of carrier but for which additional carrier has not been purposefully added. Radionuclides produced by neutron activation reactions generally contain substantial amounts of nonradioactive isotope remaining from unreacted target material and thus cannot be considered carrier free. However, there are select cases in which this is not the case, such as ($n,p$) reactions.

The radioactivity per unit volume of a medium or vehicle containing a radionuclide is referred to as the "radioactivity concentration", "specific concentration", or "strength" and is expressed in units such as Bq/mL or Ci/mL. The radioactivity of a radionuclide per unit mass is referred to as "specific activity" and is expressed in units such as Bq/g, Ci/g, or Bq/mol. The

maximum specific activity of a radioactive preparation exists when it is in a carrier-free state; the addition of a carrier results in lowered specific activity.

## 3.13 Radiochemical Identity and Purity

"Radiochemical identity" may be defined as the molecular structure of the compound that contains the radionuclide. Because it is nearly impossible to analyze the structure of radiolabeled compounds with the traditional tools used for organic structure determination, the radiochemical identity of a radiopharmaceutical is often determined indirectly. This process begins with the preparation and characterization of a nonradioactive analog, which is commonly referred to as the "cold compound". The radiolabeled compound is often chromatographically analyzed simultaneously with the cold compound. The identical response of the two compounds demonstrates the structural identity of the radiolabeled compound.

The radiochemical purity of a radiopharmaceutical preparation refers to the fraction of the stated radionuclide present in the stated chemical form. Radiochemical purity is important for radiopharmaceuticals because radiochemical impurities may affect the biodistribution and interfere with image interpretation (diagnostic accuracy). In addition, radiochemical impurities may alter radiation absorbed doses to various organs. When using therapeutic radiopharmaceuticals, radiochemical purity is very important because altered biodistribution associated with radiochemical impurities may result in insufficient irradiation of the target tissue (suboptimal treatment response) or excessive irradiation of other tissues (undesired radiation damage).

Radiochemical impurities in radiopharmaceuticals may result from byproducts of the preparative method or from decomposition. Radiation causes decomposition of water, a main component of aqueous radiopharmaceutical preparations, leading to the production of reactive hydrogen atoms and hydroxyl radicals, hydrated electrons, hydrogen, hydrogen ions, and hydrogen peroxide. Hydrogen peroxide is formed in the presence of oxygen radicals, originating from the radiolytic decomposition of dissolved oxygen. Many radiopharmaceuticals show improved stability if oxygen is excluded or restricted. Radiation may also affect the radiopharmaceutical itself, giving rise to ions, radicals, and excited states. These species may combine with one another and/or with the active species formed from water. Radiation decomposition may be minimized by the use of chemical agents that act as electron or radical scavengers. Radiochemical purity must meet compendial standards throughout the time of use until the stated expiration of the radiopharmaceutical.

Determination of radiochemical purity is typically a two-stage process: 1) the different chemical species are separated by paper, thin-layer, or column chromatography or other suitable analytical separation technique; and 2) the radioactivity content in each of the separated chemical species is measured with a suitable radiation detector and counting device. The ultimate confirmation of acceptable radiochemical purity of a radiopharmaceutical is its intended biodistribution after administration.

## 3.14 Radionuclidic Identity and Purity

"Radionuclidic identity" is a critical parameter in radiopharmacy because the radionuclide used determines the radiation dose to the patient, the biodistribution of the radiopharmaceutical, the quality of any images obtained, or the efficacy of any therapeutic preparation. Radionuclide identity can be established either by measuring the half-life or the energy of the radiations emitted by the sample.

The radionuclidic purity of a radiopharmaceutical preparation refers to the fraction of radioactivity attributable to the desired radionuclide in the total radioactivity measured. Hence, a radionuclidic impurity is the presence of an unwanted radionuclide. Radionuclidic purity is important for radiopharmaceuticals, because unwanted radionuclides may cause several undesired consequences:

- Radionuclidic impurities may cause the radioactive assay of the radiopharmaceutical to deviate from the prescribed amount.
- Radionuclidic impurities may deliver higher-than-desired, radiation-absorbed doses to various organs and tissues.
- In some situations, radionuclidic impurities may interfere with image interpretation (diagnostic accuracy).
- It should be remembered that radionuclidic purity will change with time and is generally specified as a percentage of the desired radionuclide's activity at the time of calibration or at the time of administration (e.g., molybdenum-99 in technetium-99m).

The radionuclidic purity must meet compendial standards throughout the useful life of the radiopharmaceutical. In addition, the impurity(ies) themselves will decay. Consideration must be given to the acceptable minimum and maximum allowable times between expiration of the product and analysis for impurities.

Radionuclidic impurities commonly arise during radionuclide production relating to impurities in target materials, differences in the values of various competing production cross-sections, and different excitation functions of competing reactions at the energy of the bombarding particles. In the case of generator-produced radionuclides, some generator breakthrough of parent radionuclide typically occurs and represents a radionuclide impurity in the eluate of the daughter radionuclide.

Determination of radionuclidic purity is typically based on evaluation of radioactive emissions, the principal analysis of the gamma spectrum obtained from a sample of the product. For short-lived isotopes, the half-life measurement could be an appropriate approach to assess radionuclidic purity. In cases involving radionuclidic impurities that have long half-lives relative to the desired radionuclide, measurement of the radionuclidic impurities can be performed after a sufficient time delay to allow the desired radionuclide to fully decay. In cases involving radionuclidic impurities that have substantially higher energy gamma emissions relative to the desired radionuclide, measurement of the radionuclidic impurities can be performed after placing the product inside a properly calibrated radiation shield that affords differential attenuation of the gamma rays emitted from the desired radionuclide versus those emitted from the radionuclidic impurities. Positron-emitting radionuclides typically cannot be differentiated, because their emitted energy (511 keV) is the same for each radionuclide; thus, gamma-ray spectrometry is not a recommended prerelease test for radionuclidic identity for PET radionuclides. Some positron-emitting radionuclides have characteristic gamma-ray emissions in addition to 511 keV, which may be used for purposes of identification (e.g., germanium-69 and sodium-22). In any case, the appropriate instrument should be chosen to detect potential impurities and should be properly calibrated to accurately quantify any identified impurities.

### 3.15 Chemical Purity

The chemical purity refers to the fraction of the total chemical species present in the product as the specified chemical component(s). Hence, a chemical impurity is the presence of an unwanted nonradioactive chemical. Chemical purity is important for radiopharmaceuticals, because chemical impurities may cause undesirable consequences such as chemical interactions (e.g., precipitation) and toxic biologic effects.

Chemical impurities are typically associated with production procedures and may include contaminants from raw materials, synthetic byproducts, solvents, excipients, equipment, preparative or purification columns, and containers. For certain radiopharmaceuticals, chemical impurities may also be associated with generator breakthrough of resin material from the generator column (e.g., alumina) in the eluate solution.

Determination of chemical purity is generally not performed and reported as a single attribute. Rather, determinations of individual chemical impurities are performed and compared to specifications (limits) for the respective individual chemical impurities. Such determinations of chemical impurities use analytical techniques as appropriate and described in the individual radiopharmaceutical monograph.

### 3.16 Labeling

Individual radiopharmaceutical monographs indicate that the labeling is to include the date and time of calibration, the amount of radioactivity associated with the radiopharmaceutical expressed as total MBq (μCi or mCi) and concentration as MBq (μCi or mCi)/mL at the time of calibration, the expiration date (and time, if appropriate), and the statement, "Caution—Radioactive Material". The labeling indicates that in making dosage calculations, a correction is to be made for radioactive decay and also indicates the radioactive half-life of the radionuclide. Other labeling requirements may apply to biologics or articles intended for injection. Beyond-use dates of compounded preparations should be included as appropriate. Additional labeling requirements may be required by various regulatory agencies.

### 3.17 Naming Conventions for Isotopes

Various naming conventions exist for isotopes that are associated with radiopharmaceuticals and radioactive devices. For example, the name of an isotope may or may not use a superscripted value for the mass number. Superscripted values should precede the elemental symbol for the isotope, and non-superscripted values should follow the elemental symbol, preferably with a hyphen between the symbol and the mass number. Examples include $^{68}$Ga and O-18, respectively. Square brackets should be used to denote a specific isotope when necessary within a chemical name, for example, 2-[$^{18}$F]fluoro-2-deoxyglucose. Individual radiopharmaceutical monographs use nonproprietary names assigned by the U.S. Adopted Names (USAN) Council, which use the elemental symbol followed by the mass number separated by a space, for example, *Thallous Chloride Tl 201 Injection*. Although exceptions to these conventions undoubtedly exist, efforts should be made to adopt standardized conventions for radiopharmaceuticals and radioactive devices that fall within the scope of this general chapter.

## 4. INSTRUMENTATION FOR DETECTION AND MEASUREMENT OF RADIOACTIVE EMISSIONS AND APPLICATIONS

### 4.1 Ionization Chambers

Radioactive materials are not readily detected by ordinary chemical or physical methods. Instead, detection methods for radioactive materials rely on the ionization of matter that results from the emitted radiation. The charge separation created during this process forms the basis of radiation detection systems, which may be based on the ionization properties of gaseous, liquid, and solid materials.

An ionization chamber is an instrument that directly measures ions produced in a gas as the result of the interaction of radiation with the gas. The most common usage in nuclear medicine applications is as the detector used in a dose calibrator. The dose calibrator is an instrument used to measure the quantity of radioactivity in a radiopharmaceutical. The key component of a dose calibrator is an argon-filled chamber with an applied electrical potential that allows the detection of ions produced by the passage of gamma rays through the chamber. Calibration of the system may involve one or more radionuclides with gamma energies and quantities that span the range of typical analyses. The calibration of the ionization chamber should be performed, when possible, with suitable NMI-traceable radionuclide standards. Routine system suitability testing should include checks for these parameters. Frequency of testing should occur as appropriate. Please refer to ⟨821⟩ for additional details on typical instrument requirements.

The position of the radioactive sample in the dose calibrator is ideal when it simulates 4π geometry. The geometric goal is placement of the sample at a point in the center of the cylindrical detector. Reproducibility of placement within the chamber is critical, because the response typically drops off at the top and bottom of the cylinder because of a combination of geometry and electronic effects. The value of the ionization current per unit of radioactivity, known as the "calibration factor", is characteristic of each gamma-ray-emitting radionuclide. The current produced in a dose calibrator is related to the mean energy of the emitted radiation and is proportional to the intensity of the radiation. The calibration of the dose calibrator for a specific radionuclide is ideally performed with a radioactive calibration source of the same radionuclide. Alternatively, it may be performed by measuring radioactive calibration sources with gamma energies above and below the gamma energy for the radionuclide to be measured and interpolating these values, also correcting for differences in gamma abundance, to establish the calibration factor for that radionuclide.

The upper limit of the dose calibrator is normally specified by the manufacturer. If not, testing is required to ascertain this upper limit. With a deep reentrant well-type chamber, reproducibility within approximately 5% or less can be readily obtained

@2024 USPC

in a few seconds for quantities of radioactivity in the MBq (mCi) range and within about 30 s for quantities in the kBq (µCi) range.

The calibration of a dose calibrator should be maintained by relating the measured response of a standard to that of a long-lived reference standard, such as radium-226 in equilibrium with its daughters, cesium-137 in equilibrium with its daughters, barium-133, cobalt-60, or cobalt-57. The instrument should be checked on each day of use with the reference standard source to ascertain the stability over a long period of time. This check should include reference standard readings at all radionuclide settings used. Any necessary corrections for radioactive decay of the reference standard source should first be applied. It is also recommended that the reproducibility and/or stability of multi-range instruments be checked with the use of standards with appropriate activities for all ranges.

The size, shape, and location of a radioactive sample within the well will affect the response of a dose calibrator. This is usually referred to as "geometry". The shape, composition, and dimensions of the container holding the radioactive material can affect the result. Effects relating to container properties are generally more pronounced with radionuclides that emit beta particles (because of differences in Bremsstrahlung production) or emit low energy gamma or X-rays (because of differences in photon attenuation). It is important that geometric correction factors, if needed, be determined for each combination of radionuclide and configuration (i.e., size, shape, location with the well chamber, volume within the container, and container properties). The manufacturer's calibration factor for each radionuclide is determined using a specific geometry and container, which may not match the geometry or container used operationally.

## 4.2 Liquid Scintillation Counters

The liquid scintillation counter (LSC) detection method uses liquid scintillation cocktails to transform emitted radiation into detectable light photons. Alpha- and beta-emitting radionuclides may be assayed with the use of a liquid-scintillation detector system. In the liquid scintillator, the emitted radiation is converted into light quanta that are usually detected by two multiplier phototubes arranged to detect only coincidence radiation. The liquid scintillator is a solution consisting of a solvent, primary and secondary solutes, and additives. As the emitted particle dissipates energy in the solvent, a fraction of this energy is converted into fluorescent light by the primary solute. The function of the secondary solute is to absorb the primary fluorescence and re-emit the light at a longer wavelength that is more efficiently detected by the multiplier phototubes. Traditionally used solvents (cocktails) are toluene and *p*-xylene; primary solutes are 2,5-diphenyloxazole (PPO) and 2-(4′-*tert*-butylphenyl)-5-(4-biphenylyl)-1,3,4-oxadiazole (butyl-PBD); and secondary solutes are 2,2′-*p*-phenylenebis[4-methyl-5-phenyloxazole] (dimethyl-POPOP) and *p*-bis(*o*-methylstrylyl)benzene (bis-MSB). Many aqueous scintillating solution cocktails that are less hazardous are available. Aqueous solutions tend to have a shorter shelf-life; therefore, it is important to ensure that they have not expired before use. As a means of attaining compatibility and miscibility with aqueous samples to be assayed, additives, such as surfactants and solubilizing agents, are also incorporated into the scintillator. For an accurate determination of radioactivity of the sample, care should be exercised to prepare a sample that is truly homogeneous. Quenching is a major concern for liquid scintillation and refers to any mechanism that causes a reduction of emitted light by the source. Quenching can result from multiple factors, including oxygen and dilution effects; therefore, it is critical to perform quenching corrections by counting comparative measurements of standard samples using the same conditions of volume, additives, and solvent to accurately account for these effects.

Alternatively, an external source, typically barium-133 or europium-152, is placed in close proximity to the sample vial to release Compton electrons. The shape of the resulting spectrum is analyzed to compute a quench-indication parameter. This parameter can then be related to the counting efficiency by measuring sources of known radioactivity at a determined level of quenching agent. The resulting quench curve allows the determination of the radioactivity of an unknown sample knowing the count rate and value of the quenching parameter. The scintillation fluid may require special handling for disposal, in addition to any residual radioactivity. Static electricity on the vials may also cause spurious counts in the system, especially in the case where low-energy beta emitters are being assayed. This problem is often greater in a low-humidity environment.

The disintegration rate of a beta-emitting source may be determined by a procedure in which the integral count rate of the sample is measured as a function of the pulse-height discriminator bias, and the emission rate is then obtained by extrapolation to zero bias. Energetic alpha-emitters may be similarly measured by this method.

## 4.3 Nuclear Spectroscopy Systems

### GAMMA-RAY SPECTROMETRY

Each gamma-emitting radionuclide has a unique spectrum of mono-energetic photons emitted that allows the identification and quantification of radioactive materials in a sample by comparing the energy(ies) of the photon(s) detected and the intensity at each energy. This gamma spectrum allows for both the quantitative determination of purity as well as identity of the radionuclide. Gamma-spectrum analysis can be performed by using either a scintillation crystal, typically sodium iodide activated with thallium [NaI(Tl)], or by using a semiconductor detector consisting of a germanium–lithium (Ge–Li) crystal or a high-purity germanium detector (HPGe). Semiconductor detectors have a much higher energy resolution than NaI(Tl) detectors, with the ability to resolve gamma rays differing in energy by only a few keV, as opposed to the 20–80 keV required for a NaI(Tl) detector. Because of their increased resolution, semiconductor detectors are the preferred analytical method for gamma spectral analysis. A lanthanum–bromide detector is also available that has a significantly better resolution (10–12 keV) than the NaI(Tl) detector, without the necessary requirement of liquid nitrogen cooling for a HPGe detector. The use of spectroscopy software to automate the analysis is acceptable; however, the operator should have an understanding of the parameters chosen to ensure that the performance of the system is adequate to meet test requirements.

Semiconductor detectors are, in essence, solid-state ionization chambers, but the energy required to create an electron-hole pair or to promote an electron from the valence band to the conduction band in the semiconductor is about one-tenth the energy required for creation of an ion-pair in a gas-filled ionization chamber or proportional counter. This energy threshold is

@2024 USPC

also far less than the energy needed to produce a photon in a NaI(Tl) scintillation crystal. The energy resolution is a measure of the ability to distinguish the presence of two gamma rays closely spaced in energy and is defined by convention as the full width of the photopeak at its half maximum (FWHM), expressed as a percentage of the photopeak energy. For example, with 1.33 MeV gamma rays from cobalt-60, a HPGe detector has an energy resolution of about 0.3% FWHM, whereas a 3-in × 3-in NaI(Tl) crystal has a value of about 6%.

Gamma-ray spectra exhibit one or more sharp, characteristic photopeaks, or full-energy peaks, as a result of total absorption in the detector of the full energy of incident gamma radiations. These photopeaks are useful for identification purposes. Other secondary peaks are observed as a consequence of backscatter, annihilation radiation, coincidence summing, fluorescent X-rays, and other factors, accompanied by a broad band known as the "Compton continuum", which arises from the scattering of photons in the detector and surrounding materials. Because the photopeak response varies with gamma-ray energy, calibration of the gamma-ray spectrometer should be achieved with radionuclide standards having well-known gamma-ray energies and emission rates from an NMI. The shape of the gamma-ray spectrum is dependent upon the shape and size of the detector, the types of shielding materials used, and the electronic processing characteristics of the instrument.

One of the most useful applications of gamma-ray spectrometry is the identification of radionuclides and the determination of radionuclidic impurities. When confirming the identity of a radionuclide by gamma-ray spectrometry and/or quantifying the radioactivity, it is necessary to ensure that the detector has been accurately calibrated using a known source, as described above, and in the same geometry as the unknown sample. Where the radionuclides emit coincident gamma or X-radiations, the character of the pulse-height distribution often changes quite dramatically because of the summing effect of these coincident radiations in the detector as the efficiency of detection is increased (e.g., by bringing the source closer to the detector); this is referred to as "cascade summing". Such an effect is particularly evident in the case of iodine-125. Most commercially available software packages include an ability to correct this source of error.

When identification of a radionuclide by means of a calibrated spectrometry system is not possible, the identity of the radionuclide may instead be established by measuring two or more of the following nuclear decay scheme parameters: (1) half-life; (2) energy of each gamma ray or X-ray emitted; (3) the abundance of each emission; and (4) $E_{max}$, the maximum energy of emitted beta particles, for those radionuclides that decay with beta-particle emissions. Such measurements should be performed as directed in ⟨821⟩. Agreement of two or more of the measured parameters within 10% of the corresponding published nuclear decay scheme data confirms the identity of the radionuclide.

As with other types of detectors, the background should be determined and subtracted from the measurement. In addition, the background should be stable, especially in situations where long counting times are required. This can be achieved by running a background spectrum before analysis and comparing it to a previously obtained background spectrum. Generation of a background spectrum will also allow the calculation of a minimum detectable activity for each possible impurity.

## BETA PARTICLE COUNTING SYSTEMS

Beta (β) particles are emitted with a distribution of energies ranging from zero to a definite maximum value. The maximum energy of the electrons is characteristic of a particular radionuclide and is normally the $E_{max}$ shown in nuclear data tables. The determination of the maximum beta energy may aid in the identification of the beta-emitting radioisotope, and careful measurements can routinely quantify activities. Emitted beta particles rarely possess the maximum energy. On average, emitted beta particles possess one-third of the maximum energy. Beta particles can be difficult to detect because they only penetrate small thicknesses of solid materials. [NOTE—Radioisotopes that emit gamma radiation in addition to beta radiation are more easily quantified and identified by using gamma-ray spectroscopy. In some cases, gamma-ray detection is the preferred method for measuring these radioisotopes and is usually the best means of identification of a beta/gamma-emitting radionuclide.]

Several detectors can be used for the detection and measurement of beta particles. These can be ionization chambers, proportional counters, and scintillation counters with their associated electronics. Self-absorption and backscattering can be an issue in beta-particle analysis and can result in a lower or higher number. Ionization chambers and proportional counters can be used for the quantitation of beta particles but are less suited for identification, because they cannot measure the maximum beta energy. Scintillation counters can be used for both the quantitation and identification of beta particles. When all or part of the energy of beta radiation is dissipated within scintillators, photons of an intensity proportional to the amount of dissipated energy are produced. These pulses are detected by an electron multiplier phototube and converted to electrical pulses, which are subsequently analyzed with a pulse-height analyzer to yield a pulse-height spectrum related to the energy spectrum of the incident radiation. In general, a beta-particle, scintillation pulse-height spectrum approximates the true beta-energy spectrum, provided that the beta-particle source is prepared in such a manner that self-absorption is minimized. Beta-particle energy spectra may be obtained by using calcium fluoride or anthracene as the scintillator. The spectra of charged particles may also be obtained using silicon semiconductor detectors.

The penetration power of beta particles is significantly larger than for alpha particles; a few millimeters of aluminum will stop beta particles. Care should be taken for the Bremsstrahlung X-rays that are created during the deceleration of the beta particles, because they may influence the measurement and can be a radiation safety concern.

Beta emitters can be quantitatively measured with ionization chambers and proportional counters that measure electrical current generated by the ionization of a select gas in a high-voltage field. Depending on the energy of the beta particle, the composition of the sample and container, and the design of the detector, the measurement may be based on Bremsstrahlung. For a radionuclide in solution, most of the beta energy is absorbed by the solvent, leaving only Bremsstrahlung exiting the sample. In the case of ionization chambers (e.g., dose calibrators), the walls housing the ionizable gas effectively convert all beta energy to secondary photons. As is the case for all radiation measurements, quantitative determinations with an ion chamber or a proportional counter depend on rigorous calibration and standardization of the sample type and geometry.

Depending on the detection setup, alpha particles can interfere with measurement of the beta particles. This can be easily prevented by positioning an absorber for alpha particles between the source and the measuring equipment. However, because low-energy beta particles (<200 keV) may also be absorbed, the count rate should be corrected for the absorption of these low-energy beta particles.

An LSC can also be used for the quantification of beta particles and aid in radionuclide detection. Because of the high efficiency of the method, LSC is particularly useful in measuring very low levels of radioactivity and is commonly used for complex biological samples. The sample is normally dissolved in a solution containing a phosphor that converts the beta emission to light pulses, which are detected by a very sensitive system of photomultiplier tubes. At energies greater than ~100 keV, the energy conversion and therefore the counting efficiency, is essentially 100%. The method is somewhat compromised by quenching effects, but these can be easily overcome with careful calibration.

When high energy (>800 keV) beta particles are measured, it is possible to count without scintillation cocktails, because the beta particles create Cherenkov radiation, which can be directly detected with a photomultiplier. [NOTE—Although alpha particles can interfere with beta counting, this problem can be corrected for by use of thin absorbers or by instrumental energy discrimination.]

The identification of pure beta-emitting radioisotopes without accompanying gammas is best done by a combined measurement of the half-life of the radioisotope and the maximum energy of the beta radiation emitted by the radioisotope.

The approximate maximum energy of a beta particle can be determined by two procedures: (1) by measuring the radioactivity as a function of absorber thickness; and (2) by plotting the logarithm of the count rate versus the thickness of the absorber in $mg/m^2$; then, an absorption curve can be made. The absorption curve can be compared with standardized absorption curves, which aids in the identification of the radioisotope.

Using LSC, by measuring the pulse height over a calibrated energy range, a beta-energy spectrum can be generated from which the maximum energy can be estimated. LSC instruments typically automate the calibration factor, but care should be taken in correcting for quenching effects.

#### ALPHA PARTICLE COUNTING SYSTEMS

Several detectors can be used for the detection and measurement of alpha particles. These can be ionization chambers, proportional counters, silicon semiconductor detectors, and scintillation counters with their associated electronics. For the identification and quantification of alpha particles, ionization chamber and proportional counters are not suitable.

Special precautions should be taken in the measurements of alpha particles because of their high energy but limited penetration power (about 40 µm in human skin).

For the identification and assay of alpha-particle emitters, spectrometry using liquid scintillation is mostly used. For the identification and determination of radionuclidic purity of alpha-particle emitters, spectrometry using a silicon-diode semiconductor detector can be used.

In a scintillation counter, the energy of the alpha particle is transformed to a light pulse, which can be detected by a photomultiplier tube. The intensity of the pulse is a measure of the energy of the detected alpha particle. Solid scintillation counters or phosphor detectors can be used as well as liquid scintillation.

When solid-state detectors are used, the sample is usually electroplated on a planchet disc, and the detector is brought close to or immediately on the sample. The counting efficiency of solid-state detectors tends to be low. In liquid scintillation counting, when the sample is dissolved in the appropriate medium, the efficiency can very high. Each method of counting has its own advantages and disadvantages. For solid detectors, advantages are lower background noise and a better differentiation between alpha and beta particles. Disadvantages are that no volatile samples can be measured, and self-absorption by the sample material (related to thickness of the sample layer) can lower the detected count rate, giving a falsely low outcome of the assay.

For liquid scintillation, advantages are the ease of sample preparation and no self-absorption, because the sample is mixed with the scintillation fluid. Disadvantages are higher background noise levels and poor separation between alpha and beta particles.

## 4.4 Detector Systems for Chromatographic Applications

Chromatographic applications, wherein the radioactive components of a mixture are separated based on their distribution between a stationary phase and a mobile phase, represent a unique usage of radiation detection systems. The most common chromatography applications include thin-layer chromatography (TLC), gas chromatography (GC), and liquid chromatography (high-pressure liquid chromatography and high-performance liquid chromatography, typically denoted as HPLC). Depending on the chromatographic application and the type of emitted radiation, various detector systems may be used in the analysis of separated radioactive components.

Gamma-ray detector systems can be used to dynamically measure separated radioactive components in GC and HPLC applications. In these applications, the eluate from the chromatography column is directed over or through the scintillating detector. Typically, these detector systems are not used for radionuclide identification; therefore, NaI(Tl) crystals tend to be the detector of choice in these applications. Depending on the required sensitivity of the technique, the geometry of detector may consist of a well that surrounds the eluate tubing, or a flow cell that passes the eluate across the surface of the detector. In either case, the design of the system should provide a reproducible geometric relationship between the tubing and the detector. In addition, the detector should be shielded sufficiently to prevent spurious peaks or baseline drift due to background radiation. For this application, the output pulses of the photomultiplier tube may be converted into an analog signal whose voltage is proportional to the number of pulses (i.e., the amount of radioactivity). In this manner, the resulting electric signal is used by a data acquisition and chromatography system to provide a chromatogram in a similar fashion as more traditional chromatography detection systems. The flow rate of the eluate and the amount of radioactivity in the eluate should be controlled to provide a count rate that is within the linear range of the detector system.

LSC methods can also be used in HPLC separations of beta-emitting components. Several techniques may be used in this application. In the first, the eluate from the chromatographic column is collected in discrete fractions. Each fraction is then mixed with the liquid scintillation cocktail before analysis in the LSC. Additional processing steps may be necessary before the addition of the cocktail to minimize quenching. In the second technique, the scintillation cocktail may be mixed with the eluate from the column before passage of the resulting mixture through an online flow cell surrounded by the photomultiplier tubes. Finally, inline solid scintillators may be used with in situ mixing of the eluate with a liquid scintillation cocktail.

Beta-particle detector systems can be used to measure separated radioactive components in TLC applications. In this application, windowless gas ionization detectors are most commonly used, and the detector is automatically scanned over the TLC plate, yielding a two-dimensional plot of the radioactivity. Because of the nature of the sample, self-adsorption is negligible, and the beta radiation is efficiently counted. If all of the components on the TLC plate contain the same beta emitter, the output signal is proportional to the fraction of radioactivity in the separated components. If the separated species contain different radionuclides, the detector should be calibrated with each radionuclide to correct for different signal responses. Alternatively, if such a detector is not available, the TLC plate can be cut into multiple strips and counted by an appropriate detector. The individual strips should be counted using the same geometry. For the highest sensitivity, the strips may be extracted with solvent and then counted by LSC.

## GLOSSARY

**Alpha particles** ($\alpha$)**:** Positively charged particles that are emitted from nuclei during radioactive decay. Alpha particles are Helium-4 nuclei, consisting of two protons and two neutrons but no electrons.

**Beta particles** ($\beta^-$)**:** Negatively charged particles that are emitted from nuclei during radioactive decay. Beta particles are electrons.

**Bremsstrahlung:** Electromagnetic radiation produced by the acceleration or especially the deceleration of a charged particle after passing through the electric and magnetic fields of a nucleus.

**Calibration factor:** The coefficient used to convert the measured ionization chamber current to a nominal radioactivity. This term is often referred to as the "calibration coefficient".

**Calibration time:** An arbitrary time at which the specified amount of radioactivity is present on a specific date.

**Carrier free:** A preparation free from stable isotopes of the same element as the radionuclide.

**Counting assembly:** An instrument that consists of a sensing unit and an electronic scaling device. The sensing unit may be a Geiger-Müller tube, a proportional counter, a scintillation detector in which a photomultiplier tube is used in conjunction with a scintillator, or a solid-state semi-conductor.

**Dose calibrator** (also referred to as radionuclide calibrator)**:** A well-type ionization chamber commonly used to assay radiopharmaceuticals. Display units are typically in curies (μCi or mCi or Ci) or becquerels (kBq or MBq or GBq).

**Gamma rays** ($\gamma$-rays)**:** Electromagnetic radiation emitted from nuclei during radioactive decay. Gamma rays have a wide range of energies. The gamma rays emitted from a given radionuclide are always at the same energy(ies), providing a unique signature that enables the identification of a gamma-emitting radionuclide.

**Geiger-Müller counter** (often referred to as a G-M counter or Geiger counter)**:** An instrument in which a high-voltage potential is applied across a volume of inert gas for the purpose of collecting ions produced by a radiation field. The negative electrons are internally multiplied to produce a readily detectable current pulse. Display units are typically counts per minute (cpm) or milliroentgen per hour (mR/h).

**Geometry:** The characteristics of a radioactive source (i.e., container type, container wall thickness, volume and position of the container in the well chamber) that along with the physical characteristics of the ionization chamber affect the magnitude of the calibration coefficient for a specific radionuclide. The principal geometry considerations that may affect the accuracy of a source measurement in a dose calibrator are container configuration, source volume, position of the source in the chamber well, and the radionuclide itself. [NOTE—It is customary to compare a standardized preparation and radiopharmaceutical drug or preparation using identical geometry conditions for assay, identification, and other parameters. The validity of the result is critically dependent upon the reproducibility of the spatial relationships of the source to the detector and its surroundings and upon the accuracy of the standardized preparation.]

**Ionization chamber:** An instrument in which an electric field is applied across a volume of inert gas for the purpose of collecting ions produced by a radiation field. The positive ions and negative electrons drift along the lines of force of the electric field and are collected on electrodes, producing an ionization current. The most commonly used form of ionization chambers for measurement of the activities of radiopharmaceuticals is a well-type ionization chamber known as a dose calibrator.

**Isobars:** Nuclides with the same mass number (protons + neutrons).

**Isomers:** Atoms with the same number of protons and neutrons, but a different nuclear energy configuration. Short-lived radioactive isomers are generally referred to as metastable. Different isomers are different nuclides based on their nuclear energy configurations.

**Isotones:** Nuclides with the same number of neutrons and a different number of protons. Isotones are different elements with different atomic masses.

**Isotopes:** Nuclides with the same number of protons and a different number of neutrons. Isotopes are the same element with a different atomic mass.

**Isotopic carrier** (also referred to as carrier)**:** A stable isotope of the element concerned either present in or added to the radioactive preparation in the same chemical form of the radionuclide.

**Liquid scintillation counter** (LSC)**:** An instrument that detects scintillation light from the absorption of radiation energy in a scintillation liquid. This instrument is used primarily for beta-emitting radionuclides that do not also emit gamma photons. For best results, the radioactive sample must be able to be dissolved in the scintillation liquid.

**Minimum detectable activity:** The smallest quantity of radioactivity that can be detected above the background with a specified level of confidence.

**National Metrology Institute** (also known as NMI)**:** A measurement standards body that is a laboratory of metrology that establishes standards for a country or organization. For example, the National Institute of Standards and Technology (NIST) is the NMI for the United States.

**No carrier added:** A preparation where no stable isotopes of the same element as the radionuclide being tested are intentionally added in the stated chemical form or at the position of the radionuclide in the molecule being tested.

**Nuclide:** An atom with a specific number of protons and neutrons in a given nuclear energy state.

**Positrons** ($\beta^+$)**:** Positively charged particles emitted from a nucleus during radioactive decay. Positrons are anti-electrons.

**Radioactivity:** (1) The spontaneous transformation of nuclei characterized by the emission of particles or photons. Radioactivity is typically described as atoms undergoing radioactive decay per unit time (or disintegrations per unit time). (2)

DOI: https://doi.org/10.31003/USPNF_M9778_01_01

The quantity of radioactive material, as measured in units of curies (U.S. units) or becquerels (SI units). The quantity of radioactive material may also be referred to as activity.

**Radiochemical identity:** The molecular structure of the intended active radioactive drug ingredient that is present in the radiopharmaceutical preparation.

**Radiochemical purity:** The ratio, expressed as a percentage, of the radioactivity of the intended active radiopharmaceutical ingredient to the total radioactivity of all radioactive ingredients present in the radiopharmaceutical preparation.

**Radioisotope:** A radioactive atom, generally used in the context of an isotope of an element.

**Radionuclide:** An unstable nuclide that undergoes radioactive decay; a radioactive nucleus. The terms radionuclide and radioisotope are commonly used interchangeably.

**Radionuclidic identity:** The intended radionuclide in the radiopharmaceutical preparation.

**Radionuclidic purity:** The ratio, expressed as a percentage, of the radioactivity of the intended radionuclide to the total radioactivity of all radionuclides in the radiopharmaceutical preparation.

**Radiopharmaceutical** (radiopharmaceutical preparation/radioactive drug)**:** A finished dosage form that contains a radioactive substance in association with one or more other ingredients and that is intended to diagnose, stage a disease, monitor treatment, or provide therapy. A radiopharmaceutical includes any nonradioactive reagent kit or radionuclide generator that is intended to be used in the preparation of any such substance. The terms radiopharmaceutical and radioactive drug are commonly used interchangeably.

**Scintillation crystal counter:** An instrument consisting of a crystal scintillator, such as NaI(Tl), with an attached photomultiplier tube and associated electronics. Scintillation light produced from the absorption of gamma and X-rays in the crystal is converted to electrons and amplified in the photomultiplier tube. The resultant current pulse may be further analyzed with regard to photon energy. A commonly used form of this instrument that has a hole in the crystal of sufficient size to allow placement of a test tube or similar container is known as a well counter.

**Semiconductor detector:** An instrument consisting of a semiconductor material, such as silicon or germanium crystals, that detects ionizing radiation through generation of charge carriers (passage of electrons through holes). The current pulse produced by migration of these charge carriers, under the influence of a voltage potential across the material, can be further amplified and analyzed to determine the quantity and energy of the incident radiation.

**Solid-state detector:** A crystal-based detector, in contrast to a gas-based detector; often is used as a synonym for a semiconductor detector.

**Specific activity:** The radioactivity of a radionuclide per unit mass of the element or compound. The unit of specific activity is radioactivity per mass expressed on a gram or mole basis [e.g., mCi/µg (MBq/µg); Ci/mmol (GBq/mmol)].

**Strength:** The radioactivity concentration of the radiopharmaceutical at the calibration time. The unit of strength is the amount of radioactivity on a volume basis (e.g., mCi/mL or MBq/mL).

**Total radioactivity:** The radioactivity of the radionuclide, expressed per unit (e.g., vial, capsule, ampule, generator, and others) at the calibration time.

**Validation:** Establishment of documented evidence that a method, process, or system meets its intended requirements.

**Verification:** Confirmation that an established method, process, or system meets predetermined acceptance criteria.

**X-rays:** A type of electromagnetic radiation emitted from the electron orbitals. Although they do not arise from the nucleus, they are often present immediately after a decay event if there are interactions between the emitted radiation and the orbital electrons.

## 1. INTRODUCTION

Positron emission tomography (PET) drugs contain radionuclides that undergo nuclear transformation, or radioactive decay, predominantly by the emission of a positron. Positrons undergo annihilation upon interaction with electrons to produce two photons that are emitted in nearly opposite directions to each other. Each photon possesses an energy of 511 keV, which lies in the gamma ray portion of the electromagnetic spectrum. These radionuclides are used in a wide range of PET imaging studies, including research, investigational, and clinical applications.

The radionuclides used in PET imaging studies typically possess short physical half-lives (denoted as $T_{1/2}$). Some common examples of PET radionuclides and their associated half-lives are included in *Table 1*. Note that *Table 1* includes radionuclides currently in predominant use and is not intended to illustrate all positron-emitting radionuclides used in PET.

**Table 1**

| PET Radionuclide | Half-Life, $T_{1/2}$ |
|---|---|
| Fluorine-18 | 109.8 min |
| Carbon-11 | 20.4 min |
| Nitrogen-13 | 10.0 min |
| Oxygen-15 | 2.0 min |
| Copper-64 | 12.7 h |
| Gallium-68 | 68 min |
| Rubidium-82 | 75 s |

Because certain of these radionuclides such as *Carbon-11* and *Nitrogen-13* when found in biological systems have the same chemical and physical properties as their stable counterparts found in biological systems, PET offers a unique platform for *in vivo* imaging studies of complex biochemical pathways. As a result, PET radionuclides have found widespread use in cardiology, oncology, and neurology applications. PET drugs have also attracted interest as potential tools to accelerate and reduce the cost of therapeutic drug discovery efforts.

Most PET radionuclides are produced at the point of use by a particle accelerator (e.g., a cyclotron) or a radionuclide generator. A cyclotron accelerates charged particles such as protons or deuterons to velocities sufficient to induce a nuclear transformation of the target nucleus into a different element. High-energy particles and/or radiation are emitted from the target nucleus during the transformation process. An example of a transformation is the bombardment of stable Oxygen-18 nuclei with accelerated protons to produce *Fluorine-18* nuclei along with the concomitant emission of a neutron. This process may be summarized according to the following shorthand notation:

$$^{18}O(p,n)^{18}F$$

The chemical form and physical state of the bombarded nuclei vary, depending on the target and the subsequent usage of the PET radionuclide. This allows the production of PET radionuclides in gaseous, solid, and solution phases.

Radionuclide generators offer an alternative method for point-of-use access to some PET radionuclides. A radionuclide generator contains an immobilized parent radionuclide that undergoes radioactive decay to a daughter radionuclide, which may be eluted from the generator. An example of a PET radionuclide generator is the Germanium-68/Gallium-68 generator. The parent Germanium-68 ($T_{1/2}$ = 271 days) is adsorbed onto the column packing material. The Germanium-68 undergoes radioactive decay by electron capture into Gallium-68, which is not adsorbed onto the column packing material and may be eluted from the generator.

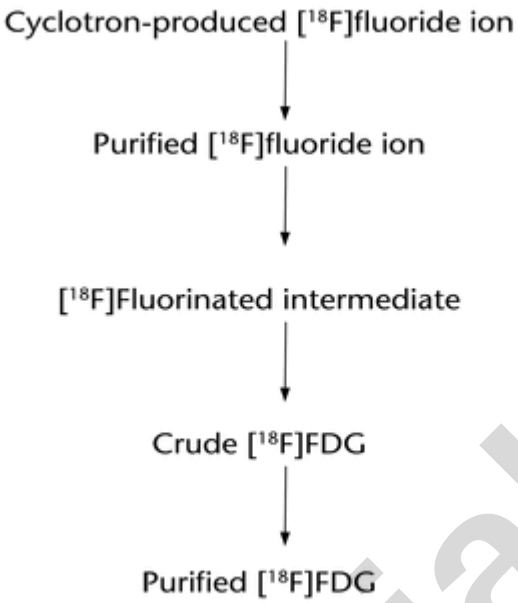
Regardless of the production method, other radionuclides may be present in addition to the desired PET radionuclide. In the case of cyclotron-produced PET radionuclides, other radionuclides may result from the bombardment of the target holder and/or other nuclei present in the target material. For generator-produced PET radionuclides, break-through of the parent radionuclide may occur. Safeguards are readily available to avoid unnecessary contamination with radionuclidic impurities of the final PET drug.

Once the PET radionuclide has been produced, it should be processed into a suitable form of a PET drug. The simplest form of processing involves the purification and/or formulation of the PET radionuclide. An example is the purification of the [$^{18}$F]fluoride ion. After production of the [$^{18}$F]fluoride ion by cyclotron bombardment, ion exchange procedures may be used to remove impurities and yield a formulation suitable for PET imaging studies. Another example is the purification of gaseous [$^{15}$O]oxygen through various solid supports before administration of the finished PET drug by inhalation.

Simple forms of processing are rare, because PET drug products are typically synthesized from the appropriate radionuclide through multiple synthetic processing steps. The exact process depends on the desired PET drug. The synthesis of 2-[$^{18}$F]fluoro-2-deoxyglucose ([$^{18}$F]FDG) provides an illustration. The first step in this synthesis is the preparation of the anhydrous [$^{18}$F]fluoride ion from cyclotron-produced Fluorine-18. The [$^{18}$F]fluoride ion is activated with a phase transfer catalyst such as tetraethylammonium or [2.2.2]-cryptand to enhance its reactivity toward nucleophilic substitution. The resulting complex reacts with mannose triflate to yield a fluorinated $^{18}$F intermediate, which is deprotected and purified to yield [$^{18}$F]FDG. This process is summarized in the following set of equations:

Official

https://pharmacopeia.cn/



Official

In addition to the chemical processing and/or purification steps used to generate the desired radiochemical of interest, other steps are typically required to formulate the PET drug product. For injectable PET drug products, formulation steps may include dilution, addition of a stabilizer, pH adjustment, and other steps. The final formulation of the PET drug product should take place in a manner that minimizes the presence of bacterial endotoxins and bioburden. Finally, the product should be sterilized (e.g., by passage through a membrane sterilizing filter) to provide a solution suitable for intravenous administration. In the above example, [$^{18}$F]FDG becomes the drug product *Fludeoxyglucose F 18 Injection*.

Before use, the finished PET drug product should be tested to ensure that the product meets suitable standards of identity, strength, quality, and purity. Because of the short half-life of PET radionuclides, testing should be completed in a timely fashion; however, it is not possible to complete certain quality control (QC) tests within a suitable timeframe. In some cases, it may be necessary to adopt a "sub-batch" approach for QC testing, wherein a sub-batch of the PET drug product is prepared solely for purposes of QC testing. Examples of PET drug products with such short half-lives include [$^{15}$O]water and [$^{13}$N]ammonia.

Ultimately, the short half-lives of PET radionuclides create unique constraints for the production and testing of PET drug products and define how these products are used in research, investigational, and clinical settings. PET drugs are a unique class of products defined by the following characteristics:

- The mass of the radioactive ingredient in a PET drug product usually ranges from nanogram to microgram quantities. This affects pharmacological and toxicological considerations for PET drugs, usually by creating large safety margins due to low mass of the active ingredient in the administered dose.
- An entire batch of a PET drug product may be contained in a single vial. Samples withdrawn for QC testing are representative of the entire batch. PET drug products produced in this fashion undergo 100% QC testing.
- PET drug products are produced and handled in environments with overlapping areas of regulatory authority. For example, a site may be subject to requirements of any combination of the following authorities: Nuclear Regulatory Commission or Agreement State Agency, Food and Drug Administration, Environmental Protection Agency, occupational safety entities, etc. These agencies may have different and conflicting requirements of the manufacturing facility, some through regulation, some through guidelines published by the authorities, and some through license commitments made by the facility.
- PET drug products are generally produced at or near their point of use in small-scale facilities with limited personnel and resources. This requires:
  - Allowance for multiple operations in one area with adequate controls
  - Allowance for making and testing multiple PET drug products using shared equipment with appropriate cleaning between batches
  - Appropriate requirements for aseptic operations
  - Appropriate requirements for system suitability and other day-of-use activities
  - Appropriate QC requirements for components, materials, and supplies
  - Self-verification of significant steps in radionuclide production, PET drug production, compounding, and testing
  - Single-person oversight of production or compounding, testing, review of batch records, and release authorization
- PET drug products do not enter a traditional distribution chain. Instead, PET drug products require just-in-time deliveries typically performed by dedicated carriers with experience in handling radioactive materials.
- It is not possible to complete sterility testing for PET drug products before their use. Therefore, considerations are made to provide for the assurance of sterility for injectable PET drugs intended for human use.

https://pharmacopeia.com/

- Procedures should be in place to notify the responsible individuals in a timely manner if a PET drug product is found to be in noncompliance after release for human use.

## 2. TECHNIQUES FOR PRODUCTION AND QUALITY CONTROL

The unique characteristics of PET drug products play a large role in the choice of instrumentation and techniques used in production and QC testing. Production techniques and analytical methods should be efficient and rapid. The selection of techniques and methods is also strongly influenced by the development stage of the PET drug. For example, early development efforts focus on radiolabeling, purification, QC methods development, and others. These efforts are designed to support the usage of the PET drug for *in vitro* studies, animal studies, and may even include first-in-human studies. At this stage, relatively small quantities of the PET drug are required at a limited number of institutions or geographic areas. Manual production techniques or semi-automated equipment may provide sufficient quantities to meet this demand. Analytical methods should also be suitable for the usage of the PET drug at the early stages of development. Typically, method development efforts focus on accuracy, precision, and linearity. Before the use of injectable PET drugs in human studies, provisions are made to ensure that bacterial endotoxins are controlled at suitable levels and that the product is sterile.

In later development stages, larger quantities of the PET drug may be required in more geographic areas. At this point, the synthesis, purification, and testing of the PET drug product should be well defined to support clinical trials. Development efforts at this stage typically focus on optimization and reliability of the production process. Manual production techniques are rarely used. Instead, semi-automated or fully automated techniques are typically required to provide sufficient quantities of the PET drug at multiple geographic locations. This approach simultaneously assures consistent quality attributes of the PET drug at multiple production facilities and minimizes radiation exposure of operators. Method development activities at this stage focus on specificity, ruggedness, robustness, and other characteristics required to support QC testing of the PET drug at multiple geographic locations.

Finally, at the commercial stage of production, semi-automated or fully automated techniques and equipment may be required to provide sufficient quantities of the PET drug in numerous geographic areas. Production techniques and analytical methods for commercial PET drug products should be well defined and adequately described in the appropriate marketing authorization.

Not all PET drugs are intended to advance through the various development stages from *in vitro* studies, to animal studies, to clinical trials, to commercial production. For example, a PET drug product may be produced at several institutions for research purposes without the intention of commercialization. In other instances, a PET drug product may be Food and Drug Administration (FDA) approved but is only available in a single geographic area. These factors often result in different strategies for production techniques, analytical methodologies, and the underlying studies and documentation to support these strategies.

## 3. QUALITY ASSURANCE

The goal of quality assurance (QA) is to ensure that the techniques and equipment used in production and testing result in a product that meets established standards for that specific PET drug product. The QA program should be sufficient to establish the reliability and suitability of the techniques and equipment as appropriate to the development stage of the PET drug product. The following topics should be considered in a QA program.

### 3.1 Reagents and Materials

Reagents and materials used in the synthesis and testing of a PET drug product should conform to established acceptance criteria. Procedures for procuring, receiving, testing, storage, and use of reagents and materials should also be considered. An audit trail may be established for the traceability of specific lots of reagents and materials to specific batches of product. These acceptance criteria, procedures, and the audit trail should be appropriate for the development stage of the PET drug product.

### 3.2 Change Control

Changes in the synthesis and test methods should be evaluated for their potential for altering the product quality and be approved in advance through established procedures. If the resultant PET drug product does not meet the criteria appropriate to the development stage, the process change is unacceptable. Acceptable changes should be appropriately documented.

### 3.3 Validation

Production and analytical test methods should be validated at a level that is appropriate for the development stage of the PET drug product. Validation of the production process should result in a process that is reliable and consistent. Analytical method validation demonstrates that a method can quantitatively measure a PET drug product reliably and reproducibly. It is not necessary to validate analytical methods that are described in USP compendia. The emphasis on validation typically increases as the PET drug product moves through the development stages toward commercialization. Validation of the computer software used to control automated production equipment should also be considered as appropriate.

#### QUALIFICATION

Equipment used in the synthesis and testing of PET drug products should be qualified as appropriate for the development stage of the PET drug product. This may include qualification procedures (installation, operational, and performance), as well

Printed by: USP NF
Do Not Distribute
Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-May-2017
DOI Ref: c57om
DocId: GUID-705AF335-D1D4-4D6C-A155-E5D3F9C89D49_1_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M9779_01_01

as procedures for periodic maintenance and equipment calibration. For commercially available equipment, the equipment vendor may be able to support qualification requirements.

STABILITY STUDIES

Stability studies should be performed on PET drug products to establish suitable storage conditions and the expiration time and date. Quality attributes such as radiochemical purity, appearance, pH, stabilizer, preservative effectiveness, and chemical purity should be evaluated. The frequency and extent of these studies should be appropriate for the development stage of the PET drug product. Significant process changes require stability studies to be repeated.

# 4. PRODUCTION

## 4.1 Equipment for Manual Synthesis

Equipment intended for the manual synthesis of PET drug products may be based on apparatus found in a typical chemistry laboratory such as glass reaction vessels, heating blocks, tubing, and other items. These items should be suitable for their intended use and selected according to the needs of the process. Items that are reused and come into contact with the reactants and/or final drug product of the synthesis should be cleaned and depyrogenated as appropriate for the use of the final product.

Written procedures for the manual syntheses of PET drug products should contain sufficiently detailed steps to ensure that a reproducible process is followed for each batch by the operator. Observations of critical process parameters should be documented as appropriate in the batch record.

## 4.2 Equipment for Automated Synthesis

Preparation of *Fludeoxyglucose F 18 Injection* and other common PET drug products can be adapted readily to automated synthesis. The use of programmable controllers and/or computers with switches, solenoids, and sensors allows the operator to control the sequence of steps in an automated fashion. Thus, an automated synthesis requires minimal operator intervention, and batch-to-batch consistency is maintained with each step executed in a reproducible manner. Software may provide feedback to the operator such as alarm conditions, status reports, or an end-of-synthesis report. Modules for automated synthesis may be commercially available. These modules may use individual reagents or cassettes required for the appropriate PET drug product synthesis. The cassettes provide preassembled collections of reagents, reaction vessels, tubing, filters, and other items necessary to produce a batch of a PET drug product.

Laboratory robots may be appropriate in situations where complex manipulations are required for the procedure, such as the physical movement of a reaction vessel from one station to another, or the dispensing of doses from a vial into individual syringes. Customized equipment may also be fabricated to perform a specific function in the PET drug product synthesis.

# 5. QUALITY CONTROL

QC tests should be designed and executed in a manner that is appropriate for PET drugs. The short half-life of PET radionuclides significantly limits the timeframe for the performance of QC tests, and it may not be possible to complete all QC tests before the use of the PET drug product.

## 5.1 Quality Control Sampling

In most cases, the entire batch of a PET drug is contained within a single vial. The relatively small batch volume of PET drugs limits the amount of material available for QC testing. This is different from traditional manufacturing practices, where a batch may consist of numerous vials and not all vials are sampled for purposes of QC testing. QC sampling of PET drug products use a larger proportion of the drug volume, and thereby offers a greater degree of assurance that quality-related problems will be identified in the QC testing process.

## 5.2 Reference Standards

Reference standards are necessary to identify the API and impurities in the PET drug product. Reference standards may be commercially available or prepared in-house. Commercial reference standards should include documentation from the supplier to ensure they are properly characterized. The characterization and qualification of reference standards should be appropriate for the development stage of the PET drug product.

## 5.3 Conditional Release

When a required QC test for a PET drug product cannot be completed because of a malfunction of test equipment, it may be appropriate to conditionally release the batch. It is not appropriate in the absence of critical QC tests to conditionally release batches (e.g., radiochemical identity and purity). Procedures should be developed to describe the conditional release process, including the role of historical data, other QC test results, sample retention, and other procedures.

Official

https://pharmacopeia.cn/v29240/

### 5.4 Out-of-Specification Results

When the results of a QC test do not meet product specifications, an investigation should be conducted to determine if the result is due to an analytical error (false positive) or if the result is due to a product failure. Because of the short half-life of PET radionuclides, it may not be possible to conduct investigations in the same manner as in traditional drug testing laboratories.

## 6. ANALYTICAL METHODOLOGIES

Various analytical methodologies and chromatographic techniques may be used for the testing of PET drug products. The most commonly used methodologies are discussed in this section for purposes of illustration. Similar principles should apply to other methodologies not included in this section.

### 6.1 Thin-Layer Chromatography

Thin-layer chromatography (TLC) involves separation, identification, and quantification of analytes using a stationary phase on a support or plate and a developing solvent that may also be known as mobile phase. The stationary phase may be silica or alumina spread in a uniform layer onto a plate of glass, metal, or plastic. A small sample of the PET drug product is applied (spotted) onto the stationary phase, and the plate is developed in a chromatographic tank. The mobile phase moves through the stationary phase by capillary action, and the analytes are separated based on partition, ion exchange, and/or adsorption. The retardation factor ($R_f$) and radiochemical purity of the PET drug on the developed plate can be determined by either counting the developed plate on a radio–TLC scanner, or cutting the plate into pieces and counting each piece in a radiation detector. The $R_f$ of an analyte, under specific TLC conditions, is considered an identifying characteristic of the analyte.

### 6.2 Gas Chromatography

Gas chromatography (GC) involves separation, identification, and quantification of volatile analytes using a stationary phase and a gaseous mobile phase. A small sample of the solution is introduced into the GC instrument, which vaporizes the sample for passage over the stationary phase that is immobilized within a GC column. As the gaseous mobile phase passes over the stationary phase, the analytes are separated based on their partition between the gas and stationary phases. A detector located at the exit of the column provides an electronic signal to produce the gas chromatogram.

A GC instrument consists of a gas source, injection port, column, detector, and a data collection device. The injection port, column, and detector are temperature controlled and may be varied as part of the analysis. The gas source depends on the column and detector in use. The type of detector depends on the nature of the compounds analyzed. Typical detectors include flame ionization and thermal conductivity. In addition, radiation detectors may be used in GC analysis. Detector output is recorded over time, and the instrument response, measured as peak area or peak height, is a function of the amount present. The retention time of an analyte under specific GC conditions is considered an identifying characteristic. GC analysis is most typically used to quantify residual solvents in PET drug products but may also be used to determine radiochemical and chemical purity of the PET drug product formulation.

### 6.3 High-Performance Liquid Chromatography

High-performance liquid chromatography (HPLC) is an analytical technique used to separate, identify, and quantify the components of a solution. HPLC separations are based on the interaction of the analytes between the stationary and mobile phases, which in turn leads to the retention of the analytes. The mechanism of interaction between the analytes and stationary phase may be partition, size exclusion, adsorption, and/or ion exchange chromatography. The retention time of an analyte under specific HPLC conditions is considered an identifying characteristic.

HPLC instruments consist of a reservoir containing the mobile phase, a pump to force the mobile phase through the system at high pressure, an injector to introduce the sample into the mobile phase, a chromatographic column, a detector, and a data collection device. The type of detector used depends on the nature of the compounds analyzed. In addition to mass detectors such as refractive index, ultraviolet, and conductivity, radiation detectors are also used in HPLC analysis. An HPLC system with a radiation and mass detector allows the simultaneous determination of radiochemical and chemical purity, retention time, and the subsequent identity of the PET drug product. This configuration also allows the determination of specific activity. Elution methods include gradient or isocratic methods with aqueous and/or organic buffers.

The calibration of a GC or HPLC instrument may be achieved by different means. One approach involves the creation of a calibration curve from a range of standards with known concentrations. The calibration curve may be used over a specified period of time for product testing. A second approach for calibration involves the creation of a single-point calibration at the beginning of each testing cycle. The results may be averaged and used to provide a calibration factor for product testing. Regardless of the approach for calibration, the tailing factor and chromatographic resolution (or column efficiency as appropriate) should be determined routinely as a part of system suitability. Routine system suitability testing should include checks for these parameters.

### 6.4 Radiation Detectors Used in Chromatographic Techniques

Radiation detectors used in TLC, GC, and HPLC for quantitative measurements should be calibrated when possible with suitable NMI-traceable radionuclide standards at appropriate frequency. Routine system suitability testing should be performed on the radiation detection system to ensure proper operation. Because of the nature of TLC, system suitability for a radio–TLC

DOI: https://doi.org/10.31003/USPNF_M9779_01_01

scanner should address uniformity, positional accuracy, detector linearity, and resolution. The calibration of radiation detectors should be repeated as appropriate.

### 6.5 Multichannel Analyzer

A multichannel analyzer (MCA) is an instrument used to obtain a spectrum of gamma rays emitted by a PET radionuclide. The key component of a MCA is an energy-sensitive detector. On the basis of the gamma spectrum of a sample, radionuclides present in the sample may be identified and quantified. Calibration of the system is typically performed with certified standards and may involve one or more radionuclides with gamma energies and quantities that span the range of typical analyses at appropriate frequency.

### 6.6 Ionization Chamber

An ionization chamber, often referred to as a dose calibrator, is an instrument used to measure the quantity of radioactivity in a PET drug product. The key component of an ionization chamber is an argon-filled chamber with an applied electrical potential that allows the detection of ions produced by the passage of gamma rays through the chamber. Calibration of the system is typically performed with certified standards at appropriate frequencies and may involve one or more radionuclides with gamma energies and quantities that span the range of typical analyses.

## 7. QUALITY ATTRIBUTES

Quality attributes should be defined and assessed for each PET drug. These attributes should be suitable for the intended use of the PET drug and should also reflect the dosage form. Because most PET drug products are administered by intravenous injection, this section focuses on quality attributes associated with injectable PET drug products. Different attributes may be appropriate for other dosage forms. In addition, the definition and assessment of quality attributes may vary with the development phase of the PET drug product in comparison to the final drug phase.

### 7.1 Appearance

Injectable PET drug products should be free of visible particulate matter. Because of the radioactive nature of PET drug products, the test for appearance should be a visual inspection that meets radiation safety requirements. The use of a visual standard should be considered to ensure the accuracy of appearance determinations.

### 7.2 pH

Injectable PET drug products should be in the pH range suitable for intravenous administration. Because of the limited volume of a PET drug product, pH measurement is typically performed using narrow-range paper strips. The use of pH standards should be considered to ensure the accuracy of pH determinations.

### 7.3 Total Radioactivity and Strength

The total radioactivity of a PET drug product may be determined by an ionization chamber and should be stated at a given date and time. From the total radioactivity and the volume of the PET drug product, the strength may be determined. The strength of the PET drug product should be stated, along with the date and time of the determination of total radioactivity.

### 7.4 Radionuclidic Identity

Half-life (also referred to as approximate half-life) is a characteristic of the radionuclide that may be used for its identification. To adequately confirm the identity of a PET radionuclide, the half-life should be measured in a suitable counting device over a period of time appropriate to the half-life of the radionuclide.

### 7.5 Radionuclidic Purity

By definition, all positron-emitting radionuclides emit 511 keV gamma rays but may also emit gamma rays with different energies. Therefore, it is generally not possible to determine the radionuclidic purity of PET drug products with a MCA. One suitable solution to this problem is the use of validation studies to ensure the removal and/or decay of accelerator-produced radionuclidic impurities during the production process. Other approaches may be appropriate depending on the characteristics and source of the radionuclidic impurities. In addition, periodic analysis of decayed samples in routine production with a MCA may be used to quantify radionuclidic impurities developed.

### 7.6 Radiochemical Identity and Purity

Depending on the physical and chemical properties of the PET drug product, the radiochemical identity and purity may be determined by TLC, HPLC, or GC. The identity of the active pharmaceutical ingredient (API), and possibly other analytes, should be based on the known retention time of the analyte. The simultaneous use of reference standards during sample analysis should

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M9779_01_01
@2024 USPC

be considered for purposes of radiochemical identification. The radiochemical purity of the PET drug product should be determined based on the sum of all chemical forms of the radionuclide of interest. As appropriate, it should be established during validation that all radiochemical analytes are eluting from the chromatographic system and that the radioactive detector is operating within its linear range.

### 7.7 Chemical Purity

The chemical purity of the PET drug product should be assessed for the presence of volatile impurities, residual reagents and/or precursors, and by-products. For example, residual solvents, such as acetonitrile and ethyl alcohol, may assessed by GC. [2.2.2]-Cryptand, a common reagent used in the preparation of PET drug products, may be assessed by colorimetric techniques.

### 7.8 Total Mass of the Active Pharmaceutical Ingredient and Specific Activity

Potential toxicity issues and pharmacological effects may be associated with the API in a PET drug product (e.g., the mass-dependent localization of neurotransmitters or other more generalized forms of toxicity). In these instances, the total mass of the API should be determined before use of the PET drug product. The total mass of the API contained in a patient dose should be defined for PET drug products where mass-related localization or toxicity concerns require such assessment, which may be determined by HPLC or GC. On the basis of the mass of the API, the specific activity may be calculated. To determine the appropriate quality of the injected drug product in the patient dose, any two of three measured parameters (total mass, total activity, or specific activity) are sufficient. Specific activity should be stated along with the date and time of determination.

### 7.9 Bacterial Endotoxin

The quantity of bacterial endotoxin in an injectable PET drug product should comply with USP standards (<175 USP Endotoxin Units/patient dose). The test for bacterial endotoxin uses a solution of limulus amebocyte lysate (LAL). Various methods exist for this test, including gel-clot, chromogenic, and others. Test samples should be obtained and handled in a manner that minimizes contamination before testing. In addition, control measures should be used to ensure accurate test results without interferences from the test solution, such as certain formulations that enhance or inhibit the interaction of LAL with bacterial endotoxin. This effect may be corrected by dilution of the PET drug product before testing. The necessity of dilution in this test is determined in the validation of the specific formulation of the PET drug product.

### 7.10 Sterility

Injectable PET drug products should be sterile. For reasons described in *1. Introduction*, it is not possible to complete the sterility test before the use of PET drug products. The test for sterility should consist of inoculating a test sample into media capable of supporting the growth of aerobic and anaerobic microbes, which may be established with an appropriate certificate of analysis. The test samples should be obtained and handled in a manner that minimizes contamination before testing. To reduce radiation exposure to operators, the test samples may be allowed to decay before inoculation. The inoculation should use techniques that minimize the potential for false positives during the sterility test. In addition, control measures should be used to ensure accurate test results without interferences from the test solution. After inoculation, the sterility test samples should be incubated for the appropriate period of time at the prescribed temperature. If visible growth is detected during the incubation period, the investigator or physician should be informed in a timely manner, and an investigation should be initiated to determine whether the growth was due to accidental contamination during the sample handling process or to a true product failure. The investigation should include identification of the microbe(s) in the sterility test sample to determine the source of the contamination. This aspect of the investigation may be limited if production and sterility test sampling occur in the same laboratory.

## 8. STERILITY ASSURANCE

A suitable sterility assurance program should be established for PET drug products that are intended for intravenous injection. This section describes appropriate measures that assure the routine production of a sterile product suitable for injection.

### 8.1 Sterile Membrane Filtration

Injectable PET drug products are typically sterilized by passage of the solution through a sterile membrane filter into a presterilized vial. To provide the greatest assurance of sterility, the PET drug product should pass through an appropriate sterilizing filter into a presterilized vial that has been assembled using aseptic techniques.

### 8.2 Aseptic Techniques

Critical steps that affect the sterility of the PET drug product should be identified and, where appropriate, aseptic techniques should be used to complete these steps. Aseptic techniques should include the use of a suitable gowning, proper handling of components, environmental controls, and others. Aseptic techniques should be described in written procedures.

DocId: GUID-705AF335-D1D4-4D6C-A155-E5D3F9C89D49_1_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M9779_01_01

## 8.3 Presterilized Components

PET drug production typically employs various components and containers that are presterilized and pyrogen free. Appropriate sterile components are generally assembled aseptically in a controlled environment before use in production. Presterilized vials and sterile diluents such as sterile water for injection or sodium chloride solution are typically used. Other sterile components are sometimes utilized in nonsterile applications in production where a commercially available product may be useful. An example is use of a sterile transfer line for fluid transfer prior to a sterilizing filter, where the diameter or length of a commercially available sterile line is appropriate to the application.

## 8.4 Environmental Controls

The environment where aseptic techniques are executed should be controlled to ensure appropriate aseptic conditions. These controls may include temperature and humidity, ventilation and air filtration, cleaning and disinfection, equipment maintenance, proper garb, and microbiological monitoring. Air filtration standards should conform to local and/or national standards relevant to environmental standards, for example, International Organization for Standardization (ISO) standards.

## 8.5 Media Fills

A media fill, also known as a “process simulation”, is the performance of an aseptic procedure using a sterile microbiological growth medium in place of the PET drug product. The goal of a media fill is to test whether the aseptic procedure is adequate to prevent microbiological contamination during the actual process. Media fills may be used to evaluate aseptic techniques used in the assembly of presterilized components and to qualify operators for aseptic techniques. A media fill should be designed to ensure that the simulation is representative of the aseptic manipulations performed during the actual process, including personnel, components, gowning, locations, batch size, number of replicates, and other factors. After completing the media fill, components filled with media should be incubated appropriately to permit the growth of microbes. The use of negative controls should be considered during the media fill procedure.

## 8.6 Suitability of Media

Sterility test media should be tested before use to ensure that the media adequately support the growth of microbes. These tests are typically referred to as growth-promotion tests and may be conducted in-house, by the supplier, or by a contract laboratory. Media should be used within the manufacturer’s expiration date.

## 8.7 Suitability of the Sterility Test Method

The sterility test should be tested to ensure that the PET drug product is not bacteriostatic or fungistatic. The suitability of the sterility test may be conducted in-house or by a contract laboratory.

## 8.8 Membrane Filter Integrity Test

To ensure the proper sterilization of the PET drug product by passage through a membrane sterilization filter, the bubble point of the filter should be determined after completing the filtration process. The bubble point of the filter, measured in pounds per square inch (psi), is the pressure required to force air through the pores of the wetted membrane in the device. Other suitably validated procedures may be used.

## 8.9 Operator Training and Qualification

Operators involved in aseptic techniques should be trained in proper gowning, environmental controls, handling sterile components, and other techniques. Operators should be qualified through successful completion of media fills. Media fills should be periodically repeated to ensure ongoing competency of the technique.

# 9. LABELING

The labeling associated with PET drug products may evolve as the drug progresses through the various development stages. For example, the labeling for PET drug products used for *in vitro* and animal studies may be very simple and designed to avoid mix-ups in the routine use of the PET drug product. In later development stages, the labeling may include information required for the investigational use of the PET drug product in humans. Finally, at the commercial stage of production, the labeling should include ingredients, warnings, approved indications, and other elements required by the appropriate regulatory agencies (e.g., FDA, Nuclear Regulatory Commission, and others).

# GLOSSARY

The following definitions apply to words and phrases as they are used in this chapter:

**Accuracy:** The closeness of test results obtained by that method to the true value established across the range of the method.

**Active pharmaceutical ingredient (API):** A radioactive substance that exhibits spontaneous disintegration of unstable nuclei by the emission of positrons and is incorporated into a PET drug product to furnish a direct effect in the diagnosis or

https://mathuseorgcoa.mn.com/

monitoring of a disease or a manifestation of a disease in humans, or monitoring treatment of disease or therapeutic procedures (e.g., tumor therapy). Both radioactive and nonradioactive forms of the PET drug are included in the API.

**Batch:** A quantity of PET drug product that is intended to have uniform character and quality, within specified limits, and that is made in a single, defined operational cycle.

**Chemical purity:** The purity of a PET drug product based on the nonradioactive components of the formulation, for example, residual solvents and/or volatile impurities, reagents, and or precursors used in the synthesis and purification, stabilizers, excipients, or by-products produced in the synthesis.

**Compounding:** The process of synthesis or formulation of a PET drug for use under the practice of pharmacy and medicine.

**Conditional final release:** A final release for patient administration before completion of a required test because of a breakdown of analytical equipment.

**Limit of detection:** The lowest amount of analyte in a sample that can be detected but not necessarily quantified under the stated method conditions.

**Linearity:** The ability to elicit test results that are, directly or by a well-defined mathematical transformation, proportional to the concentration of analyte in samples within a given range.

**Lot:** A quantity of materials (e.g., reagents, solvents, gases, purification columns, and other auxiliary materials) that have uniform character and quality within specified limits and are used to make a PET drug product.

**Lower limit of quantification:** The lowest amount of an analyte in a sample that can be determined with acceptable precision and accuracy under the stated method conditions.

**National Metrology Institute (NMI):** A measurement standards body that is a laboratory of metrology that establishes standards for a country or organization. The National Institute of Standards and Technology (NIST) is the NMI for the United States.

**PET drug:** A radioactive substance (active pharmaceutical ingredient) that exhibits spontaneous disintegration of unstable nuclei by the emission of positrons and is incorporated into a PET drug product to furnish direct effect in the diagnosis or monitoring of a disease or a manifestation of a disease in humans, or monitoring treatment of disease or therapeutic procedures (e.g., tumor therapy).

**PET drug product:** A finished dosage form that contains a PET drug, whether or not in association with one or more other ingredients.

**Precision (as repeatability):** The degree of agreement among individual test results when the method is applied repeatedly to multiple samplings of a homogenous sample within a lab over a short period of time using the same analyst with the same equipment.

**Quality assurance (QA):** A planned and systematic program to ensure that a PET drug product possesses the quality required for its intended purpose.

**Quality control (QC):** A system for testing the quality of components, materials, supplies, and PET drug products by procedures, tests, analytical methods, and acceptance criteria.

**Radiochemical identity:** The molecular structure of the intended active radiopharmaceutical ingredient that is present in the radiopharmaceutical preparation.

**Radiochemical purity:** The ratio, expressed as a percentage, of the radioactivity of the intended active radiopharmaceutical ingredient to the total radioactivity of all radioactive ingredients present in the radiopharmaceutical preparation.

**Radionuclidic identity:** The intended radionuclide in the radiopharmaceutical preparation.

**Radionuclidic purity:** The ratio, expressed as a percentage, of the radioactivity of the intended radionuclide to the total radioactivity of all radionuclides in the radiopharmaceutical preparation.

**Range:** The interval between the upper and lower levels of a quality attribute that can be determined with a suitable level of precision and accuracy.

**Reagents and materials:** A reagent is a chemical used in the synthesis and/or testing of a PET drug, whereas a material is an ancillary object, such as tubing, glassware, vials, and others.

**Retardation factor (TLC):** The ratio of the distance the analyte moved from the origin line divided by the distance the solvent moved from the origin line denoted by the variable $R_f$.

**Retention time (HPLC or GC):** The time required, after the injection, for the analyte to move through the column and reach the detector.

**Robustness:** The measure of the capacity of an analytical method to remain unaffected by small variations in method parameters.

**Ruggedness (as reproducibility):** The degree of reproducibility of test results obtained by the analysis of the same samples under a variety of conditions, such as different labs, different analysts, different instruments, different lots of reagents, different assays, and different days.

**Specific activity:** The radioactivity of a radionuclide per unit mass of the element or compound. The unit of specific activity is the amount of radioactivity on a mass basis [e.g., mCi/μg (MBq/μg) or Ci/mmol (GBq/mmol)].

**Specificity:** The ability to assess unequivocally the analyte in the presence of components that may be expected to be present such as impurities, degradation products, and matrix components.

**Strength:** The radioactivity concentration of the active pharmaceutical ingredient in a PET drug product at a given date and time. The unit of strength is the amount of radioactivity on a volume basis [e.g., mCi/mL (MBq/mL)].

**Sub-batch:** A quantity of PET drug product having uniform character and quality, within specified limits, that is produced during one succession of multiple irradiations using a given synthesis or purification operation. A group of sub-batches collectively forms a batch that is intended to have uniform character and quality, within specified limits. Sub-batches may be required for PET drug products with very short-lived radionuclides (e.g., $^{13}N$ and $^{15}O$), because QC tests cannot be completed before use.

**System suitability:** Requirements used to verify that the system performs according to established criteria.

**Tailing factor (symmetry factor):** A measure indicating the non-ideality of a chromatographic peak resulting from the distribution and the migration of the analyte through the chromatographic column.

Official

https://pharmacopeia.cn/v29240/

**Validation:** Establishment of documented evidence that a method, process, or system meets its intended requirements.
**Verification:** Confirmation that an established method, process, or system meets predetermined acceptance criteria.

## 1. INTRODUCTION

The proliferation and spread of substandard and falsified (SF) medical products has been and continues to be a growing global concern. Examples have been reported on a range of SF medicinal products, including but not limited to essential medicines. These products threaten global public health by jeopardizing patient safety, adding to the cost of care, diminishing confidence in health workers and systems, increasing the risk of treatment failure, wasting valuable resources, and contributing to the development of drug resistance.

Fortunately, many analytical technologies and tools exist to evaluate product quality within the laboratory. In general, these technologies are well understood and characterized. Over the last decade, many of these tools have been miniaturized for portability to help combat the growing proliferation of SF medical products. One of the benefits of the field-deployable platform of these technologies is that it facilitates the screening of samples as part of a risk-based testing approach.

The capabilities of the portable screening technologies complement, but do not obviate the need for, laboratory-based technologies and their confirmatory power. Portable tools may help conserve the limited resources of these laboratories and drive a sustainable "work smart" approach to ensuring medicine quality by utilizing complementary methodologies of progressively increasing complexity to rapidly and reliably analyze large numbers of samples. The following examples describe where and how these technologies are currently used or may be used in the future:

- Manufacturing controls
- Supply chain screening
- Border control
- Customs inspection
- Post-market quality surveillance or regulatory monitoring
- Point-of-care screening

However, the potential and actual capabilities and limitations of many of these portable screening tools, and especially their performance in field settings, have not been established. To address this need, this chapter provides the structure and suggested requirements for performing an appropriate and pragmatic review of a given technology. Such a review would typically comprise general information, a performance evaluation, and a field evaluation. The information garnered from the review can then be used to inform selection, procurement, and deployment of the technology of interest. Within this chapter, the term technology refers to screening instruments, solutions, technologies, or tools that provide basic information about the authenticity or quality of a drug substance or product.

## 2. APPLICATION OF THE TECHNOLOGY

The first and most important aspect of an evaluation is to identify the target application of the technology. A clear understanding of the intended application of any technology will help identify the parameters that need to be evaluated and inform the decision as to whether multiple screening technologies might be needed in a particular setting. For example, some screening technologies evaluate non-chemical features of a product, such as appearance, packaging, labeling, and origin. The technology will need to correctly identify a falsified medicine, but it will not need to determine the level of chemical impurities within the drug product.

Furthermore, the intended application of the technology comprises that of both the original equipment manufacturer (OEM) and the user. If these applications align, then the initial part of an evaluation should involve reviewing the technology against the manufacturer's claims. However, if these applications do not align, further steps should be taken to evaluate the technology against the user's requirements and intended application. Intended applications may vary based on factors such as:

- Medicine types
- Anticipated users

Official

https://pharmacopeia.com/

- Geographic locations
- Points within the supply chain
- The public health consequences related to poor-quality medicines within supply chains

## 3. GENERAL INFORMATION ABOUT THE TECHNOLOGY

The first step of a review, prior to implementing the performance and field evaluations, is to acquire general information about the technology of interest. This should include, but is not limited to, answering the questions listed below.

### 3.1 Specifications, Relative Cost, and Data

SPECIFICATIONS

Questions regarding specifications include:

- Which model or version of the technology is being reviewed?
- What technique (e.g., Raman spectroscopy, infrared spectroscopy, chromatography) does the technology employ?
- What are the dimensions (i.e., size, weight) of the technology?
- What type of power source (i.e., electricity, battery, solar) is needed to run the technology?
- What additional power requirements (i.e., converters, power conditioners, uninterrupted power supply) are involved?
- Are there any safety precautions that should be taken into consideration before using the technology (i.e., lasers, heat generating)?
- Is waste generated when using the technology? If so, what kind of waste, and how is it safely handled?
- How easily can the technology's equipment be cleaned?
- What additional resources (i.e., chemicals, water, electricity) are required to clean the technology?

RELATIVE COST

Questions regarding relative cost include:

- What is the up-front cost of the technology?
- What are the recurring costs and how much are they (e.g., consumables, maintenance costs)?
- What is the cost of performing a test?
- Will the technology and intended methods be utilized with enough frequency to offset the cost?
- What warranties are available when purchasing the technology, and how comprehensive are they?

DATA

Questions regarding data include:

- What alternative languages are available for the hardware/software?
- Does the technology have a readily accessible user manual?
- Does the technology need or have internet connectivity capabilities?
- What format are data files in?
- Can data be transferred between devices?
- Can data be transferred to external sources?
- How can the data be displayed?
- Can the data be easily summarized into a report that supports decision-making?
- Can the software capabilities maintain data integrity?
- What are the levels of software permissions (i.e., administrator, user, guest), and what level of access do they provide?
- Does the instrument have a usable bar or Quick Response (QR) code reader?

It is important to note that some of these questions complement and supplement those listed in *5. Field Evaluation*. Generally speaking, the questions listed in that section can be answered through the review of publicly available information on the technology of interest or discussion with the OEM.

## 4. PERFORMANCE EVALUATION

The analytical performance portion of an evaluation may include parameters discussed in various guidances and standards on method development and validation. These include *Validation of Compendial Procedures* ⟨1225⟩ (*1*); *Analytical Instrument Qualification* ⟨1058⟩ (*2*); the Food and Drug Administration (FDA) Guidance for Industry, *Analytical procedures and methods validation for drugs and biologics* (*3*); and the International Council for Harmonisation (ICH) (harmonised tripartite guideline), *Validation of analytical procedures: text and methodology Q2(R1)* (*4*). However, except for ⟨1058⟩, these references are geared toward the validation of a method; their application in the context of this chapter should therefore focus on the performance qualification of a specific instrument rather than a procedure.

## 4.1 Technology Applications and Analytical Performance Characteristics to Evaluate

This section provides potential reviewers with the performance characteristics to evaluate, depending on the intended applications of a given technology. Ideally, this analytical performance evaluation will take place in a laboratory where variables can be controlled and a confident assessment can be made regarding the technology's analytical capabilities and whether they align with the reviewer's needs. With the exception of *Application I*, below, the performance evaluation should also encompass a comparison of the analytical results of the screening technology with those of a well-accepted confirmatory or compendial procedure (e.g., high-performance liquid chromatography) using reference material or standards. This will help inform the application and implementation of the technology within a broader quality assurance and quality control system.

*Table 1*, *Table 2*, and the *Applications* below, have been adapted from ⟨1225⟩ and tailored to the context of this chapter. However, they provide a broad guide and should be adapted to fit the needs of the user and the capabilities of the technology of interest. Definitions of the listed characteristics are included in the *Glossary*.

QUALITATIVE APPLICATIONS

**Application I:** Verification of packaging, labeling, origin, and appearance of the sample or drug product
**Application II:** Identification of bulk drug substances or active pharmaceutical ingredients (APIs) in finished pharmaceutical products
**Application III:** Identification of contaminants or impurities in bulk drug substances or finished pharmaceutical products

**Table 1. Qualitative Analytical Characteristics to Evaluate**

| Analytical Characteristic | Application I | Application II | Application III |
|---|---|---|---|
| Specificity | Yes | Yes | Yes |
| Detection limit | No | No | Yes |

QUANTITATIVE APPLICATIONS

**Application IV:** Quantification of major components of bulk drug substances or APIs in finished pharmaceutical products
**Application V:** Quantification of contaminants, impurities, or adulterants in bulk drug substances or finished pharmaceutical products
**Application VI:** Determination of product performance characteristics (e.g., disintegration, dissolution, drug release) in finished pharmaceutical products.

**Table 2. Quantitative Analytical Characteristics to Evaluate**

| Analytical Characteristic | Application IV | Application V | Application VI |
|---|---|---|---|
| Accuracy | Yes | Yes | Yes |
| Precision | Yes | Yes | Yes |
| Specificity | Yes | Yes | Yes |
| Detection Limit | No | No | No |
| Quantitation Limit | No | Yes | No |
| Linearity | Yes | Yes | Yes |
| Range | Yes | Yes | Yes |

# 5. FIELD EVALUATION

A field fitness evaluation of a screening technology should be conducted as a follow-up to a performance evaluation. This part of the review assesses the ability of a technology to operate effectively and efficiently in field settings, which may include, but is not limited to, resource-limited areas. Certain parameters should be assessed and certain questions answered. Although some of these parameters can be evaluated through online searches and discussion with the instrument manufacturers, other parameters will need to be evaluated in the field and this should be taken into consideration when planning a review. The parameters and questions listed in the section below are not exhaustive and some may not be applicable, depending on the technology. However, they provide baseline information necessary for making an informed decision about the field suitability of a given technology within a given country.

Determine whether the results provided by the technology when analyzing a medical product in the field correspond to results obtained from the performance evaluation in the laboratory. This does not mean that the exhaustive analytical testing done in the laboratory needs to be replicated in the field, but a smaller, pragmatic subset of samples and tests should be run to give the reviewer confidence that the technology does, indeed, function in a field setting.

## 5.1 Access, Handling, Maintenance, and Repair

Some questions to address include:

- Is the technology commercially available in the country?

Official

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Nov-2020
DOI Ref: hux79
DocId: GUID-E43742F7-8522-4D65-91B3-B6E9D33461AC_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M12295_02_01
@2024 USPC

- In countries where the technology is commercially available but needs to be imported, what are the marketing authorization requirements for importing the technology?
- What are the control requirements for exporting this technology out of its country of origin or distribution?
- Are there local service providers or authorized distributors in the country?
- Can the technology be maintained and repaired by trained users or is a local service provider required?
- If there is a local service provider, then where is it located and how can it be reached (i.e., in country office, via email, or by phone)?
- Are there other shipping requirements if there is a need to send the technology for calibration or repair?
- Are there additional resources required to calibrate, recalibrate, or repair the technology (i.e., internet access, reagents, standards, spare parts)?
- How accessible are these additional resources in terms of availability and affordability?
- How often are recalibration and performance maintenance of the technology required?

## 5.2 Durability and Use

DURABILITY

Some considerations regarding durability of the technology include:

- What is the operating temperature range of the technology?
- How is the technology affected by humidity?
- How are results affected by changes in temperature or humidity?
- How tolerant is the technology of various changes in the operational environment?
  - Temperature
  - Humidity
  - Dust
  - Vibration
  - Electromagnetic interference
  - Light
  - Water
  - Electrical variability (e.g., voltage, surge, frequency)
- How tolerant is the technology of rough handling by users?
- Is the technology intrinsically safe and suitable for the intended environment (e.g., temperature, humidity)?
- Can the technology withstand a drop test [i.e., according to U.S. Military Standard [MIL-STD]-810G *(5)*, International Electrotechnical Commission [IEC] 60068 *(6)*, or ASTM D5276-98 *(7)*]?

USE

Some considerations regarding use of the technology include:

- Is the technology suitable to use for the intended application?
- What level of training (e.g., remote vs. in-person, time, complexity) is required to use the tool?
- What are the sample preparation requirements for analysis and is the testing destructive or non-destructive?
- What additional accessories, consumables, reagents, and standards are required for sample analysis?
- How long does it take to analyze a sample and how easily can the results be interpreted?
- How many samples can be run simultaneously?
- What offline data analysis is required to interpret the results?
- What offline data analysis is available for experienced users?
- What requirements are there for fleet management of multiple instruments?
- What types of products (e.g., tablets, injections) can the technology analyze?
- Can models and/or methods developed on another instrument be remotely transferred to field units as needed?

## 5.3 Protocol and Statistics

PROTOCOL

When evaluating a screening technology for suitability, the applicable sections of this chapter should be used to develop a robust, practical, and ideally, standardized protocol that specifically outlines the work to be done. After selection of the applicable sections, additional variables need to be taken into account to ensure that the evaluation generates evidence-based data that can inform decision-making. These variables include but are not limited to the following:

- Number of units of the screening technology needed to determine variability between instruments (any evaluation should include at least two units of the technology in question)
- Types of dosage forms (e.g., solid oral dosage forms, injectables) to use for the evaluation
- Types of APIs to use for the evaluation

Official

https://pharmacopeia.com/

- Number of batches per product to use for the evaluation
- Number of units per sample to use for the evaluation

STATISTICS

The prudent use of statistics as part of an evaluation is a critical component for ensuring the integrity and reliability of any data generated. When possible, the specific statistical approaches and methodologies to be used should be identified, and a professional statistician should be consulted to devise an appropriate protocol. Concomitantly, it is valuable to collect available information from the literature and specific OEMs about the statistics associated with various applications of the technology. This approach provides a strong baseline to expand upon.

The following statistical guidances, references, and standards can be used to help with planning statistical approaches and methodologies:

- *Analytical Data—Interpretation and Treatment* ⟨1010⟩ (*8*)
- *Statistical Tools for Procedure Validation* ⟨1210⟩ (*9*)

- ISO 3534-3 *Statistics—vocabulary and symbols—part 3: design of experiments* (*15*)
- ISO 5725-1 *Accuracy (trueness and precision) of measurement methods and results—Part 1: general principles and definitions* (*16*)

## GLOSSARY

For reference purposes, some definitions are based on ⟨1225⟩.

**Accuracy:** The accuracy of an analytical procedure is the closeness of the test results obtained by that procedure to the true value. The accuracy of an analytical procedure should be established across its range. [NOTE—The definitions of accuracy in ⟨1225⟩ and the ICH harmonized tripartite guideline, *Validation of analytical procedures: text and methodology* Q2 (R1) (*4*) correspond to unbiasedness only. In the *International Vocabulary of Metrology* and documents of ISO, "accuracy" has a different meaning. In ISO 5725, accuracy combines the concept of unbiasedness (termed "trueness") and precision, and is defined as the closeness of agreement between a test result and the accepted reference value.]

**Adulterant:** Any substance that has been (1) mixed or packed with a drug so as to reduce its quality or strength or (2) substituted wholly or in part for the drug.

**Detection limit:** The detection limit is a characteristic of limit tests. It is the lowest amount of analyte in a sample that can be detected, but not necessarily quantitated, under the stated experimental conditions. Thus, limit tests merely substantiate that the amount of analyte is above or below a certain level. The detection limit is usually expressed as the concentration of analyte (e.g., percentage, parts per billion) in the sample.

**Linearity:** ICH documents define linearity as the ability to obtain test results that are proportional to the concentration of analyte in the sample across a given range.

**Precision:** The precision of an analytical procedure is the degree of agreement among individual test results when the procedure is applied repeatedly to multiple samplings of a homogeneous sample. The precision of an analytical procedure is usually expressed as the standard deviation or relative standard deviation (coefficient of variation) of a series of measurements. Precision may be a measure of either the degree of reproducibility or of repeatability of the analytical procedure under normal operating conditions. In this context, reproducibility refers to the use of the analytical procedure in different laboratories, as in a collaborative study. Intermediate precision (also known as ruggedness) expresses within-laboratory variation, as on different days or with different analysts or equipment within the same laboratory. Repeatability refers to the use of the analytical procedure within a laboratory over a short period of time using the same analyst with the same equipment.

**Quantitation limit:** The quantitation limit is a characteristic of quantitative assays for low levels of compounds in sample matrices, such as impurities in bulk drug substances and degradation products in finished pharmaceuticals. It is the lowest amount of analyte in a sample that can be determined with acceptable *Precision* and *Accuracy* under the stated experimental conditions. The quantitation limit is expressed as the concentration of analyte (e.g., percentage, parts per billion) in the sample.

**Range:** The range of an analytical procedure is the interval between the upper and lower levels of analyte (including these levels) that have been demonstrated to be determined with a suitable level of *Precision*, *Accuracy*, and *Linearity* using the procedure as written. The range is normally expressed in the same units as the test results (e.g., percent, parts per million) obtained by the analytical procedure.

**Robustness:** The robustness of an analytical procedure is a measure of its capacity to remain unaffected by small but deliberate variations in procedural parameters listed in the procedure documentation. Robustness provides an indication of the procedure's suitability during normal usage. Robustness may be determined during development of the analytical procedure.

**Screening:** The process by which a sample undergoes an initial assessment of quality to determine acceptability or the need for additional testing.

**Specificity:** ICH documents define specificity as the ability to identify the analyte in the presence of components that may be expected to be present, such as impurities, degradation products, and matrix components (*4*). [NOTE—Other reputable international authorities (e.g., International Union of Pure and Applied Chemistry, AOAC-International) have preferred the term

"selectivity," reserving "specificity" for those procedures that are completely selective.] The definition of specificity, above, has the following implication for the tests discussed below:

1. Identification tests ensure the identity of the analyte.
2. Purity tests ensure that all the analytical procedures performed allow an accurate statement of the content of impurities of an analyte (e.g., heavy metals, organic volatile impurities).
3. Assays provide an exact result, which allows an accurate statement of the content or potency of the analyte in a sample.

**Supply chain:** The system of manufacture, distribution, and dispensing of pharmaceutical products.

# ⟨1852⟩ ATOMIC ABSORPTION SPECTROSCOPY—THEORY AND PRACTICE

***Change to read:***

## THEORY

The instrumental technique of atomic absorption spectrometry (AAS▲ (USP 1-Aug-2022)) uses the Beer–Lambert Law (Beer's Law), which relates the concentration of an analyte in a sample to the sample's absorption of electromagnetic radiation. Beer's Law states that the optical absorbance of a chromophore in a transparent solvent is linearly proportional to the chromophore's concentration and also to the sample cell path length. Beer's Law is applicable only if the spectral bandwidth of the light is narrow compared to the spectral line widths in the spectrum and is expressed as follows:

$$A = \varepsilon bc$$

$A$ = absorbance
$\varepsilon$ = molar absorptivity [L/(mol · cm)]
$b$ = path length of the sample cell (cm)
$c$ = concentration (mol/L)

In addition:

$$A = \log_{10}(P_0/P) = \log_{10}(1/T) = \log_{10}(100/\%T) = 2 - \log_{10}\%T$$

$P_0$ = intensity of light passing through a sample
$P$ = intensity of light leaving the sample
$T$ = transmittance
$\%T$ = $100 \times T$

AAS methods fall into two categories: flame (FAAS) and flameless. Flameless methods include graphite furnace AAS (GFAAS), also known as electrothermal vaporization AAS (ETVAAS), for ultra-trace analyses. Other flameless methods are cold vapor AAS (CVAAS), intended specifically for the analysis of mercury, and hydride generation AAS (HGAAS), intended specifically for the analysis of arsenic, bismuth, germanium, lead, antimony, selenium, tin, and tellurium.

A basic AAS consists of a radiation source, a sample introduction device, a means to atomize the sample, a monochromator or a polychromator, a detector, and some means of acquiring data (usually a computer). Most instruments also have some sort of background correction system, which will be discussed later in this chapter.

In the case of FAAS, the flame through which the sample passes is considered to be the sample cell. In the case of electrothermal vaporization (ETV), the graphite tube into which the sample is deposited is considered to be the sample cell. In the case of CVAAS, a quartz absorption cell is mounted on top of the burner head, and the space above the burner in the optical path is considered to be the sample cell. In the case of hydride generation, hydrides are swept into a heated cell.

## INSTRUMENTATION

Figure 1. Basic components of an atomic absorption spectrophotometer.

All atomic absorption spectrophotometers share fundamental components (*Figure 1*). A wide variety of AAS is available commercially and is based on one of two designs: a single-beam or a double-beam light path.

*Figure 2* illustrates the light path for a single-beam spectrophotometer. The dotted line represents the modulated light signal from the external light source (line source), and the solid line represents the direct current signal from the atomizer, represented by a flame. The ovals represent lenses.

In this example, the beam from the line source is electrically modulated, and an amplifier placed after the detector is tuned to this modulation frequency. The beam from the line source becomes coded in this manner. The result is that the noise from the radiation emitted at all frequencies, except for the resonance frequency, is rejected, and the signal-to-noise ratio is improved.

Single-beam spectrophotometers rely on a very stable line source to maintain accuracy. It is also necessary to run a separate blank solution in order to provide a correct 100% $T$ adjustment.

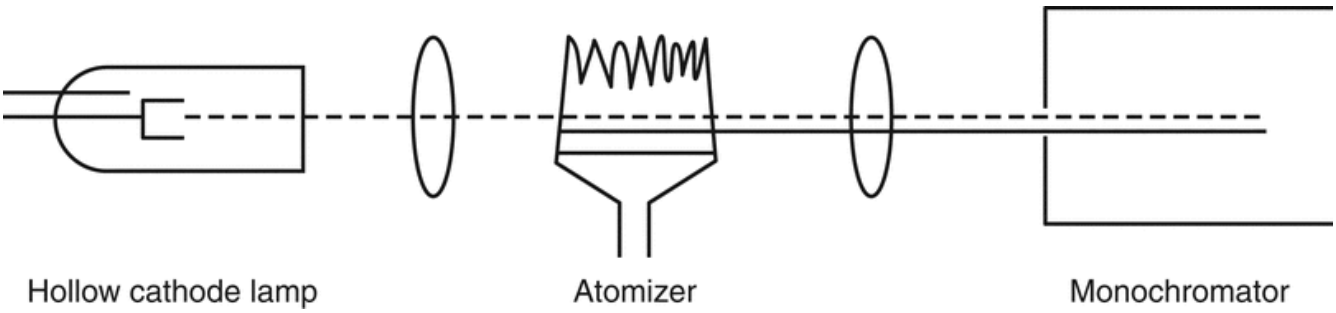

Figure 2. Schematic of a single-beam atomic absorption spectrophotometer. Reproduced with permission of the Royal Society of Chemistry.

*Figure 3* illustrates the light path for a double-beam spectrophotometer. The radiation beam from the line source is divided by a mirrored chopper. One half is directed through the atomizer (sample beam), and the other half is directed around it (reference beam). Note that the beam from the line source is mechanically modulated by the chopper. The two beams are then recombined by a half-silvered mirror and are directed into a monochromator where the photons at the characteristic wavelength are measured by the detector. The ratio between the sample signal and the reference signal is amplified and processed as the absorbance reading. Because the sample and reference beams are generated from a common line source, are separated into their characteristic wavelengths by the same monochromator, and are processed by the same electronics, any variations in the radiation source, detector properties, or electronics are canceled out. In principle, the stability of a double-beam spectrophotometer is superior to that of a single-beam spectrophotometer.

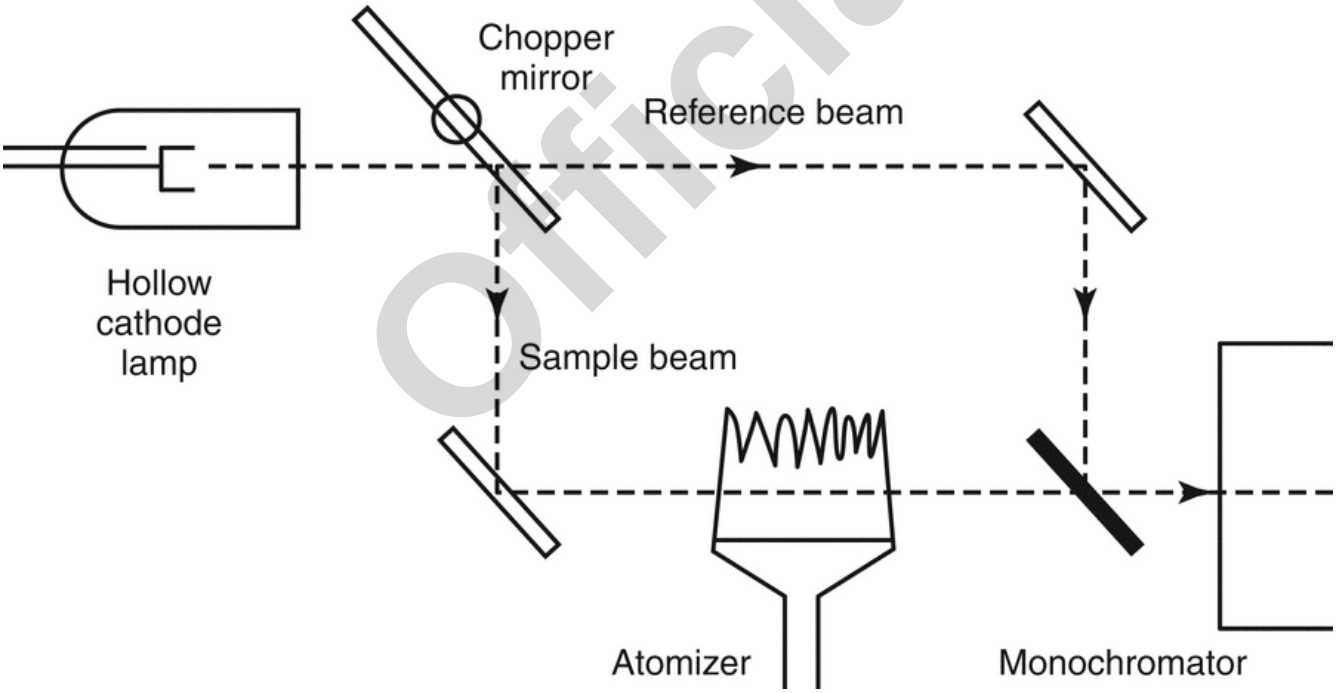

Figure 3. Schematic of a double-beam atomic absorption spectrophotometer. Reproduced with permission of the Royal Society of Chemistry.

## SAMPLE CELL DESIGNS

### Flame Atomic Absorption Spectrometry

In FAAS, a liquid sample is aspirated into a flame via a nebulizer. Via the nebulizer, the sample is converted to a mist that is composed of uniform droplets that are easily introduced into the flame. The flame desolvates and atomizes the sample providing a source of neutral atoms or molecules for analysis in the spectrophotometer.

Although other flame types have been documented, the most commonly used flame is an air–acetylene flame. Because the temperature of the air–acetylene flame is not sufficient to destroy oxides that might form or are present, a nitrous oxide–

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M6960_02_01
@2024 USPC

acetylene flame often is used, depending on the analyte and nature of the sample. The air–acetylene flame burns within a temperature range of 2125°–2400°, but the nitrous oxide–acetylene flame burns within a temperature range of 2650°–2800°.

Flames can be optimized for a particular analysis by either increasing or decreasing the fuel to oxidant ratio. The fuel to oxidant ratio can be adjusted to be either lean or rich—oxidizing or reducing—depending on the analyte of interest. Most instrument manufacturers provide guidance regarding the type of flame to use for a specific element, and analysts should refer to the manual provided by the instrument manufacturer for optimal flame conditions for a given analyte.

Some AAS can also be used in the flame emission mode. In flame emission, the atoms and molecules achieve an excited electronic state following thermal collisions within the flame, and upon their return to a lower or ground electronic state they emit light at characteristic wavelengths for each analyte. Although instrumentation may be capable of operation in the flame emission mode, this will not be discussed further in this chapter.

## Electrothermal Vaporization and Graphite Furnace Atomic Absorption Spectrometry

In ETVAAS or GFAAS, a liquid sample is deposited through a small opening into a graphite tube known as a mini-Massmann furnace. Inside the furnace, the sample is heated at increasing temperatures until the solvent is evaporated, solid residue is ashed or pyrolyzed, and neutral atoms are atomized in their ground states. The atoms are then excited by absorption of radiation at characteristic wavelengths. Samples can be deposited either directly onto the wall of the graphite furnace or onto a small graphite platform, known as a L'vov platform, which sits inside of the graphite furnace. With ETVAAS, a series of heating steps is usually employed, including drying, charring or ashing, atomizing, and clean-out. Other intermediate heating steps can be used, depending on the nature of the sample. Throughout the heating process, the graphite furnace is purged with an inert gas, usually nitrogen or argon. At the atomization step, the furnace is quickly heated to a high temperature (usually to incandescence). The purge gas flow is stopped temporarily as a transient absorption signal produced by the atomized analyte is measured. As in FAAS, Beer's Law can be used to relate the concentration of the analyte and the absorption signal.

▲A figure of merit commonly used in GFAAS analyses is the characteristic mass. The characteristic mass is defined as the mass of an element required to produce an absorbance of 1% (99% transmittance, *T*) or 0.0044 absorbance units (AU). The characteristic mass, in picograms, is calculated as follows:

$$M = (0.0044 \times C \times V)/A$$

*M* = characteristic mass (pg)
*C* = concentration of the sample (pg/µL)
*V* = volume of the sample (µL)
*A* = measured absorbance (AU)

The optimum characteristic mass for each element is often provided by the instrument manufacturer or publication authors and can be useful for method development of difficult matrices.▲ (USP 1-Aug-2022)

## Cold Vapor and Hydride Generation Atomic Absorption Spectrometry

Cold vapor and hydride generation techniques are often used for the determination of mercury or for some hydride-forming elements such as tin, arsenic, selenium, antimony, and bismuth.

In the case of mercury, a chemical reduction generates atoms, and a stream of inert gas sweeps the cold vapor into a cold quartz cell in the optical path of the instrument. The technique is very sensitive and has detection limits that range from parts per billion (ppb) to parts per trillion (ppt) depending on the sample and the laboratory environment.

In the case of hydride-forming elements, a reaction with sodium borohydride and hydrochloric acid generates the hydride of the analyte of interest. The resulting gas is swept into an inert quartz cell that is positioned on top of the burner. The cell can be externally heated, or it can be heated by an air–acetylene flame. The heat of the flame breaks down the hydride and creates the elemental form of the analyte. This is known as the direct-transfer mode of hydride generation. Commercial direct-transfer hydride generators are available in two configurations, continuous flow and flow injection. As with the cold vapor detection of mercury, hydride generation also can be very sensitive and has detection limits in the ppb or ppt range.

***Change to read:***

# LINE SOURCES

An external light source (line source) is used to emit spectral lines corresponding to the energy required to elicit the electronic transition from the ground state to an excited state in the sample. The external light sources most commonly used are hollow cathode lamps (HCL) or continuum electrodeless discharge lamps (EDL). Absorption of radiation from the external light source is proportional to the population of the analyte species in the ground state, which is proportional to the concentration of the analyte that is aspirated into the flame, thereby making it possible to use Beer's Law to determine the concentration of an analyte in the sample. The absorption is measured by the difference in transmitted signal in the presence and absence of the analyte.

A suitable line source for AAS must:

- Produce lines of sufficiently narrow bandwidths specific to a particular atomic absorption peak
- Produce a beam of radiation of sufficient intensity to allow high signal-to-noise absorption measurements
- Produce a beam of radiation that is stable for extended periods of time
- Be easy to start and have a short warm-up time and an extended shelf life.

@2024 USPC

The gas contained within the HCL tube is ionized when an electrical potential is applied across the electrodes. Gaseous cations then acquire sufficient kinetic energy to dislodge some of the metal atoms from the anode surface, a process known as sputtering. A portion of the resulting cloud of metal ions is excited. Upon relaxation to the ground state, the ions emit photons at the characteristic wavelengths for that metal. HCLs are available in a variety of configurations and can be specific for a single element or multiple elements.

For certain elements, EDLs produce much more intense radiation beams than do HCLs. They are available for the analysis of antimony, arsenic, bismuth, cadmium, cesium, germanium, lead, mercury, phosphorus, selenium, tellurium, thallium, tin, and zinc. They are similar to HCLs because they rely on the sputtering of a metal by accelerated ions, but they ionize the inert gas by means of an intense radio-frequency field instead of hard-wired electrodes.

The requirement for an individual line source for each metal limits AA to a single-element technique. Some modern systems allow multi-element analyses by automatic lamp switching or by positioning multiple lamps in an array. High-resolution continuum source AAS combines a high-resolution echelle monochromator with a Xenon short-arc lamp to obtain multi-element analytical capabilities (see ▲the first entry in *Additional Sources of Information*▲ (USP 1-Aug-2022) for additional details).

## WAVELENGTH SELECTORS

Because atomic resonance lines are narrow, spectrometers are frequently equipped with monochromator gratings of moderate resolution, such as Ebert and Czerny–Turner monochromator systems.

Although the application is not common, high-resolution echelle polychromators have been used in AAS designed for simultaneous measurements of multiple elements. Spectrophotometers of this type usually mate a high-resolution polychromator with either a Xenon arc continuum source or several individual line sources. They typically are equipped with a solid-state detector system.

## DETECTION SYSTEMS

Detection systems convert radiant energy, photons, into a concentration-proportionate electronic signal. This signal is amplified and processed into an absorbance reading or a concentration, as illustrated in *Figure 1*. Photomultiplier tubes (PMTs) are widely used in AAS to convert photons passed through the monochromator into voltages. Some spectrophotometers are designed so that the applied PMT currents are under operator control. As mentioned above, some modern AAS are equipped with solid-state detection systems. There are two types: a charge-injection device or a charge-coupled device. Advantages and disadvantages of each design depend on specific applications. In some applications, a solid-state detector can produce a superior signal-to-noise ratio, provide a flatter response across the UV/Vis spectrum, and/or have improved background correction capabilities when compared to a PMT.

## BACKGROUND CORRECTION

Nonspecific absorption can compromise the accuracy of AAS measurements. This is particularly the case for ultra-trace analyses using GFAAS. The type of background correction used for GFAAS can have a large impact on the success of the analysis. Three types of background correction designs are available for modern AAS: continuum source, Smith–Hieftje or variable giant pulse, and Zeeman effect.

### Continuum Source

A continuum source, frequently a deuterium lamp, is configured in the spectrophotometer optics so that radiation from the continuum source and the line source is alternately passed through the sample cell by a beam chopper (*Figure 4*). The width of the continuum source bandpass is equal to the slit width.

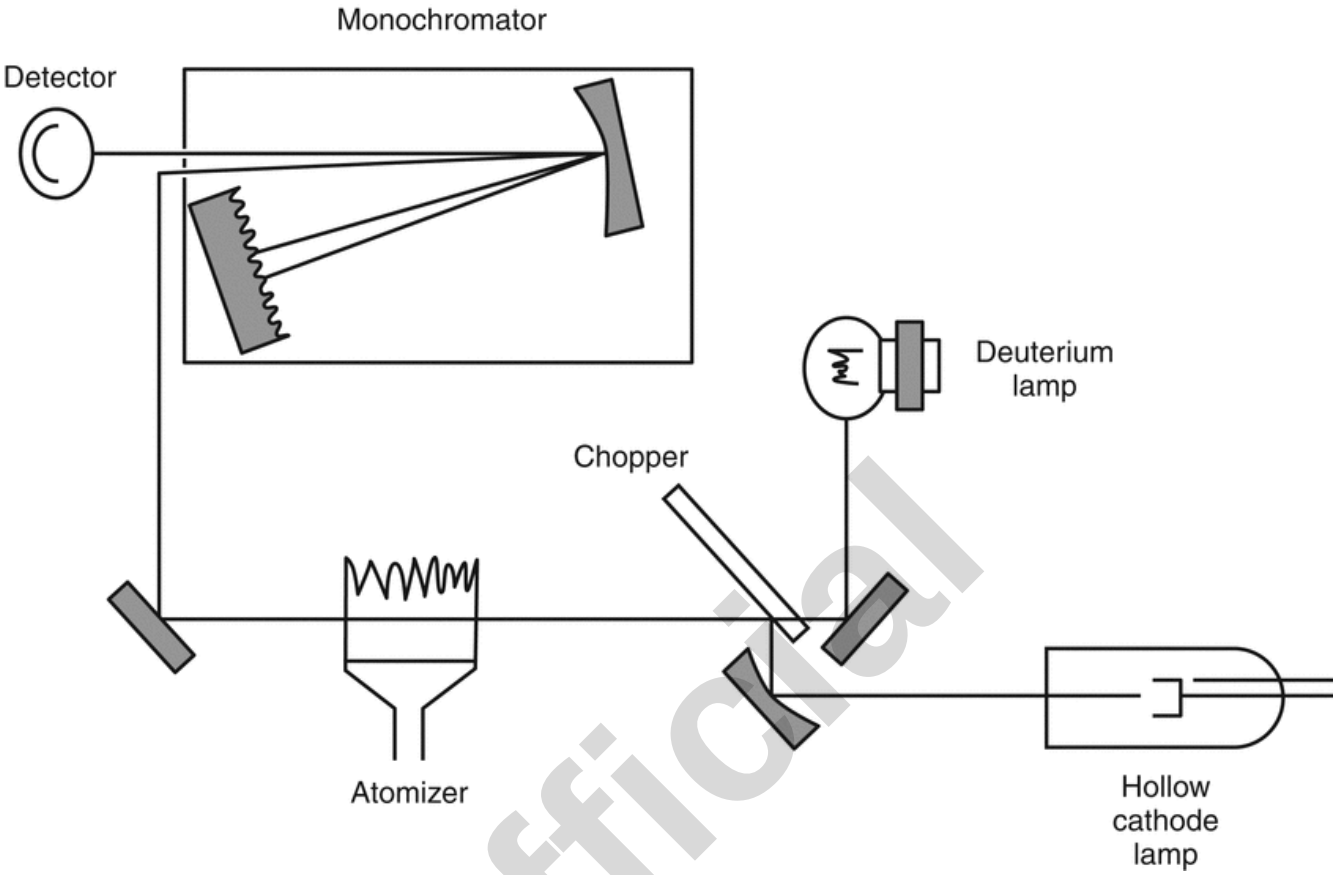

Figure 4. Schematic of an atomic absorption spectrophotometer with a continuum source background corrector. Reproduced with permission of the Royal Society of Chemistry.

The signal intensity from both sources can then be measured, and the ratio can be calculated.

*Figure 5* displays the operation of a continuum-source background-correction system. Note that before the analysis, the intensity of the deuterium lamp and the HCL are equalized at the analyte's resonance wavelength. Also note that the bandwidth of the continuum source is equal to the width of the monochromator's exit slit, usually 0.2–0.7 nm, compared to the width of the resonance line of approximately 0.002 nm. If a solution containing the analyte of interest is introduced, the signals from both sources are attenuated because of atomic absorption (*Figure 5*, Panels A and B). If a solution containing the analyte of interest plus components that lead to nonspecific broad-band absorbance is introduced, the intensity of atomic absorption of the line source (HCL) is correctly subtracted from the intensity of the continuum source (*Figure 5*, Panels C and D).

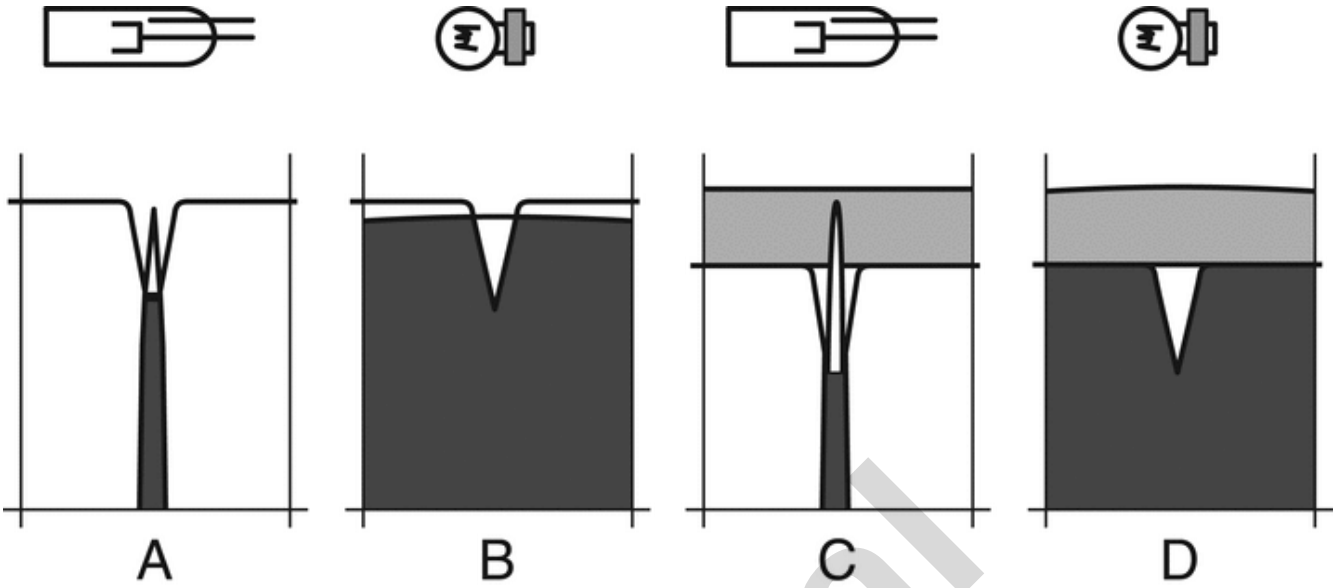

Figure 5. Panels A and B: atomic absorption only. Panels C and D: atomic absorption with background absorption. Reproduced with permission of the Royal Society of Chemistry.

Although continuum-source background correction is a useful design, it has some limitations. Basically, the introduction of an additional lamp and chopper causes a degradation of the overall signal-to-noise ratio of measurements. In addition, if the line source and the continuum source are not in perfect alignment, an erroneous correction will result when the individual beams are passed through an inhomogeneous gaseous sample, as this frequently occurs in the sample cell. This is particularly the case for highly structured backgrounds. The radiant intensity of the deuterium source in the visible region is too low to use for analytical wavelengths above 350 nm. Some instrument manufacturers equip their spectrophotometers with alternative continuum sources, such as tungsten halogen lamps, to remedy this issue.

## Smith–Hieftje

When high currents are applied to an HCL, the emission-line profile is altered: the line is broadened and a dip appears in the center because of self-absorption. Self-absorption occurs when the photons emitted by excited atoms are absorbed by gaseous ground-state atoms contained within the quartz tube of the HCL. At currents used for normal data acquisition, the HCL is used to measure the sum absorbance of the element of interest and the nonspecific background. At high lamp currents, the measured absorbance is predominantly caused by the background. The absorbance caused by the element of interest is the difference between the intensities of analyte and nonspecific background absorbances. *Figure 6* illustrates the Smith–Hieftje background correction process.

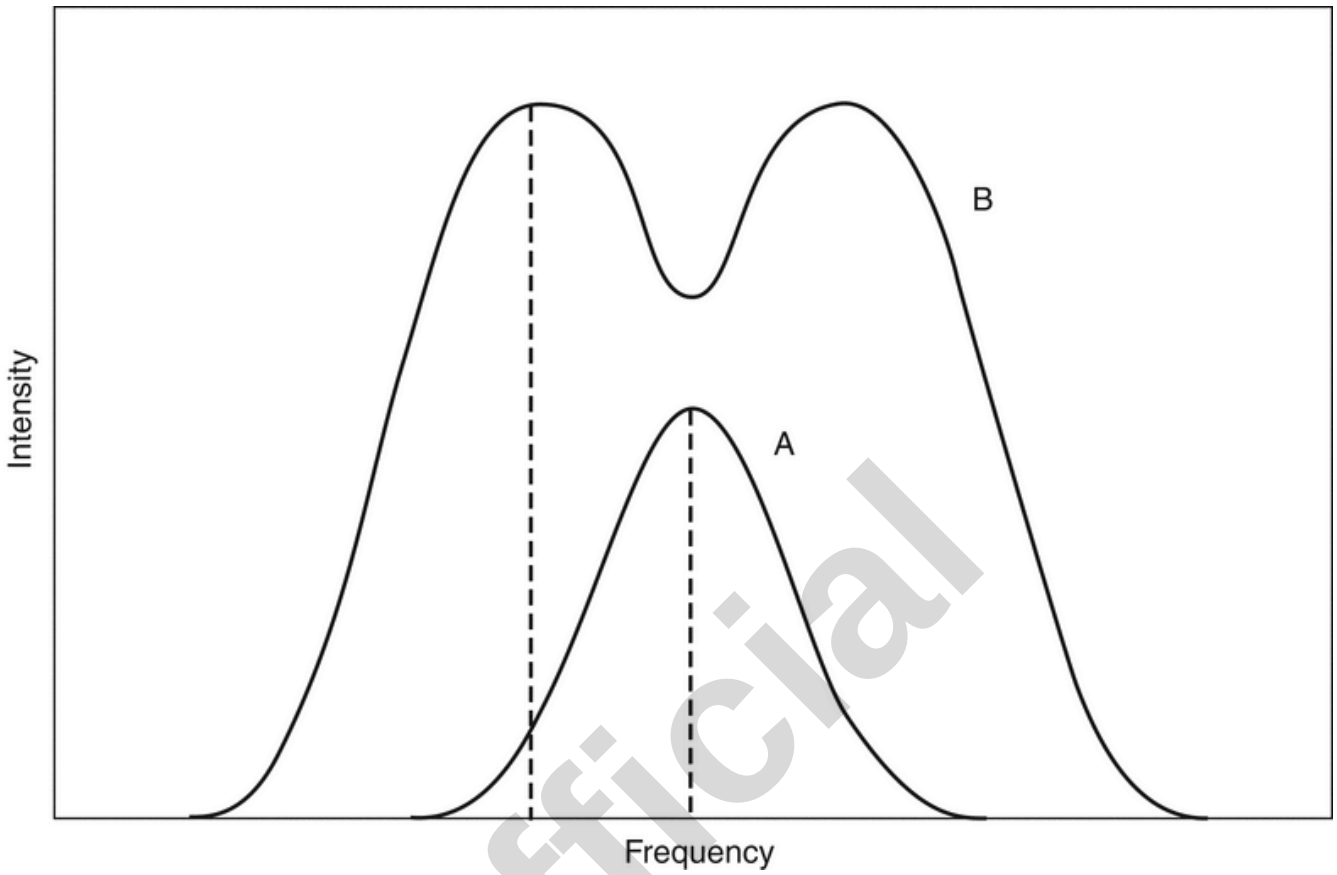

Figure 6. Emission profile of an HCL at (A) low current and (B) high current. Low current absorbance is caused by background plus analyte. High current is background absorbance only. Adapted from S.B. Smith, Jr. and G.M. Hieftje, *Applied Spectroscopy*, 1983, 37, 419.

The advantages of Smith–Hieftje background correction are that the HCL serves as the single source for any analytical wavelength, obviating any alignment issues arising from alternative continuum source. This system allows correction of structured backgrounds very near the resonance wavelength. Disadvantages are that the lifetimes of the HCLs are notably shortened. Compared with continuum-source background correction, the Smith–Hieftje procedure may result in a shorter dynamic range and/or may require higher sample dilutions to reduce background absorbances.

## Zeeman Effect

The Zeeman effect background correction is based on the principle that in the presence of a magnetic field, the absorption line of an element is split into three optically polarized components. The π component is positioned at the center of the resonance line. Positioned at equal distances on either side of the π component are the σ+ and σ– components. The σ components are linearly polarized perpendicular to the magnetic field. The distance of the separation of the σ+ and σ– components from the π component increases as the magnetic field strength increases. Commercial instruments use magnets with field strengths of approximately 1 Tesla, which corresponds to a σ component separation of approximately 0.01 nm on each side of the π component.

Absorbance lines from different elements have normal or anomalous Zeeman patterns. Normal Zeeman patterns are composed of a single π component and two σ components. A normal Zeeman pattern occurs for absorbance wavelengths that correspond to a singlet electron transition. An anomalous Zeeman pattern has further splitting of the π and σ components and occurs for wavelengths that correspond to more complex electron transitions.

Three basic designs are available for commercial AAS equipped with Zeeman background correction: transverse DC Zeeman AAS, transverse AC Zeeman AAS, and longitudinal AC Zeeman AAS.

### TRANSVERSE DC ZEEMAN ATOMIC ABSORPTION SPECTROMETRY

This design uses a DC magnet positioned around the atomizer. The term *transverse* refers to the parallel alignment of the magnetic field with the optical axis. The Zeeman effect is permanently applied in this design. A rotating polarizer is positioned in the light path between the line source and the atomizer. This splits the incident radiation from the line source into the characteristic π and σ components. See *Figure 7* for a schematic of the configuration and an illustration of the operation of DC Zeeman AAS.

## TRANSVERSE AC ZEEMAN ATOMIC ABSORPTION SPECTROMETRY

This design uses an AC magnet positioned around the atomizer. The magnetic field is in parallel alignment with the optical axis. The AC magnet is switched on and off at one-half the modulation frequency of the line source (50 or 60 Hz, typically). A fixed polarizer is positioned between the atomizer and the monochromator. See *Figure 8* and *Figure 9* for illustrations of the operation of transverse AC Zeeman AAS.

Zeeman effect background correction offers the advantage of background correction at the resonance wavelength and correction of relatively high nonspecific absorbances. Compared to continuum source background correction, Zeeman effect background correction can result in a reduction of the linear dynamic range in some applications and may require additional dilution of test solutions. Depending on the specific analyte and application, Zeeman effect background correction offers advantages and disadvantages that must be considered for each application.

## ANALYTICAL CONSIDERATIONS

### Sample Preparation

FAAS requires the introduction of a liquid sample into the nebulizer. ETVAAS/GFAAS is normally performed using liquid samples, but analyses can be performed using slurries and solid samples. Because the analysis of liquid slurries is far more common, the analysis of solid samples is not discussed in this chapter.

Samples can be prepared in a variety of ways to dissolve or solubilize them. In some cases, direct dilution of a solid sample can be performed using deionized water, dilute acids, or organic solvents. When a sample does not dissolve, however, some form of acid digestion is required. Acid digestion is also required if the sample is first ashed. Options for acid digestion include hot-plate digestions, open-vessel microwave digestion, and closed-vessel microwave digestion. Procedures for acid digestion are specific for a given sample matrix and analyte. When using microwave digestion systems, analysts should refer to the microwave manufacturer's guidelines for use and programming of the instrument.

### Interferences

AAS is subject to several types of interferences. The most common are:

- Spectral interferences: Spectral interferences can arise when there is an overlapping signal from another element that is a component of the sample or sample matrix.
- Ionization of the analyte: Some elements such as sodium, potassium, calcium, and cesium are easily ionized, and ionization of the analyte reduces the analytical signal.
- Matrix effects: Interferences can arise from differences between sample, standard, and blank viscosities or can be introduced by surface tension.

DOI: https://doi.org/10.31003/USPNF_M6960_02_01
@2024 USPC

- Spectral line broadening: Spectral line broadening can occur as a result of several factors, including self-absorption, Lorentz effect, Doppler effect, or quenching.
- Compounds that do not dissociate in the flame.

## Matrix Modification, Releasing Agents, and Ionization Suppressants

To counteract potential interferences or to enhance their ability to monitor an analyte, analysts sometimes use a matrix modifier, a releasing agent, or an ionization suppressant.

Matrix modifiers are added to samples, standards, and blanks with GFAAS with the chief goals of changing the nature of the sample or analyte in the sample by:

- Increasing the volatility of the sample matrix so that matrix components are removed during the ashing or pyrolysis step
- Reducing the volatility of the analyte, which helps to eliminate loss of the analyte during the ashing or pyrolysis step
- Reducing background absorption by eliminating matrix components so that they do not interfere with the analyte signal during atomization.

It may be necessary to use more than one matrix modifier during an analysis. Commonly used matrix modifiers include magnesium nitrate, nickel nitrate, palladium, and lanthanum. Manufacturers of graphite furnace instrumentation provide detailed information regarding the use of matrix modifiers, and analysts should consult that information when they perform an analysis. In some instances, GFAAS analyses require applying the method of standard additions in order to overcome matrix induced result biases. Many modern GFAAS systems are equipped with autosamplers that automatically spike sample solutions at multiple levels specified by the analyst, perform the linear regression, and report the final concentration result based upon the intercept.

Releasing agents and ionization suppressants are used in FAAS to eliminate certain potential interferences. Releasing agents are added in excess to samples, standards, and blanks to prevent the formation of refractory compounds by combining with a potential interferent. Ionization suppressants are added in excess to samples, standards, and blanks to help control ionization of the analyte. By adding an ionization suppressant that has an ionization potential lower than that of the analyte, analysts create an excess of electrons in the flame, and the ionization of the analyte is suppressed. Commonly used releasing agents include lanthanum and strontium. Commonly used ionization suppressants include sodium, potassium, cesium, and lanthanum. Manufacturers of flame atomic absorption (AA) instrumentation provide detailed information regarding the use of releasing agents and ionization suppressants, and analysts should consult that information when performing an analysis.

Because of the separation of the analyte from the matrix in cold-vapor and hydride-generation AA, spectral interferences are notably reduced when compared to the other AA methods. Nonselective background interferences can occur, however, when a sufficient amount of an absorbing species is transported to the cell. Typically this occurs when an excess of another hydride-forming species is introduced from the sample matrix or in the case of hydride formation when nonaqueous media are used. Transport interferences take place during transport of a hydride from the sample solution to the sample cell. This either causes a delay in hydride formation, known as transport kinetics interference, or loss of the hydride altogether, known as transport efficiency interference. Volatile compounds transported to the cell with the hydride can also interfere nonselectively. These interferences can be remedied either by using the method of standard additions or by further diluting the sample.

## ▲Method of Standard Additions

For the validation of procedures that use the method of standard additions, it is important to consider the appropriate standard addition concentrations applied to the linear regression and the impact on the associated intercept that defines the test solution concentration. It is important to consider not only how well correlated the linear regression is determined to be via the correlation coefficient or the coefficient of determination calculations but also the error of each measurement at each standard addition concentration. If, for example, standard addition concentrations are significantly higher than the targeted sample concentration, the regression line is likely to be very highly correlated but will carry a large bias error at the intercept. It is for this reason that the accuracy validation parameter for a method using the method of standard additions applies to the recovery of a spiked sample determined by the intersection of the concentration axis by the standard addition regression line. The same practice also applies to the system suitability standard measurement. This process is simplified by manufacturers of modern AA spectrometers, which provide for an automated method of standard addition analyses.▲ (USP 1-Aug-2022)

# ⟨1853⟩ FLUORESCENCE SPECTROSCOPY—THEORY AND PRACTICE

## THEORY

Fluorescence is a two-step process that requires an initial absorption of light followed by emission. [NOTE—Many terms and variables used in this general chapter are explained in the *Glossary*.] Fluorescence spectroscopy is an electronic spectroscopic method related to ultraviolet–visible–near infrared (UV–Vis–NIR) absorption spectroscopy. It is also a background-free method that involves light emitted from the sample in all directions, as is the case with Raman spectroscopy. The initial absorption of a photon by a molecule in the sample promotes an electron to an excited state. The excited electron returns to the ground electronic state by emitting a photon. If the emission arises from an "allowed" transition that typically has a short lifetime between 1 ns and 10 ns, then it is called *fluorescence*. If the emission arises from a "forbidden" transition that typically has a long lifetime between 1 ms and 1 s, then it is called *phosphorescence*. Under similar conditions phosphorescence usually is less intense than fluorescence. This general chapter discusses fluorescence spectroscopy, but many points raised here also apply to phosphorescence. The basic concepts behind fluorescence spectroscopy have been well established, but its applications and standardization are still expanding and progressing, making it a developing rather than a mature method.

The most common type of fluorescent sample is a dilute, transparent solution that absorbs light following the Beer–Lambert Law and that emits a corresponding fluorescence intensity that is directly proportional to the concentration, the absorptivity, and the fluorescence quantum yield of the fluorescent species or fluorophore. A conventional fluorescence spectrometer has both excitation and emission wavelength selectors. It collects a spectrum by fixing the wavelength of one of the selectors and scanning the other wavelength selector over a range. When the excitation wavelength is fixed and the emission wavelength is scanned, the resulting spectrum is termed an *emission spectrum*. When the emission wavelength is fixed and the excitation wavelength is scanned, the resulting spectrum is termed an *excitation spectrum* (*Figure 1*). The fluorescence spectrum is plotted as relative intensity or counted photons of fluorescence vs. wavelength. The appearance of a fluorescence spectrum is much like a UV–Vis–NIR absorption spectrum. In fact, the shape or contour of an excitation spectrum often is identical to that of the corresponding absorption spectrum for an organic dye in solution over the same wavelength range.

@2024 USPC

Polyatomic fluorophores in condensed media (e.g., solutions, thin films, and solids at room temperature) exist in ground or excited electronic states in a broad distribution of vibrational energy levels and cause homogeneous broadening of excitation or emission spectra, respectively. A microenvironment or shell also surrounds each fluorophore in condensed media, and differences in the structures of these shells among individual fluorophores cause inhomogeneous broadening. These two types of broadening cause fluorescence spectra to be broader than some other types of spectra (e.g., mid-infrared or Raman spectra). The typical width of a fluorescence band is between 10 nm and 100 nm. Once it is electronically excited, a polyatomic fluorophore experiences vibrational relaxation before emitting a photon, causing a red shift or Stokes shift of the fluorescence spectrum relative to the wavelength at which it was excited.

Few naturally occurring biological compounds fluoresce strongly. However, the development of a large array of fluorescent indicator dyes, used mainly to bind to ions or indicate pH or polarity, has led to increased interest in the use of both direct and secondary fluorescence techniques, e.g., fluorescence resonance energy transfer (FRET). While many of these probes inherently do not have very high quantum yields, their fluorescence changes greatly upon binding and upon the associated solution chemistry. For instance, the pH of the sample solution is an important factor to control when considering not only its impact on the fluorescence of the probe, but also on the detection of other possible fluorescing of fluorescent dye binding species. Some fluorescent probes, such as fluorescein (pH dependent) and rhodamine and its derivatives, have very large absorptivities and quantum yields approaching one—i.e., they fluoresce nearly as many photons as they absorb. Fluorescence methods are also termed *background-free* because very little excitation light reaches the detector. These advantages make fluorescence detection highly sensitive, down to single-molecule detection in some cases. Specificity and sensitivity are two of the more important strengths of fluorescence methods. Fluorescence spectroscopy also typically is not destructive to the sample, and measurements can be made quickly (on the order of seconds to minutes).

A right-angle or 0°/90° geometry often is used to measure dilute solutions and other transparent samples. In such cases, the excitation beam is normal to the sample, and fluorescence is detected at a 90° angle relative to the beam (*Figure 2a*). A front-face geometry is used to measure optically dense samples where the excitation beam is incident on the sample at <90° and the fluorescence is collected at an angle ≤90° (*Figure 2b*). The epifluorescence geometry is a special case of the front-face geometry that often is used in fluorescence microscopy and optical fiber–based fluorometers. In epifluorescence geometry the excitation beam and collected fluorescence are both normal to and are on the same side of the sample, i.e., a 0°/0° geometry. A 0°/180° transmitting geometry often is used in microscopy (*Figure 2c*).

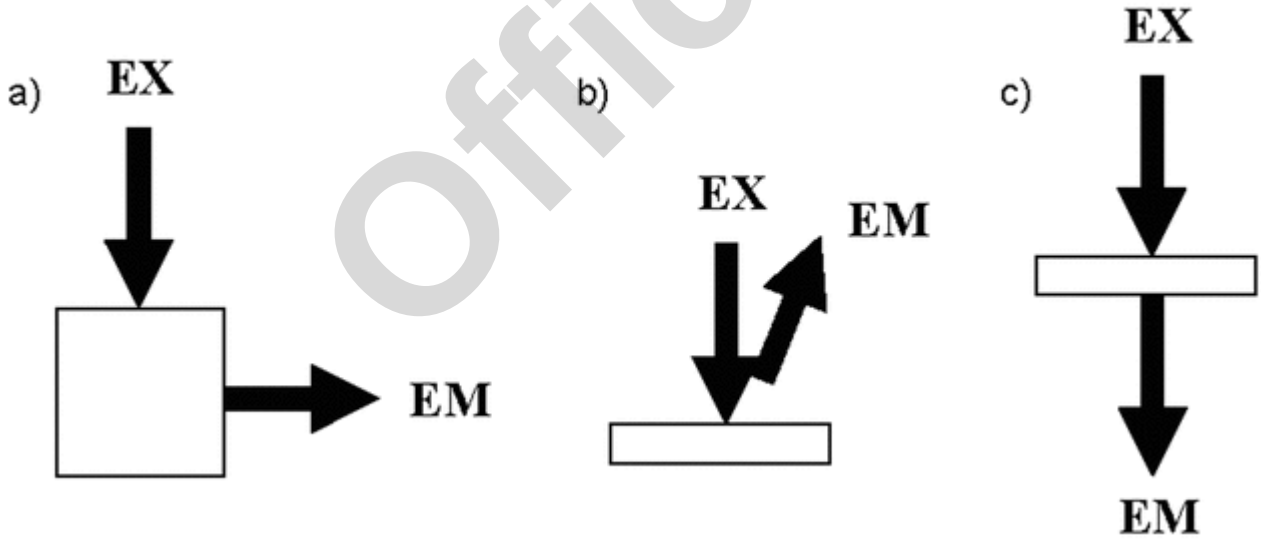

Figure 2. Schematic of the excitation beam (EX) and detected emission (EM) orientations for (a) 0°/90° right-angle transmitting, (b) front-face, and (c) 0°/180° transmitting geometries.

The number of chemical assays and screening methods using fluorescence detection continues to increase rapidly and has resulted in a corresponding increase in the need for standardization of fluorescence measurements. Only a few standard methods and reference materials have been well established and are readily available at present for the characterization of fluorescence measuring systems. National metrology institutes and international standards organizations are working to provide new fluorescence standard materials and methods in the near future. This general chapter briefly discusses the major issues that should be considered by users of fluorescence instruments who aim to achieve high-quality measurements. Standard methods and materials are also described where appropriate. A few guidelines and recommendations have appeared, but this general chapter aims to be most useful to nonexpert users of fluorescence spectrometers.

## INSTRUMENTATION

All modern fluorescence measurements involve irradiating the sample with the beam from a suitable light source, selecting the excitation wavelength, collecting the resulting fluorescence, rejecting the Rayleigh-scattered light, selecting the emission

Official

https://mathuseonly.com/

wavelength, and detecting the fluorescence signal. The following functions will be discussed individually, along with the equipment used to achieve these functions in commercial instruments:

1. excitation light source
2. excitation wavelength selector
3. sampling device
4. emission wavelength selector
5. detector.

### Excitation Light Source

A variety of lamps, lasers, and light-emitting diodes (LEDs) are used as excitation sources. Continuous and pulsed versions of these sources are used for steady-state and time-resolved instruments, respectively. Xenon lamps are the most commonly used because of their relatively high intensity and broad wavelength range (UV to NIR). Lasers are the highest-intensity sources and are used in applications where short collection times and small amounts of sample are required, e.g., for flow cytometry or microarrays.

### Excitation Wavelength Selector

The intensity of scattered light at the excitation wavelength (i.e., Rayleigh scattering) can be comparable to or greater than that of the fluorescence at the sample. Therefore, the excitation wavelength profile should not overlap the emission wavelength region being detected. This is achieved for lamps by using an excitation wavelength selector (e.g., a filter or a monochromator with a known peak transmission wavelength and bandwidth) between the lamp and sample. The inherent bandwidth of the radiation from a laser or an LED often is narrow enough that an excitation wavelength selector is not necessary. This selector also enables fluorescence excitation spectra to be resolved.

### Sampling Device

The sampling device includes all optics and other equipment needed to deliver the excitation beam to the sample, collect the emission from the sample, and hold the sample in place. Sample formats include cuvettes, microwell plates, microarrays, microscope slides, and flow systems and may be accompanied by a variety of optical delivery and collection systems, including conventional transmitting, front-face, and epifluorescence systems and fiber optic–based probes.

### Emission Wavelength Selector

As with the selector for excitation, the emission wavelength selector helps to ensure that the emission wavelength region being detected does not overlap with the excitation wavelength profile. This approach enables individual fluorescence bands to be detected when multiple bands are present and allows fluorescence emission spectra to be resolved. Emission wavelength selectors also are important for the rejection of stray light. Filters, monochromators, and grating polychromators often are used for emission wavelength selection.

### Detector

For the detection of emitted light, a photomultiplier tube (PMT) or a charge-coupled device (CCD) array is placed after the emission wavelength selector. The detection of the excitation beam in order to monitor its intensity commonly is done by a quantum counter detector or a photodiode placed before the sample and to which a small fraction of the excitation beam is split off from the rest.

## FACTORS THAT AFFECT QUANTITATION

### Instrument-Based Factors

Measurements on a fluorescence instrument require that instrument parameters such as wavelengths, bandwidths, and detector gain be set. All of these parameters can be set with varying degrees of repeatability and accuracy, depending on the instrument used. These factors can introduce measurement uncertainty or bias that is particularly significant when measured values are compared between instruments. For instance, the measured peak positions of the emission bands of two analytes may differ between instruments because of a wavelength bias. A corresponding bias between instruments could be introduced in the results of an assay that depends on the ratio of the fluorescence intensities at the two specified emission wavelengths.

The intensity of the excitation beam can change significantly with excitation wavelength or with time because of the wavelength dependence of the intensity of the light source and the transmittance of the excitation wavelength selector or the time dependence of the light source intensity. Thus analysts should monitor the excitation beam intensity and correct the measured fluorescence intensity for these fluctuations. This monitoring can be particularly important when excitation spectra are collected because the excitation intensity often has sharp peaks and valleys when lamp sources such as a xenon (Xe) lamp are used.

The responsivity of a detection system is not linear with intensity at all intensities, so analysts should know the linear intensity range of the detection system used. The linear range for most detection systems ranges from its limit of detection up to a

@2024 USPC

threshold intensity above which the responsivity becomes increasingly nonlinear with increasing intensity. Analysts should establish the linear range of the fluorescence detection system before they attempt to calibrate the responsivity of the detection system.

The responsivity of the detection system also is a result of the wavelength dependence of the transmittance of the emission wavelength selector and the responsivity of the detector. These factors can affect the shape of a measured emission spectrum.

The diffraction efficiency of gratings and the responsivity of detectors often depend on polarization. Changes to instrumental polarization settings can result in changes in the observed excitation intensity and the responsivity of the detection system. Even when polarizers are not used within the instrument, the excitation beam may be polarized by the optical system itself and may affect the responsivity of the detection system, and is instrument dependent. In addition, emission polarization effects not only can cause intensity differences but also can change spectral correction factors.

The passing of multiple wavelengths by a diffraction grating can introduce unexpected sharp peaks into a fluorescence spectrum. So that incident light is diffracted at a desired wavelength, a grating equation is used to set the angle of the grating with respect to incident light:

$$m\lambda = d(\sin\alpha + \sin\beta),\ m = 0, 1, 2, \ldots$$

$m$ = diffraction order
$d$ = groove spacing on the grating
$\alpha$ = angle of the incident wavefront relative to the grating normal
$\beta$ = angle of the diffracted wavefront relative to the grating normal

The value of $m\lambda$, not $\lambda$, is fixed, where $m$ is an integer termed the *diffraction order*. Therefore, the grating equation can be satisfied by more than one wavelength for a single grating position. For instance, if a grating in an emission monochromator is set to pass 500-nm light at first order, it also will pass 250-nm light at second order. As a result, the scattered light from a 250-nm excitation beam will be detected as a peak at an emission wavelength of 500 nm unless a suitable optical filter is inserted in the beam.

## Sample-Based Factors

The fluorescence intensity of optically dense samples (e.g., absorbance $A$ >0.05 at a path length of 1 cm) does not increase linearly with concentration because of significant absorption of the excitation beam and/or emission (reabsorption) by the sample. These inner filter effects also can greatly reduce the amount of fluorescence that reaches the detector, especially when a right-angle transmitting geometry is used. The fluorescence intensity can become strongly dependent on sample position and optical geometry. At even higher concentrations, aggregation of fluorophores often occurs, causing the shape of the fluorescence spectrum to be different from that of a dilute sample and also causing nonlinear concentration behavior.

The fluorescence intensity of a sample may decrease with time of exposure to light because of photobleaching and photodegradation. This is particularly true of most organic dyes, which are the most widely used fluorescent probes. Analysts should limit the time that such samples are exposed to light in order to obtain reproducible fluorescence intensities and in some cases even reproducible spectral shapes.

The fluorescence intensity of fluorophores is temperature dependent. Typically, the rates of fluorescence quenching processes, such as collisional quenching in solutions, increase with temperature and cause a decrease in fluorescence intensity. Temperature coefficients for fluorescence intensity for particular fluorophores can be used to correct for this temperature dependence.

The absorbance and consequently the intensity of fluorescence from a sample depend on the orientation of the sample's absorption transition dipole with respect to the polarization of the excitation light. The polarization of fluorescence is parallel to the direction of polarization of the fluorescent species' emission transition dipole. Fluorescence polarization is parallel to the orientation of the fluorescent species' emission transition dipole. Fluorescence anisotropy ($r$) is used to describe the extent of polarization of emission and is defined by:

$$r = (I_{\parallel} - I_{\perp})/(I_{\parallel} + 2I_{\perp})$$

$I_{\parallel}$ = observed fluorescence intensity when the fluorometer's emission polarizer is oriented parallel to the direction of the polarized excitation
$I_{\perp}$ = observed fluorescence intensity when the fluorometer's emission polarizer is oriented perpendicular to the direction of the polarized excitation

A sample whose fluorophores are oriented nonrandomly and have a rotational period that is long compared to their fluorescence lifetime will emit anisotropic fluorescence. The spectral shape and intensity of such fluorescence depend on the viewing angle and the instrument's polarization factors.

A fluorophore's fluorescence intensity and peak position, and sometimes even its spectral shape, often depend on the environment, including changes caused by the solvent used, the solution's pH, or the species to which the fluorophore is bound. For the above reasons care should be taken during the experimental design of a new methodology to consider and evaluate these effects, and matrix match the reference and unknown as appropriate.

A Raman signal can introduce peaks into the fluorescence spectrum. The Raman peaks of the sample's solvent or matrix are those most commonly encountered. For instance, the Raman peak of water, which is found red-shifted 3382 $cm^{-1}$ from the chosen excitation wavelength, typically is observed in the fluorescence spectrum of any aqueous solution excited by UV or blue light.

# CALIBRATION OF FLUORESCENCE INSTRUMENTS

Two types of fluorescence instrument calibrations are used. The first and most commonly used is analyte specific and determines the relationship between the response of the instrument (fluorescence intensity) and the concentration or amount of a specific analyte. The second is analyte independent and is intended for spectral instruments. In this case, the wavelength accuracy for emission and excitation and the spectral responsivity of the detection system are calibrated across the entire or a continuous part of the wavelength range of the instrument.

## Analyte Concentration—Calibration Curves

Calibration curves of instrument response (fluorescence intensity) vs. analyte concentration are determined using reference materials that contain the analyte of interest. For instance, the fluorescence intensities of a set of solutions at different, known analyte concentrations that cover a desirable concentration range can be measured and plotted vs. concentration. The plot then is fitted to a polynomial, typically a straight line. The resulting calibration curve is both analyte and instrument specific and can be used to determine analyte concentrations of unknown samples. This type of calibration may not be accurate when the microenvironment surrounding the fluorophore is different in the reference and unknown samples. In addition, users must ensure that the fluorescence intensities of samples are reproducible and do not decrease over the time when they are being excited and measured because the organic dyes typically used may be prone to photobleaching.

In some cases, calibration samples at known concentrations and prepared from appropriate reference materials may not be available. Firstly, organic dyes that are used as fluorescent probes often are not commercially available at a known high purity that enables production of reference solutions. Secondly, in complex systems where fluorophores are bound to large molecules, cells, or microbeads, the concentration of bound fluorophores in a solution or suspension may be difficult to determine. In the latter case, the molecules of equivalent soluble fluorophore (MESF) scale has been proposed as an alternative way to use calibration curves to quantify fluorescence intensity for a particular analyte.

## Emission Wavelength and Spectral Slit Width

A variety of reference standards have been proposed for use in the determination of emission wavelength accuracy, including atomic lamps and inorganic and organic fluorophores. The most widely used and best characterized of these are low-pressure atomic lamps, commonly termed *pen lamps.* In this case, the type of pen lamp (e.g., Hg, Xe, etc.) is chosen so that its radiated atomic lines are within the desired wavelength range. The lamp is placed at the sample position so that its light is centered in the optical path of the detection system of the instrument. The accuracy of this method may decrease if the pen lamp is not properly aligned. The emission wavelength selector–detector then measures the signal over the wavelength range of interest. The measured wavelength positions of the resulting sharp peaks then are compared with the known positions to determine wavelength accuracy.

The spectral slit width accuracy of the emission wavelength selector can be confirmed by measuring the spectral bandwidth, taken to be the full width at half the peak maximum, of a single line of a pen lamp. For fluorescence spectrometers with both excitation and emission monochromators, an alternative method can be used when one monochromator is scanned over the position of the other.

## Excitation Wavelength and Spectral Slit Width

Many of the reference samples that are used for determining emission wavelength accuracy also can be used for excitation wavelength accuracy. For instance, a pen lamp can be placed at the excitation light source position so that the resulting spectrum is detected after the excitation wavelength selector using the instrument's reference detector. However, in this case, a relatively weak signal may limit the number of useful atomic lines, and therefore alignment of the pen lamp is more critical in this instance than for the emission wavelength accuracy determination.

Once the accuracy of the emission wavelength selector has been determined, use a diffuse scatterer, e.g., a scattering solution or a diffuse reflector, at the sample to scatter a fraction of the excitation beam into the detection system to determine excitation wavelength accuracy. One wavelength selector is set at a fixed wavelength and the other is tuned over the same wavelength to obtain a spectrum. The wavelength bias between the two wavelength selectors is equal to the difference between the set wavelength position and the observed peak position of the collected spectrum. This method can be used at any wavelength, unlike many other methods that depend on a limited number of set excitation wavelengths determined by the reference material chosen. Methods similar to those used for spectral slit width accuracy of the emission wavelength selector also can be used to determine the spectral slit width accuracy of the excitation wavelength selector.

## Linearity of the Detection System

Several approaches are available to determine the detection system's linear intensity range. They can be separated into three types, based on the tools used to vary the intensity of light that reaches the detector: (1) double aperture, (2) optical filters and/or polarizers, and (3) fluorophore concentrations. The double-aperture method is the best established and probably is the most accurate when done correctly, but it also is the most difficult to perform. A variety of methods using optical filters, polarizers, or a combination of the two have been reported. These methods require high-quality, often costly, components and some user expertise. The third method is the most popular and is easiest. It uses a set of solutions obtained by serial dilution of a fluorescent stock solution that is similar to one used for obtaining calibration curves for analyte concentration, as described earlier. In this case, analysts use solutions with low concentration ($A$ <0.05 at 1-cm path length), but fluorophore adsorption to cuvette walls may affect measurements at very low concentrations. Users must ensure that the fluorescence intensities of

Official

https://pharmacopeia.cn/v-download/

samples are reproducible and do not decrease over the time that they are being excited and measured because the organic dyes typically used may be prone to photobleaching.

## Signal Level (Relative Emission)

Calibration of the relative responsivity of the emission detection system with emission wavelength, also referred to as spectral correction of emission, is necessary for successful quantification when intensity ratios at different emission wavelengths are compared or when the true shape or peak maximum position of an emission spectrum must be known. Such a calibration is required because the relative spectral responsivity of a detection system can change significantly over its wavelength range (*Figure 3*). Analysts should know the degree of photometric precision required for successful quantitation. The linear range of the detection system is determined before this calibration is performed, so that appropriate steps are taken (e.g., the use of attenuators) to ensure that all intensities measured during this calibration are within the linear range. When one uses an emission polarizer, the spectral correction for emission depends on the polarizer setting.

Two methods are preferred for calibrating photometric responsivity: one (*Method A*) uses light from a calibrated source (CS), and the other (*Method B*) uses certified reference materials (CRMs). Both give results that are traceable to national metrology institutes. A calibrated tungsten white light source is used most commonly for *Method A* and covers the wavelength range from about 350 nm into the NIR. Standard reference materials from the U.S. National Institute of Standards and Technology and CRMs from the German Federal Institute for Materials Research and Testing currently are available for use in *Method B*. Corrected emission spectra of some commonly used dyes also have been reported in the literature. *Method A* is more difficult to implement than *Method B* and requires periodic recertification of the CS. A third method, *Method C*, uses a calibrated detector and a calibrated diffuse reflector. This method typically has larger uncertainties than *Method A* and *Method B* but is recommended in UV and NIR wavelength regions that are not covered by the other two methods.

Official

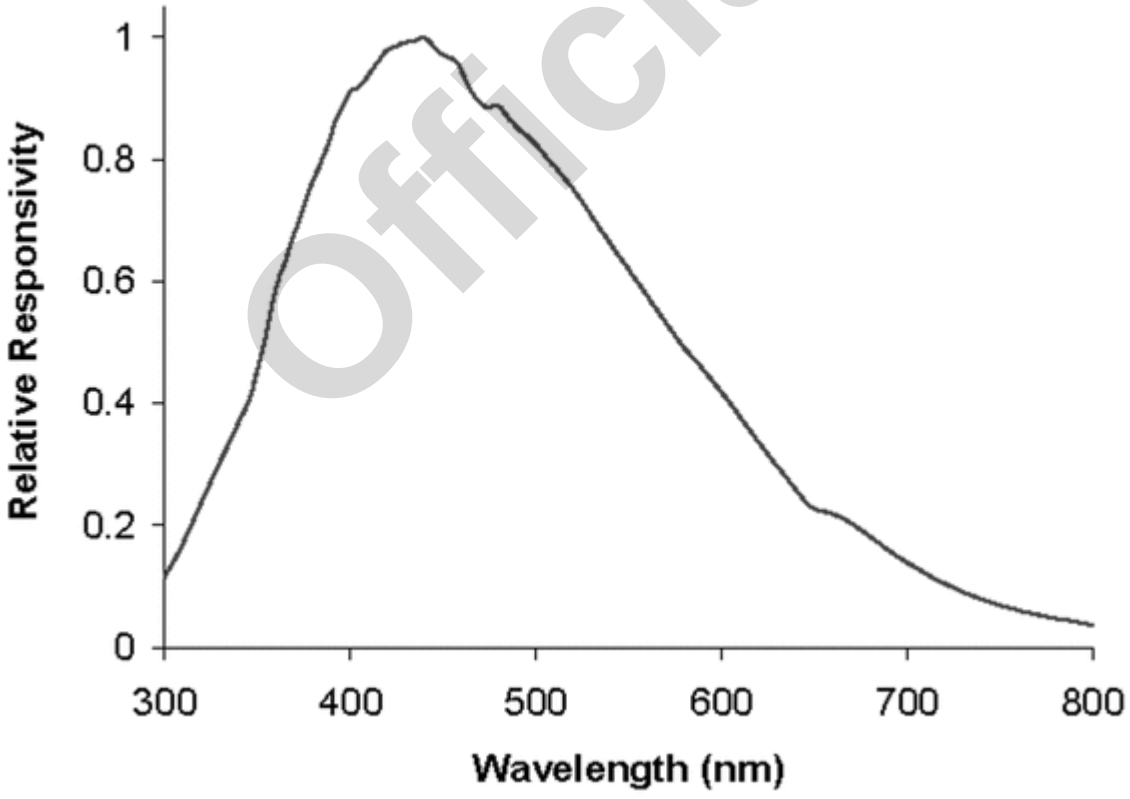

Figure 3. Example of the relative spectral responsivity of an emission detection system (PMT-based grating monochromator) for which a correction must be applied to a measured emission spectrum to obtain the true spectral shape (relative intensities).

### METHOD A

In *Method A*, analysts direct CS light into the emission detection system by placing the CS at the sample position. If the CS is too large to be placed at the sample position, analysts can place a calibrated diffuse reflector (CR) at the sample position to reflect the light from the CS into the emission detection system. The emission wavelength selector is scanned over the emission region of interest using the same instrument settings as used with the sample, and the signal channel output ($S'$) is collected.

@2024 USPC

The known radiance of the CS incident on the detection system ($L$) can be used to calculate the relative correction factor ($C_{CS}$) so that:

$$C_{CS} = L/S''$$

$C_{CS}$ = relative correction factor
$L$ = radiance of the CS incident on the detection system
$S''$ = signal channel output

The corrected emission intensity is equal to the product of the signal output of the sample and $C_{CS}$.

METHOD B

In *Method B*, analysts place the fluorescence standard at the sample position. Its spectrum is collected and is compared to the certified spectrum according to the instructions given on the accompanying certificate, which yields spectral correction factors for the instrument.

METHOD C

*Method C* involves two steps: Step 1 uses a calibrated detector (CD) at the sample position to measure the flux of the excitation beam as a function of excitation wavelength. Step 2 uses a CR to reflect a known fraction of the flux of the excitation beam into the detection system. This is done by placing the CD at the sample position at a 45° angle, assuming a 0°/90° instrument geometry, and synchronously scanning both the excitation and emission wavelength selectors over the emission region of interest while collecting both the signal output and the reference output. This method allows analysts to calculate the relative correction factor. This method has larger uncertainties than those for *Method A* or *Method B* and typically is more difficult to implement.

## Reference Signal Level (Relative Excitation)

Calibration of the excitation intensity with excitation wavelength is necessary for successful quantitation when analysts compare intensity ratios at different excitation wavelengths or when analysts must know the true shape or peak maximum position of an excitation spectrum. Such a calibration is necessary because the relative spectral flux of an excitation beam at the sample can change extensively over its wavelength range (see *Figure 4*). The neglect of excitation intensity correction factors can cause even greater errors than neglect of emission correction factors. Fortunately, many fluorescence instruments have a built-in reference detection system to monitor the intensity of the excitation beam. This monitoring usually is done using a photodiode, PMT, CCD, or a quantum counter detector to measure a fraction of the excitation beam that is split off from the rest of the beam. The collected reference signal can be used to correct the fluorescence signal for fluctuations caused by changes in the excitation beam's intensity. Reference detectors often are not calibrated with excitation wavelength, which introduces errors that can be particularly large over longer excitation wavelength ranges (e.g., >50 nm) or in a wavelength region where the excitation intensity changes rapidly with excitation wavelength (e.g., the UV range). When an excitation polarizer is used, the spectral correction for excitation intensity depends on the polarizer setting.

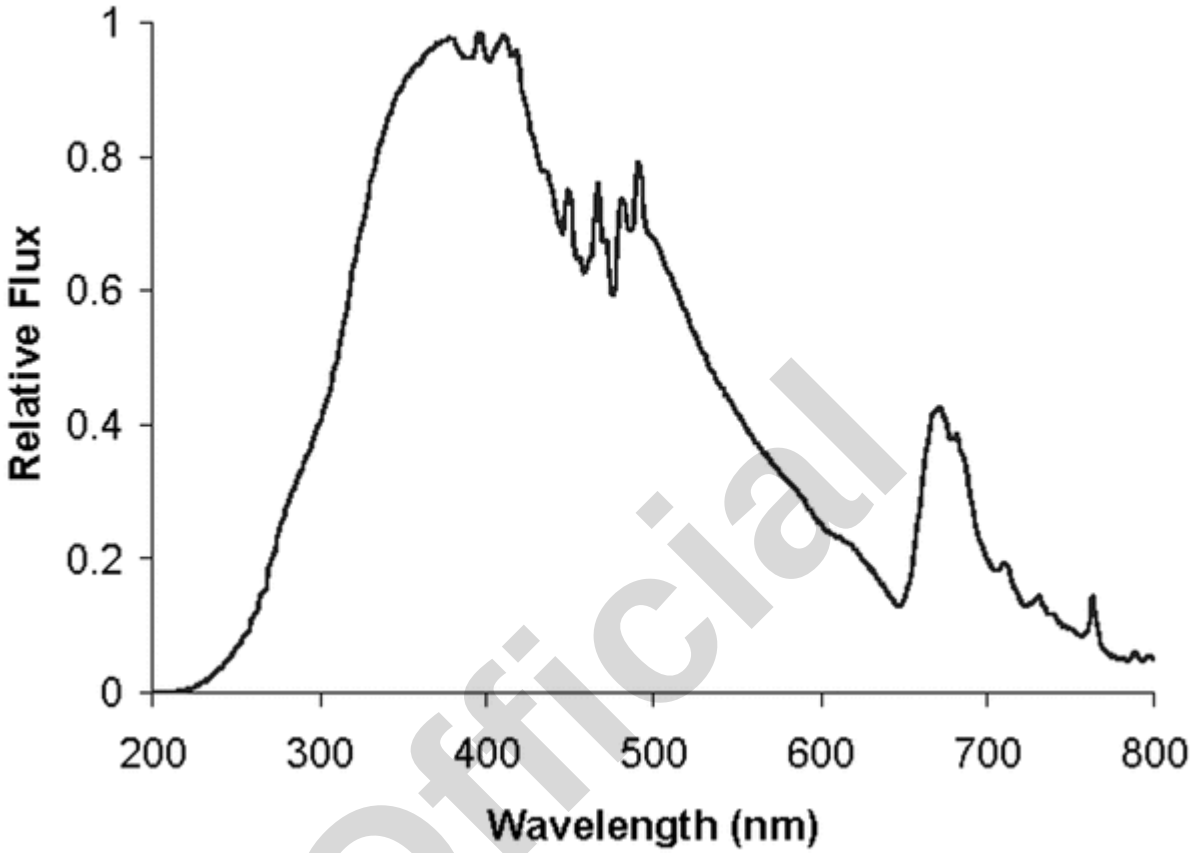

Figure 4. Example of the relative flux of an excitation beam (Xe lamp grating monochromator) for which a correction must be applied to a measured excitation spectrum in order to obtain its true spectral shape.

When a reference detector is not built into an instrument, a spectral correction for the reference channel or an independent spectral correction of excitation intensity is required. Three methods can be used to determine the spectral correction of excitation intensity: a CD (Method 1); a calibrated diffuse reflector (Method 2); or a quantum counter (Method 3). The latter two methods use the instrument's fluorescence detection system as a detector.

For Methods 1 and 2, the detector and diffuse reflector are calibrated for responsivity and reflectance, respectively, as a function of wavelength. For Method 2, excitation and emission wavelength selectors are scanned synchronously, and the spectral correction for the emission channel [see *Signal Level* (*Relative Emission*)] must be applied to the measured intensities. Method 3 should be used only in the quantum counter's effective wavelength range where a wavelength-independent response can be achieved. Method 1 using a CD has fewer caveats than do the other two methods. A CD is placed in the sample position, and the output is measured as a function of emission wavelength by scanning the excitation wavelength selector over the excitation region of interest using the same instrument settings as those used with the sample. The known responsivity of the CD is used to calculate the flux of the excitation beam. If the instrument's reference detector is used to measure the intensity of the excitation beam simultaneously with the CD, then the correction factor for the responsivity of the reference detector also can be calculated.

## Intensity and Sensitivity

The absolute value of the fluorescence signal measured by the detection system depends not only on the sample itself but also on the excitation intensity of the sample and the optical geometry of the instrument. Therefore, determination of instrument-independent fluorescence intensity of any sample or the absolute responsivity of any detection system in terms of the intensity of the sample or measured by the detector, respectively, relative to the excitation intensity can be difficult.

The most accurate way to calibrate an instrument for absolute intensity is to use conventional standards-based methods such as those that employ a calibrated light source or a calibrated detector in combination with a calibrated reflector. These methods require user skill and knowledge. Also, the (typically annual) certification and recertification are expensive. In addition, these standards tend to be bulky and are not compatible with many instruments. Thus, most researchers use simpler alternative standards and methods.

One approach is to correlate fluorescence signals to analyte concentrations using calibration curves or MESF units (see *Analyte Concentration—Calibration Curves*). Another approach is to measure the intensity of a standard sample that can be expected to always give the same fluorescence intensity under the same conditions.

Organic dyes, such as those used as fluorescent probes, generally are not good choices for intensity standards because of issues with photobleaching, stability, and reproducible concentration. If organic dyes are used, then those with known high purity and known shelf life, such as those produced by national metrology institutes, are recommended for single use (i.e., analysts should use a fresh solution for every measurement).

A better alternative is to use fluorescent samples that are stable over time even when exposed to light. For example, fluorescent, inorganic glasses with well-characterized photostability and spectral properties and long shelf lives are commercially available. Such materials can be used for determining a quasi-absolute intensity scale by measuring fluorescent signal at fixed wavelength values within their recommended range using specified experimental parameters such as bandwidths, excitation intensities, and temperatures.

The sensitivity of a fluorescence instrument is determined by measuring the signal-to-noise ratio of the fluorescence signal of intensity standards. The Raman line of water often is used to measure sensitivity in a similar way, but the Raman signal typically is strong enough only to be useful in the UV region. Analysts can use organic dye solutions to measure instrument sensitivity or limits of detection with caveats that are identical to those that apply when the solutions are used as intensity standards.

The methods outlined here yield a quasi-absolute intensity scale that should be instrument independent for instruments with similar optical geometries, designs, and settings. Results of these measurements enable comparison of the sensitivity of different fluorescence instruments, but these comparisons should be approached with caution because of the relatively large and difficult-to-quantify uncertainties involved.

## PROCEDURE VALIDATION

Validation of an analytical procedure using fluorescence demonstrates that the result is valid within a specified, acceptable uncertainty budget. Instrument qualification, which also may involve instrument calibration, usually is part of the process, and analysts also must consider sample-related errors (see *Sample-based Factors*). These can arise from concentration, anisotropy, photostability, and shape of the sample, in combination with effects of the instrument's optical geometry. All suspected errors should be quantified and combined to give a total estimated error that must be less than the method-specific, acceptable limit.

## GLOSSARY

**Absorptivity (a):** A measure of the absorption of radiation from an incident beam as it traverses a sample, which is equal to the quotient of:

$$A/bc$$

$A$ = absorbance
$b$ = path length (cm)
$c$ = concentration (mg/mL)

Also referred to as *specific absorption coefficient* by the International Union of Pure and Applied Chemistry.

**Absorption coefficient (α):** A measure of absorption of radiation from an incident beam as it traverses a sample according to Bouguer's Law:

$$I/I_0 = e^{-ab}$$

$I$ = transmitted intensity
$I_0$ = incident intensity
$e$ = base of natural logarithm
$a$ = absorptivity
$b$ = path length of the beam through the sample

Note that transmittance $T = I/I_0$ and absorbance $A = -\log T$.

**Beer–Lambert law (or Beer's law or Beer–Lambert–Bouguer law):** In the absence of any other physical or chemical factors, $A_\lambda$ is proportional to path length, $b$, through which the radiation passes and to the concentration, $c$, of the substance in solution in accordance with:

$$A_\lambda = \varepsilon_\lambda cb$$

$\varepsilon_\lambda$ = molar absorptivity
$c$ = solute concentration (M/L)
$b$ = path length (cm)

**Calibrated detector (CD):** A light detector whose responsivity as a function of wavelength has been determined along with corresponding uncertainties.

**Calibrated light source (CS):** A light source whose radiance as a function of wavelength has been determined along with corresponding uncertainties.

**Calibrated diffuse reflector (CR):** A Lambertian reflector whose reflectance as a function of wavelength has been determined along with corresponding uncertainties.

**Certified reference material (CRM):** A material with properties of interest, the values and corresponding uncertainties of which have been certified by a standardizing group or organization. A "reference material, accompanied by documentation issued by an authoritative body and providing one or more specified property values with associated uncertainties and traceabilities, using valid procedures" [International Vocabulary of Metrology (VIM) 5.14].

**Diffuse scatterer:** A material that scatters light in multiple directions. This includes diffuse reflectors, which often are Lambertian, and scattering solutions, which are not Lambertian.

**Fluorescence anisotropy (*r*):** A measure of the degree of polarization of fluorescence:

$$r = (I_{\parallel} - I_{\perp})/(I_{\parallel} + 2I_{\perp})$$

$I_{\parallel}$ = observed fluorescence intensity when the fluorometer's emission polarizer is oriented parallel to the direction of the polarized excitation

$I_{\perp}$ = observed fluorescence intensity when the fluorometer's emission polarizer is oriented perpendicular to the direction of the polarized excitation

**Fluorescence band:** A region of a fluorescence spectrum where the intensity passes through a maximum, usually corresponding to a discrete electron transition.

**Fluorescence lifetime:**[1] A parameter describing the time decay of the fluorescence intensity of a sample component. If a sample decays by first-order kinetics, this is the time required for its fluorescence intensity and corresponding excited-state population to decrease to $1/e$ of its initial value.

**Fluorescence quantum efficiency:** The ratio of the number of fluorescence photons leaving an emitter vs. the number of photons absorbed.

**Fluorescence quantum yield (Φ):** The probability that a molecule or species will fluoresce once it has absorbed a photon. This quantity is an innate property of the species and typically is calculated for a sample as the ratio of the number of molecules that fluoresce vs. the number of molecules that absorb. Fluorescence quantum yield values range from 0 (i.e., no molecules fluoresce) to 1 (theoretical maximum in which all molecules that had absorbed radiation fluoresce).

**Flux (or radiant flux):** The rate of propagation of radiant energy, typically expressed in watts. *Spectral flux* is the flux per unit spectral bandwidth, typically expressed in watts per nanometer.

**Grating equation:** It describes the relationship between the angle of diffraction and the wavelength of radiation that is incident on a grating:

$$m\lambda = d(\sin\alpha + \sin\beta)$$

$m$ = diffraction order

$d$ = groove spacing on the grating

$\alpha$ = angle of the incident wavefront relative to the grating normal

$\beta$ = angle of the diffracted wavefront relative to the grating normal

**Inner filter effects:** A decrease in the measured quantum efficiency of a sample caused by extensive absorption of the excitation beam or reabsorption of the emission by the sample itself. This causes the measured quantum efficiency to depend on the absorbance, concentration, and excitation and emission path lengths of the sample.

**Intensity:** A measure of the amount of electromagnetic energy present. This general definition is synonymous with or directly proportional to the signal output of a photodetector or the flux of a sample or light source. A more specific definition often used in radiometry is: the radiant flux per unit solid angle from a point source, which typically is expressed as watts per steradian ($W/sr$). [NOTE—Steradian corresponds to the SI unit of solid angle.]

**Lambertian reflector:** A surface that reflects light according to Lambert's law, i.e., the light is unpolarized and has a radiance that is isotropic or independent of viewing angle.

**Limit of detection (LOD):** An estimate of the lowest concentration of an analyte that can be measured with a given procedure, often taken to be the analyte concentration with a measured signal-to-noise ratio of 3.

**Noise level:** The peak-to-peak noise of a blank.

**Photobleaching:** A loss of emission or absorption intensity by a sample caused by exposure to light. This loss can be reversible or irreversible, and the latter typically is referred to as *photodegradation* or *photodecomposition.*

**Quantum counter:** A photoluminescent emitter with a quantum efficiency that is independent of excitation wavelength over a defined spectral range. When a quantum counter is combined with a detector to give a response proportional to the number of incident photons, the pair is called a *quantum counter detector*.

**Quasi-absolute fluorescence intensity scale:** A fluorescence intensity scale that has been normalized to the intensity of a fluorescent reference sample or artifact under a fixed set of instrumental and experimental conditions. This artifact should demonstrably yield a fluorescence intensity that is reproducible with time and between instruments under a fixed set of conditions.

**Raman scattering:** The inelastic scattering of radiation (the wavelengths of the scattered and incident radiation are not equal) by a sample that occurs because of changes in the polarizability of the relevant bonds of a sample during a molecular vibration. Unlike fluorescence, the radiation being scattered is not required to be in resonance with electronic transitions in the sample.

**Rayleigh scattering:** The elastic scattering of radiation by a sample; i.e., the scattered radiation has the same energy (same wavelength) as the incident radiation.

**Responsivity (spectral):** The ratio of the photocurrent output and the radiant power collected by a light-detection system. *Spectral responsivity* is the responsivity per unit spectral bandwidth.

**Sensitivity:** A measure of an instrument's ability to detect an analyte under a particular set of conditions.

[1] Boens N, Qin W, Basaric N, et al., Fluorescence lifetime standards for time and frequency domain fluorescence spectroscopy. *Anal Chem.* 2007;79(5): 2137–2149.

Official

https://pharmacopeia.cn/v-download/

**Spectral bandwidth (or spectral bandpass or resolution):** A measure of the capability of a spectrometer to separate radiation or resolve spectral peaks of similar wavelengths. Usually observed as the triangular dispersion of an emission line, this parameter is taken to be the full width at half the peak maximum (FWHM).

**Spectral slit width:** The mechanical width of the exit slit of a spectrometer divided by the linear dispersion in the exit slit plane. In practice, observed as the triangular dispersion of an emission line, this width includes all the transmitted wavelengths for a given slit setting.

**Transition dipole moment:** An oscillating dipole moment induced in a molecular species by an electromagnetic wave that is resonant with an energy transition of the species, e.g., an electronic transition. Its direction defines the transition polarization, and its square determines the intensity of the transition.

# ⟨1854⟩ MID-INFRARED SPECTROSCOPY—THEORY AND PRACTICE

## PRINCIPLES OF MID-INFRARED SPECTROSCOPY

Mid-infrared (mid-IR) spectroscopy involves measurement of the absorption of electromagnetic radiation over the wavenumber range of 4000–400 $cm^{-1}$ (which corresponds to the wavelength range of 2.5–25 μm) caused by the promotion of molecules from the ground state of their vibrational modes to an excited vibrational state. The most commonly used parameter to denote the energy of the transitions is the wavenumber, i.e., the number of waves per centimeter. The wavelength, λ (μm), and wavenumber, $\tilde{\nu}$ ($cm^{-1}$), of radiation are related by the expression:

$$\tilde{\nu} = 10^4/\lambda \quad (1)$$

The mid-IR spectrum extends from 4000 $cm^{-1}$ (2.5 μm) to 400 $cm^{-1}$ (25 μm). Molecules can move in a certain number of vibrational modes. The energy of mode, *i*, is given by:

$$E_i = hc\tilde{\nu}_i\left(v_i + 1/2\right) + hc\tilde{\nu}_i \times x_i\left(v_i + 1/2\right)^2 \quad (2)$$

$h$ = Planck's constant
$c$ = velocity of light
$\tilde{\nu}_i$ = fundamental vibrational frequency of mode *i* ($cm^{-1}$)
$v_i$ = vibrational quantum number of this mode
$x_i$ = so-called anharmonicity constant

The strongest bands in the mid-IR spectrum are caused by fundamental transitions from the ground state of a given mode ($v_i = 0$) to its first excited vibrational state ($v_i = 1$), although weaker overtone and combination bands also are observed in the spectrum. Overtone bands are caused by the promotion of molecules from their ground state to their second and higher vibrational states ($v_i = 2$, 3, etc.). Overtones are observed only for those modes for which $x_i$ is non-zero. Combination bands are caused by the simultaneous promotion of molecules to two excited vibrational states.

Vibrational modes involve the motion of all atoms of the molecule. Many modes involve only large-amplitude vibrations of the atoms in localized regions of the molecule, and the remaining atoms are largely unaffected. When molecules contain a certain functional group, the transitions often occur in narrow spectral ranges. In this case, the wavenumbers at which these transitions occur are known as *group frequencies*. When a vibrational mode involves atomic motions of more than just a few atoms, the frequencies occur over wider spectral ranges and are not characteristic of a particular functional group. Instead, they are more characteristic of the molecules as a whole. Such bands are known as *fingerprint bands*. All strong bands that absorb at wavenumbers above 1500 $cm^{-1}$ are group frequencies. Strong bands that absorb below 1500 $cm^{-1}$ can either be group frequencies or fingerprint bands. Thus, not all strong bands in the IR spectrum of a given molecule can be attributed to the presence of a particular functional group.

The motion of atoms during a particular vibrational mode, *i*, is characterized by the normal coordinate, $Q_i$. The intensity of fundamental bands is governed by the square of the change in dipole moment, μ, during the vibrational cycle $(\partial\mu/\partial Q_i)^2$. Thus vibrational transitions of modes involving polar groups, such as C–O, C=O, O–H, N–H, and C–F, typically give rise to strong bands in the spectrum. Where $(\partial\mu/\partial Q_i)$ is small, transitions are weak. When the symmetry of a molecule leads to the condition that $(\partial\mu/\partial Q_i) = 0$ for a certain mode, the band corresponding to this mode does not appear in the IR spectrum. Overtone and combination bands are always weaker than the fundamental modes from which they are derived.

For functional groups that have the form $XY_2$ (such as $–CH_2$, $–NH_2$, $–NO_2$, and $–SO_2$) and $XY_3$ (such as $–CH_3$ and $–NH_3^+$), first-order coupling can occur so that the mode is split into a symmetrical mode (where both the Y atoms move to and from the X atom with the same phase) and an antisymmetrical mode (where one Y atom moves 180° out of phase with the other). The amount by which the two bands are split depends on the Y–X–Y angle. The more closely this angle approaches 180°, the greater the splitting. Thus, for example, for the symmetric and antisymmetric stretching modes of ketenes and isocyanates where the angle is approximately 180°, the splitting can approach 1000 $cm^{-1}$, whereas for $CH_2$ and $CH_3$ groups where the angle is approximately 108°, the splitting is on the order of 100 $cm^{-1}$.

Second-order coupling, sometimes known as Fermi resonance, occurs when an overtone or combination band happens to occur at the same (or near coincident) wavenumber as a fundamental mode of the molecule that involves motion of the same atoms. In this case, the overtone or combination borrows intensity from the fundamental band, and the two bands split apart by as much as 40 $cm^{-1}$. The closer the bands that interact in this manner, the greater the splitting and the closer the intensity for the resulting bands.

## SAMPLING PROCEDURES

Mid-IR spectra can be measured by transmission, external reflection, internal reflection [often called attenuated total reflection (ATR)], diffuse reflection, and photoacoustic spectroscopy. Each of the major approaches is presented below.

## Transmission Measurements

The alkali halide disk and mulling procedures are the traditional mid-IR transmission sample presentation methods for materials that are in the form of a finely divided powder, as is the case for many drug substances and excipients. During preparation of a sample suitable for IR spectroscopy, the powdered material is uniformly dispersed throughout either the alkali halide or mulling agent, which acts as a support matrix for the analyte. Other procedures by which transmission spectra can be acquired include the use of solutions and compression cells. Neat compounds can be examined in a compression cell, as a self-supporting film (for polymers), as a capillary film between the IR-transparent cell windows (for liquids and semisolids), and as a gas.

The ratio of the single-beam spectrum of the sample and an appropriate background spectrum at a given wavenumber, $\tilde{\nu}$, is known as the transmittance, $T$-($\tilde{\nu}$). A transmittance spectrum is the direct output of most prism or grating spectrophotometers. For spectra measured on a Fourier transform-IR (FT-IR) spectrophotometer, the two single-beam spectra are measured at different times and are ratioed subsequently. An appropriate background spectrum should be measured. For alkali halide disks and mineral oil mulls where the diameter of the sample is usually greater than that of the focused beam, the background is measured with nothing in the sample compartment. If the sample diameter is smaller than that of the beam, the empty sample holder should be in place when the background spectrum is being measured. Similarly, the background for measurements made with an IR microscope should be measured with the same aperture that is used to measure the sample spectrum. For the measurement of ATR spectra, the background spectrum should be the clean internal reflection element.

Because transmission spectra of nonscattering samples obey the Beer–Lambert Law (usually abbreviated as Beer's Law), the transmittance commonly is converted to absorbance, $A$ ($\tilde{\nu}$), i.e., $\log_{10} 1/T$ ($\tilde{\nu}$). Beer's Law states that the absorbance of component $i$ at wavenumber, $A_i$ ($\tilde{\nu}$), is the product of the absorptivity of $i$ at that wavenumber, $a_i$ ($\tilde{\nu}$), the path length of the sample, $b$, and the concentration of $i$, $c_i$. The measured absorbance of a mixture at each wavenumber is the sum of the absorbances of each component of the mixture. Certain powdered alkali halides, such as potassium bromide, potassium chloride, and caesium iodide, coalesce under high pressure and can be formed into self-supporting disks that are transparent to mid-IR radiation.

## Potassium Bromide (KBr) Disks

The alkali halide most commonly used is powdered, dry, highly pure potassium bromide, which is transparent to mid-IR radiation to approximately 400 $cm^{-1}$. From this point, alkali halide disks will be referred to as *KBr disks* even though they can be made with other alkali halides such as potassium chloride and caesium iodide. IR spectroscopic-grade potassium bromide with a particle size of 100–200 mesh (about 100 µm in diameter) can be purchased commercially. Nonspectroscopic-grade material may contain impurities with absorption bands in the mid-IR region. One of the more common impurities is potassium nitrate, which has a sharp absorption band at approximately 1378 $cm^{-1}$. Powdered potassium bromide has a tendency to adsorb molecules from the air over a long period of time, so it must be stored properly. If the potassium bromide is not dry, its spectrum exhibits a broad absorption band caused by adsorbed water at approximately 3400 $cm^{-1}$, along with a weaker band near 1640 $cm^{-1}$.

Commercial presses and dies in a range of diameters are available for the preparation of alkali halide and similar disks. The most common diameter of KBr disks is 13 mm, but mini-disks with a diameter as small as 0.5 mm can be prepared using commercially available presses. Follow the manufacturer's recommended procedures for operating the disk-making accessory and the press.

Typically, the weight ratio of sample to alkali halide is on the order of 1 part of the sample to 100–400 parts of potassium bromide. An optimal procedure for preparing a 13-mm diameter disk is to pregrind the sample to a fine particle size in an agate mortar. A vibrating agate or steel ball mill also can be used. Then 1–2 mg of the ground sample is weighed and transferred to a clean mortar (or vial). A weighed amount of dry ground potassium bromide powder (300 mg) is then added and mixed gently with the analyte to form a homogeneous mixture. The optimum way of achieving homogeneity is to add about 10 mg of ground potassium bromide to the sample in a mortar and then to gently mix with the pestle. This is followed by successively adding doubled quantities of potassium bromide (i.e., approximately 20, 40, 80, and 160 mg) with mixing after each addition. The applied pestle action should induce good mixing with minimal grinding because further reduction of the potassium bromide particle size will lead to increased water absorption. (If the mixing is done in a vial, then the mixing time is shortened.) The mixture of potassium bromide and analyte is then transferred completely to a clean 13-mm die, which is filled and assembled according to the manufacturer's instructions. When the die is connected to a rotary vacuum pump, evacuate for about 2 min. The die (still under vacuum) is placed in a hydraulic press, and a pressure sufficient to form a disk that shows uniform transparency is applied. Discard any disk that visually shows lack of uniform transparency or exhibits poor transmittance at about 2000 $cm^{-1}$. Faulty, unsatisfactory, or poor-quality disks may be a consequence of inadequate or excessive grinding, moisture/humidity, or impurities in the dispersion medium.

## Mulls

To prepare a mull, homogeneously distribute the finely divided powder sample in a thin layer of a viscous liquid that is semi-transparent to mid-IR radiation and has a refractive index closely matched to that of the sample. The prepared mull is sandwiched between a pair of mid-IR–transparent windows, and a transmission spectrum of the mull preparation is recorded. The mull, which should have the consistency of a paste, is formed in such a manner as to minimize radiation scattering effects (radiation scatter from particles is worse when there is greater mismatch between the refractive index of the dispersant and surrounding medium). The sandwich can be clamped together in a mull cell. Commercial mull cells are available for both macro- and micro-preparations.

The most widely used mulling agent for the mid-IR region is a saturated hydrocarbon mineral oil (liquid paraffin, Nujol). This material has strong absorption bands of 3000–2800 $cm^{-1}$ and of 1500–1340 $cm^{-1}$, and a weaker band at 720 $cm^{-1}$ that may

Official

Printed by: USP NF
Do Not Distribute

obscure the absorption bands of the sample in these regions. In this case, a mull may require preparation in a chemically different oil. This can be achieved by the use of a perhalogenated oil mulling agent such as chlorofluoro substituted polymers. Combining the spectra of the sample prepared in the two mulling oils and ignoring the regions where one of them has strong absorption bands enables observation of the full mid-IR absorption spectrum with minimal interference.

For the preparation of a mineral oil mull, the particle size of the sample must be reduced to below that of the shortest wavelength of the interrogating radiation (2.5 µm) in order to minimize light-scattering effects that decrease spectral contrast and cause band distortions. The spectrum from a coarse powder or one that is poorly ground will show a high degree of scatter that is manifested as a sloping baseline that decreases toward shorter wavelengths (higher wavenumbers). Also, a coarser powder will increase the Christiansen effect, which is caused by reflection from the interface between materials of different refractive index. The refractive index of materials with strong absorption bands varies in a way that is similar to the first derivative of the profile of the absorption band—a phenomenon that is referred to as *anomalous dispersion*. The Christiansen effect is manifested as a transmission increase on the short-wavelength (high-wavenumber) side of an absorption band with a concomitant decrease on the longer wavelength side. Furthermore, a coarse, poorly dispersed powder can lead to a severely distorted mid-IR spectrum in which the relative intensity of the weaker bands is enhanced and the intensity of the more intense bands in the spectrum appears weaker and distorted. These effects are a consequence of radiation that has reached the detector but has not been transmitted through a representative sample of the analyte. Similar effects can be seen in the spectra of poorly prepared KBr disks.

During the preparation of mulls and KBr disks, some work is done on the analyte, either in the form of grinding, mixing, or pressing, and consequently there is the potential to induce solid-state form transformations. Although laboratory mechanical mills can produce powders with a small particle size, hand grinding using a mortar and pestle usually achieves better control and less aggressive processing for organic pharmaceutical materials. Practitioners generally accept that of the two procedures, the mull procedure is the less aggressive and is less prone to induce solid-state form changes such as changes in the crystallinity (polymorphism) or changes in the hydration or solvation state (pseudopolymorphism). The KBr disk procedure does, however, have advantages over the mull presentation method because potassium bromide exhibits no absorption bands above 400 $cm^{-1}$ (neglecting any adsorbed water or impurities) and is better adapted to micro-sample preparations. When the sample is a salt, as is frequently the case for active pharmaceutical ingredients (APIs), ion exchange can occur between the analyte and alkali halide, and the sample is better prepared as a mull.

## Compression Cells

The use of a compression cell has become a popular sampling procedure for recording a mid-IR transmission spectrum of a small or limited-quantity solid sample such as a single particle of an API or excipient, a contaminant such as a short length of fiber, or a small fragment from a packaging material. This is particularly the case for investigations using an IR microscope system. Type IIa diamonds are quite transparent over much of the mid-IR region, although they exhibit fairly strong absorption between approximately 2000 and 2400 $cm^{-1}$. Because of the high strength of diamond, it is commonly used as the window material of compression cells. The sample is placed between the diamond windows of the cell, the cell is then tightened, and the sample thickness is reduced to an optimum for a transmission measurement. The compressed sample can be examined while it is contained within the compression cell.

## Self-Supported Polymer Films

The mid-IR transmission spectrum of many polymers used as packaging materials can be recorded from samples prepared as thin self-supporting films. Films of appropriate thickness can be prepared by, for example, hot compression moulding a sample or microtoming a thin section from a sample. Soft and low-melting solids that do not crystallize when cooled can be prepared either as a thin layer sandwiched between two mid-IR–transparent windows by gently warming the sample or from the melt. Thin films from some materials can be cast from solution onto an IR-transparent window.

## Capillary Films

Nonvolatile liquids can be examined neat in the form of a thin layer sandwiched between two matching windows that are transparent to IR radiation. The liquid layer must be free of bubbles and must completely cover the diameter of the IR beam focused onto the sample.

## Liquids and Solutions in Transmission Cells

For the examination of liquid and solution samples, transmission cell assemblies that comprise a pair of windows constructed of mid-IR–transparent materials such as potassium bromide spacers, filling ports, and a holder are available commercially in both macro- and micro-sample configurations. They can be sealed, semi-permanent, or flow-through. A wide range of standard thickness spacers and window materials is available. For laboratory applications, spacers are typically formed from lead, poly(tetrafluoroethylene), or poly(ethylene terephthalate) and can be supplied, depending on spacer materials, in standard thickness path lengths from approximately 6 µm to 1 mm or larger.

The optimum path length required for examining a particular liquid or solution usually must be determined empirically and depends on its absorption characteristics and whether the application is qualitative or quantitative. In some instances for qualitative work, transmission cells can be replaced with disposable porous media such as polyethylene or poly(tetrafluoroethylene) mounted on a suitable backing.

## Gases

Mid-IR transmission cells for static or flow-through gas and vapor sampling are available in a wide range of materials to suit the application, from laboratory to process scale. In the laboratory, the traditional gas cell has been a 10-cm long cylinder made from borosilicate glass or stainless steel with an aperture of about 40 mm at each end. Each open end is covered with an end cap that contains one of a pair of mid-IR–transparent windows constructed from, for example, potassium bromide, zinc selenide, or calcium fluoride. The cell body is fitted with appropriate inlet and outlet ports. Different gases may present different sealing requirements that should be taken into account. For the detection of gases at the ppm level, long-path length cells constructed from borosilicate glass or metal are used. These cells can be of fixed path length of up to about 2 m or of variable path lengths of 10–200 m. Gas cells can be jacketed and operated at temperatures of 250° or greater, and their pressure ratings can range from vacuum to more than 50 atmospheres. Small differences in temperature and pressure have significant effects on the spectrum, and care must be taken to ensure that the calibration and analysis are performed under similar conditions such that the calibration remains valid.

## Attenuated Total Reflection Spectroscopy

Attenuated total reflection (ATR) spectroscopy, alternatively known as internal reflection spectroscopy or evanescent wave spectroscopy, has become a widely used procedure. This is largely a consequence of a new generation of simple-to-use single-reflection accessories.

ATR spectroscopy relies on the optical property that radiation passing through a medium of high refractive index, $n_2$ [the *optically dense* medium, also known as the internal reflection element (IRE)], at an angle of incidence greater than the critical angle will be totally internally reflected at a boundary in contact with a material of lower refractive index, the sample, $n_1$ (the *optically rare* medium). The critical angle, $\theta_C$, is given by $n_1/n_2$. The electric field of the radiation penetrates a short distance into the optically rare medium. The intensity of this electric field, which is known as the *evanescent wave*, is confined within the vicinity of the surface of the denser medium. Its intensity decreases exponentially with distance, normal to the surface, into the optically rare medium. It can, therefore, be envisaged as penetrating the surface layer of the rarer medium. The depth of penetration, $d_p$, is a convenient comparative term for different experimental arrangements. It is the distance from the surface of the IRE at which the amplitude of electric field amplitude falls to 37% ($1/e$) of its value at the surface:

$$d_p = \frac{\lambda_0}{2\Pi n_2 \sqrt{\left(\sin^2(\theta) - {n_{12}}^2\right)}} \quad (3)$$

(3)

$\lambda_0$ = wavelength of the radiation in vacuum
$\theta$ = angle at which the beam strikes the internal surface of the IRE
$n_{12} = n_2/n_1$

Note that, to achieve total internal reflection, $\theta$ must be greater than $\theta_C$, so that $n_2$ is usually greater than 2.3. Some of the more commonly used IRE materials are the following: zinc selenide ($n_2$ ~ 2.4), Type IIa diamond ($n_2$ ~ 2.4), silicon ($n_2$ ~ 3.4), and germanium ($n_2$ ~ 4.0). Furthermore, $d_p$ decreases with increasing angle of incidence and increases with increasing wavelength (decreasing wavenumber). As a consequence of the increase in $d_p$ with increasing wavelength, the band intensities within an ATR spectrum appear—by comparison with a conventional transmission spectrum—to be relatively increasingly enhanced with decreasing wavenumber.

Furthermore, the refractive index of all molecules is not constant and varies across absorption bands (anomalous dispersion). For strong absorption bands, $n_1$ can vary between approximately 1 and 2. This effect causes a shift in the measured wavenumber of a band with respect to transmission spectra. Particularly when equipment is operating at high angles of incidence or with an IRE with a low refractive index such as zinc selenide or diamond, strong bands may also be accompanied by the appearance of an underlying first-derivative-like shape (see above for a discussion of the Christiansen effect in KBr disks).

Many different geometrical shapes and sizes are used for IREs. A trapezoidal IRE is commonly incorporated into so-called horizontal ATR (H-ATR) units. Hemispherical IREs are the core of some micro-sampling ATR accessories. Rod or rod-like multiple internal reflection IREs are often used for on-line monitoring of liquid processes.

Multiple internal reflection (MIR) elements allow the internally reflected radiation in the IRE to interact several or many times with the surface layer of the sample with which it is in contact, thereby increasing the intensity (effective path length) of the recorded sample spectrum. Still, the spectrum recorded is characteristic only of the depth probed by a single reflection. The number of internal reflections depends on the length and thickness of the IRE. MIR elements may be several centimeters in length. A typical configuration for a vertically mounted 45° angle of incidence IRE may allow 25 internal reflections. Today the most commonly used MIR systems in the pharmaceutical laboratory are those in which the IRE is mounted horizontally. These are often referred to as H-ATR accessories. MIR systems based on cylindrical rods with cone-shaped ends or similar geometries are often incorporated as liquid-sampling devices in flow-through solution cells or are used for on-line process monitoring. The trapezoidal-shaped MIR elements incorporated into H-ATR accessories enable or facilitate study of a wide range of sample forms, including liquids, solutions, dispersions, creams, pastes, waxes, semi-solids and soft powders, continuous flat surface solids, solutions, films cast from solution, and many more. Micro– and macro–H-ATR accessories are commercially available with 1, 3, 9, or more sample-interaction reflections.

Single-reflection, simple prism, and novel design IREs are also used in commercial H-ATR units. They provide an effective and convenient means of analyzing and studying samples in a diverse range of physical forms. In particular, small contact area, single-reflection, fixed angle of incidence H-ATR accessories have become popular no-preparation sampling devices within the pharmaceutical industry because they provide a ready means to record, in a simple, quick manner, a mid-IR spectrum from a

@2024 USPC

limited quantity of almost any condensed-phase material. Hemispherical IREs act as focusing lenses so that the area sampled is generally smaller than that sampled with prismatic IREs. Even though the IRE may be opaque to visible light, many accessories listed above allow some form of viewing capability so that the sample under test can be inspected.

Single-reflection micro-ATR units have the advantage of virtually no requirement for a solid sample to have a uniformly flat surface. The test sample is placed in contact with the IRE sampling area and, if it is a solid, a clamp is used to compress and secure the sample against the IRE. Hemispherical ATR elements of zinc selenide, germanium, and silicon also form the sensing elements for ATR objectives that can be fitted to mid-IR FT-IR microscopes. Several of the accessories are capable of operation at controlled elevated temperatures that permit, for instance, studies relating to thermally induced, solid-state form transformations.

The hardness, scratch resistance, chemical inertness, and mid-IR transparency over a wide wavenumber range make the Type IIa diamond a unique material for ATR measurements. Even though it does have a broad absorption feature between approximately 2400 and 2000 $cm^{-1}$, for most pharmaceutical applications, this is not prohibitive because this is the region in which only characteristic stretching bands occur for triple and cumulated double bonds. Because of cost, the use of Type IIa diamond as an IRE material is usually restricted to micro-ATR accessories or when the IRE is used as the sensing element in an ATR immersion probe for process monitoring. Diamond has a refractive index that is closely matched to that of zinc selenide, so composite IREs can be constructed. Lower-cost focusing or support optics made from zinc selenide can be optically interfaced with a Type IIa diamond ATR sensing element, thereby minimizing the overall cost of the IRE while still benefiting from the properties of the diamond. On the basis of this technology, 3- and 9-reflection MIR configurations have been designed for both laboratory systems and process probes.

## External Reflection Spectroscopy

Several types of external reflection IR spectra can be measured. Among them are Fresnel reflection, transflection, reflection–absorption spectroscopy, and photoacoustic spectroscopy, but with the exception of diffuse reflection they are not widely used in pharmaceutical applications.

## Diffuse Reflection

Spectra recorded from powders or fairly fine granular samples are known as *diffuse reflection* (DR) spectra. Most of the spectrum originates from radiation that has penetrated through the surface of the sample and has been transmitted through multiple particles. A relatively small fraction of the DR spectrum originates from radiation that has been reflected from the front surface of the samples and therefore has the shape of a Fresnel reflection spectrum. Because the shapes of bands in mid-IR Fresnel reflection spectra are asymmetrical, the fraction of Fresnel reflection that contributes to a DR spectrum should be reduced to be as small as possible. This may be achieved in a number of ways, the most important and commonly used of which is to dilute the sample by mixing it with 90%–99% of a nonabsorbing diluent such as finely powdered potassium bromide or potassium chloride. The sample dilution has the added benefit of reducing absorption band intensities to an appropriate level.

DR spectra largely result from photons that have been transmitted through tens to hundreds of particles and, therefore, have an appearance similar to that of transmission spectra. However, DR spectra do not obey Beer's Law. Instead, the DR spectrum measured at infinite depth, $R_\infty$ (i.e., band intensities do not change if the thickness of sample is increased), is converted by the Kubelka–Munk function:

$$f\left(R_\infty\right) = \frac{\left(1 - R_\infty\right)^2}{2R_\infty} \quad (4)$$

The function $f(R_\infty)$ is equal to the ratio of the absorption coefficient to the scattering coefficient of the sample. DR is usually calculated by taking the ratio of the single-beam spectrum of the diluted sample to the single-beam spectrum of the neat diluent. Ideally, the sample is ground to the point that the average particle diameter is <5 µm. The sample–diluent mixture is thick enough that any increase in its thickness does not lead to a change in the spectrum. Samples measured in this way are said to be measured at *infinite depth*, and the reflectance is given the symbol, $R_\infty$. For mid-IR DR spectrometry, the infinite depth criterion is usually obeyed when the thickness is at least 100 µm, but to be conservative the depth of most sampling cups for mid-IR DR spectrometry is at least 1 mm.

A common way of preparing samples for DR spectrometry is to overfill the cup and to level the sample with a spatula or razor blade. However, this way of preparing the sample can lead to a difference between the scattering coefficient near the surface and in the bulk of the sample. Because the intensity of DR spectra depends on the scattering coefficient, a better sample preparation procedure is to slightly overfill the cup and to tap the base of the cup on a bench until the top surface is level with the rim of the cup.

Several types of accessories are used for the measurement of DR spectra. On-axis, or bright-field, DR accessories are similar to very efficient specular reflection accessories. They are the most efficient devices for the measurement of DR spectra but generally give the least rejection of Fresnel reflection. Off-axis, or dark-field, DR accessories are less efficient than on-axis devices but reject specular reflection more efficiently. Compound parabolic concentrators also have been adapted for DR measurements and appear to be intermediate in efficiency and Fresnel reflection between on-axis and off-axis accessories. Finally, integrating spheres have been used for DR spectrometry. These devices are the most accurate photometrically but are the least efficient.

# MICROSPECTROSCOPY AND IMAGING

## Transmission Microscopy

In any microscope, the area of a sample under study is defined by one or more remote masking apertures mounted at focused image planes conjugate to the sample focus plane. If the sample is mounted on a computer-controlled *x*–*y* stage, then successive neighboring or specified regions can be measured sequentially. These single-point spectra can be used to generate absorbance-intensity contour maps or false-color images that highlight differences or inhomogeneities across the area mapped. Such maps can also be generated by moving the sample manually, but this procedure can be very time consuming. The linear dimension of the smallest sample that can be studied by mid-IR FT-IR microscopy is approximately equal to the wavelength, i.e., approximately 10 µm. In practice, one can usually record a single-point spectrum of acceptable signal-to-noise ratio (SNR) and spectral resolution within a reasonable time-scale from a masked sample area of 10-µm diameter in about 1 min. For mapping over a relatively large sample area, where hundreds or even thousands of spectra are needed, a much more time-efficient process is to use an FT-IR microscope equipped with an array detector. Variable-temperature studies with thermomicroscopy observations and variable-temperature studies undertaken on an FT-IR microscope can be particularly useful for studying solid-state form and thermally induced transitions in situ.

As with macroscopic sampling, micro-samples presented for transmission FT-IR microscopy measurements should be flat. For a full mid-IR fingerprint spectrum, they should be of an appropriate thickness which, in the case of many APIs, may require a sample of approximately 10-µm thickness or less. Compression cells are particularly useful for thinning a sample. A thinned sample can be examined under compression or (less preferably) with the top window of the cell removed and the thinned sample examined while supported on the bottom window. A good practical means of providing an appropriate sample from which to record a single-beam background spectrum is to mount a small particle of potassium bromide alongside the sample and thin both by compression under the same conditions. The single-beam spectra of the sample and reference materials then can be measured under the same conditions simply by moving the compression cell using the *x*–*y* stage of the microscope.

Many continuous solids such as polymers used in packing or fibers found as contaminants can be prepared to an appropriate thickness and examined in a compression cell by FT-IR microscopy. Rolling with a tool specifically designed for this purpose can also sometimes decrease the thickness of soft samples. Laminated samples can be sectioned using a microtome and can be examined either free-standing or supported on an IR-transparent window. Analysts commonly use a microtome to get a cross-section from a multi-layer polymer laminate film so that its layer structure can be analyzed by FT-IR microscopy.

## Reflection Microscopy

All major types of reflection spectroscopy discussed above can be implemented on microscopes. Most microscopes have optical configurations that enable them to be switched from transmission to reflection measurements if the operator switches a simple flip mirror. The angle of incidence for these measurements is usually between 30° and 45° so that both Fresnel reflection and transflection measurements can be carried out easily. In contrast, special microscope objectives are required for ATR or reflection–absorption spectrophotometry.

For ATR microspectroscopy, the sample under investigation is supported on the microscope stage, and the ATR objective is lowered until the IRE is in optical contact with the uppermost surface of the sample. Reproducible contact pressure can be achieved by the use of a pressure gauge. A disadvantage of using a germanium IRE is that, unlike zinc selenide, it does not transmit visible light, which precludes in situ visual inspection of the sample. ATR mapping using a computer-controlled mapping stage in a manner analogous to that of transmission mapping is also possible, but this is usually restricted to soft materials.

## Hyperspectral Imaging

The term *hyperspectral imaging* came into use to describe the process whereby a focal plane array (FPA) detector is used to record simultaneously an array of spectra from a stationary sample. Each pixel of the array records a spectrum of a different region of the sample. This approach is a much more time-efficient process than single-point mapping if many spectra are measured from a large sample area. Typical array sizes for mid-IR applications are 256 × 256, 128 × 128, and 64 × 64. The individual mercury cadmium telluride (MCT) detector elements (pixels) of most FPAs are 6.25 µm × 6.25 µm. The detectors that are incorporated in the FPA are photovoltaic (PV) detectors, unlike the single-element photoconductive (PC) MCT detectors that are used for many FT-IR measurements (see below). Whereas PC MCT detectors operate at least to 750 $cm^{-1}$, PV detectors that are installed in FPAs typically have a low wavenumber cut-off in the region of approximately 900 $cm^{-1}$. Advances in digital electronics and FPA design enable 64 × 64 MCT FPAs to be used with an FT-IR spectrophotometer operating in the more conventional continuous-scan mode. The three-dimensional array of data sets, two spatial and one spectral, recorded in such an imaging measurement has become known as a *hypercube* or data cube.

An alternative way of hyperspectral imaging that is now commercially available is a hybrid approach in which a linear array of small PC MCT detectors is used in combination with a computer-controlled mapping stage. Adjacent regions are rapidly repositioned under the array detector until the full spatial region of interest has been covered. The full field image is built up as a mosaic of the individual area images recorded. In one system, which incorporates a 16-detector linear array, the lower wavenumber cut-off is approximately 700 $cm^{-1}$.

# INSTRUMENTATION

The majority of mid-IR spectra are measured with an FT-IR spectrophotometer. These instruments generally incorporate an incandescent silicon carbide (Globar®-type) source. The radiation emitted by the source is collimated and passed into a

continuous scanning two-beam interferometer. The rate of change of optical path difference in the interferometer (usually known as the *optical velocity*) is typically on the order of 0.2–5.0 cm · $s^{-1}$. The actual value depends on the detector and the analog-to-digital converter (ADC). The beam emerging from the interferometer is then focused at the center of the sample compartment of the spectrophotometer by an off-axis paraboloidal mirror. After being transmitted through, or reflected from, the sample, the beam is focused onto the detector. This signal is called an *interferogram*. The interferogram is a record of the variation of the AC component of the energy incident on the detector as a function of the optical path difference (retardation) of the interferometer. The Fourier transform of the interferogram is the single-beam spectrum.

The measurement usually involves passing a laser beam through the center of the interferometer, with the resulting sinusoidal interferogram measured by a detector of visible radiation at the same time the IR interferogram is measured by the IR detector. The usual laser used for this purpose is a helium–neon (HeNe) laser with a wavelength of 632.8 nm (15,802 $cm^{-1}$). This laser interferogram allows the exact position of the moving optical element in the interferometer to be determined. In FT-IR spectrophotometers equipped with an externally triggerable ADC, the IR signal is digitized at each wavelength of the laser interferogram, typically at the zero crossings. If the IR interferogram is sampled once per wavelength of a HeNe laser, the spectral range is restricted to 0–7901 $cm^{-1}$, i.e., one-half the wavenumber of the laser. In some contemporary FT-IR spectrophotometers, a sigma-delta ADC is used. These ADCs sample the interferogram at constant time intervals rather than at constant intervals of optical path difference, but they have a greater dynamic range than do externally triggered ADCs. In the latter case, the instrument's software calculates what the value of the interferogram would have been at the laser zero crossings.

In obtaining the spectrum of a sample, the single-beam spectrum of the sample and an appropriate reference are measured, and the ratio of these two single-beam spectra is calculated. If the spectrum is obtained in the transmission mode, the ratio is known as the transmittance spectrum, $T(\tilde{\nu})$. For many measurements, the negative logarithm of $T(\tilde{\nu})$ is calculated to give the absorbance, $A(\tilde{\nu})$. If the sample is interrogated in the reflection mode, the ratio is the reflectance spectrum, $R(\tilde{\nu})$. For ATR, transflection and reflection–absorption measurements, $R(\tilde{\nu})$, are usually converted to absorbance in the same way as for transmission spectroscopy. Conversion to $A(\tilde{\nu})$ is essential for quantitative measurements. For Fresnel reflection measurements, $R(\tilde{\nu})$ is often subjected to a Kramers–Kronig transformation to yield the absorption index spectra, $k(\tilde{\nu})$, and the refractive index spectra, $n(\tilde{\nu})$. For mid-IR diffuse reflection measurements, $R(\tilde{\nu})$ is usually converted by the Kubelka–Munk function (see *Equation 4*).

The standard detector used in FT-IR spectrophotometers is a room-temperature pyroelectric bolometer, most commonly deuterated triglycine sulfate (DTGS) or deuterated L-alanine-doped triglycine sulfate. These detectors respond to IR radiation of all wavelengths, and their low wavenumber cut-off is determined by the window behind which they are mounted. The window is typically selected to match the material on which the beamsplitter is deposited and is usually potassium bromide, so that the range is restricted to 400 $cm^{-1}$.

When the sensitivity of pyroelectric bolometers is inadequate, e.g., for measurements made through a microscope or with a gas chromatography interface, the more sensitive MCT detector is used. MCT detectors are generally operated in the photoconductive mode and are usually cooled to 77 K with liquid nitrogen ($LN_2$). Thermoelectrically cooled MCT detectors are available, but their low wavenumber cut-off is usually well above 1000 $cm^{-1}$, and they are not as sensitive as $LN_2$-cooled MCT detectors. Liquid nitrogen-cooled indium antimonide (InSb) detectors can also be used. These detectors are more sensitive than MCT but have a cut-off at 1800 $cm^{-1}$.

Two problems with MCT detectors should be noted. First, because they are more sensitive than DTGS detectors, they should be used only when the sample or sampling accessory attenuates the beam by at least a factor of 10. Otherwise, the ADC will be overloaded and the photometric accuracy of the spectrophotometer will be seriously affected. If the instrument is equipped only with an MCT detector (a rare circumstance), a neutral-density filter can be mounted in the spectrophotometer beam to reduce the energy of the beam at the detector to an appropriate level. Second, even when the ADC is not saturated, the response of MCT detectors is often nonlinear at high signal levels near the centerburst of the interferogram. The effect of this nonlinearity is to cause the baseline of the calculated single-beam spectrum to be displaced from zero. This effect can be seen readily when one plots the single-beam spectrum between 0 and 4000 $cm^{-1}$. If the average energy in the single-beam spectrum between, for instance, 400 and 300 $cm^{-1}$ is above or below zero, the detector is responding in a nonlinear manner in the region of the centerburst, and the photometric accuracy of the measurement is degraded concomitantly. Some vendors supply software to correct for this effect, but in general the signal should be reduced by inserting a neutral-density filter, not an aperture stop, in the beam.

## FACTORS THAT IMPACT MEASUREMENT PERFORMANCE

### Spectral Resolution

The main factor that affects the resolution of an FT-IR spectrophotometer is the maximum optical path difference of the interferogram. The nominal resolution, $\Delta\tilde{\nu}$, is the reciprocal of the maximum optical path difference.

The divergence angle of the beam passing through the interferometer may also degrade the resolution. The effective collimation of the beam that passes through the interferometer is determined by the limiting aperture of the optical system. In instruments designed for high resolution ($\Delta\tilde{\nu} > 0.5$ $cm^{-1}$), an adjustable aperture that serves the same purpose as the entrance aperture of a monochromator is installed at a focus between the source and the interferometer. As the desired resolution is increased (i.e., $\Delta\tilde{\nu}$ is made numerically smaller), the diameter of this aperture, which is known as the *Jacquinot stop* or J-stop, is decreased, making the divergence angle of the beam in the interferometer smaller; however, this procedure may increase the noise in the spectrum. In lower resolution instruments (typically those with a maximum resolution of 1 or 2 $cm^{-1}$), the detector serves the purpose of the Jacquinot stop.

If the true full-width at half-height of the bands or lines in the spectrum is less than $\Delta\tilde{\nu}$, side lobes are seen on each narrow spectral feature. These side lobes can be eliminated by apodization, i.e., multiplying the interferogram by a function that is equal to 1 at the centerburst and decays monotonically with optical path difference. Besides reducing the amplitude of the side

@2024 USPC
DOI: https://doi.org/10.31003/USPNF_M5512_02_01

lobes, apodization also has the effect of degrading the resolution (broadening the bands). When an interferogram is not weighted, it is often (incorrectly) said to be apodized with a boxcar apodization function, although a better term would be a boxcar truncation function. The selection of apodization function should be made on the basis of the purpose of the experiment, but it is usually limited to a few choices.

The Norton–Beer weak, medium, and strong apodization functions give the optimum combination of side-lobe amplitude for a loss in resolution of 20%, 40%, and 60%, respectively. The Norton–Beer medium apodization function is generally appropriate for many measurements of condensed-phase samples. The Happ–Genzel apodization function is also a nearly optimal function that degrades the resolution by about 50% (i.e., it is midway between the Norton–Beer medium and strong functions). A commonly available function is the triangular apodization function. This function has the effect of causing significant deviations from Beer's Law and is not recommended.

## Wavenumber Accuracy

The main factors that affect wavenumber accuracy are the alignment of the laser and IR beams in the interferometer and the divergence of the beam passing through the interferometer as observed with the IR detector. One might think that because the wavenumber of the laser beam is known very accurately, the wavenumber scale of a spectrum measured on an FT-IR spectrophotometer should be known to equal accuracy. However, the laser beam is highly collimated, whereas the beam from the IR source is not (a collimated beam can be obtained only from a point source). Because both the source and detector have a finite size, equal accuracy (of the wavenumber of the laser beam and the wavenumber scale of the spectrum measured) is never the case. As the diameter of the Jacquinot stop is decreased, a small wavenumber shift (always less than 0.25 $\Delta\tilde{\nu}$) will be observed. When the diameter of a sample is less than the diameter of the beam focus in the sample compartment or the sampling accessory, the effect is also to vignette the beam (i.e., to stop the beam down), and a small wavelength shift will be observed.

## Photometric Accuracy

The main factor that affects the photometric accuracy of FT-IR spectrophotometers is the linearity of the detector response. As noted above, the response of pyroelectric bolometers usually varies linearly with the energy on the detector, but this is not the case for MCT detectors. With MCT detectors, the best way of detecting photometric error is measurement of the nonphysical energy in the single-beam spectrum below the detector cut-off.

## Sensitivity

The sensitivity of the instrument can be determined by measuring two single-beam spectra under exactly the same conditions and calculating their ratio to produce what is commonly known as a 100% line. The noise level in different spectral regions can be estimated either as the peak-to-peak noise, i.e., the difference between the maximum and minimum values of the percent transmission in the selected spectral region(s), or the root-mean-square (RMS) noise, i.e., the standard deviation of the spectrum in that region. The RMS noise level is the preferred metric because this calculation involves all the data in the selected region rather than just the two most deviant points. An example of suitable measurement conditions to test the sensitivity of an FT-IR spectrophotometer equipped with a DTGS detector are 16 co-added scans, a resolution of 2 $cm^{-1}$, and Norton–Beer medium apodization. The most commonly used spectral region is 2200–2000 $cm^{-1}$ because (a) this is where the performance of most mid-IR spectrophotometers is highest, and (b) no common atmospheric interferent such as water or carbon dioxide absorbs strongly in this region. However, other regions should be tested close to the ends of the spectrum, such as 650–450 $cm^{-1}$ and 4000–3800 $cm^{-1}$. The SNR of the spectrophotometer operating with certain parameters in a given spectral region is estimated as 100/(RMS noise level in percent transmission).

## Beer's Law Linearity

For quantitative measurements, the spectrum is measured at a resolution that is at least twice as narrow as the narrowest band in the spectrum. The use of either the Norton–Beer medium or Happ–Genzel apodization function is recommended. For optimal photometric accuracy, the maximum absorbance of the analytical bands is no greater than 1.0 absorbance unit. Higher absorbance values can be tolerated with certain combinations of resolution and apodization functions. The effect of band width and peak absorbance on Beer's Law linearity for strong bands depends on the resolution and apodization function, and should be validated on a case-by-case basis.

## 1. THEORY

Near-infrared (NIR) spectroscopy is a technique with broad and varied applications in pharmaceutical analysis. The NIR spectral region lies between the ultraviolet (UV)-visible and infrared regions, and at one time was considered the forgotten region of the electromagnetic spectrum. It is a branch of vibrational spectroscopy that shares many of the principles that apply to other spectroscopic techniques. The NIR spectral region comprises two sub-ranges (see *Figure 1*) associated with detectors used in instrumentation. The short-wavelength (Herschel) region extends from approximately 780–1100 nm (12,821–9000 $cm^{-1}$), and the longer wavelengths, which fall between 1100 and 2500 nm (9000–4000 $cm^{-1}$), compose the traditional NIR spectral region. It is common to express the wavelength ($\lambda$) in nanometers (nm) and the frequency ($\nu$) in reciprocal centimeters (wavenumber) as acquired by the instrument. Usually, Fourier-transform (FT) spectrometers report the *x*-axis in wavenumber ($cm^{-1}$), whereas a dispersive, monochromator-based instrument will show the *x*-axis in wavelength (nm).

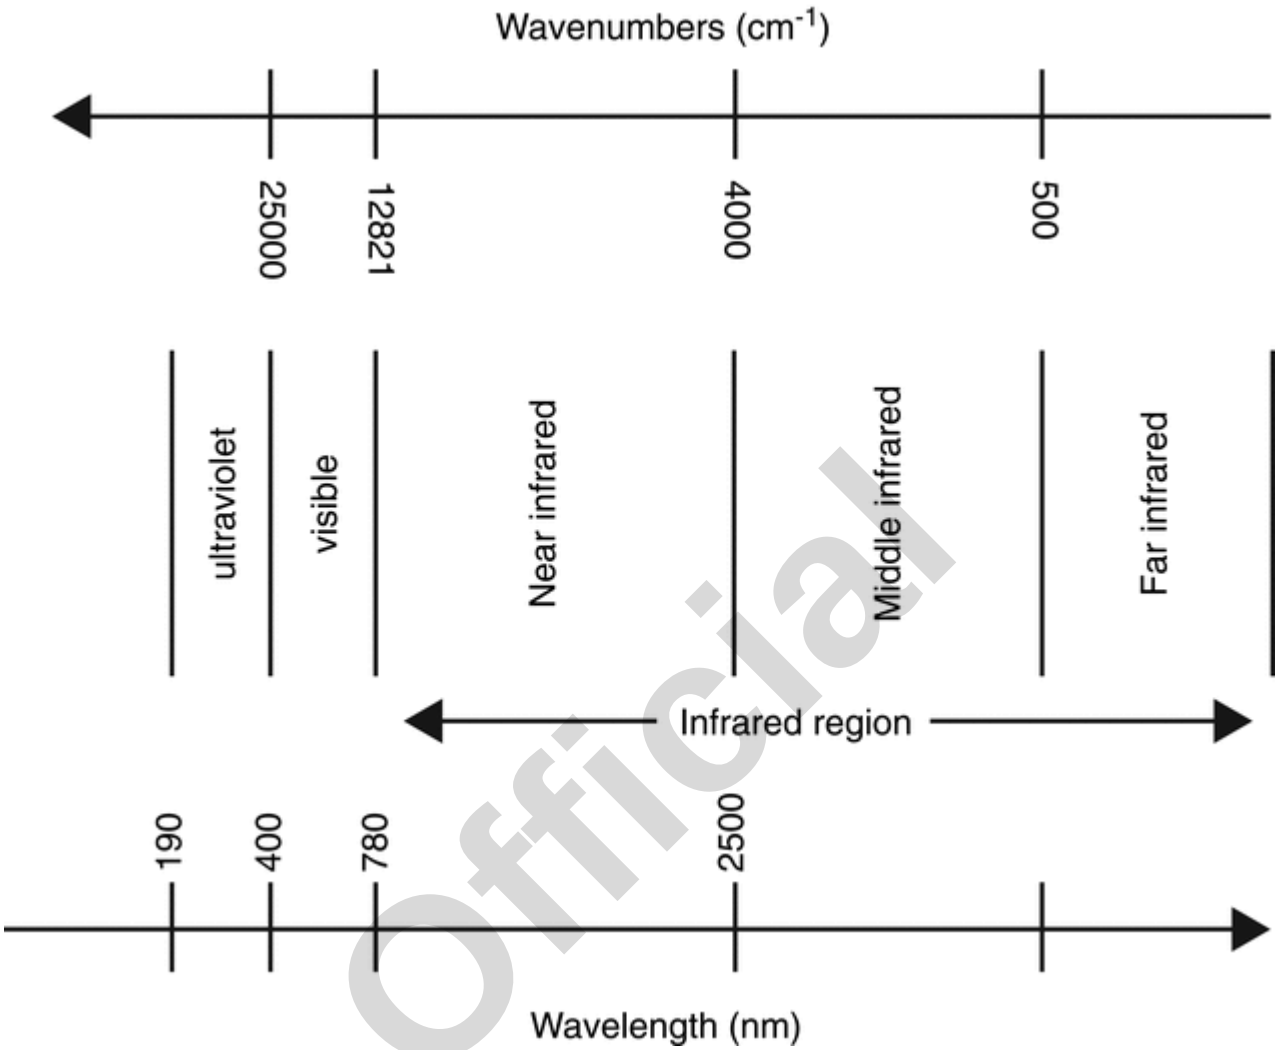

Figure 1. NIR region of the electromagnetic radiation spectrum.

NIR spectra are dominated by C-H, N-H, O-H, and S-H overtone resonances and combinations of fundamental mid-infrared vibrational modes from which they originate. Because molar absorptivities in the NIR range are low, radiation can penetrate several millimeters into materials, including solids where it can be absorbed when the wavelength of the radiation corresponds to a transition between the ground vibrational state of the analyte and either a harmonic of a given vibrational mode (an overtone) or the sum of two or more different modes (a combination band). Fiber-optic technology is readily implemented in the NIR range, which allows real-time, or near real-time, monitoring of processes in environments that might otherwise be inaccessible. As is the case with other spectroscopy measurements, interactions between NIR radiation and matter provide information that can be useful for both qualitative and quantitative assessment of the chemical composition of samples. In addition, qualitative and quantitative characterization of a sample's physical properties can be made because of the sample's influence on NIR spectra.

Measurements can be made directly on samples in situ in addition to applications during standard sampling and testing procedures. Applications of qualitative analysis include identification of raw material, in-process control testing, and finished-product release testing. NIR measurements can be performed off-line, but also at-line, in-line, and on-line for process analytical technology. These applications often involve comparing an NIR spectrum from a sample to a reference spectrum and assessing similarities against acceptance criteria developed and validated for a specific application. In contrast, applications of quantitative analysis involve the development of a predictive relationship between NIR spectral attributes and sample properties. Because of the highly covariant nature of the NIR signal, these applications typically use chemometrics models to quantitatively predict chemical and/or physical properties of the sample on the basis of its spectral attributes.

## 2. TRANSMISSION, REFLECTION, AND TRANSFLECTION MODES

The most common measurements performed in the NIR spectral range are transmission and reflection spectroscopy. Incident NIR radiation is absorbed or scattered by the sample and is measured as transmittance or reflectance, respectively.

## 2.1 Transmission Mode

Transmittance ($T$) is the intensity ratio of the transmitted radiation ($I$) to the incident radiation ($I_0$), which represents the decrease in intensity at given wavelengths when radiation is passed through the sample. The sample is placed in the optical beam between the source and the detector. The arrangement is analogous to that in many conventional spectrophotometers, and the result can be presented directly in terms of transmittance and/or absorbance ($A$). NIR spectra are usually measured in absorbance ($A$).

$$T = \frac{I}{I_0} \text{ or } T = 10^{-A}$$

$I$ = intensity of transmitted radiation
$I_0$ = intensity of incident radiation

The measurement of transmittance is dependent on a background transmittance spectrum for its calculation. Examples of background references include air, a polymeric disc, an empty cell, a solvent blank, or in special cases, a reference sample. The method generally applies to gases, liquids (diluted or undiluted), dispersions, solutions, and solids, including tablets and capsules. For transmittance measurements of solids, a suitable sample accessory is to be used. Tablets and capsules can be analyzed using suitably engineered holders, thereby ensuring reproducible measurements. Liquid samples are examined in a cell of suitable path length (typically 0.5–4 mm) that is transparent to NIR radiation, or alternatively by immersion of a fiber-optic probe of a suitable configuration. Gases are usually measured using dedicated long path-length, multiple reflection cells.

## 2.2 Reflection Modes

### 2.2.1 REFLECTANCE

Reflectance ($R$) is the ratio of the intensity of light reflected from the sample, $I$, to that reflected from a background or reference reflective surface, $I_R$.

It is composed of both the specular (mirror) and the diffuse components (see *Figure 2*).

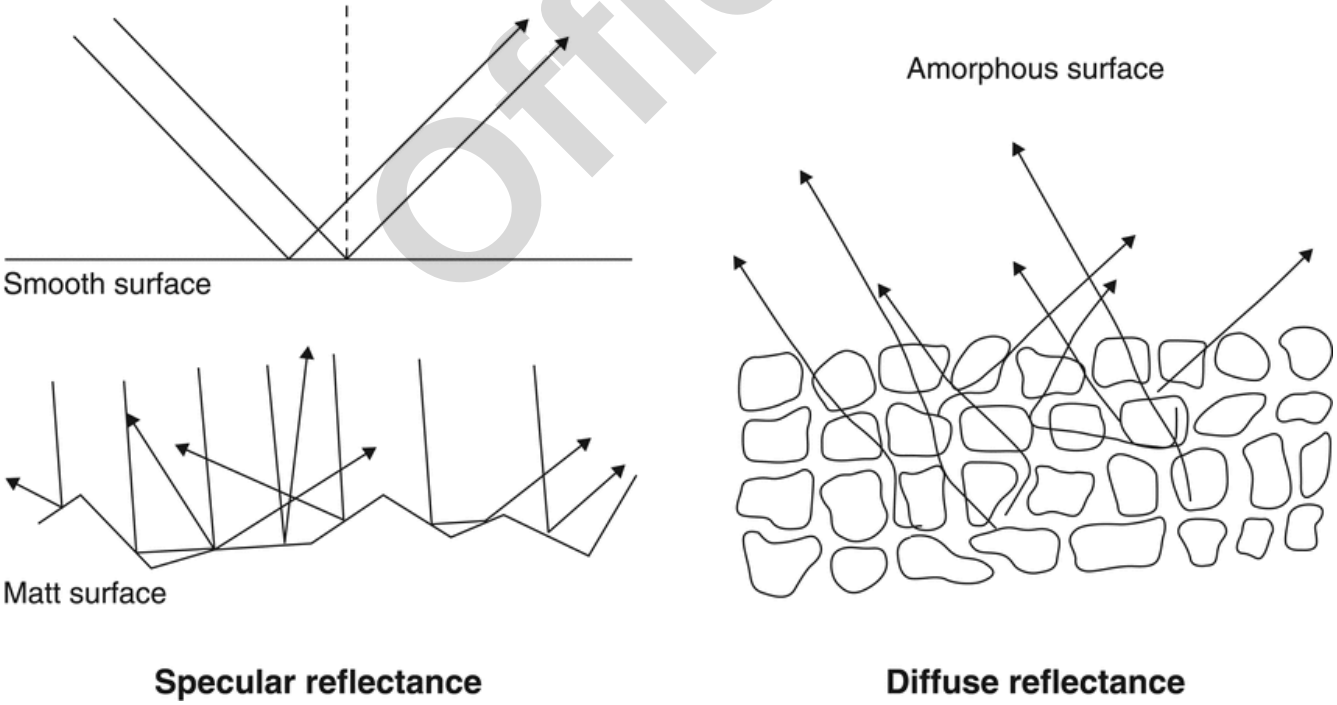

Figure 2. Specular and diffuse reflectances.

The determination of reflectance requires the measurement of a reference reflection spectrum to determine the attenuation of reflected light relative to the unattenuated incident beam. The reflectance spectrum is calculated as the ratio of the single-beam spectrum of the sample to that of the reference material.

$$R = \frac{I}{I_R}$$

$I$ = intensity of light diffusively reflected from the sample

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99838_02_01
@2024 USPC

$I_R$ = intensity of light reflected from the background or reference reflective surface

Most reflection measurements in the NIR spectral region are made of scattering samples such as powders and slurries. For such materials, NIR radiation can penetrate a substantial distance into the sample, where it can be absorbed when the wavelength of the radiation corresponds to a transition between the ground vibrational state of the analyte and either a harmonic of a given vibrational mode (an overtone) or the sum of two or more different modes (a combination band). Nonabsorbed radiation is scattered back from the sample to the detector. NIR reflectance spectra typically are accessed by calculating and plotting log (1/*R*) versus wavelength. Other abscissa data transformations can also be used. This logarithmic form is the pseudo-absorbance of the material and is commonly called absorbance.

#### 2.2.2 Diffuse Reflection

The diffuse reflection mode gives a measure of reflectance (*R*) (penetrating the sample surface, interacting with the sample, and passing back through the sample's surface), which is the ratio of the intensity of light reflected from the sample (*I*) to that reflected from a background or reference reflective surface ($I_r$), where by using careful instrumental design, the specular component is often excluded. NIR radiation can penetrate a substantial distance into the sample, where it can be absorbed by vibrational combinations and overtone resonances of the analyte species present in the sample. Nonabsorbed radiation is partially reflected back from the sample to the detector.

$$R = \frac{I}{I_r}$$

$I$ = intensity of light diffusively reflected from the sample
$I_r$ = intensity of light reflected from the background or reference reflective surface

This mode generally applies to solids. The sample is examined in a suitable device. For process monitoring, material can be analyzed through a polished glass (e.g., sapphire) window interface, or using an in-line probe. Care must be taken to ensure that the measuring conditions are as reproducible as possible from one sample to another. The reflected radiation of a background reference is scanned to obtain the baseline, and then the reflectance of one or more analytical samples is measured. Common reflectance references include ceramic tiles, thermoplastic resins, and gold. Other suitable materials may be used. In some process-analysis situations, it may be impossible to remove a probe for reference background data collection; in these cases, consider various options including internal referencing; measurement of a background reference using a second detector; and others. Only spectra measured against a background possessing the same optical properties can be compared directly with one another.

### 2.3 Transflection Mode

The term transflection (*T**) is used to describe any double-pass transmission technique. Transflection spectrometry is a hybrid of transmission and reflection wherein a reflector is placed behind the sample so that the optical path through the sample and back to the detector is doubled, compared with a transmission measurement of a sample of the same thickness. Nonabsorbed radiation is reflected back from the sample to the detector. The light may be reflected from a diffuse or specular (mirror) reflector placed behind the sample.

$$T^* = \frac{I}{I_{T^*}}$$

$I$ = intensity of transflected radiation measured with the sample
$I_{T^*}$ = intensity of transflected radiation of the reference material as background

This mode generally applies to liquids and clear plastic materials. This configuration can be adapted to share the same instrument geometry with reflectance and fiber-optic probe systems where the source and the detector are on the same side of the sample. The sample is examined through a cell with a mirror or a suitable diffusive reflector made of either metal or an inert substance (e.g., dried titanium dioxide) not absorbing in the NIR region. Liquids can also be measured using in-line transflectance probes to increase intensity levels for more sensitive applications.

## 3. FACTORS THAT AFFECT NIR SPECTRA

NIR spectroscopy is advantageous because, as a result of lower molar absorptivities in this region of the electromagnetic spectrum, accurate measurements can often be made quickly without destroying the sample, and with minimal or no sample preparation; this applies whether the samples are solid, semi-solid, liquid, or gas. The NIR spectrum contains information on overtone resonances and combination of fundamental vibrational modes of the sample that can yield both sample and process understanding. Samples may be analyzed directly through packaging or directly in media that is transparent to wavelengths in the NIR spectral region. In addition, by definition NIR spectra are produced using the corresponding NIR radiation, and therefore standard glass/quartz and fiber optics may be used.

The following discussion is not exhaustive, but it includes many of the major factors that affect NIR spectra.

Official

https://pharmacopeia.com/

## 3.1 Environmental Factors

The environmental temperature and humidity must be considered before carrying out measurements. Ideally, ambient conditions will be controlled to meet the operating specifications of the instrument manufacturer. However, tighter controls may not always be practical to the degree necessary for the application, and as such, another justifiable means of accounting for the influence of the environment (e.g., spectral preprocessing) should be utilized, with frequent verification. This is particularly relevant when considering the effect of temperature when using fiber-optic probes.

## 3.2 Sampling Factors

Depending on the measurement mode, sample preparation and presentation can vary. The following factors should be considered for all sampling techniques:

- Find the best suitable measurement mode for the intended application (transmission, diffuse reflection, or transflection)
- Find the best suitable accessory (e.g., transmission or immersion probes)
- Optimize path length in transmission and transflection modes
- Find a suitable spectroscopic background reference sample
- Show that the background reference sample is reliable over time and that the measurement of the background is reproducible and stable over time
- When measuring moving materials or samples (for process-related measurements), it is important to obtain a representative spectrum (e.g., by adjusting the measuring time or number of scans, by co-adding individual spectra, or by increasing the beam size)
- Ensure that there is not fouling of the sensor, for example, with build-up of material or contamination
- When measuring through packaging material, consider the variability of content and thickness
- Where multiple crystalline forms are present, care must be taken to ensure that the model calibration samples have a distribution of forms relevant to the intended application

### 3.2.1 SAMPLE PRESENTATION AREA

The sample presentation area or probe end must be clean and free of residue prior to the measurement. Similarly, the in-line or on-line interface to the sample should not have significant product or contamination build-up, which would interfere with the desired measurement.

### 3.2.2 SAMPLE TEMPERATURE

Sample temperature influences spectra obtained from aqueous solutions and other hydrogen-bonded liquids, and a difference of a few degrees may result in significant spectral changes. Temperature may also affect spectra obtained from less polar liquids, as well as solids that contain solvents and/or water.

### 3.2.3 MOISTURE AND SOLVENT

Moisture and solvent that are present in the sample material and analytical system may change the spectrum of the sample. Both absorption by moisture and solvent, and their influence on hydrogen bonding of the active pharmaceutical ingredients and excipients, can change the NIR spectrum.

### 3.2.4 SAMPLE THICKNESS

Sample thickness is a known source of spectral variability and must be understood and/or controlled, particularly for tablet and capsule analysis. The sample thickness in transmission mode is typically controlled by using a fixed optical path length for the sample. In diffuse reflection mode, the sample thickness may be controlled by using samples that are “infinitely thick” relative to the detectable penetration depth of NIR light into a solid material. Here, the term “infinite thickness” implies that the reflection spectrum does not change if the thickness of the sample is increased. For the measurement of compressed powders, an infinite thickness is typically reached after 5 mm of sample depth (e.g., in a filled vial).

### 3.2.5 SAMPLE OPTICAL PROPERTIES

With solids, both surface and bulk scattering properties of model calibration standards and analytical samples must be taken into account. Surface morphology and refractive index properties affect the scattering properties of solid materials. For powdered materials, particle size and bulk density influence scattering properties and the NIR spectrum. The spectra of physically, chemically, or optically heterogeneous samples may require sample averaging, examination of multiple samples, or spinning the sample to obtain a representative spectrum of the sample. Certain factors, such as differing degree of compaction or particle size in powdered materials and surface finish, can cause significant spectral differences.

### 3.2.6 SOLID-STATE FORMS

The variations in solid-state forms (polymorphs, hydrates, solvates, and amorphous forms) influence vibrational spectra. Hence, different crystalline forms as well as the amorphous form of a solid may be distinguished from one another on the basis of their NIR spectra. Where multiple crystalline forms are present, care must be taken to ensure that the calibration samples have a distribution of forms relevant to the intended application.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99838_02_01
@2024 USPC

#### 3.2.7 AGE OF SAMPLES

Samples may exhibit changes in their chemical, physical, or optical properties over time. Depending on the storage conditions, solid samples may either absorb or desorb water/solvent, and portions of amorphous materials may crystallize. Materials used for NIR model calibration are representative of future samples and their matrix variables. Hence, care must be taken to ensure that samples for NIR analysis are representative.

## 4. PRETREATMENT OF NIR SPECTRAL DATA

NIR spectral data to be used in qualitative or quantitative applications often need preprocessing to attenuate environmental or sampling factors, enhance a certain signal, or for other purposes that may include transformation, normalization, or other mathematical treatment. Preprocessing of samples (rows of data) may include mean or median centering, scaling, and other procedures. NIR responses (columns of data) also can be transformed, centered, or scaled. Because of the highly covariant nature of the NIR signal, it is common to remove linear or polynomial trends or apply filtering or smoothing techniques such as derivatives, wavelets, or a Savitzky–Golay filter. Spectral pretreatment techniques may include the numerical calculation of the first- or second-order derivative of the spectrum. Higher-order derivatives are not recommended because of increased spectral noise. For more detail, see *Chemometrics* ⟨1039⟩.

## 5. INSTRUMENTATION

### 5.1 Apparatus

All NIR measurements result from exposing material to incident NIR light radiation and measuring the attenuation of the emerging (transmitted, scattered, or reflected) light. Spectrophotometers for measurement in the NIR region consist of a suitable light source, such as a highly stable quartz–tungsten lamp, a monochromator or interferometer, and a detector. Common monochromators are acousto-optical tunable filters, gratings, or prisms. Traditionally, many NIR instruments have had a single-beam design, although some process instruments use internal referencing and can therefore be dual beam (for example, in diode array instruments). Silicon, lead sulfide, and indium gallium arsenide are examples of detector materials. Examples of sampling devices include conventional cuvette sample holders, fiber-optic probes, transmission dip cells, neutral borosilicate vials, and spinning or traversing sample holders. The choice is made on the basis of the intended application, with particular attention paid to the suitability of the sampling system for the type of sample to be analyzed. Suitable data processing and evaluation units (e.g., software and computer) are usually part of the system.

### 5.2 Imaging Techniques

NIR imaging is a combination of NIR spectroscopy with digital image processing. A NIR imaging system is basically composed of an illumination source, an imaging optic, a spectral encoder selecting the wavelengths, and a focal plane array. NIR imaging in particular has a huge potential for gaining rapid information about the chemical structure and related physical or biopharmaceutical properties of all types of pharmaceutical dosage forms, thus improving product quality and enhancing production speed.

Within a given material, the distribution of the various compounds can be characterized three-dimensionally by using imaging. Use of NIR imaging allows for the collection of detailed chemical information. NIR microscopy techniques have the following advantages:

- No preparation of the sample required
- Good spatial resolution
- Clear image quality
- Excellent chemical differentiation

It is possible to collect a signal from the entire sample (e.g., a tablet), disperse it into a spectrum using a spectrometer, and detect the spectrum using a multi-channel detector such as a charge couple detector or photo-diode array. In this case, instead of obtaining trivial cumulative information about the spot signal intensity, one can obtain a signal spectrum which can be transformed into detailed information about the chemical composition of the given spot on a sample. The three-dimensional array of data sets, two spatial and one spectral, recorded in such an imaging measurement has become known as a hypercube or data cube. These microscopy systems are capable of determining a spatial resolution down to approximately 1–5 µm.

NIR imaging systems are capable of characterizing the structure and distribution of the active components, and excipients within formulations, dosage forms, and delivery devices, to name a few. For example, chemical mapping for homogeneity testing of solid oral dosage forms, creams, and ointments may be useful in select applications.

### 5.3 Instrument Calibration Considerations

NIR instrument calibration involves three components: wavelength accuracy and uncertainty (*x*-axis); photometric linearity and response stability (*y*-axis); and photometric noise. *Table 1* provides an overview of performance verification criteria for a wide range of NIR systems.

### 5.3.1 PHOTOMETRIC NOISE

For any given method, the validation should include an estimation of the photometric noise of the system, as a change in this parameter may affect any future model calibration.

### 5.3.2 WAVELENGTH ACCURACY AND UNCERTAINTY (*X*-AXIS)

In the case of FT-NIR instruments, primary instrument wavelength-axis calibration is maintained, at least to a first approximation, with an internal helium–neon laser. NIR spectra collected by the conventional grating based spectra from sample and/or reference standard materials can be used to demonstrate an instrument's suitable wavelength-dispersion performance against target specifications. Suitable materials for demonstrating wavelength-accuracy performance include methylene chloride, talc *R*, spectral calibration lamps, polystyrene, mixtures of rare earth oxides, and absorption by water vapor. Certified traceable standards are available from the National Institute of Standards and Technology (NIST) for transmittance measurements (SRM 2035a) and reflectance (SRM 2036) and can be used for wavelength verification. Other suitable standards may also be used. Instrument manufacturers may use polystyrene films (thickness of 0.75–2 mm) as an internal standard for wavelength qualification and control. However, because of the weak asymmetric signals emanating from polystyrene at short wavelengths, this material may not be suitable as a reference standard across the whole NIR range. When choosing an appropriate reference standard, it is important to confirm that the operating parameters (e.g., resolution, band width, and others) are within the limits of the certified material.

The effect of temperature on assignment of wavelength must be taken into account. Typically, standards are measured in environments near 25°C, and the temperature at which certified values were taken will be indicated. The effect of resolution can also have an impact on the measured values. Resolution for FT-NIR spectrometers is typically 8 $cm^{-1}$, but modern spectrometers are capable of higher resolutions (2 $cm^{-1}$ or 1 $cm^{-1}$).

Standard certificates will indicate resolution and possibly even peak assessment algorithms. The choice of reference standard for a performance test should always match the resolution and environmental conditions expected for the execution of the test. Additional standards may be necessary, depending on the range of wavelengths or reference standards meeting these conditions.[1] Refer to *Table 1* and *Table 2* for additional information.

### 5.3.3 PHOTOMETRIC LINEARITY AND RESPONSE STABILITY (*Y*-AXIS)

Calibration of the photometric axis can be critical for successful quantification. Both FT-NIR and dispersive NIR spectrometers should undergo similar instrument calibration procedures. The tolerance of photometric precision acceptable for a given measurement should be assessed during the method development and validation stages.

NIR spectra from samples and/or reference standard materials with known relative transmittance or reflectance can be used to demonstrate a suitable relationship between NIR light attenuation (resulting from absorption) and instrument response. Verification of photometric linearity and verification of photometric noise are not required for instruments using methods to perform simple identifications that do not use the photometric absorbance as part of the model strategy (e.g., simple correlation with absorbing wavelengths). The USP Near IR System Suitability RS is recommended, but other certified traceable standards exist in the market and may be used. For reflectance measurements, commercially available reflectance standards with known reflectance properties are often used.

Spectra obtained from reflection standards are subject to variability because the experimental conditions under which they were factory calibrated differ from those under which they are subsequently put to use. Hence, the reflectance values supplied with a set of calibration standards may not be useful in the attempt to establish an "absolute" calibration for a given instrument. The reproducibility of the photometric scale will be established over the range of standards provided that 1) the standards do not change chemically or physically, 2) the same reference background is also used to obtain the standard values, and 3) the instrument measures each standard under identical conditions (including precise sample positioning). Subsequent measurements on the identical set of standards provide information on long-term stability. Refer to *Table 1* and *Table 2* for additional information.

Photometric linearity is demonstrated by using a set of transmission or reflection standards with known values for percentage transmittance or reflectance. For reflectance measurements, carbon-doped polymer standards are available. It is important to ensure that the absorbance of the materials used is relevant to the intended linear working range of the method. Nonlinear calibration models, which are acceptable, may be used, as long as the user can demonstrate adequate justification for this approach.

**Table 1. Control of Bench/Mobile Instrument Performance**

| Measurement Mode | Reflection | Transflection | Transmission |
|---|---|---|---|
| | Measure talc via a suitable medium or by fiber-optic probe. Talc has suitable-for-calibration, characteristic peaks at 948, 1391, 2077, and 2312 nm. Alternatively, other suitable standards may also be used that ensure wavelength accuracy in the region of working methodology. For example, measure an internal polystyrene standard if built in, or measure an NIST standard or other traceable material (e.g., USP Near IR System Suitability RS) and assess 3 peaks across the wavelength range for calibration. | A suspension of 1.2 g of dry titanium dioxide in about 4 mL of methylene chloride is used directly through the cell or using a probe. Titanium dioxide has no absorption in the NIR range. Spectra are recorded with a maximum nominal instrument bandwidth of 10 nm at 2500 nm (16 $cm^{-1}$ at 4000 $cm^{-1}$). Methylene chloride has characteristic sharp bands at 1155, 1366, 1417, 1690, 1838, 1894, 2068, and 2245 nm. Choose 3 peaks across the wavelength range for calibration. Other suitable standards may also be used, such as TS5 liquid mixed with titanium dioxide or some other reflective medium. | Methylene chloride may be used and has characteristic sharp bands at 1155, 1366, 1417, 1690, 1838, 1894, 2068, and 2245 nm. Choose 3 peaks across the wavelength range for calibration. Other suitable standards may also be used, such as NIST SRM 2065, Polystyrene 65 μm, and TS5 liquid. |
| Verification of wavelength scale (except for filter apparatus) | For FT instruments, the calibration of the wavenumber scale may be performed using a narrow, isolated water-vapor line (for example, the line at 7306.74, 7299.45, or 7299.81 $cm^{-1}$). | | |
| Verification of wavelength repeatability (except for filter apparatus) | The standard deviation of the wavelength is consistent with the specifications of the instrument manufacturer, or otherwise scientifically justified. Verify the wavelength repeatability using a suitable external or internal standard. | | |
| Verification of photometric linearity and response stability[a] | Measure 4 photometric standards across the working method absorbance range. Analyze 4 reference standards, for example, in the range of 10%–90%, including 10%, 20%, 40%, and 80% with respective absorbance values of 1.0, 0.7, 0.4, and 0.1. Evaluate the observed absorbance values against the reference absorbance values (for example, perform a linear regression). Acceptable tolerances are 1.00 ± 0.05 for the slope and 0.00 ± 0.05 for the intercept for the first verification of photometric linearity of an instrument. Subsequent verifications of photometric linearity can use the initial observed absorbance values as the reference values. | | |
| Verification of photometric noise | Determine the photometric noise using a suitable reflectance or transmittance standard (for example, white reflective ceramic tiles or reflective thermoplastic resins [i.e., polytetrafluoroethylene (PTFE)]). Follow the manufacturer's methodology and specifications. Scan the reflectance standard over a suitable wavelength range in accordance with the manufacturer's recommendation and calculate the photometric noise as peak-to-peak noise. | | |

[a] Burgess C, Hammond J. Wavelength standards for the near-infrared spectral region. *Spectroscopy*. 2007;22(4):40–48.

**Table 2. Control of Process Instrument Performance**

| Measurement Mode | Reflection | Transflection | Transmission |
|---|---|---|---|
| Verification of wavelength scale (except for filter apparatus) | If it is not practically possible to measure a traceable standard material at the point of sample measurement, use internal material such as polystyrene, fiberglass, or solvent and/or water vapor. Alternatively, adopt a second external fiber/probe. For FT instruments, the calibration of the wavenumber scale may be performed using a narrow, isolated water-vapor line (for example, the line at 7306.74, 7299.45, or 7299.81 $cm^{-1}$) or a narrow line from a certified reference material. | | |
| Verification of wavelength repeatability (except for filter apparatus) | The standard deviation of the wavelength is consistent with the specifications of the instrument manufacturer, or otherwise scientifically justified. Verify the wavelength repeatability using a suitable external or internal standard. | | |
| Verification of photometric linearity and response stability[a] | Measure 4 photometric standards across the working method absorbance range. | | |
| | If photometric reflectance standards cannot be measured at the point of sample measurement, use the manufacturer's internal photometric standards. Process instruments can use internal photometric standards for photometric linearity. Follow the manufacturer's verified tolerances in such cases. | Analyze 4 reference standards to cover the absorbance values over the working absorbance range of the modelled data. Evaluate the observed absorbance values against the reference absorbance values (for example, perform a linear regression). Acceptable tolerances are 1.00 ± 0.05 for the slope and 0.00 ± 0.05 for the intercept for the first verification of photometric linearity of an instrument. Subsequent verifications of photometric linearity can use the initial observed absorbance values as the reference values. | |
| Verification of photometric noise | Determine the photometric noise using a suitable reflectance or transmittance standard [for example, white reflective ceramic tiles or reflective thermoplastic resins (i.e., PTFE)]. Follow the manufacturer's methodology and specifications. | | |
| | As above, or if not practically possible, use the manufacturer's internal standard for noise testing and specifications. | Scan the transmittance high-flux standard over a suitable wavelength/wavenumber range in accordance with the manufacturer's recommendation and calculate the photometric noise as peak-to-peak noise. | |

### 5.3.4 EXTERNAL INSTRUMENT CALIBRATION

Detailed functional validation employing external reference standards is recommended to demonstrate instrumental suitability of laboratory instruments, even for instruments that possess an internal calibration approach. The use of external reference standards does not obviate the need for internal quality-control procedures; rather, it provides independent documentation of the fitness of the instrument for the specific analysis or purpose. For instruments installed in a process location or in a reactor where positioning of an external standard routinely is not possible, including those instruments that employ an

internal calibration approach, the relative performance of an internal versus an external calibration approach should be evaluated periodically. The purpose of this test is to check for changes or drifts in components (e.g., the process lens or fiber-optic probe) that might not be included in the internal calibration method; this could, for example, affect the photometric calibration of the optical system.

#### 5.3.5 MULTI-INSTRUMENT CALIBRATION

There are many approaches for ensuring a transferable calibration across multiple instruments of the same type (same make and model) and different types. This is an area of growing interest because of the globalization of manufacturing and regulatory controls. Today, reference standards have been developed to cover this region, but many deficiencies still exist regarding wavelength uncertainty and photometric response curves. Therefore, verification of compendial procedures, method transfers, and spectrometer platform changes is compromised by the bias involved in differences between instruments. Understanding the risk associated with these variations should be a part of any quality-by-design initiative to use NIR spectroscopic procedures for product control.

The use of appropriate certified reference materials can be helpful in establishing instrumental variance and/or bias. As stated above, the value assignments included on the certification of such materials will contain significant contributions to the overall expanded uncertainty budget from the instrumental factors used in generating these values. For example, the optical geometry, polarization, and other aspects of a reflectance measurement will significantly affect the measured value, and therefore wherever possible these characteristics should be matched to the required measurement configuration. However, by definition, a reference material should have the essential characteristics of appropriate stability and homogeneity to at least allow comparative measurements to be made, albeit they may be biased by known or unknown factors.

## 6. APPLICATIONS

NIR spectroscopy has a wide variety of applications for chemical, physical, and process analysis.

For chemical analysis, the applications include:

- Identification of active substances, excipients, dosage forms, manufacturing intermediates, chemical absorbance materials, and packaging materials
- Qualification of ingredients, intermediates, and drug products, including batch-to-batch spectral comparison and supplier change assessment
- Quantification of active substances and excipients; determination of chemical values such as hydroxyl value; determination of absolute water content; determination of degree of hydroxylation; and control of solvent content

For physical analysis, the applications include:

- Crystalline form and crystallinity, polymorphism, solvates, and particle size
- Analysis of intact pharmaceutical dosage forms: tablets, capsules, lyophilized products, and implants (e.g., polymeric and microspheres)
- Dissolution behavior, disintegration pattern, and hardness
- Examination of film properties

For process monitoring and process control analysis, the applications include:

- Monitoring of unit operations such as synthesis, crystallization, blending (e.g., powder), pelletization, tableting, capsule filling, drying, granulation, coating (e.g., film), and packaging for the purpose of process control

Measurements in the NIR spectral region are influenced by many chemical and physical factors. The reproducibility and relevance of the results depend on the control of these factors. Usually, measurements are only valid for a defined system.

### 6.1 Qualitative Analysis: Identification and Characterization

#### 6.1.1 ESTABLISHMENT OF A SPECTRAL REFERENCE LIBRARY

To establish a spectral reference library, record the spectra of a suitable number of representative samples of the substance; the samples should have known, traceable identities. These representative samples should exhibit the variation that is typical for the substance to be analyzed (e.g., variation in solid-state form and particle size). The set of spectra obtained represents the information that can be used for chemical and/or physical identification of the sample to be analyzed.

The collection of spectra in the library may be represented in different ways, which are defined by the mathematical technique used for identification. These may be:

- All individual spectra representing the substance
- A mean spectrum of the measured batches for each chemical substance or physical form
- If necessary, a description of the variability within the substance spectra

The number of substances to be included in the library depends on the specific application. All spectra in the library will have the same spectral range and number of data points; technique of measurement; and data pretreatment. If subgroups (libraries) are created, the above criteria should be applied independently to each group. Origin spectral data for the preparation of the spectral library must be archived. Caution must be exercised when performing any mathematical transformation, as artifacts can be introduced or essential information can be lost. The suitability of the algorithm chosen should be demonstrated by successful method validation, and in all cases, the rationale for the use of transformation must be documented.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99838_02_01
@2024 USPC

#### 6.1.2 NIR REFERENCE SPECTRA

NIR references provide known, stable measurements to which other measurements can be compared; thus, they are used to minimize instrumental and environmental variations that would affect the measurement. Direct comparison of representative spectra of the substance to be examined and a reference substance for qualitative chemical or physical identification purposes may not require use of a reference spectral library, where specificity permits.

#### 6.1.3 DATA EVALUATION

Direct comparison is made between the representative spectrum of the substance to be examined and the individual or mean reference spectra of all substances in the database on the basis of their mathematical correlation or other suitable algorithms. A set of known reference mean spectra and the variability around this mean can be used with an algorithm for classification; alternatively, this can be achieved visually by overlaying spectral data if specificity is inherent. Different calibration techniques are available, such as principal component analysis, cluster analysis, etc.

#### 6.1.4 VALIDATION OF THE MODEL

Chemical or physical identification methods using direct spectral comparison must be validated in accordance with identification method validation procedures. The validation parameters for qualitative methods are robustness and specificity.

#### 6.1.5 RELATIVE COMPARISON OF SPECTRA

A model calibration is not required when comparing a set of spectra for limit analysis purposes, such as determining the maximum or minimum absorbance at which an analyte absorbs. Also, in-process control of a drying operation may use a qualitative approach around a specific absorbing wavelength. Appropriate spectral ranges and pretreatments (if used) must be shown to be fit for purpose.

#### 6.1.6 SPECIFICITY

The relative discriminatory power and selectivity of a limit test must be demonstrated. The extent of specificity testing is dependent on the application and the risks being controlled. Variations in matrix concentrations within the operating range of the method must not affect the measurement.

### 6.2 Trend Analysis

#### 6.2.1 RELATIVE COMPARISON OF SPECTRA

NIR-based models can also be used to assess process trajectories. An example application is the use of NIR-based models to determine the endpoint of blending operation. Typically, a reference trajectory is defined based on a pool of batches that are deemed to present nominal variability; then each new batch trajectory gets compared with the reference trajectory and associated tolerances.

A model calibration is not necessarily required when comparing a set of spectra for trend analysis purposes, for example, using the moving-block approach to estimate statistical parameters such as mean, median, and standard deviation. For example, blend-uniformity monitoring using NIR spectroscopy has adopted such data analysis approaches. Appropriate spectral ranges and algorithms must be used for trend analyses.

#### 6.2.2 SPECIFICITY

The relative discriminatory power and selectivity for trend analysis must be demonstrated. The extent of specificity testing is dependent on the application and the risks being controlled. Variations in matrix concentrations within the operating range of the method must not affect the trend analysis.

### 6.3 Quantitative Analysis

#### 6.3.1 SPECTRAL REFERENCE LIBRARY FOR A CALIBRATION MODEL

Calibration is the process of constructing a mathematical model to relate the response from an analytical instrument to the properties of the samples. Any calibration model that can be defined clearly in a mathematical expression and gives suitable results can be used. Record the spectra of a suitable number of representative samples with known or future-established values of the attribute of interest (for example, content of water) throughout the range to be measured. The number of samples for calibration will depend on the complexity of the sample matrix and interferences (e.g., temperature, particle size, and others). It is encouraged to take a risk management approach to identify critical interferences that may need to be assessed. All samples must give quantitative results within a calibration interval as defined by the intended purpose of the method. Multiple linear regression, principal component regression (PCR), and partial least squares regression (PLS) are commonly used. For PLS or PCR calibrations, the regression coefficients and/or the loadings should be plotted, and the regions of large coefficients or loadings should be compared with the spectrum of the analyte. Predicted residual error sum of squares plots or similar plots are useful for facilitating the optimization of the number of PCR or PLS factors. For more information, see ISO 12099.

Official

https://pharmacopeia.com/

### 6.3.2 PRETREATMENT OF DATA

Wavelength selection, or exclusion of certain wavelength ranges, may enhance the efficiency of calibration models. Wavelength compression (wavelength averaging) techniques, multiplicative signal correction (MSC), standard normal variate transformation (SNV), and derivatives may be applied to the data.

### 6.3.3 MODEL VALIDATION PARAMETERS

Analytical performance characteristics to be considered for demonstrating the validation of NIR methods are similar to those required for any analytical procedure. Specific acceptance criteria for each validation parameter must be consistent with the intended use of the method. Validation parameters for quantitative methods are accuracy, linearity over the operational range, precision (repeatability and intermediate precision), robustness, and specificity.

### 6.3.4 ONGOING MODEL EVALUATION

NIR models validated for use are subjected to ongoing performance evaluation and monitoring of validation parameters. If discrepancies are found, corrective action is necessary.

## 7. PROCEDURE VALIDATION

Validation of NIR methods will follow the same protocols described in *Validation of Compendial Procedures* ⟨1225⟩ in terms of accuracy, precision, and other suitable parameters. It may be necessary to determine QL for methods of detection and quantification of an impurity or polymorphic form.

Detector linearity must be confirmed over the range of possible signal levels. Method precision must also encompass sample position. The sample presentation is a critical factor for both solids and liquids, and must be either tightly controlled or accounted for in the calibration model. Sample-position sensitivity can often be minimized by appropriate sample preparation or sample holder geometry, but will vary from instrument to instrument on the basis of excitation and optical configuration. In addition, many suitable chemometric algorithms for data pretreatment and calibration are available. Selection of an algorithm should be based on sound scientific judgment and suitability for the intended application.

## 7.1 Ongoing Method Evaluation

Validated NIR methods should be subject to ongoing performance evaluation, which may include monitoring accuracy, precision, and other suitable method parameters. If performance is unacceptable, corrective action is necessary. This involves conducting an investigation to identify the cause of change in method performance, and may indicate that the NIR method is not suitable for continued use. Improving the NIR method to meet measurement suitability criteria may require additional method development and documentation of validation experiments demonstrating that the improved method is suitable for the intended application. The extent of revalidation that is required depends on the cause of change in method performance and the nature of corrective action needed to establish suitable method performance. Appropriate change controls should be implemented to document ongoing method improvement activities.

Revalidation of a qualitative model may be necessary as a result of the following:

- Changes in instrument hardware
- Addition of a new material to the spectral reference library
- Changes in the physical properties of the material
- Changes in the source of material supply
- Identification of previously unknown critical attribute(s) of material(s)

Revalidation of a quantitative model may be necessary as a result of the following:

- Changes in the composition of the test sample or finished product
- Changes in the manufacturing process
- Changes in the sources or grades of raw materials
- Changes in the reference analytical method
- Major changes in instrument hardware

## 7.2 Method Transfer

Controls and measures for demonstrating the suitability of NIR method performance following method transfer are similar to those required for any analytical procedure. Any exceptions to general principles for conducting method transfer for NIR methods should be justified on a case-by-case basis. The transfer of an NIR method is often performed by using an NIR calibration model on a second instrument that is similar to the primary instrument used to develop and validate the method. When a calibration model is transferred to another instrument, procedures and criteria must be applied to demonstrate that the calibration model meets suitable measurement criteria on the second instrument. The selection of an appropriate calibration-model transfer procedure should be based on sound scientific judgment.

## GLOSSARY

[NOTE—This section refers to the technique of NIR in general. Please see *Analytical Instrument Qualification* ⟨1058⟩ and ⟨1039⟩ for additional information.]

**Absorbance:** Absorbance (*A*) is represented by the equation:

$$A = -\log T = \log (1/T)$$

where *T* is the transmittance of the sample. Absorbance is also frequently given as:

$$A = \log (1/R)$$

where *R* is the reflectance of the sample.

**Background spectrum:** This is used for generating a sample spectrum with minimal contributions from instrument response; it is also referred to as a "reference spectrum" or "background reference". The ratio of the sample spectrum to the background spectrum produces a transmittance or reflectance spectrum dominated by NIR spectral response associated with the sample. In reflection measurements, a highly reflective, diffuse standard reference material is used for the measurement of the background spectrum. For transmission measurement, the background spectrum may be measured with no sample present in the spectrometer or using a cell with the solvent blank or a cell filled with appropriate reference material.

**Diffuse reflectance:** Ratio of the spectrum of radiated light (penetrating the sample surface, interacting with the sample, and passing back through the sample's surface) reaching the detector to the background spectrum. This is the component of the overall reflectance that produces the absorption spectrum of the sample.

**Fiber-optic probe:** This consists of two components: optical fibers that may vary in length and number, and a terminus, which contains specially designed optics for examination of the sample matrix.

**Installation qualification:** The documented collection of activities necessary to establish that an instrument is delivered as designed and specified and is properly installed in the selected environment, which is suitable for the instrument's intended purpose.

**Instrument bandwidth or resolution:** A measure of the ability of a spectrometer to separate radiation of similar wavelengths.

**Operational qualification:** The process of demonstrating and documenting that an instrument performs according to specifications and that it can perform the intended task. This process is required following any significant change, such as instrument installation, relocation, or major repair.

**Overall reflectance:** The sum of diffuse and specular reflectance.

**Performance qualification:** The process of using one or more well-characterized and stable reference materials to verify consistent instrument performance. Performance qualification may employ the same or different standards for different performance characteristics.

**Photometric linearity:** Also referred to as "photometric verification", it is the process of verifying the response of the photometric scale of an instrument.

**Pseudo-absorbance:** *A*, is represented by the equation:

$$A = -\log R = \log (1/R)$$

where *R* is the diffuse reflectance of the sample.

**Reference spectrum:** See *Background spectrum*.

**Reflectance:** Is described by the equation:

$$R = \frac{I}{I_R}$$

in which *I* is the intensity of radiation reflected from the surface of the sample and $I_R$ is the intensity of radiation reflected from a background reference material and its incorporated losses due to solvent absorption, refraction, and scattering.

**Root-mean-square (RMS):** Calculated using the equation:

$$\text{RMS} = \sqrt{\sum_{i=1}^{N} \frac{\left(\hat{A} - A_i\right)^2}{N}}$$

where $\hat{A}$ is the mean absorbance over the spectral segment; $A_i$ is the absorbance for each data point; and *N* is the number of points per segment.

**Specular (surface) reflectance:** The reflectance from the front surface of the sample, where the angle of reflection matches the angle of incidence (mirror effect).

**Standard error of calibration (SEC):** A measure of the capability of a model to fit reference data. SEC is the standard deviation of the residuals obtained from comparing the known values for each of the calibration samples to the values that are calculated from the calibration. SEC should not be used as an assessment tool for the expected method accuracy (trueness and precision of prediction) of the predicted value of future samples. The method accuracy should generally be verified by calculating the *Standard error of prediction (SEP)* using an independent validation set of samples. An accepted method is to mark a part of the calibration set as the validation set. This set is not fully independent but can be used as an alternative for the determination of the accuracy.

**Standard error of the laboratory (SEL):** A calculation based on repeated readings of one or more samples to estimate the precision and/or accuracy of the reference laboratory method, depending on how the data were collected.

**Standard error of prediction (SEP):** A measure of model accuracy of an analytical method based on applying a given calibration model to the spectral data from a set of samples different from, but similar to, those used to calculate the calibration model. SEP is the standard deviation of the residuals obtained from comparing the values from the reference laboratory to those from the method under test for the specified samples. SEP provides a measure of the model accuracy to be expected when one measures future samples.

**Surface reflectance:** Also known as "specular reflection", it is that portion of the radiation not interacting with the sample but simply reflecting back from the sample surface layer (i.e., the sample–air interface).

**Transflection:** A transmittance measurement technique in which the radiation traverses the sample twice. The second time occurs after the radiation is reflected from a surface behind the sample.

**Transmittance:** Represented by the equation:

$$T = \frac{I}{I_0} \text{ or } T = 10^{-A}$$

where $I$ is the intensity of the radiation transmitted through the sample; $I_0$ is the intensity of the radiant energy incident on the sample ; and $A$ is the absorbance.▲ (USP 1-May-2020)

# ⟨1857⟩ ULTRAVIOLET-VISIBLE SPECTROSCOPY—THEORY AND PRACTICE

***Change to read:***

## THEORY

Ultraviolet-visible (UV-Vis) spectroscopy is an electronic transition spectroscopic technique in which the interaction between incident radiation and electrons results in the promotion of one or more of the outer or the bonding electrons from a ground state into a higher-energy state. This quantum effect results in a specific absorption of radiation, the frequency and wavelength of which are governed by the equation:

$$E = h\nu = \left(\frac{hc}{\lambda}\right) \times 10^9$$

where:

$E$ = energy
$h$ = Planck's constant ($6.63 \times 10^{-34} J \cdot s$)
$\nu$ = frequency (Hz), related to the energy change $\Delta E$, induced when electromagnetic radiation is absorbed ($\Delta E = h\nu$ per photon)
$c$ = velocity of light ($2.998 \times 10^8$ m/s)
λ = wavelength (nm)

▲All absorption of ultraviolet (UV) and visible (Vis) radiation in organic molecules is restricted to certain functional groups (chromophores) that contain valence electrons of low excitation energy. The spectrum of a molecule containing these chromophores is complex. This is because the superposition of rotational and vibrational transitions on the electronic transitions gives a combination of overlapping lines. This appears as a continuous absorption band, in the form of a bell-shaped peak. As a general rule, small molecules absorb somewhere in the ultraviolet region, and the greater the extent to which the p electrons are delocalized over a ring or a larger complex multiple-ring or branched structure, the longer the wavelength of the first absorption band (i.e., the band of lowest energy and longest wavelength). This delocalization over multiple-ring structures can shift the wavelength into the visible region and is responsible for the observed color of the substance.▲ (USP 1-Dec-2022)

***Change to read:***

## ▲UV-VIS SPECTROMETERS▲ (USP 1-DEC-2022)

All modern UV-Vis measurements involve detecting and measuring the intensity ratio of the radiation at a certain wavelength in the presence or absence of the absorbing sample ▲(transmitted radiation and incident radiation). *Figure 1* shows schematics of four typically encountered optical designs: single-beam, single split-beam (where the reference detector is located within the internal optics of the system), double-beam, and reverse optic array spectrometers.▲ (USP 1-Dec-2022) Dispersion of light to achieve the desired resolution can occur before ▲(as in the first three configurations)▲ (USP 1-Dec-2022) or after introduction of the sample, but all commercial UV-Vis instruments share the following features to perform these functions:

- Continuum source
- Monochromator or polychromator
- Sampling area
- Detector

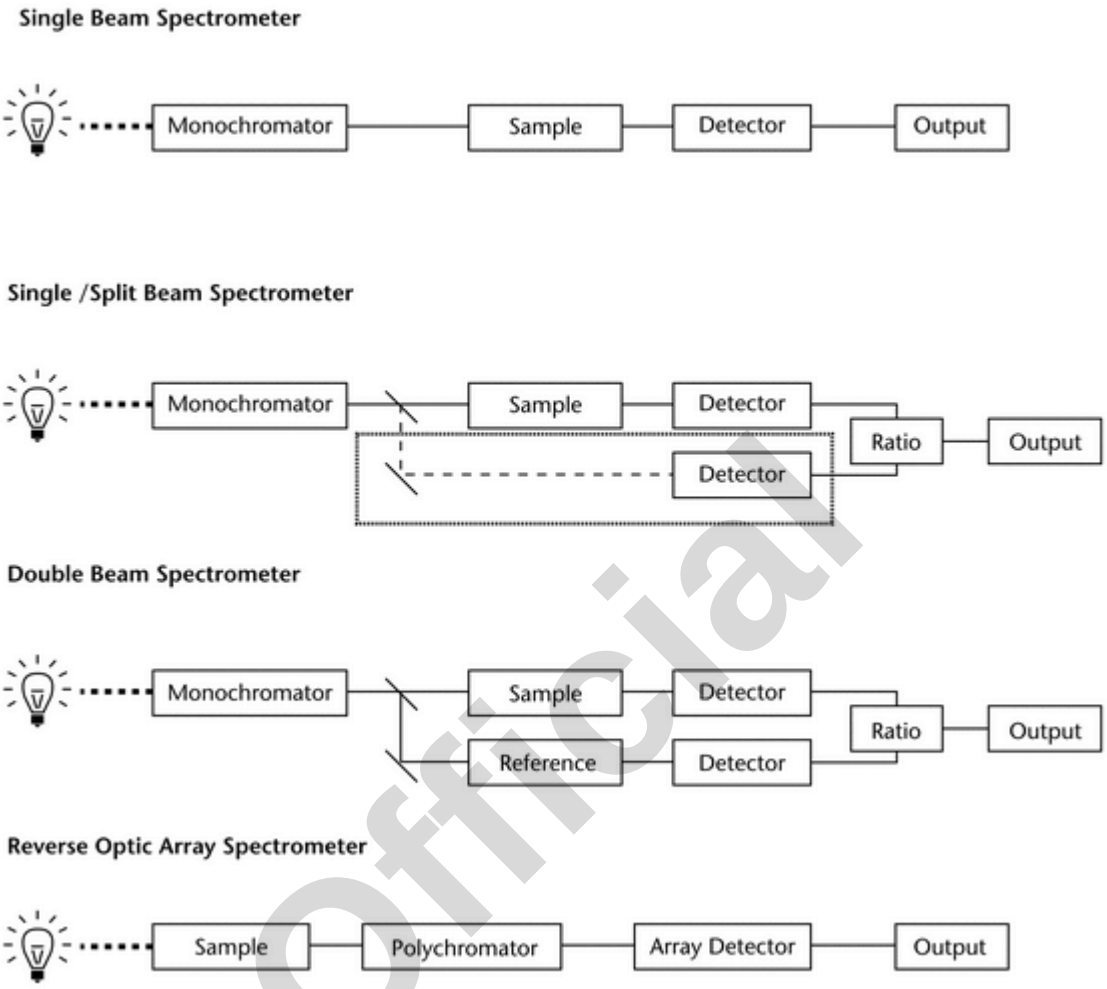

Figure 1. Typical spectrometer designs.

▲ (USP 1-Dec-2022)

Care must be taken to ensure that the sample is not degraded by the incident light beam and that any heating effects are minimized. This is particularly important when ▲photodiode array▲ (USP 1-Dec-2022) instruments are used because the sample is irradiated at all wavelengths.

## Continuum Source

Two major types of continuum source are currently in use: continuous and pulsed. Continuous sources include tungsten halogen for visible, deuterium arc for UV, and xenon arc for both. The source for pulsed radiation is the xenon flash lamp. Many UV-Vis instrument systems use a combination of deuterium and tungsten halogen to effectively cover the UV and visible regions, respectively. By necessity, source selection is achieved either by the use of a mirror ▲system to select the appropriate source, positioned manually or by using a hardware and software combination.▲ (USP 1-Dec-2022) This change usually is performed in the region of 320–350 nm, and thus qualification of the system must be performed using both source and mirror positions. Systems based on xenon lamps have the benefit of a single source and a higher energy output, but they are more expensive.

## Monochromator

The wavelength scale can be encoded by either a scanning monochromator or a grating polychromator (see *Figure 2*), as is the case for ▲spectrometers▲ (USP 1-Dec-2022) equipped with linear or two-dimensional array detectors. A discussion of the specific benefits and drawbacks of each of the dispersive designs is beyond the scope of this general chapter. Any properly qualified instrument should be suitable for qualitative measurements. Care must be taken when selecting an instrument for quantitative measurements because dispersion, response linearity, and stray light may not be uniform across the full spectral range. ▲Appropriate qualification procedures can be found in *Ultraviolet-Visible Spectroscopy* ⟨857⟩.▲ (USP 1-Dec-2022)

## Sampling Area

Numerous sampling arrangements are available in addition to the ▲cuvette▲ (USP 1-Dec-2022) holders that are designed to accommodate various path-length configurations based on conventional rectangular ▲cuvettes.▲ (USP 1-Dec-2022) These include flow ▲cuvettes,▲ (USP 1-Dec-2022) fiber-optic-based immersion probes, ▲multi-channel▲ (USP 1-Dec-2022) plate configurations, and automated sample changers, among others. Considerations such as sampling volume, speed of measurement, and reproducibility of sample presentation should be evaluated to optimize the sampling device for specific applications.

## Detector

Photoelectric detectors, which are the most common form of UV-Vis detectors, generate an electric current that is directly proportional to the intensity of the radiant energy incident upon them. They may take the form of photosensitive semiconductor devices, either discrete detectors, linear or two-dimensional arrays, or photomultipliers. Photosensitive semiconductor devices include solid-state photodiodes, charge-coupled device arrays (CCDs), and phototransistors. The most common semiconductor material is silicon, which is sensitive to wavelengths of 400–800 nm, but some silicon devices have extended sensitivity from as short a wavelength as 190 nm to as long a wavelength as 1100 nm. The dynamic response of these detectors typically is four orders of magnitude. Most ▲photodiode▲ (USP 1-Dec-2022) array detectors are made of silicon and hence have a similar wavelength response. Other semiconductor materials can provide wavelength response to several micrometers.

In contrast, photomultipliers are vacuum detectors that have a photocathode in which photon energy releases electrons that are directed by the field applied to electron-sensitive plates. By a cascade effect, these dynodes amplify the electrons released initially by the absorption of the incident radiation. Photomultipliers have typical wavelength responses of 160–900 nm, although some photocathode materials can provide response to higher wavelengths. The dynamic response of these detectors typically is six orders of magnitude or higher.

## ALTERNATIVE UV-VIS ▲SPECTROMETER▲ (USP 1-DEC-2022) CONFIGURATIONS

### ▲Photodiode Array Spectrometers

With photodiode array detection,▲ (USP 1-Dec-2022) the optical configuration is reversed from that in a conventional ▲spectrometer,▲ (USP 1-Dec-2022) and the light beam passes through the sample before being dispersed by the polychromator. This gives the benefit of fast, full spectral data with no moving parts that can wear out. The perception is, therefore, that ▲photodiode▲ (USP 1-Dec-2022) arrays are more reliable than other detectors. This is true, but the reverse-optics design requires that both the sample and optics before the dispersing element (usually a grating) are subjected to the full-spectrum radiation also encountered by these components in a conventional ▲spectrometer.▲ (USP 1-Dec-2022) In a conventional ▲spectrometer,▲ (USP 1-Dec-2022) the sample and optics are outside the monochromator, and optical beam deflection and/or scattering simply reduces the intensity of the light that enters the monochromator. In an array-based ▲spectrometer,▲ (USP 1-Dec-2022) deflection occurs within the ▲polychromator,▲ (USP 1-Dec-2022) causing scatter within the confined environment ▲of these devices, resulting in▲ (USP 1-Dec-2022) an associated increase in stray light. ▲As detailed in *Stray Light*, that leads to a reduction in optimum photometric range as shown in *Figure 3*.▲ (USP 1-Dec-2022)

### HPLC ▲UV-Vis▲ (USP 1-Dec-2022) Detectors

The design of a UV-Vis ▲spectrometer▲ (USP 1-Dec-2022) is always the result of a number of considered compromises. For example, optical performance (absolute wavelength resolution) is governed by the focal length of the monochromator, which in turn dictates the physical size of the instrument. In the case of HPLC ▲UV-Vis▲ (USP 1-Dec-2022) detectors ▲used for peak homogeneity assessment and identification procedures using the spectrum at the peak apex,▲ (USP 1-Dec-2022) the need to provide a high-stability, low S/N ratio output at high transmittance levels through a small-aperture flow ▲cuvette▲ (USP 1-Dec-2022) requires that by design these systems may not have the dynamic range or wavelength accuracy of their conventional spectroscopic counterparts.

### Fiber-Optic-Based Modular Systems

In recent years there has been a rapid increase in the availability and use of systems built around the ability of fiber optics to channel and multiplex optical systems. Although these systems have the advantages of flexibility and ease of use and they allow measurements to be performed on ▲multi-channel plate readers, modular user-designed and -built systems, etc.,▲ (USP 1-Dec-2022) analysts must consider the following disadvantages:

- Some analysts assume that these array-based fiber-optic systems are immune to room light interference at the sample interface, which may or may not be true. This assumption is easily tested by using a black photographic film-changing bag or a simple black cloth. Use of a masking technique should not change the measured value if the assumption is true.
- Custom-built systems ▲may▲ (USP 1-Dec-2022) not have additional shuttering, stray light filtering, and other capabilities that are found in commercially designed ▲spectrometers.▲ (USP 1-Dec-2022) Light levels transmitted directly down fibers from high-intensity sources such as Xenon flash lamps may cause photodegradation ▲of the sample being measured by the system. In these▲ (USP 1-Dec-2022) systems, the source may be coupled by fiber directly to the sample interface, and the only control is the source on/off switch.
- ▲Therefore, by design, the performance characteristics, i.e., the optimum photometric range, may have to be significantly reduced, if possible, to allow the system to be qualified according to ⟨857⟩.▲ (USP 1-Dec-2022)

***Add the following:***

## ▲UV-VIS INSTRUMENT PERFORMANCE INDICATORS

### Spectral Bandwidth—Effect on Resolution and Signal-to-Noise Ratio

Appropriate spectral bandwidth (SBW) is important to ensure adequate peak resolution. The selection of the SBW always requires balancing adequate resolution against maximization of the signal-to-noise (S/N) ratio. During method development, analysts should optimize the resolution by selecting the narrowest slit width that provides an adequate S/N ratio because optimum resolution is achieved when the S/N ratio is maximized. By design, the entrance and exit slits of the monochromator will be mechanically matched together to achieve the same physical separation and associated dispersion (usually triangular) to produce the required SBW. If access to a variable-bandwidth instrument is available, then the optimum setting can be defined as the narrowest slit width at which no significant reduction in peak intensity is observed. If accurate absorbance measurements must be made on benzenoid compounds or other compounds with sharp absorption bands (natural half-bandwidths of <15 nm), the SBW of the spectrometer used should not be greater than $1/8^{th}$ of the natural half-bandwidth of the compound's absorption; i.e., this equates to a spectrometer with a SBW of 2 nm or less. In practical terms, for molecules of pharmaceutical interest in solution, this bandwidth of 2 nm is considered adequate in also providing the required balance of high resolution while maintaining good S/N ratio.

However, it should be noted that nicotinic acid, which is shown to be acceptable for use as a photometric accuracy reference, does have transmittance characteristics that are highly correlated to the SBW, and therefore it is always necessary to match the SBW of the certified absorbance values to those of the instrument system being qualified.

## Stray Light

Stray radiation, commonly referred to as stray light, can be defined as radiant energy at wavelengths other than those indicated by the monochromator setting and all radiant energy that reaches the detector without having passed through the sample or reference solutions (see *Figure 3*). It may be caused by any scattered radiation from imperfections in the dispersing medium, which commonly is a grating. The use of a holographic grating substantially reduces the levels of this source of stray radiation. Higher-quality ruled gratings yield a low level of scattered radiation. In higher-performance instruments, stray radiation can be reduced by the use of double monochromators or double-pass monochromators. Stray radiation, or apparent stray radiation, also may be caused by light leaks in the system, incorrect wavelength calibration, incorrect optical alignment, reduced source output, or reduced detector response.

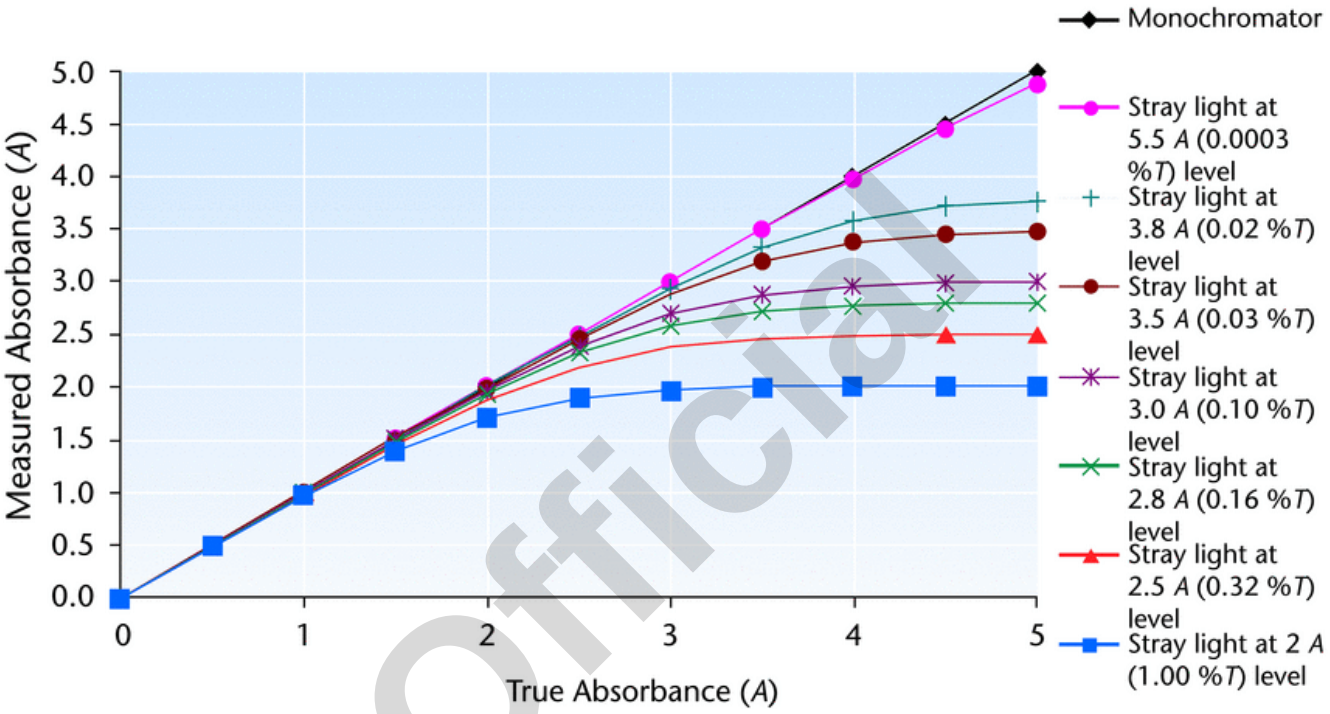

Figure 3. Effect of stray light on measured absorbance.

The usual way of assessing stray light is to measure, at the desired analytical wavelength, a sample that totally absorbs the radiation at that wavelength but transmits at all other wavelengths. Any light detected by the instrument is then stray light.

In 1982, Mielenz et al. at the National Institute of Standards and Technology (NIST) defined stray light as spurious radiant energy that has departed from its regular path in a spectrometer and then re-enters the path so that it is sensed by the detector and causes false readings of transmittance and absorbance. Mielenz also offered a refinement on the estimation method in current use at the time. This method has since been incorporated into ⟨857⟩, *Qualification of UV-Vis Spectrometers, Estimation of the Limit of Stray Light (Stray Radiant Energy), Procedure A*. In this method, the reference beam is attenuated by a 5-mm path length cuvette containing the same edge filter solution as used in a 10-mm path length cuvette placed in the sample beam. A maximum peak differential absorbance is observed ($\Delta A$) while scanning through the edge absorbance, which is related empirically to the stray light level ($s_\lambda$) by:

$$s_\lambda = 0.25 \times 10^{-2\Delta A}$$

*Table 1* provides a list of differential absorbance values, the "Mielenz measured absorbance", and their corresponding stray light levels.

**Table 1. Value Comparison Table and Critical "Mielenz" Measured (Differential) Absorbance Values**

| "Mielenz" Measured Absorbance ($\Delta A$) | Stray light level, $s_\lambda$, expressed as... | | |
|---|---|---|---|
| | Transmittance (*T*) | % Transmittance (%) | Absorbance (*AU*) |
| 0.3 | 0.063 | 6.3 | 1.2 |
| 0.5 | 0.025 | 2.5 | 1.6 |
| 0.7 | 0.01 | 1.0 | 2.0 |
| 1.0 | 0.0025 | 0.25 | 2.6 |

Official

https://pharmacopeia.cn/v29240/

**Table 1. Value Comparison Table and Critical "Mielenz" Measured (Differential) Absorbance Values** *(continued)*

| "Mielenz" Measured Absorbance (Δ*A*) | Stray light level, $s_\lambda$, expressed as... | | |
|---|---|---|---|
| | Transmittance (*T*) | % Transmittance (%) | Absorbance (*AU*) |
| 1.5 | 0.00025 | 0.025 | 3.6 |
| 2.0 | 0.000025 | 0.0025 | 4.6 |
| 25 | 0.0000025 | 0.00025 | 5.6 |

This method therefore avoids the potentially difficult procedure (see ⟨857⟩, *Qualification of UV-Vis Spectrometers, Estimation of the Limit of Stray Light (Stray Radiant Energy), Procedure B*) to find appropriate attenuation filters in the UV region required to "back-off" the system, especially if using a modern double-monochromator spectrometer, and also avoids the measurement performed at the limit of the instrumental range and analog-to-digital electronic resolution. *Figure 4* shows spectral profiles acquired of a potassium chloride solution using both ⟨857⟩, *Procedure A* and ⟨857⟩, *Procedure B*.

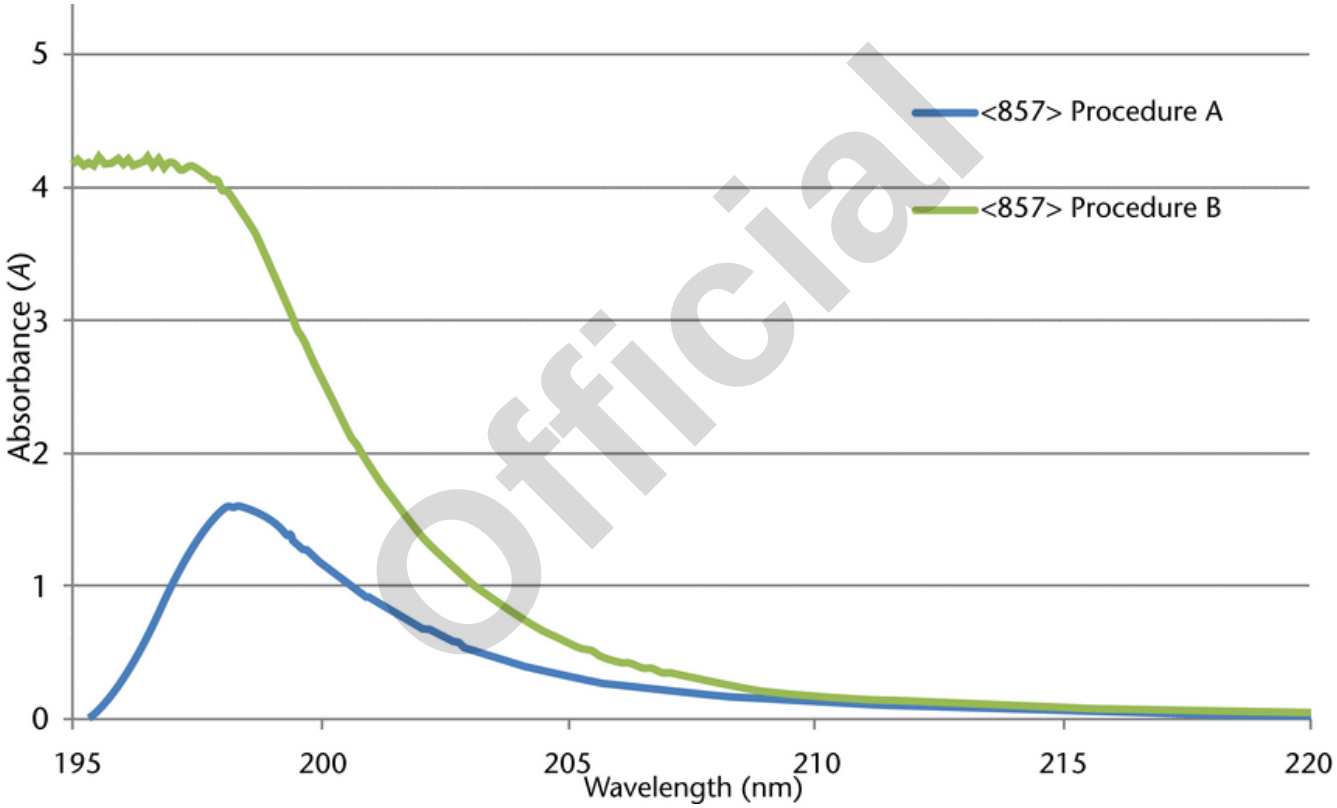

Figure 4. Typical spectrum of 1.2% aqueous potassium chloride vs. water as reference, 10-mm path length (*Procedure B*). Differential absorbance spectrum of 1.2% aqueous potassium chloride, 10-mm path length, vs. the same solution as reference, 5-mm path length (*Procedure A*).

## Optimum Working Photometric Range

Determination of the optimum photometric range is fundamental to establishing the capability of a given instrument before and during method validation. The importance of this procedure can be shown by the fact that in 1945 Vandenbelt et al. attempted to establish the optimum absorbance range on the then-new Beckman DU spectrometer (*1*). They suggested a simple approach in which the molar absorptivities, $A^{1\%}_{1\ \mathrm{cm}}$, of various compounds are measured at different concentrations. This approach is shown theoretically in *Figure 5*, where the center plateau is used to define the photometric range.

@2024 USPC

A more rigorous method for estimating an instrument's region of maximum precision is given by Youmans and Brown (*3*). The error in the measurement of the concentration of a solution of transmission $T$ can be expressed as:

$$\Delta c = \frac{1}{\epsilon b}\log\frac{T_{\text{av}}}{T_{\text{min}}}$$

where $\Delta c$ is the change in concentration, $\varepsilon$ is the molar absorptivity of the compound, $b$ is the path length, and $T_{av}$ and $T_{min}$ are the mean and minimum values, respectively, from a series of $n$ measurements on the sample.

The statistical error is (see *Figure 7*):

$$\frac{\Delta c}{c} = \frac{1}{-\log\left(T_{\text{av}}\right)}\log\frac{T_{\text{av}}}{T_{\text{min}}}$$

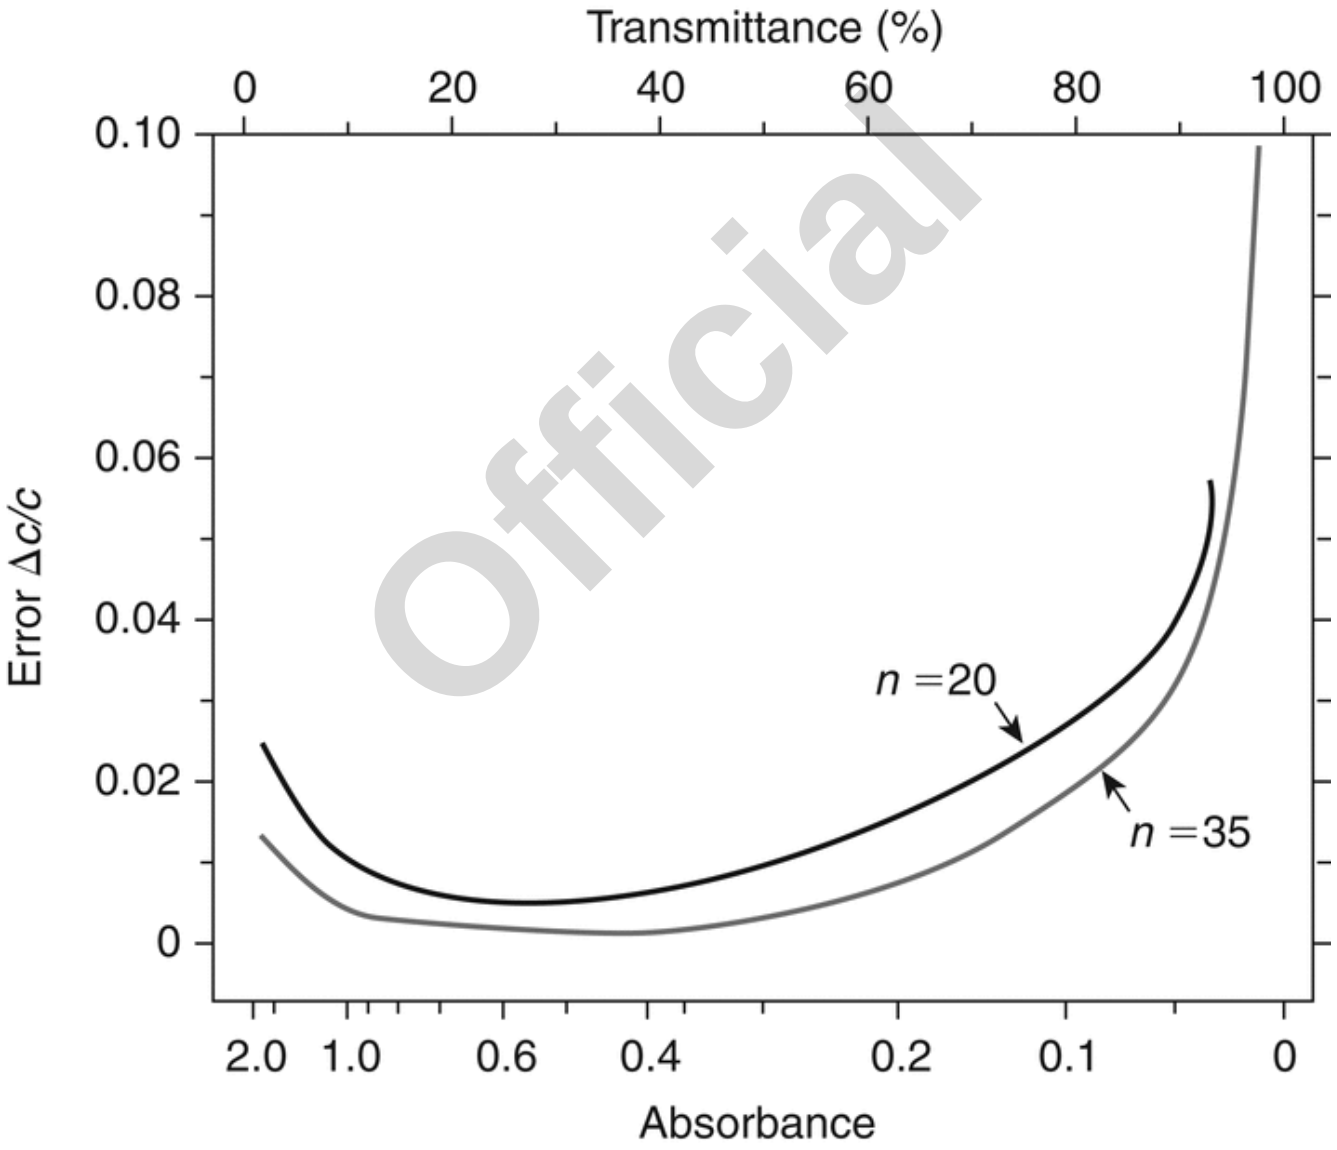

Figure 7. Youmans and Brown plot (*2*).

The noise levels, and hence the precision of measurement, depend primarily on detector noise type, as shown in *Figure 8*.

| Standard deviation of a measurement $\sigma_T$ | Source of variability | Relative error function |
|---|---|---|
| $\sigma_T = k_1$ | Thermal detector, amplifier, and dark current noise. [Independent of $T$] | $\frac{\sigma_c}{C} = \frac{0.4343}{\log_{10} T}\frac{k_1}{T}$ |
| $\sigma_T = k_2\sqrt{T^2 + T}$ | Shot noise from the detector | $\frac{\sigma_c}{C} = \frac{0.4343}{\log_{10} T}k_2\sqrt{1+\frac{1}{T}}$ |
| $\sigma_T = k_3 T$ | Cell positioning, non-parallelism errors and incident beam intensity fluctuations | $\frac{\sigma_c}{C} = \frac{0.4343}{\log_{10} T}k_3$ |

Figure 8. Measurement precision as a function of noise type (*4*).

Both approaches clearly show that in addition to the expected increasing error at higher absorbance levels caused by stray light and other factors, there is a similar, if not larger possibility for increasing error at low absorbance levels caused by instrumental variances in the form of noise from the detector, source, etc. This variance often is overlooked in the desire for economy of scale, when analysts use smaller samples and shorter path lengths and therefore lower measured absorbance values.

Good practice is to optimize the measured absorbance within 0.2–2.0 absorbance units (AU), where possible. In addition, the use of shorter path length cuvettes should be the preferred option to reduce a measured solution absorbance rather than the corresponding ratio dilution with solvent. Invariably, the path length tolerances on a modern manufactured cuvette are significantly smaller than those associated with volumetric glassware; and not diluting the sample avoids the risk of solution chemistry changes caused by dilution.▲ (USP 1-Dec-2022)

## CALIBRATION

UV-Vis ▲spectrometer▲ (USP 1-Dec-2022) calibration involves two components: primary wavelength (*x*-axis) and ▲photometric scale▲ (USP 1-Dec-2022)(*y*-axis), and often is performed when the instrument is initialized. Most dispersive UV-Vis

@2024 USPC

▲spectrometers▲ (USP 1-Dec-2022) use atomic emission lines from either the source or a secondary lamp for primary wavelength (*x*-axis) calibration, in addition to the zero-order position in the monochromator. ▲How (and to what level of "user") these fundamental calibration procedures are made available will depend on the vendor's configuration of the instrument. Calibration of both the wavelength (*x*-axis) and the photometric scale (*y*-axis) is critical for successful quantitation and method transfer between instruments. In many cases, the effect of wavelength error in the *x*-axis can be minimized by the use of careful method selection, e.g., wavelength at a spectral peak.▲ (USP 1-Dec-2022) Although the fundamental measurement relies on a simple ratio measurement, modern instruments may use several gain settings or amplification factors to ensure a linear detector response, particularly at low intensity levels and high-power settings. These gain settings often are initially set by the manufacturer, but the settings may be recalibrated as the optics age or as other changes take place.

Detailed functional validation based on certified reference materials ▲as detailed in ⟨857⟩▲ (USP 1-Dec-2022) is recommended to demonstrate the suitability of laboratory instruments, even for instruments that possess an internal calibration capability. The use of external reference materials does not obviate the need for internal quality control procedures. Rather, it provides independent documentation of the fitness of the instrument to perform the specific analysis.

***Change to read:***

## ANALYTICAL CONSIDERATIONS

### ▲Temperature and Coefficient of Expansion Effects

Temperature impacts absorption measurements and, thereby, the photometric accuracy in several significant ways. Changes in temperature can induce expansion or contraction of the solvent, leading to lower or higher concentrations and absorbances. While this is a particular issue with some organic solvents, careful temperature control, i.e., within ±2° may be required where high-accuracy absorbance values are required for aqueous solutions, for example, to verify compliance with photometric value assignments stated for a reference material and/or calculation of a molar extinction coefficient. In ⟨857⟩, this accurate control of temperature is particularly important when liquid photometric accuracy references are being used in the qualification process, i.e., nicotinic acid and acidic potassium dichromate solutions. In such cases, additional temperature monitoring and/or control of the sample measurement process may be required. Also, shifts in equilibria between the chemical forms of an analyte may cause the nature of the absorbing species to be changed.

### Solvent Selection Effects

Solvents play an important role in UV spectra. In a spectrum, the compound peak can be obscured by the solvent peak. So, a most suitable solvent is one that does not itself absorb and is transparent in the region under investigation. As a general rule, it should be possible to measure a solvent at the wavelength of interest at a transmittance value of >75%.

A dilute solution of sample is always prepared for analysis. See *Table 2* for a list of most commonly used solvents. In this table, approximate wavelengths below which the solvent absorbance may be unacceptable are specified. For quantitative applications, the cut-off may be set at a wavelength ($L_0$) where the absorbance for the 10-mm path length of the solvent exceeds 0.05 AU (relative to water), i.e., $A_{1\ cm} > 0.05$ AU. For qualitative work, it may still be feasible to operate at significantly lower wavelengths; most analysts accept a cut-off based on the wavelength ($L_1$) for $A_{1\ cm} > 1.0$ AU.

**Table 2. Solvent Cut-Off of Commonly Used Solvents**

| Solvent (Common Name) | $L_0$ (nm) | $L_1$ (nm) |
|---|---|---|
| Acetone | 340 | 330 |
| Acetonitrile | 200 | 190 |
| Isobutanol | 250 | 200 |
| *n*-Butanol | 245 | 215 |
| *n*-Butyl acetate | 275 | 255 |
| Cyclopentane | 220 | 195 |
| Decalin | 250 | 230 |
| Dichloromethane | 245 | 230 |
| Diethyl ether | 255 | 220 |
| *N,N*-Dimethylformamide | 300 | 270 |
| Dimethylsulfoxide | 330 | 285 |
| Ethanol | 240 | 205 |
| Ethyl acetate | 280 | 260 |
| Heptane | 230 | 200 |
| Hexane | 225 | 195 |
| Methanol | 240 | 205 |

**Table 2. Solvent Cut-Off of Commonly Used Solvents** *(continued)*

| Solvent (Common Name) | $L_0$ (nm) | $L_1$ (nm) |
|---|---|---|
| Isopropanol | 240 | 205 |
| *n*-Propanol | 250 | 210 |
| Tetrachloroethylene | 320 | 290 |
| Tetrahydrofuran | 280 | 220 |
| Water | 190 | 185 |

In addition, there are three other solvent related effects. First, dissolved gases may cause absorption at wavelengths above the pure solvent cut-off. For example, dissolved atmospheric gases may cause absorption to occur at 190–205 nm in an aqueous system. Second, organic solvents may contain other stabilizing chemicals that will absorb at higher wavelengths. Last, changes in physical solvent properties, e.g., polarity or degree of hydrogen bonding, may cause chromatographic shifts in the band spectrum.▲ (USP 1-Dec-2022)

## Sample-Based Factors

The most important sample-based factors that negatively affect quantitative UV-Vis ▲spectrometry▲ (USP 1-Dec-2022) are fluorescence and light scattering. If the sample matrix includes fluorescent compounds, the measured signal usually will contain a contribution from fluorescence. The wavelength range and intensity of the fluorescence depend on the chemical composition of the fluorescent material. Suspended particles scatter light by the Tyndall effect, causing a decrease in the measured intensity that increases as the wavelength decreases. Unless there is no alternative, absorbance should not be determined on turbid samples. Procedures for removing turbidity include filtering, centrifuging, or flocculating the sample and are performed before any additional procedures that generate a chromophore, provided that they do not affect the concentration of the analyte or the chromophore in the test solution. Any measurements performed on a turbid solution are highly instrument specific and can be used only for comparative purposes in the same system. A further complication can arise at higher analyte concentrations with respect to the coordination chemistry and system matrix. Ionic association, complex formation, and similar factors can cause deviation from the expected linear response.

## Sampling Factors

### ▲SOLUTION PREPARATION

As previously stated, all solutions used for measurement should be particle free and prepared as accurately as possible. The errors associated with any solution preparation can be minimized by ensuring that all gravimetric processes are used within the center median of the given working range of the balance(s) and that a gravimetric process, in preference to a volumetric process, is used for all subsequent required dilutions. Again, the use of reduced path length cuvettes should be chosen in preference to an additional dilution step.

### CUVETTES▲ (USP 1-Dec-2022)

Quantitative absorbance measurements usually are made on solutions of the substance in liquid-holding ▲cuvettes.▲ (USP 1-Dec-2022) The most common ▲cuvette▲ (USP 1-Dec-2022) path length is 10 mm, although path lengths from 0.01–100 mm are commercially available (see *Figure 9*). For samples with low absorbance, improved sensitivity generally can be obtained by increasing the ▲cuvette▲ (USP 1-Dec-2022) path length. For example, the theoretical absorbance of a solution in a 50-mm ▲cuvette▲ (USP 1-Dec-2022) is greater by a factor of 5 compared to the same solution in a 10-mm ▲cuvette.▲ (USP 1-Dec-2022) Errors in absorption readings arising from ▲cuvettes▲ (USP 1-Dec-2022) almost always are caused by dirty windows that can absorb a significant proportion of the incident light beam. Less frequent causes of error are an incorrect choice of ▲cuvette▲ (USP 1-Dec-2022) material for the wavelength required, e.g., use of glass ▲cuvettes▲ (USP 1-Dec-2022) less than 320 nm, nonrepeatability of ▲cuvette▲ (USP 1-Dec-2022) positioning, differences in ▲cuvette▲ (USP 1-Dec-2022) window thickness, nonparallel optical windows, or impurities in ▲cuvette▲ (USP 1-Dec-2022) window materials. A 10-mm ▲cuvette▲ (USP 1-Dec-2022) manufactured with a ±0.05 mm tolerance will add a 0.005 AU contribution to the overall uncertainty, when measuring absorbance values at the 1 AU level. There are 10-mm ▲cuvettes▲ (USP 1-Dec-2022) with a ±0.01 mm tolerance commercially available. As a general guide, the ▲cuvette▲ (USP 1-Dec-2022) chosen should have a transmittance value of >75% when filled with the appropriate solvent▲, as previously discussed,▲ (USP 1-Dec-2022) and measured at the wavelength of interest.

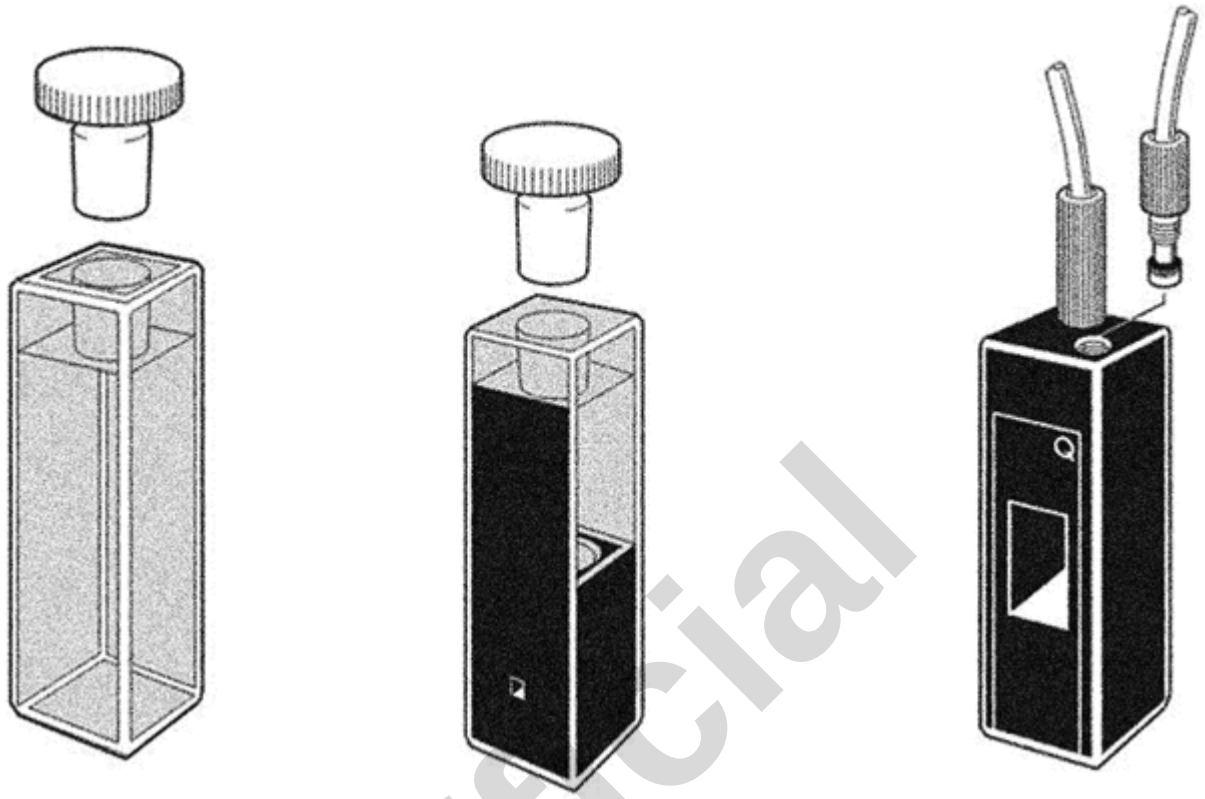

Figure 9. Commonly used ▲cuvette▲ (USP 1-Dec-2022) types: 10-mm regular, low-volume, and flow ▲cuvettes▲ (USP 1-Dec-2022) (from left to right).

Analysts can mitigate the variability introduced by ▲cuvettes▲ (USP 1-Dec-2022) by adhering to the following set of best practices. Carefully clean ▲cuvettes▲ (USP 1-Dec-2022) before use, and store them in a manner that avoids contamination when they are not in use. ▲Cuvettes▲ (USP 1-Dec-2022) in frequent and repeated use, e.g., flow ▲cuvettes,▲ (USP 1-Dec-2022) can be stored wet in high-purity water or 1% (v/v) nitric acid. Do not use cracked or scratched ▲cuvettes.▲ (USP 1-Dec-2022) Wipe ▲cuvettes▲ (USP 1-Dec-2022) carefully with a soft, clean, lint-free cloth before they are placed in the ▲spectrometer.▲ (USP 1-Dec-2022) Do not use lens-cleaning paper or any other form of paper cleaning tissue because these will either scratch or allow contamination of the optical face.

It is preferable to use a single ▲cuvette▲ (USP 1-Dec-2022) for all measurements of both the reference and samples▲, and where possible, never move the cuvette if you can move the solution. Liquid transfer should be made using plastic-tipped devices to avoid scratching the optical surfaces. This approach, which eliminates interreflection errors and nonparallelism effects, should always be used if work of the highest accuracy is needed. The use of a flow cuvette with peristaltic aspiration is recommended.▲ (USP 1-Dec-2022) When several sample ▲cuvettes▲ (USP 1-Dec-2022) must be tested against one reference ▲cuvette,▲ (USP 1-Dec-2022) they all should be closely matched in their characteristics. Whenever possible, measure standards and samples at the same time and under the same conditions to minimize the potential for bias. The reference ▲cuvette▲ (USP 1-Dec-2022) should contain the same solvent as the sample ▲cuvette▲ (USP 1-Dec-2022) and should be checked against the sample ▲cuvette▲ (USP 1-Dec-2022) at all wavelengths for which measurements are required. Analysts can apply corrections for differences between ▲cuvettes▲ (USP 1-Dec-2022) to absorbance readings obtained from the solutions under examination. The maximum allowable correction is ±0.01 AU. Best practices include using the same ▲cuvette▲ (USP 1-Dec-2022) in the reference beam with the same face incident to the light beam, and flushing the sample ▲cuvette▲ (USP 1-Dec-2022) three times with the sample solution before the final filling before measurement. ▲When solutions using volatile solvents are to be measured, it is advisable to use polytetrafluoroethylene (PTFE) stoppered-cuvettes, ideally one of the many screw-capped variants available.▲ (USP 1-Dec-2022)The use of flow ▲cuvettes▲ (USP 1-Dec-2022) effectively addresses many of these ▲handling and filling▲ (USP 1-Dec-2022) issues. The contents in both the sample ▲cuvette▲ (USP 1-Dec-2022) and the reference ▲cuvette▲ (USP 1-Dec-2022) must be free from gas bubbles and particles. If flow ▲cuvettes▲ (USP 1-Dec-2022) are used, analysts may be required to degas the solution(s) before measurement in order to avoid the formation of air bubbles in the ▲cuvette.▲ (USP 1-Dec-2022)

A sequence of activities is used to monitor the quality of the measurement process and to ensure that the contents are representative of the sample under measurement. Drift of the ▲spectrometric▲ (USP 1-Dec-2022) baseline can be detected by measuring the blank at the start and end of the sample sequence▲and also at interim points if the time scale requires them.▲ (USP 1-Dec-2022) Adequate flushing of the ▲cuvette▲ (USP 1-Dec-2022) can be confirmed by alternating between measurement of the standard (high concentration) and the blank (zero concentration) at the start of the measurement sequence. The latter check is particularly important for automated systems that can generate reproducible but inaccurate results because of inadequate flushing.

### CARE OF ▲CUVETTES▲ (USP 1-Dec-2022)

Contaminated ▲cuvettes▲ (USP 1-Dec-2022) are the greatest single source of error in ▲UV-Vis spectrometry. Cuvettes▲ (USP 1-Dec-2022) should never be handled by the optical polished faces, and analysts should rinse off residual or spilled solution. If ▲cuvettes▲ (USP 1-Dec-2022) are properly cared for, rigorous cleaning methods rarely will be needed, especially if the ▲cuvettes▲ (USP 1-Dec-2022) are cleaned immediately after use. Although acid solutions will simply contaminate surfaces, alkaline solutions can etch all types of polished glass surfaces, and the degree of attack depends on the pH and contact time. When cleaning ▲cuvettes,▲ (USP 1-Dec-2022) analysts should ensure that the optical faces are not scratched or chipped. Commercial cleansing solutions are available and can be used, provided that they are diluted before use in accordance with the manufacturers' recommendations. After they are cleaned with such agents, the ▲cuvettes▲ (USP 1-Dec-2022) should be carefully and thoroughly rinsed with high-purity water. If this fails to clean the ▲cuvettes,▲ (USP 1-Dec-2022) then soaking them in cold, concentrated nitric or hydrochloric acid is acceptable. Flow ▲cuvettes▲ (USP 1-Dec-2022) are best cleaned in situ, provided that the solvent does not interact with the connecting tubing. If the ▲cuvettes▲ (USP 1-Dec-2022) are stored for an extended period, then they should be dried quickly after cleaning by blowing dry with a compressed gas stream in a clean, dust-free environment. ▲Many laboratory "compressed air gas lines" may contain lubricating oil from the machinery and thereby deposit a film of oil on the optical face.▲ (USP 1-Dec-2022)

### ALIGNMENT AND FILLING OF ▲CUVETTES▲ (USP 1-Dec-2022)

Analysts should align the ▲cuvettes▲ (USP 1-Dec-2022) so that the same optical face is always incident to the light beam. Most ▲cuvettes▲ (USP 1-Dec-2022) have type identification engraved on one face; this can be used to ensure consistent orientation. If there are no markings, a small mark can be made on one face outside the area of the light beam. The use of ▲cuvettes▲ (USP 1-Dec-2022) with no type markings is not recommended, but, if ▲cuvettes with type markings▲ (USP 1-Dec-2022) are used, analysts should confirm their suitability for the intended application. If ▲cuvettes▲ (USP 1-Dec-2022) are provided with the instrument, individual ▲cuvette▲ (USP 1-Dec-2022) holders should always be used in the same beam as identified, e.g., by use of appropriate markings.

### ▲CUVETTE▲ (USP 1-Dec-2022) CORRECTIONS

If multiple ▲cuvettes▲ (USP 1-Dec-2022) are used, differences in the optical transparency of individual ▲cuvettes▲ (USP 1-Dec-2022) can introduce a systematic bias unless the latter is accounted for by a ▲cuvette▲ (USP 1-Dec-2022) correction. ▲Depending on where the zero point is set, this correction can be either positive or negative; however,▲ (USP 1-Dec-2022)do not use corrections in excess of 0.01 ▲AU.▲ (USP 1-Dec-2022) To determine if ▲cuvette▲ (USP 1-Dec-2022) corrections are necessary, analysts can fill all ▲cuvettes▲ (USP 1-Dec-2022) with the appropriate solvent and measure the differences in absorbance at the required analytical wavelengths. These measurements are repeated after cleaning to ensure that differences in absorbance are related to the ▲cuvettes▲ (USP 1-Dec-2022) and are not the result of contamination. Analysts should fill and check the ▲cuvettes▲ (USP 1-Dec-2022) repeatedly until the results are consistent, and they should investigate any appreciable change in ▲cuvette▲ (USP 1-Dec-2022) correction because it indicates contamination, damage to the ▲cuvettes,▲ (USP 1-Dec-2022) or incorrect adjustment of the instrument.

## THEORY

Raman is a vibrational spectroscopic technique; it is complementary to mid-infrared (IR) and near-infrared (NIR) spectroscopy where there is center of symmetry, because both techniques rely on interaction with the molecular structure of the material. The Raman effect itself arises as a result of a change in the polarizability of molecular bonds during a given vibrational mode and is measured as inelastically scattered radiation, whereas absorption intensity at IR or NIR wavelengths occurs due to differences in dipole moments. Raman spectroscopy is particularly sensitive to non-polar bonds (e.g., C–C, single or multiple bonds), and thus, strong dipole oscillators do not show Raman scattering because the molecular geometry does not give rise to polarizability. The appearance of a Raman spectrum is much like an IR absorbance spectrum. The intensities, or the number of Raman photons counted, are plotted against the shifted energies. The *x*-axis is generally labeled "Raman shift/$cm^{-1}$" or "wavenumber/$cm^{-1}$". The Raman shift is usually expressed in terms of wavenumber and represents the energy difference between the incident photon energy and the inelastically scattered photon energy. In addition, water, which has a strong IR absorption spectrum, only exhibits a weak Raman signature and is a useful solvent for this technique. The spectral features and intensities of Raman and IR/NIR are therefore different for most organic molecules, and thus the spectra of the different techniques may be used to complement specificity and characterization.

A Raman spectrum is generated by exciting the sample of interest to an excited state with an appropriate light source. Light elastically scattered (no change in wavelength) is known as Rayleigh scatter and is not of interest in Raman spectroscopy, except for marking the laser wavelength. However, if the sample relaxes to a vibrational energy level that differs from the initial state, either up or down, the scattered radiation is shifted in energy. This shift is commensurate with the energy difference between the initial and final vibrational states. This "inelastically scattered" light is referred to as Raman scatter. Only about 1 of $10^6$–$10^8$ photons incident on the sample undergoes Raman scattering. Lasers can provide high photon densities and are used in Raman spectrometers to compensate for this inherently low Raman scattering efficiency; also, the Rayleigh scatter can be filtered easily to reduce stray light interferences. Lasers can also be tuned to avoid fluorescence from the sample or matrix or to excite to resonant modes to enhance the signal. If the Raman-scattered photon is of lower energy than the excitation source, it is referred to as Stokes scattering, and if it is of higher energy, it is referred to as anti-Stokes scattering. In practice, nearly all analytically useful Raman measurements make use of Stokes-shifted Raman scatter.

## APPLICATIONS

Raman spectroscopy can be used for a variety of applications ranging from verification of raw materials to process monitoring of drug production to quality control of products. These applications include optimizing polymorph (or crystalline structure)

https://pharmacopeia.cn/v29240/

analysis; synthesis of new drugs; gaining process understanding through real-time monitoring of reactors, crystallizers, and blenders; verifying raw materials; and ensuring product quality. Once a potential new drug is identified, the method for synthesizing the drug is developed, and Raman spectroscopy is ideal for monitoring reactant, intermediate, and product concentrations, as well as determining pathways, kinetics, mechanisms, end-points, and yields for a variety of reaction types. Quality-by-design control of the product requires assurance that its final form (e.g., gel capsules or tablets) contains the correct amount of active pharmaceutical ingredient (API), its polymorph (if appropriate), excipient, and other additives such as dyes. Raman spectroscopy has been used to monitor mixing in blenders, as well as to inspect individual products before shipment, and may be a useful alternative to HPLC in stability studies. Analysis of the data using chemometrics tools is common for many applications. Proper design of experiment, calibration standard, instrument selection, and maintenance are important considerations for any chemometric model, and it is these requirements that will dictate the specification of the instrumentation required to ensure that it is fit for purpose. For further discussion of the theory and applications of chemometrics, see *Chemometrics* ⟨1039⟩.

## QUALITATIVE AND QUANTITATIVE RAMAN MEASUREMENTS

There are two general classes of measurements that are commonly performed using Raman spectroscopy: qualitative and quantitative.

### Qualitative Raman Measurements

Qualitative Raman measurements yield spectral information about the molecular structure of the sample. Because the Raman spectrum is specific for a given compound, qualitative Raman measurements can be used as a compendial identification test. See *Spectroscopic Identification Tests* ⟨197⟩.

### Quantitative Raman Measurements

For instruments equipped with a detector that measures optical power, such as Fourier transform (FT)–Raman spectrometers, quantitative Raman measurements use the following relationship:[1, 2]

$$I(\omega_s) = I(\omega_L) N \frac{d\sigma(\omega_S)}{d\Omega} Z$$

$I(\omega_s)$ = Raman scattering intensity at wavelength $\omega_s$
$I(\omega_L)$ = incident laser intensity at wavelength $\omega_L$
$N$ = number density of scatters
$d\sigma(\omega_s)/d\Omega$ = Raman cross-section at $\omega_s$
$Z$ = geometric factor that takes into account the spectrometer depth of field

## SAMPLING FACTORS

Raman spectroscopy is a zero-background technique in that the signal at the detector is expected to be zero in the absence of a sample. This situation can be contrasted with absorption spectroscopy, where the intensity at the detector is at a maximum in the absence of a sample. Zero-background techniques are inherently sensitive because small changes in sample concentration lead to proportionate changes in the signal level. The instrument is sensitive to other sources of light that can cause sample-to-sample variations in the measured signal level. In addition, a large background signal can be caused by fluorescence. Thus, it may be very difficult to use the absolute Raman signal intensities for direct determination of an analyte. Other potential sources of variation are changes in the sample opacity and heterogeneity, changes in the laser power at the sample, and changes in optical collection geometry or sample position. These effects can be minimized by careful method design related to preparation and presentation of the sample, as well as instrument factors.

Use of an internal reference standard is the most common and robust method for eliminating variations caused by absolute intensity fluctuations. There are several options for this approach. An internal standard can be added deliberately, and isolated peak(s) from this standard can be used. Alternatively, the analyst can use a band due to a moiety such as an aromatic ring, the Raman intensity of which does not change with the way the sample is prepared. For solution spectra, an isolated solvent band can be used because the solvent will remain relatively unchanged from sample to sample. In a formulation, an excipient peak can possibly be used if it is present in a substantial excess, when compared to the analyte, in a homogeneous matrix.

A second, important sampling-based factor to consider is spectral contamination. Raman scattering is a weak effect that can be masked by a number of external sources. Common sources of contamination include sample-holder artifacts (container or substrate) and ambient light. Typically, these issues can be identified and resolved by careful experimentation.

# APPARATUS

## Components

Regarding the instrumentation, modern systems are easy to use, provide fast analysis times (milliseconds to several minutes), and are reliable. Conventional Raman systems are usually benchtop instruments. However, handheld devices based on solid-state electronics and detection systems are widely available and mainly used for the identification of raw materials. Raman spectra are ordinarily excited with visible or NIR radiation, and standard glass/quartz and fiber optics may be used. The signal is typically in the visible or NIR optical range, allowing samples to be analyzed directly through packaging or directly in media that are transparent at these wavelengths. In addition, process Raman analyzers used as process analytical technology (PAT) are also available. Acceptance criteria for fitness for purpose over their operational range are the same for both benchtop and handheld devices.

All commercial Raman instruments have the following components:

- Excitation source (laser)
- Sampling device
- Device to filter/reject light scattered at the laser wavelength
- Wavelength processing unit
- Detector and electronics

## Excitation Source (Laser)

*Table 1* identifies several common lasers used for pharmaceutical applications or Raman spectroscopy.

The danger of using high-powered lasers must be recognized, especially when their wavelengths are outside of the visible range, i.e., in either the UV or NIR regions. Fiber optic probes should be used with caution.

**Table 1. Lasers Used in Pharmaceutical Applications**

| Nominal Laser λ (nm) | Type | Typical Power at Laser | Wavelength Range (nm) (Stokes Region, 100–3000 $cm^{-1}$ shift) | Comments |
|---|---|---|---|---|
| **NIR Lasers** | | | | |
| 1064 | Solid state [neodymium-doped:yttrium–aluminum–garnet (Nd:YAG)] | Up to 3 W | 1075–1563 | Commonly used in FT instruments |
| 830 | Diode | Up to 650 mW | 836–1105 | Typically limited to 2000 $cm^{-1}$ Raman shift because of charge-coupled device (CCD) spectral response; less common than the other lasers |
| 785 | Diode | Up to 500 mW | 791–1027 | Most widely used dispersive Raman laser |
| **Visible Lasers** | | | | |
| 632.8 | Helium–Neon (He–Ne) | Up to 500 mW | 637–781 | Relatively small fluorescence risk |
| 532 | Doubled Nd:YAG | Up to 1 W | 535–633 | High fluorescence risk |
| 514.5 | Argon (Ar)-Ion | Up to 1 W | 517–608 | High fluorescence risk |
| 488.0–514.5 | Ar-Ion | Up to 1 W | 490–572 | High fluorescence risk |
| **UV Lasers** | | | | |
| 257.3 | Doubled Ar-Ion | Up to 200 mW | 258–279 | — |
| 248.3 | Neon–Copper (Ne–Cu) | 20 mW to 1.8 W peak | 249–268 | — |
| 244.0 | Doubled Ar-Ion | Up to 100 mW | 245–263 | — |
| 229.0 | Doubled Ar-Ion | Up to 10 mW | 230–246 | — |
| 224.3 | Helium–Silver (He–Ag) | 20 mW to 1.8 W peak | 225–241 | — |

## Sampling Device

Several sampling arrangements are possible, including direct optical interfaces, microscopes, fiber optic-based probes (either non-contact or immersion optics), and sample chambers, including specialty sample holders and automated sample changers. The sampling optics can also be designed to obtain polarization-dependent Raman spectra. The choice of sampling device is often dictated by the analyte and sample. However, considerations such as sampling volume, speed of the measurement, laser safety, and reproducibility of sample presentation should be evaluated to optimize the sampling device for any given application.

### Filtering Device

The intensity of scattered light at the laser wavelength (Rayleigh scatter) is many orders of magnitude more than the Raman signal and must be rejected before it reaches the detector. Notch filters are almost universally used for this purpose and provide excellent rejection and stability combined with small size. The traditional use of multi-stage monochromators for this purpose, although still viable, is now rare. In addition, various filters or physical barriers to shield the sample from external radiation sources (e.g., room lights or laser plasma lines) may be required, depending on the collection geometry of the instrument.

### Wavelength Processing Unit

The wavelength scale may be encoded by either a scanning monochromator, a grating polychromator [in charge-coupled device (CCD)-Raman spectrometers], or an interferometer (in FT-Raman spectrometers). A discussion of the specific benefits and drawbacks of each of the dispersive designs compared to the FT instrument is beyond the scope of this chapter. Any properly qualified instrument should be suitable for qualitative measurements. However, care must be taken when selecting an instrument for quantitative measurements because dispersion and response linearity might not be uniform across the full spectral range.

### Detector

The silicon-based CCD array is the most common detector for dispersive instruments. The cooled array detector allows measurements over the spectral range from 4500 to 100 $cm^{-1}$ Raman shift with low noise when most visible lasers, such as frequency-doubled neodymium-doped:yttrium–aluminum–garnet (Nd:YAG; 532 nm) or helium–neon (He–Ne; 632.8 nm) lasers, are used. When a 785-nm diode laser is used, the wavelength range is reduced to about 3100 to 100 $cm^{-1}$. The most commonly used CCD has its peak wavelength responsivity when matched to the commonly used 632.8-nm helium–neon (He–Ne) gas laser or 785-nm diode laser. FT instruments typically use single-channel germanium or indium–gallium–arsenide (InGaAs) detectors responsive in the NIR to match the 1064-nm excitation of an Nd:YAG laser.

## SPECIALIZED TECHNIQUES

In addition to “normal” Raman spectroscopy, there are several more specialized Raman-based techniques. These include Raman microscopy and confocal Raman microscopy (CRM), spatially offset Raman spectroscopy (SORS), resonance Raman (RR), deep UV resonance Raman spectroscopy (DUVRRS), surface-enhanced Raman spectroscopy (SERS), Raman optical activity (ROA), coherent anti-Stokes Raman spectroscopy (CARS), Raman gain or loss spectroscopy, and hyper-Raman spectroscopy. Some of these techniques are currently in use, and these are described below. Those that have very specialized uses in pharmaceutical laboratories are not addressed in this chapter.

### Confocal Microscopy/Imaging

The distribution of the various compounds within a given material can be characterized either on the surface by microscopy or inside the sample, three dimensionally, using confocal imaging. The use of Raman scattering allows for the collection of detailed chemical information. Raman microscopy techniques have the following advantages:

- Preparation of the sample may not be required
- Excellent spatial resolution
- Clear image quality
- Outstanding chemical differentiation

It is possible to collect a signal from a single point on a sample, disperse it into a spectrum using a spectrometer, and detect the spectrum using a multi-channel detector such as a CCD or photo diode array (PDA). In this case, instead of obtaining trivial cumulative information about the spot signal intensity, we can obtain a signal spectrum, which can be transformed into detailed information about the chemical composition of the given spot on the sample. The three-dimensional array of data sets, two spatial and one spectral, which is recorded in such an imaging measurement, has become known as a “hypercube” or data cube. These microscopy systems are capable of determining a spatial resolution down to approximately 250 nm but will be influenced by the sample matrix.

The pharmaceutical industry has specific challenges for confocal Raman microscopy in characterizing the structure and distribution of the active components within surface coatings of formulations, dosage forms, and delivery devices, to name a few. For example, high-resolution chemical mapping for homogeneity testing of solid oral dosage forms, creams, and ointments may be useful in select applications.

### Spatially Offset Raman Spectroscopy

SORS provides highly accurate chemical analysis of objects beneath obscuring surfaces (e.g., coatings or non-interfering packaging materials). Examples of uses include, but are not limited to, the identification of tablets inside plastic bottles or screening for counterfeit tablets inside blister packs.

A SORS measurement will make at least two Raman measurements: one at the surface and one at an offset position, typically a few millimeters away. The two spectra can be subtracted using a scalar to produce two spectra representing the surface and subsurface spectra. For a simple, two-layer system, such as powder in a plastic bottle, the powder spectrum can be measured without knowing the bottle material or its relative signal contribution. To do this without using an offset measurement would

involve severe restriction by the interfering signals of the packaging and any fluorescence signals originating from the surface layer. Scaled subtraction works well for two-layer systems, but multi-variate analysis may be required for more complicated situations, such as where the overlying material contains components included in the sublayer (living tissue, for example).

### Deep UV Resonance Raman Spectroscopy

DUVRRS usually uses excitation wavelengths in the 190–260 nm range. There are four major advantages of DUVRRS procedures over their near-UV, visible, or NIR counterparts. These advantages relate to:

- Sensitivity or signal enhancement
- Fluorescence background elimination
- Spectral complexity
- Ambient solar or artificial light background elimination

Current DUVRRS systems come in a large variety of configurations. These variations are primarily related to the light source (laser) and detector systems.

## CALIBRATION

Raman instrument calibration involves three components: primary wavelength (*x*-axis), laser wavelength, and intensity (*y*-axis).

### Primary Wavelength

In the case of FT-Raman instruments, primary wavelength (*x*-axis) calibration is maintained, at least to a first approximation, with an internal helium–neon (He–Ne) laser. Most dispersive instruments use atomic emission lamps for primary wavelength (*x*-axis) calibration. In all instruments suitable for analytical Raman measurements, the vendor offers a procedure for *x*-axis calibration that can be performed by the user. For dispersive Raman instruments, a calibration based on multiple atomic emission lines is preferred. The validity of this calibration approach can be verified after laser wavelength calibration by using a suitable Raman shift standard. For scanning dispersive instruments, calibration might need to be performed more frequently, and precision in both a scanning mode and a static operation mode may need to be verified.[3]

### Laser Wavelength

Laser wavelength variation can affect both the wavelength precision and the photometric (signal) precision of a given instrument. Even the most stable current lasers can vary slightly in their measured wavelength output. The Raman shift wavelength(s) for a given material must therefore be confirmed to ensure that the wavelength scale is accurate for both FT-Raman and dispersive Raman instruments. A reference Raman shift standard material such as those outlined in American Society for Testing and Materials (ASTM) E1840[3] or other suitably verified materials, where the observed peak position(s) have been verified, can be used for this purpose. [NOTE—Reliable Raman shift standard values for frequently used liquid and solid reagents required for wavenumber calibration of Raman spectrometers are provided in the ASTM Standard Guide cited. These values can be used in addition to the highly accurate and precise low-pressure arc lamp emission lines that are also available for use in Raman instrument calibration.] Spectrometric-grade material can be purchased from appropriate suppliers for this use. Certain instruments may use an internal Raman standard that is separate from the primary optical path. External calibration devices reproduce exactly the optical path taken by the scattered radiation. [NOTE—When chemical standards are used, care must be taken to avoid contamination and to confirm standard stability.]

Unless the instrument is of a continuous-calibration type, the primary wavelength (*x*-axis) calibration should be performed, as per vendor procedures, just before measuring the laser wavelength. For external calibration, the Raman shift standard should be placed at the sample location and measured using appropriate acquisition parameters. The peak center of a strong, well-resolved band in the spectral region of interest should be evaluated. The position can be assessed manually or with a suitable, valid peak-picking algorithm. The software provided by the vendor might measure the laser wavelength and adjust the laser wavelength appropriately so that this peak is at the proper position. If the vendor does not provide this functionality, the laser wavelength should be adjusted manually. Depending on the type of laser, the laser wavelength can vary with temperature, current, and voltage. Wavelength tolerances can vary depending on the specific application.

### Intensity

Calibration of the photometric *y*-axis can be critical for successful quantification using certain analytical methods and for method transfer between instruments. Both FT-Raman and dispersive Raman spectrometers should undergo similar calibration procedures. The photometric precision acceptable for a given measurement should be assessed during the procedure development stage.

To calibrate the photometric response of a Raman instrument, a broadband emission source should be used. Most manufacturers will provide appropriate calibration sources and software. If the manufacturer does not provide a procedure or method, the user can accomplish the task using a source obtained from National Institute of Standards and Technology (NIST)

and appropriate software. If a manufacturer's method is used, attention must be paid to the calibration procedure and source validity. The user should obtain appropriate documentation from the manufacturer to ensure a qualified approach.

There are two accepted methods for calibration; however, other appropriate procedures may be used. *Method A* uses a tungsten white light source.[4] The output power of such sources is traceable to the National Metrology Institute. In the United Kingdom, the National Physical Laboratory also provides calibrated light sources. Several other vendors provide NIST-traceable irradiance calibration standards. *Method A* is applicable to all common laser excitation wavelengths listed in *Table 1*. In *Method B*, NIST standard reference materials (SRMs) are used.[5, 6] Several doped-glass fluorescence standards are currently available.

METHOD A

The source should be placed at the sample location with the laser off and the response of the detector measured (using parameters appropriate for the instrument). The output of the source used for calibration should be known. The ratio of the measured response to the true response should be determined, and a correction file should be generated. This correction should be applied to all spectra acquired with the instrument.

METHOD B

The fluorescence standard should be placed at the sample location. With the laser on, a spectrum of the SRM should be obtained (using parameters appropriate for the instrument). The output of the standard used for calibration should be known. The ratio of the measured response to the true response should be determined, and a correction file should be generated. This correction should be applied to all spectra acquired with the instrument. [NOTE—*Method B* is currently appropriate for systems with 785-nm (SRM 2241), 532-nm (SRM 2242), 514.5-nm and 488-nm (SRM 2243), 1064-nm (SRM 2244), 632.8-nm (SRM 2245), and 830-nm (SRM 2246) excitation.]

## External Calibration

Detailed functional validation using external reference standards is recommended to demonstrate instrumental suitability of laboratory instruments, even for instruments that possess an internal calibration approach. The use of external reference standards does not obviate the need for internal quality control procedures; rather, it provides independent documentation of the fitness of the instrument to perform the specific analysis or purpose. For instruments installed in a process location or in a reactor where routine positioning of an external standard is not possible, including those instruments that use an internal calibration approach, the relative performance of an internal versus an external calibration approach should be checked periodically. The purpose of this test is to detect changes in components that might not be included in the internal calibration method (process lens, fiber optic probe, and others).

# SAMPLE-BASED FACTORS THAT AFFECT MEASUREMENT PERFORMANCE

The most important sample-based factor that deleteriously affects quantitative Raman spectroscopy is fluorescence. Other factors, such as local sample heating by the light source, photobleaching, absorption by the matrix or the sample itself, and the effect of polarization, can also be problematic and must be addressed during procedure development. If the sample matrix includes fluorescent compounds, the measured signal will usually contain a contribution from fluorescence. Fluorescence will be observed only if the laser excitation wavelength overlaps with an absorption band of a fluorescent compound. Fluorescence is typically observed as a broad, sloping background underlying the Raman spectrum. Fluorescence can cause both a baseline offset and a reduced signal-to-noise ratio. The wavelength range and intensity of the fluorescence depend on the chemical composition of the fluorescent material. Because fluorescence is generally a much more efficient process than Raman scattering, even minor amounts of fluorescent impurities can lead to significant degradation of the Raman signal. Fluorescence can be reduced by using longer wavelength excitation sources such as 785 or 1064 nm. As the intensity of Raman scattering is proportional to the fourth power of the absolute wavenumber of scattered light, a significant improvement in Raman scattering efficiency can be expected when higher exciting wavenumbers are used. However, the advantage of using a long-wavelength excitation laser to minimize fluorescence is at least partially offset by the reduced strength of the Raman signal. The greatest signal-to-noise ratio will be obtained by balancing fluorescence rejection, signal strength, and detector response.

Fluorescence in solids can sometimes be mitigated by photobleaching, where the sample is exposed to the laser radiation for a period of time before measurement, and operates by degrading the highly absorbing species. Although this is typically a factor to avoid, photobleaching may be used in exceptional circumstances to mitigate the effect of fluorescence, if no other preprocessing of the sample is possible. Photobleaching is less effective in liquids, where the sample is mobile, or if the amount of fluorescent material is more than a trace.

Sample heating by the laser source can cause a variety of effects, such as physical form change (melting), polymorph conversion, or sample burning. The likelihood of sample heating is greatest when the spot size at the sample is the smallest, i.e., when a microprobe or microscope is being used. This is usually an issue for colored, highly absorbing species, or very small particles that have low heat transfer. The effects of sample heating are usually observable, either as changes in the Raman spectrum over time or by visual inspection of the sample. Besides decreasing the laser flux, a variety of methods can be used

[4] NIST traceable tungsten white light source statement: While the calibration of the Raman frequency (or Raman shift, $cm^{-1}$) axis using pure materials and an existing ASTM standard is well accepted, techniques for calibration of the Raman intensity axis are not. Intensity calibrations of Raman spectra can be accomplished with certified white light sources.

to diminish laser-induced heating, such as moving the sample or laser during the measurement or improving the heat transfer from the sample with thermal contact or liquid immersion.

Absorption of the Raman signal by the matrix or the sample itself can also occur. This problem is more prevalent with long-wavelength FT-Raman systems where the Raman signal can overlap with an NIR overtone absorption. This effect will be dependent on the optics of the system, as well as on the sample presentation. Associated with this effect is variability from scattering in solids as a result of packing and particle-size differences. The magnitude of all of these effects is typically smaller than in NIR spectroscopy because of the limited depth of penetration and the relatively narrower wavelength region sampled in Raman spectroscopy.

Finally, it should be recognized that laser radiation is polarized, and the Raman spectra of crystalline materials and other oriented samples can differ significantly, depending on the way that the sample is mounted. If the Raman spectrometer is capable of producing linearly polarized radiation at the sample, then a polarization scrambler is recommended for routine sample analysis.

## PROCEDURE VALIDATION

Validation of Raman procedures will follow the protocols described in *Validation of Compendial Procedures* ⟨1225⟩. Several of these criteria are affected by variables specific to Raman spectroscopy. Fluorescence is the primary variable that can affect the suitability of a procedure. The presence of fluorescent impurities in samples can be quite variable and can have little effect on the acceptability of a material. The procedure must be flexible enough to accommodate different sampling regimens that may be necessary to minimize the effects of these impurities.

Detector linearity must be confirmed over the range of possible signal levels. Fluorescence might drive both the signal baseline and the noise higher than the levels used in the validation, in which case the fluorescence must be decreased, or the procedure must be modified to accommodate the higher fluorescence levels. This is also true for the precision, limit of detection, and limit of quantification of the procedure, as increased baseline noise will adversely affect all of these values. Because fluorescence can also affect quantification caused by baseline shifts, acceptable quantification at different levels of photobleaching, when used, should be confirmed.

The effect of the laser on the sample must be determined. Visual inspection of the sample and qualitative inspection of the Raman spectrum will confirm that the sample is not being altered (other than by photobleaching). Specific variables to confirm in the spectrum are shifts in peak position, changes in peak height and band width, and unexpected changes in background intensity.

Precision must also encompass sample position. The sample presentation is a critical factor for both solids and liquids and must be either tightly controlled or accounted for in the calibration model. Sample-position sensitivity can often be minimized by appropriate sample preparation or sample-holder geometry but will vary from instrument to instrument, based on excitation and collection optical configuration.

In addition, many suitable chemometric algorithms for data pretreatment and calibration exist. The selection of these algorithms should be based on sound scientific judgment and suitability for the intended application.

### Ongoing Procedure Evaluation

Validated Raman procedures should be subject to ongoing performance evaluation, which may include monitoring of accuracy, precision, and other suitable procedure parameters. If the performance is unacceptable, corrective action is necessary. This involves conducting an investigation to identify the cause of the change in the performance of the procedure and may indicate that the Raman procedure is not suitable for continued use. Improving the Raman procedure so that it meets measurement suitability criteria may require additional procedure development as well as validation experiments, with documentation, demonstrating that the improved procedure is suitable for the intended application. The extent of the revalidation required depends on the cause of the change in performance of the procedure and the nature of corrective action required to establish suitable performance. Appropriate change controls should be implemented to document ongoing continuous-improvement activities.

Revalidation of a qualitative model may be necessary as a result of the following:

- Addition of a new material to the spectral reference library
- Changes in the source of material supply
- Identification of previously unknown critical attribute(s) of material(s)

Revalidation of a quantitative model may be necessary as a result of the following:

- Changes in the composition of the test sample or finished product
- Changes in the manufacturing process
- Changes in the sources or grades of raw materials
- Changes in the reference analytical procedure
- Major changes in instrument hardware

#### OUTLIERS

Sample spectra that produce a Raman response that differs from the qualitative or quantitative calibration model may produce an outlier. This does not necessarily indicate an out-of-specification result, but rather an outlier indicates that further testing of the sample may be required. If subsequent testing of the sample by an appropriate procedure indicates that the property of interest is within specifications, then the sample meets its specifications. Outlier samples may be incorporated into an updated calibration model after execution and documentation of suitable validation studies. For further discussion on model lifecycle, see ⟨1039⟩.

https://pharmacopeia.cn/v-download/

## Method Transfer

Controls and measures for demonstrating the suitability of performance after method transfer are similar to those required for any analytical procedure. Exceptions to general principles for conducting method transfer for Raman procedures should be justified on a case-by-case basis. The transfer of a Raman procedure is often performed by using a Raman calibration model on a second instrument that is similar to the primary instrument used to develop and validate the procedure. When a calibration model is transferred to another instrument, procedures and criteria must be applied to demonstrate that the calibration model meets suitable measurement criteria on the second instrument. The selection of an appropriate calibration model transfer procedure should be based on sound scientific judgment.▲ (USP 1-Aug-2020)

# ▲⟨1901⟩ THEORY AND PRACTICE OF ASBESTOS DETECTION IN PHARMACEUTICAL TALC

To view the Notice from the Expert Committee that posted in conjunction with this chapter, please click https://www.uspnf.com/notices/talc-official-dates-20230601.

## INTRODUCTION

This chapter provides background information to support *Detection of Asbestos in Pharmaceutical Talc* ⟨901⟩. It describes analytical procedures for X-ray diffraction (XRD)—also termed X-ray powder diffraction (XRPD)—and polarized light microscopy (PLM), both of which can be effective for testing of asbestos in talc. Some of the principles applied in this method were first described in the J4-1 method developed by the Cosmetics, Toiletries, and Fragrance Association (CTFA)(*1*) and applied to the analysis of talc for asbestos, which was implemented in 1976, although the method applied only to the analysis of amphibole asbestos. The original asbestos test, which was added to the *Talc* monograph in 2005, expanded on this protocol, applying the principles to chrysotile and amphibole asbestos. For a full description of the current update to this procedure, see the related USP publication (*2*).

XRD in combination with PLM and/or an electron microscopy technique, such as transmission electron microscopy (TEM) or scanning electron microscopy (SEM), can ensure adequate specificity of the asbestos test because definitive microscopic identification and characterization of asbestos and mineral fibers are critical to detect the presence or confirm the absence of asbestos. Specificity encompasses a determination of a particle's mineral identity and whether or not the mineral is asbestiform. This can only be accomplished definitively by microscopy.

As with all of the techniques discussed for asbestos analysis, XRD should not be used alone for asbestos determination, as XRD cannot distinguish morphology and therefore cannot be used exclusively to determine whether amphibole or serpentine are asbestiform or nonasbestiform. However, XRD is critical for the identification of phases present in a mineral mixture and can also determine if foreign materials are present.

Both XRD and PLM allow for testing of larger sample amounts than electron microscopic methods, leading to more representative analyses in general. The largest amount of material can be analyzed in the XRD test, followed by PLM, SEM, and TEM.

The asbestos testing methods for pharmaceutical talc—including XRD, PLM, SEM, and TEM—are compared in *Table 1*.

**Table 1. Methods for Asbestos Detection and Quantification in a Talc Matrix**

| Method | Description | Advantages | Disadvantages |
|---|---|---|---|
| X-Ray diffraction | The presence of amphiboles is detected by a diffraction peak at 10.5 ± 0.1° 2θ, and the presence of serpentines is detected by diffraction peaks at 24.3 ± 0.1° 2θ to 12.1 ± 0.1° 2θ. | • Important in fully characterizing mineral assemblage<br>• Gives information about bulk purity<br>• Can give information about the origin of the talc deposit and associated risk<br>• Can indicate if problematic levels of any phase are present | • Cannot distinguish asbestos from nonasbestos forms of the same mineral<br>• Limit of detection may be too high for public health and regulatory purposes<br>• Detection limit of serpentine is severely affected by the presence of chlorite<br>• May give a false negative if used as a screening method |
| Polarized light microscopy | The presence of asbestos is confirmed by the occurrence of particles that have asbestos morphology and are identified as an asbestos mineral by optical properties and dispersion staining. | • Identification is based on morphology and phase determination; can be conclusive<br>• Particles characterized by PLM are in the size range easily distinguished as asbestos vs. nonasbestos<br>• Good for larger-size products typical of personal care talc products | • Normal quantitation limit may be too high for public health and regulatory purposes if concentration techniques are not used<br>• Particles of milled material (<5 µm) may be below the resolution limit |
| Scanning electron microscopy | The presence of asbestos is confirmed by the occurrence of particles that have asbestos morphology and are identified as an asbestos mineral by energy dispersive x-ray spectroscopy (EDS) elemental analysis. | • A larger sample size (microgram range) is analyzed relative to TEM<br>• Identification is based on morphology and elemental analysis<br>• Resolution is better than PLM<br>• Capable of disclosing surface morphology | • Fibrils of chrysotile may be below the resolution limit of older microscopes<br>• Because it is a presumed ID based on chemistry and morphology alone, it may give a false positive<br>• Structural information methods are currently in development<br>• Interferences: talc vs. anthophyllite, etc. |

**Table 1. Methods for Asbestos Detection and Quantification in a Talc Matrix** *(continued)*

| Method | Description | Advantages | Disadvantages |
|---|---|---|---|
| Transmission electron microscopy | The presence of asbestos is confirmed by the occurrence of particles that have asbestos morphology and are identified as an asbestos mineral by EDS elemental analysis and electron diffraction. | • Identification is based on morphology, elemental analysis, and electron diffraction (structural information)<br>• May be the only method with the resolution high enough to routinely detect fibrils of chrysotile | • May be prohibitive for quality control due to protracted preparation and analysis time, high cost, irreproducibility, and small sample size (nanogram range)<br>• Because it may miss the larger fibers associated with amphibole asbestos, it may give a false negative |

XRD in combination with PLM can be effective in the characterization of asbestos particles in the >5-µm size range, and PLM has, as its strength, the ability to distinguish asbestiform from nonasbestiform particles. While electron microscopy techniques such as TEM and SEM have the ability to analyze particle sizes that are below the resolution limit of optical microscopy, optical microscopy has sufficient resolution to cover the majority of the size range in coarser pharmaceutical products (e.g., 200 mesh) and a significant portion of the finest products (i.e., <325 mesh). Furthermore, due to the high tensile strength associated with asbestos and the higher hardness of serpentine and amphibole minerals relative to talc—the softest mineral known—asbestos, if present, is not likely to occur solely as individual particles in the finest size range of a milled talc–asbestos mixture, but rather as larger particles and bundles, due to resistance to grinding. This was demonstrated during round robin testing, where spiked samples were prepared using aggressive grinding to simulate production of ground product. Even though the samples were ground, asbestos bundles were still present and identifiable by PLM (*3*).

## PROCEDURE 1: X-RAY DIFFRACTION

XRD is used to determine whether amphibole and/or serpentine are present in a talc powder matrix, and when applicable, to estimate the percentage present. It is intended to be used in combination with one or more microscopy techniques capable of determining whether asbestos is present. XRD is the initial analysis in the monograph asbestos testing and is an important tool for mineral or material characterization.

XRD can be used to determine overall purity of a talc product with respect to accessory minerals and is important in determining the suitability of talc for pharmaceutical use. Depending on a talc's formation conditions, accessory minerals include, but are not limited to, dolomite, magnesite, calcite, and quartz, as well as a variety of micas, chlorites, feldspars, and sometimes serpentines and amphiboles. Chlorite group, feldspars, and dolomite minerals can interfere with the detection of serpentine group minerals during analysis. Refer to *Table 2* in *Appendix 1*, which includes XRD peak positions for talc and minerals that can be associated with talc as well as critical interferences. An example of an XRD qualitative scan of talc (used as the base material for reference material spikes) is included in *Appendix 2*.

This test method uses XRD to detect and identify the presence of total amphiboles and total serpentine in a powdered talc product. [NOTE—XRD cannot distinguish between asbestiform and nonasbestiform varieties of amphibole or serpentine and therefore on its own cannot detect if asbestos is present. XRD can, however, detect whether serpentine or amphibole minerals are present and provide information about their upper limits of occurrence.] XRD can also indicate the presence of foreign substances.

For monoclinic amphiboles (e.g., tremolite, actinolite), the primary diagnostic peak is at approximately 10.5° 2-theta (2θ), and for orthorhombic amphiboles (specifically anthophyllite), the primary diagnostic peak is at approximately 10.7° 2θ with copper Kα radiation. Refer to *Appendix 2* for examples of quantitative XRD scans of talc spiked with 1% tremolite, 1% anthophyllite, and 1% chrysotile showing peak positions for these minerals. For serpentine group minerals, partial or full overlap of peaks from chlorite group minerals can occur (i.e., serpentine diagnostic peaks at 12.1° 2θ and 24.4° 2θ can overlap with chlorite diagnostic peaks at 12.5° 2θ and 25.1° 2θ, respectively). For this method, an amphibole reporting limit of detection has been empirically determined to be 0.2%. However, a lower limit of detection for amphiboles can be attained at 0.1%, as verified by an individual laboratory. For this method, a serpentine limit of detection has been determined to be 0.2% with no chlorite interference and 1% with up to 15% chlorite interference. *Appendix 2* includes examples of quantitative XRD scans of talc spiked with 1% serpentine and 1% chlorite to illustrate the potential interference of these two minerals.

[NOTE—XRD evaluations of amphibole and serpentine minerals may have compositional variation or inherent crystallinity variation or combinations thereof that can be observed through slight shifts in *d*-values and associated peak profile variations associated with full width half maximums (FWHM).]

XRD findings on potential total amphibole or total serpentine content should be consistent with the findings from PLM and any additional microscopic techniques. For example, PLM would not be expected to exhibit percentages of amphibole or serpentine if XRD did not detect them above the detection limit.

When used under quantitative scan conditions specific to this test method, XRD can also be used to determine a relative detection limit of total amphibole and total serpentine minerals in a pharmaceutical talc product. XRD analysis, with respect to asbestos screening of bulk materials, is also discussed in the Environmental Protection Agency's (EPA/600/R-93/116) and the International Organization for Standardization's (ISO 22262-3)(*4*) methods.

For background information about talc, amphibole, and serpentine group minerals, see the relevant USP publication (*2*).

### Detection Limit

An XRD round robin study using samples prepared with known amphibole and serpentine amounts was completed to determine a relative limit of detection for amphiboles (tremolite and anthophyllite), serpentine with no chlorite interference, and serpentine with trace levels of chlorite interference (*2*). Samples included the following:

- 1% tremolite nonasbestiform

https://mathuseargcar.h.com/

- 1% anthophyllite asbestiform (A-181; as received)
- 1% serpentine—chrysotile (#1422 WCD, as received)
- 0.25% tremolite nonasbestiform
- 0.25% anthophyllite asbestiform (A-181; as received)
- 0.25% serpentine—chrysotile (#1422 WCD, as received)
- 1% serpentine—chrysotile (#1422 WCD, as received)
- 1% chlorite (highly crystalline spike, fine powder)
- Baseline talc (no chlorite, no carbonates, macro-crystalline talc)

Based on these round robin evaluations, the method provided the following:

- Acceptable resolution and detection of tremolite and anthophyllite at a concentration of 0.2%
- Easily resolved and detected tremolite and anthophyllite at a concentration of 1%
- Acceptable detection of serpentine at a concentration of 0.2% without chlorite interference
- Easily detected serpentine at a concentration of 1% without chlorite interference
- Acceptable resolution and detection of serpentine at a concentration of 1% with a chlorite level of up to 15%–20%

Individual laboratories should confirm that these detection limits (or lower) can be achieved by using similar (or lower concentration) spiked standards.

The instrument, equipment, apparatus, and supplies—as well as radiation safety—are described in *Characterization of Crystalline and Partially Crystalline Solids by X-Ray Powder Diffraction (XRPD)* ⟨941⟩.

## Lab Testing Considerations

The lab should be capable of implementing a cGMP-based quality program as described in ⟨941⟩. The use of one or more of the recommended National Institute of Standards and Technology (NIST) XRD reference materials (e.g., NIST SRM 640c–Si) noted in *Appendix 4* should be used to check the alignment of the instrument and sample as follows:

- *Instrument alignment:* A condition where the geometry of the goniometer and sample stage are ideal, and analysis will generate an accurate *d*-value
- *Sample alignment:* A condition where the specimen surface lies on the sample stage within the geometric focal plane of the goniometer and in conjunction with the instrument alignment, providing the most-precise and accurate *d*-values

It is helpful to run talc standards to become familiar with peak positions. Certified reference materials (or other noncertified talc samples) can be obtained for this purpose (see *Appendix 4*.) A list of peak positions for talc and common materials associated with talc is included in *Appendix 2*.

## Further Information

For more information on XRD procedures, laboratories should have access to either *Elements of X-Ray Diffraction* (*5*)—which covers fundamentals, experimental methods, and applications—or *X-ray Diffraction Procedures: for Polycrystalline and Amorphous Materials* (*6*), which provides an effective guide to the science and practical techniques of geometrical crystallography and XRD of crystals as well as more complete coverage of space lattices, point and space groups, production and measurement of X-rays, powder techniques, other related topics, and additional references.

# PROCEDURE 2: POLARIZED LIGHT MICROSCOPY

PLM is a transmitted light microscopic technique where optical properties of minerals can be measured and definitively identified with respect to mineral phase. Estimates of content can also be determined. PLM is described in detail in several publications (*7*–*9*).

Using standard immersion methods with PLM has three methodological strengths. First, the refractive indices (RIs) of the asbestos minerals of concern (e.g., chrysotile, anthophyllite-asbestos, tremolite-asbestos, or actinolite-asbestos) differ from talc such that individual particle identification is possible. This is especially true for the distinction of anthophyllite versus talc, which by other methods may be problematic. Second, tens of thousands of particles can be observed for selected optical properties in a relatively short time. Third, the morphology of each particle can also be determined.

Another technique, dispersion staining, is used to screen for particles of interest based on their color in dispersion staining mode. Dispersion staining is a specific configuration of the microscope, not a physical staining technique of the particles. When the RIs of the mineral and liquid are similar, the RI of the mineral can be estimated using this technique. Alternatively, additional preparations using more RI liquids can be used to determine a more precise value. A heating and cooling stage (optional for this method and discussed below) can also be used to vary the RI liquid values to determine matching indices of the phases analyzed more precisely.

Compared to *Optical Microscopy* ⟨776⟩, the addition of polarized light techniques described in this chapter, along with RI screening by dispersion staining, facilitates particle phase identification.

The PLM technique described below and in ⟨901⟩ involves a wet sieving preparation procedure to evaluate the coarser particles in the mineral powder matrix. This technique takes advantage of the tendency of talc to have a much finer particle size than harder mineral particles in a ground mineral mixture because talc is softer than all other minerals (Moh's hardness of 1 on a 1–10 scale). This causes minerals that are more difficult to grind to concentrate in the coarser size fraction of mixtures containing talc. This is further enhanced by the fact that asbestos is characteristically difficult to grind due to its inherent tensile strength, especially relative to talc. This concept is readily confirmed by attempting to grind asbestos standards using a mortar and pestle. Therefore, enhanced separation of asbestos particles from talc is achieved with wet sieving by removing talc (the

@2024 USPC

main component) from the matrix. Enhanced separation of nonasbestos particles of serpentine and amphibole is also achieved due to differences in their hardness (Moh's hardness of 5–6 versus 1, respectively), allowing for a more complete evaluation of morphology of the remaining phases. An added benefit of wet sieving is the removal of fine particles that are too small to be characterized by optical methods and act to dilute the sample.

The dispersion staining method applied to the analysis of chrysotile in talc involves immersing the particles in an RI liquid of 1.550. In the dispersion staining configuration of the PLM with the 1.550 RI liquid, talc plates appear yellow during the entire rotation of the stage. Edge-view talc appears yellow when the particle is oriented with its direction of elongation parallel to the microscope polarizer (*n* parallel) and blue when the particle is oriented with its direction of elongation perpendicular to the microscope polarizer (*n* perpendicular). In contrast, chrysotile is easily distinguished from talc, appearing magenta in the *n*-parallel orientation and blue in the *n*-perpendicular orientation. See *Appendix 3* for an example image of chrysotile with talc in a 1.550 RI liquid.

The dispersion staining method applied to the analysis of amphibole in talc involves immersing the particles in an RI liquid of 1.605. In the dispersion staining configuration of the PLM with the 1.605 RI liquid, talc plates and edge-view talc appear pale blue to white during the entire rotation of the stage. In contrast, amphibole is easily distinguished from talc, appearing yellow when the particle is oriented with its direction of elongation parallel to the microscope polarizer (*n*-parallel) and a deep blue, magenta, or yellow when the particle is oriented with its direction of elongation perpendicular to the microscope polarizer (*n*-perpendicular). Refer to *Appendix 3* for an example image of tremolite with talc in a 1.605 RI liquid.

The 1.605 RI liquid is used to screen for the presence of amphibole in talc. It will be incapable of measuring the gamma prime ($\gamma'$) RI of any amphibole and thus alone cannot be used to identify the mineral species; in some cases, the RIs and thus the colors observed are common across multiple amphiboles.

Use the appropriate matching RI liquid(s) specified in *Table 2* of ⟨901⟩, for suspected amphiboles that may not be conclusive in the dispersion staining screening step (e.g., amphiboles with both RIs significantly higher than 1.605).

The wavelength of match can be determined using dispersion staining charts in Annex C of ISO 22262-1 (*10*) or Becke lines, as shown in Figure 2 of Gunter (*11*). RIs can be determined from the wavelength of match using references (*7*,*12*–*13*). Ranges of RIs for the amphibole minerals can be found elsewhere (*9*,*14*–*15*). A table of typical RI ranges for the regulated asbestos types can be found in EPA/600/R-93/116, Table 2-2 Optical Properties of Asbestos Fibers (*16*).

Optionally, a heating and cooling stage can be used to determine RI more precisely. In this method, the heating and cooling stage can be used with 1.595 RI liquid in plane-polarized light (PPL), cross-polarized light (XPL), and cross-polarized light with the first-order red plate (RPL), starting at room temperature. Scan the entire slide using medium to high magnification. The advantage of using this stage is that one RI liquid can achieve a range of RIs at different temperatures (e.g., when using 1.595 RI liquid, the RI at 125° = 1.551, 50° = 1.584, and 0° = 1.606). For better identification, this procedure can be used to match the RIs of the mineral more precisely.

## Detection Limit

It has been determined empirically that the working detection limit of this method is 0.01%, or 100 ppm by weight (µg/g). This was established in an interlaboratory test involving five laboratories and standards with known concentrations (*3*). In some cases, a concentration of 0.001%, or 10 ppm (µg/g), was detected, although this was not achieved consistently using the average amount of material analyzed at each laboratory. Individual laboratories can establish alternative detection limits if they are validated using standards of known composition.

## Quantitation

Although quantification of results is not required in ⟨901⟩, the following is an optional quantification method using the dimensions of particles documented during analysis:

Calculate the mass of asbestos, *m*, in grams:

$$\text{Result} = l \times w^2 \times f \times \rho \times 10^{-12}$$

$l$ = length (µm)
$w$ = width (µm)
$f$ = shape factor (0.7854 for chrysotile; 0.5 for amphibole) [refer to ISO 22262-2 (*17*)]
$\rho$ = density (mg/m$^3$)

Calculate the total asbestos mass observed for all slides by summing the mass of each asbestos particle, $m_T$, in grams.

Calculate the total mass of the sample analyzed by summing the mass of sample placed on each slide, $m_A$, in grams.

Calculate the total fiber mass as a percentage:

$$\text{Result} = m_T/m_A \times 100$$

[NOTE—When quantitating the portion retained on a sieve (following wet sieve preparation), the above calculation applies only to the size fraction analyzed.]

## Lab Testing Considerations

It is helpful to ensure that the microscope is set up and aligned properly by obtaining dispersion staining colors on prepared standards of amphibole and chrysotile asbestos before analyzing unknown material.

An analyst performing this method should have training specific to PLM and the various modes of PLM operation and must have a rigorous working knowledge of all terms described.

An example of a quality control program relating to PLM analysis can be found in EPA/600/R-93/116, Section 3.0 (*16*).

## Standards and Calibration

- NIST or NIST-traceable standards should be used for all types of asbestos, both common and uncommon asbestos types (the six regulated species), as well as interfering minerals and talc itself. [NOTE—Other characterized standards may be used as well, such as those provided by the National Institute of Environmental Health Sciences (NIEHS) or the Union for International Cancer Control (UICC).]

  Mounting media calibration (RI liquids):
  - Calibrate upon opening a new bottle from the manufacturer and quarterly thereafter for RI liquids that are used on a regular basis (e.g., 1.550, 1.605)
  - Calibrate infrequently used liquids before each use
  - Perform calibration using either NIST-traceable reference particles (e.g., Cargille precision optical glass) or an Abbe refractometer calibrated with a similar NIST-traceable standard

## Appendix 4. Example Materials

[NOTE—Asbestos and nonasbestos standards are becoming difficult to obtain from national laboratories or institutes. The use of in-house or noncertified reference materials may be needed. It is recommended that permanent mounts for PLM be made or purchased to be used for lab reference. Available example materials are listed below.]

- XRD available certified reference materials
  - NIST SRM 640b or above silicon powder, *d*-spacing standard
  - NIST SRM 674b or above x-ray powder diffraction intensity set
  - NIST SRM 660a or above LaB6, line position and line shape standard
  - NIST SRM 675 or above fluorophlogopite, low angle (large *d*-spacing) standard
- Talc available certified reference materials
  - Brammer primary certified reference material; JCRM R901, R902, R903 (set of three)
  - Brammer certified reference material, BCS 203a RM asbestos and nonasbestos reference materials
- Amphibole
  - NIST 1867a, uncommon commercial asbestos—tremolite, anthophyllite, actinolite (set of three)
  - Lone Pine tremolite (as provided by Research Triangle Institute)
  - Anthophyllite and talc (Fisher A-181, Gooch filter)
- Serpentine
  - Whittaker, Clark, and Daniels #1422 asbestos (1971)
  - NIST SRM 1866a commercial asbestos—chrysotile

For XRD, homogeneity concerns must be considered when using dry preparations of reference standards, regardless of preparation size. Therefore, it is recommended that the laboratory analyst use ethanol, isopropanol, or methanol for all reference standard preparations.

Mortar and pestle preparation can be used for small preparations (<10 g) but should include multiple wet grinding or blending and drying cycles (minimum of three). For large reference standard preparations (>10 g), the laboratory analyst should use ethanol, isopropanol, or methanol in conjunction with milling or grinding using puck or puck and ring mills under shear and impact conditioning or by cylindrical media-mill grinding with impact and planar shearing.

# ⟨1911⟩ RHEOMETRY

- **Newtonian Viscosity**

If an external stress is exerted on a fluid, the latter will flow to a degree that is determined by internal friction forces derived from internal molecular interactions and by the magnitude of the external stress applied. The measure of resistance to flow is defined as the viscosity of the fluid. The coefficient of viscosity, $\eta$, historically termed the absolute viscosity, is defined by Newton's law of viscous flow:

$$\sigma = \eta \cdot \dot{\gamma} \quad (1)$$

$\sigma$ = shear stress, defined as the applied stress that causes successive parallel layers of a material body to move in their own planes relative to each other

$\dot{\gamma}$ = shear rate, defined as the rate of change of shear strain with time

It should be noted that although *stress* and *strain* are often used interchangeably, the terms are not used interchangeably in rheology: *stress* is synonymous with force per unit area or a system of forces per unit area, and *strain* refers to deformation (i.e., a change in shape or size). A fluid is said to exhibit Newtonian flow if the viscosity is a constant that is independent of the shear rate or applied shear stress. Because viscosity depends on temperature, the temperature of the substance being measured should be controlled to within ±0.1°.

In general, Newton's law is obeyed by liquids of low molecular weight and by solutions of low molecular weight solutes in low molecular weight solvents. However, liquids of high molecular weight, solutions that contain high molecular weight solutes and colloidal dispersions (e.g., suspensions and emulsions) typically do not obey Newton's law of viscous flow and are referred to as non-Newtonian fluids.

In the International System of Units (SI), the unit of viscosity is the pascal-second (Pa · s), which is equivalent to 1 kg · $m^{-1}$ · $s^{-1}$ or 10 Poise in the centimeter-gram-second (cgs) system. The viscosities of most Newtonian fluids are measured in millipascal-seconds (1 Pa · s = 1000 mPa · s; 1 mPa · s = 1 centipoise). Kinematic viscosity, $\nu$, relates the viscous force to the inertial force by relating the Newtonian viscosity of a fluid to its density, $\rho$, at the same temperature:

$$\nu = \frac{\eta}{\rho} \quad (2)$$

The units of kinematic viscosity in SI units are $m^2 \cdot s^{-1}$ or, more commonly, $mm^2 \cdot s^{-1}$. [Note—1 $mm^2 \cdot s^{-1}$ = 1 centistoke (cS or cSt). Stokes or centistokes are the units in the cgs system for kinematic viscosity.]

**Measurement of Newtonian Viscosity Using a Capillary Viscometer**

The viscosity of a Newtonian fluid is measured by the use of glass capillary viscometers, examples of which are shown in *Figure 1* (simple U-tube capillary viscometer, also referred to as an Ostwald-type capillary viscometer) and *Figure 2* (constant or suspended-level viscometer, also referred to as an Ubbelohde-type capillary viscometer). [Note—When the term viscosity is used herein, it refers to absolute or Newtonian viscosity.] The constant- or suspended-level viscometer is a more robust design that is less influenced by temperature variations.

The following example is based on *Figure 1*, and the same principle is applicable to *Figure 2*. With the apparatus in *Figure 1*, the flow time, *t*, is measured for a given volume of fluid, *V*, as defined between lines 1 and 2 of *Figure 1*, to flow through a capillary tube having a length equal to *L* and a radius equal to *r*. As long as the density of the fluid, $\rho$, is known, the viscosity can be calculated using the Poiseuille equation:

$$\eta = \frac{\pi r^4 t \Delta P}{8LV} \quad (3)$$

$P$ = pressure

The applied pressure differential, $\Delta P$, is defined as:

$$\Delta P = (h_1 - h_2) \times g \times \rho \quad (4)$$

$h_1$ = height of the fluid in the tube at line 1 measured from the bottom position
$h_2$ = height of the fluid in the tube at line 2 measured from the bottom position
$g$ = gravitational acceleration (standard value = 9.80665 $m \cdot s^{-2}$)

Glass capillary viscometers generally are categorized as low shear stress instruments because $\Delta P$ is relatively small. The typical ranges for shear stress, $\sigma$, and shear rate, $\dot{\gamma}$ (at the wall), are 0.1–15 Pa and 100–20,000 $s^{-1}$, respectively.

The absolute dimensions of a capillary tube usually are too difficult to measure conveniently. As a result, an empirical calibration is employed for each viscometer tube. Collecting all the constants in *Equations 3* and *4* into a single viscometer constant, *k*, yields the approximate equation for kinematic viscosity:

$$\nu = k \times t \quad (5)$$

To determine *k*, analysts measure the flow time for a liquid of known viscosity at a given temperature. This result is used to calculate the viscometer constant for that particular temperature.

In work requiring a high degree of accuracy, analysts can use the following equation:

$$\nu = k \times t - (E/t^2) \quad (6)$$

$E$ = kinetic energy factor, in $mm^2 \cdot s$

The viscometer constant, *k*, and kinetic factor, *E*, are determined from flow times measured for a set of stable, clean, Newtonian fluids of known kinematic viscosity (viscosity standard reference materials).

Once the viscometer constant(s) have been determined for a given temperature by the use of appropriate viscosity standards, the values can be used until the viscometer is subjected to thermal or mechanical stress that alters the dimensions of the capillary.

Generally, calibration, operation, and cleaning of viscometers should be performed according to instrument manufacturer's recommendations. Capillary viscometers must be scrupulously clean and should display no residual adsorbed or particulate organic or inorganic contamination. Surface contaminants may alter the dimensions of the capillary and the interfacial tension.

The procedures detailed in *Viscosity—Capillary Methods* ⟨911⟩ are intended for use with fluids that exhibit Newtonian behavior when subjected to shear stress. These procedures are not suitable for the characterization of non-Newtonian fluids because they may give erroneous and variable results if used with such fluids.

Capillary viscometers described in ⟨911⟩ typically measure rheological properties at only one shear rate during one pass of the sample through the capillary. Because of the nonlinearity of the shear rate–shear stress relationship for non-Newtonian fluids, this measurement is inadequate unless provisions are made for flow measurements at multiple rates of shear. Even more problematic for non-Newtonian fluids are the decrease in shear rate from the capillary wall to the center of the capillary and the variation in shear stress with time as the liquid level in the capillary viscometer decreases. Thus, capillary viscometers are inherently unsuitable for use in characterizing non-Newtonian fluids.

Because of the small $\Delta P$ attained with glass capillary viscometers, their use in measurements of high-viscosity fluids is impractical. Capillary-extrusion viscometers that use an external pressurized gas reservoir or other source of constant pressure are the only practical capillary instrumental alternative in these instances. In addition, capillary-extrusion viscometers may allow the operator to vary the shear rate or stress, thus enabling the characterization of non-Newtonian fluids. Chapter ⟨911⟩ does not address such devices.

**Measurement of Newtonian Viscosity Using a Rotational Viscometer**

The principle of the method is to measure the force (torque) acting on a rotor when it rotates at a constant angular velocity (rotational speed) in a liquid. Rotational viscometers are used for measuring the viscosity of Newtonian fluids or the apparent viscosity of non-Newtonian fluids. Detailed methods and procedures for rotational instruments are provided in *Viscosity—Rotational Methods* ⟨912⟩. Measurement of Newtonian viscosity can be performed on rotational viscometers/rheometers following the methods and procedures proposed in *Viscosity—Rotational Methods* ⟨912⟩. The calculated viscosity of Newtonian fluids should be the same (within experimental error), regardless of the rate of shear (or rotational speed).

- **NON-NEWTONIAN RHEOLOGY**

Newton's law of viscous deformation or flow, described in the section on Newtonian viscosity, describes the relationship between an applied stress, $\sigma$, and the resultant flow with a rate of shear, or velocity gradient, of $\dot{\gamma}$. Disperse systems (i.e., suspensions or emulsions) or fluids that contain macromolecular components usually do not obey Newton's law. These exceptions to Newtonian behavior are the subject of this section. The categorization of such exceptions into different flow

behaviors such as shear-thinning (pseudoplastic), shear-thickening (dilatant), Bingham, etc., is not rigid. Non-Newtonian fluids may exhibit different rheological behavior depending on shear rate, shear stress, and temperature. Time-dependent rheological behavior, such as rheopexy or thixotropy, is not considered in this chapter.

The rheological behavior of a non-Newtonian fluid is evident when shear stress is plotted as a function of shear rate. The shear stress–shear rate relationship for Newtonian compositions is linear and passes through the origin, whereas the shear stress–shear rate relationship for non-Newtonian fluids is nonlinear and may not pass through the origin, or it is linear but does not pass through the origin (Bingham body). Rheograms, or flow curves, of some typical non-Newtonian fluids are contrasted with those of Newtonian fluids in *Figure 3*.

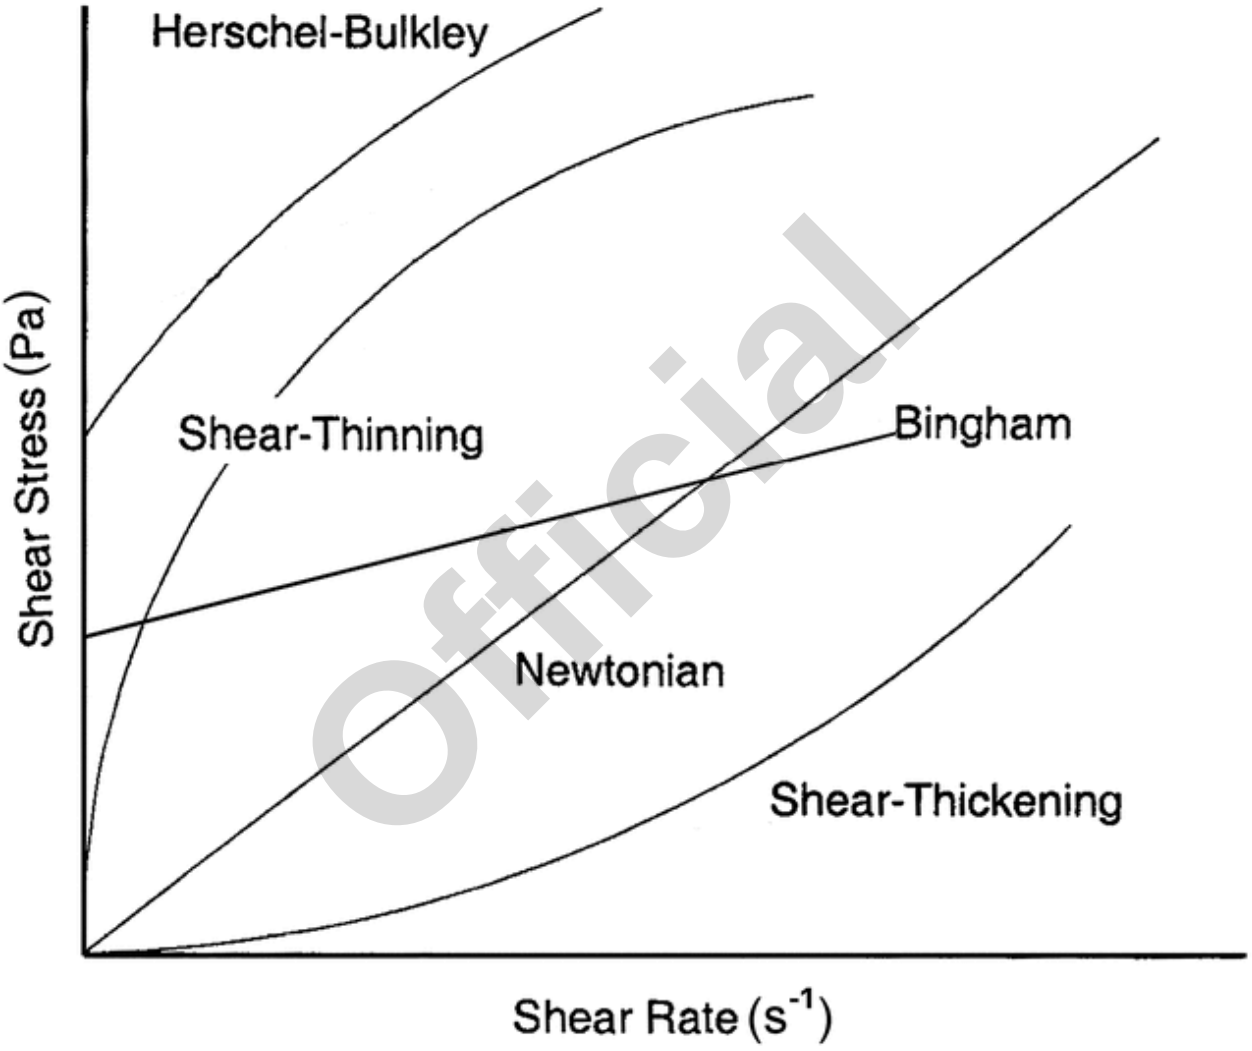

Figure 3. Rheograms of Newtonian and typical time-independent non-Newtonian fluids.

All the rheograms in *Figure 3* can be described by the Herschel–Bulkley equation:

$$\sigma = K \cdot \dot{\gamma}^{n} + \sigma_0 \quad (7)$$

$\sigma$ = shear stress, in Pa
$K$ = consistency coefficient
$\dot{\gamma}$ = shear rate, in $s^{-1}$
$n$ = the flow behavior index
$\sigma_0$ = yield stress, in Pa

For Newtonian fluids and Bingham plastics, $K$ is designated as the viscosity ($\eta$) and plastic viscosity ($\eta_{pl}$), respectively. Because the viscosity of Newtonian fluids and the plastic viscosity of Bingham plastics are independent of the shear stress or shear rate, the flow behavior index, $n$, is equal to 1 for Newtonian fluids and Bingham plastics. For shear-thinning fluids, $0 < n < 1$, and for shear-thickening fluids, $1 < n < \infty$. Shear thinning can be observed in certain complex solutions such as aqueous

hydrocolloid solutions. Dilatant behavior is generally exhibited by concentrated suspensions of nonaggregating monodisperse solid particles such as mixtures of corn starch and water. At very high viscosities or very low shear stresses, Bingham plastics exhibit a yield stress, $\sigma_0$, a shear stress below which no apparent deformation occurs (*Figure 3*). Other non-Newtonian fluids do not appear to exhibit a yield stress, $\sigma_0$, because flow occurs even at very low shear stresses. Thus, for non-Bingham bodies, in the absence of $\sigma_0$ the Herschel–Bulkley equation reduces to the power law, i.e., the Ostwald–de Waele equation:

$$\sigma = K \cdot \dot{\gamma}^{n} \quad (8)$$

Many pharmaceutical macromolecular materials exhibit non-Newtonian behavior in solution. Although the viscosity of Newtonian fluids is a constant, i.e., $\eta = \sigma/\dot{\gamma}$ so that $\eta$ is independent of shear rate or shear stress, there is no singular value of viscosity for non-Newtonian fluids because the viscosity of non-Newtonian fluids varies with shear rate or shear stress. Accordingly, applying the Newtonian concept of viscosity to non-Newtonian fluids is inappropriate. The viscosity value observed for a non-Newtonian fluid is an apparent viscosity, $\eta_{app}$, and is a function of the conditions of measurement. As the shear rate or shear stress changes, the apparent viscosity is likely to change as well. *Figure 4* depicts the dependence of $\eta_{app}$ on the shear rate for an aqueous solution of a typical hydrocolloid.

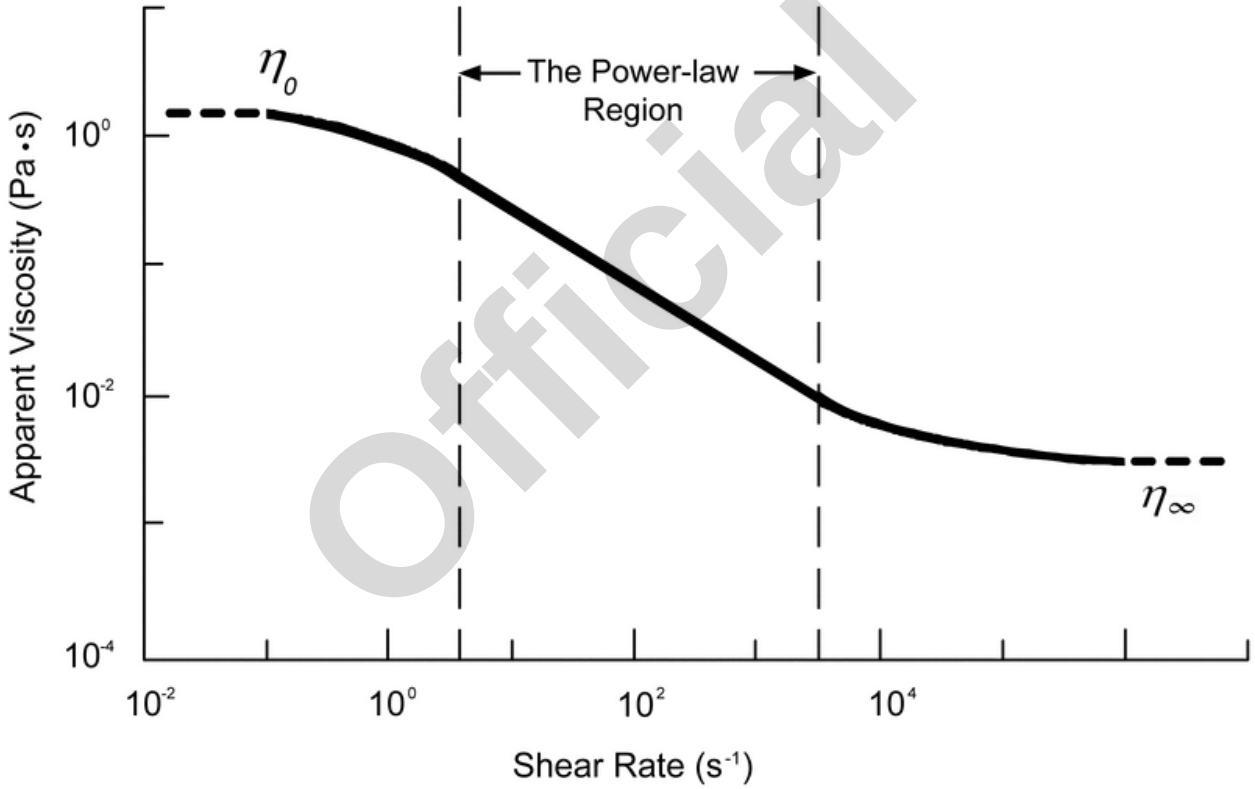

Figure 4. Log–log plot of the dependence of $\eta_{app}$ on the shear rate for an aqueous solution of a typical hydrocolloid.

*Figure 4* depicts apparent viscosities, $\eta_{app}$, ranging from high values at very low rates of shear to low values at very high rates of shear. The curve's asymptotes—corresponding to the zero-shear viscosity ($\eta_0$) and the infinite-shear viscosity ($\eta_\infty$)—together with the linear log–log region at intermediate rates of shear, are characteristic of the shear-thinning behavior of these materials.

During the course of manufacturing, in-process materials that exhibit non-Newtonian behavior may be subjected to wide ranges of shear rates and shear stresses. Fluid dynamic conditions during drug product storage and administration and release of the active constituent(s) could broaden those ranges even further. For materials that exhibit non-Newtonian behavior in a solution or dispersion, the rheological profile (rheogram or flow curve), as described in *Figure 3*, gives a better functional characterization than a single viscosity measurement of the apparent viscosity at a single shear rate.

Determination of the rheological profiles of non-Newtonian solutions or dispersions requires the use of a rheometer or a viscometer that is capable of measuring rheological behavior over the range of shear rates and/or shear stresses encompassing the conditions that the excipient or product is likely to encounter. The exact mathematical characterization of deformation and flow of a test substance requires the precise delineation of sample dimensions, the forces exerted, and the resulting deformation or flow. Instruments that enable a thorough, geometrically accurate analysis of deformation and flow are termed *absolute* rheometers. Such absolute rheometers are preferred for measurements of non-Newtonian fluids so that results can be compared from instrument to instrument for corresponding ranges of shear stresses and shear

rates. When flow or deformation is not well defined or is indeterminate, the resulting measurements are likely to correspond, at best, to approximations of the true rheological behavior of the sample. Rheometers that can provide useful information about material behavior, but do not enable the true rheological character of the material to be determined, are known as *relative* rheometers. Such instruments are subject to geometry-dependent limitations. Results obtained with relative rheometers generally are not comparable to those obtained with absolute rheometers or other differently configured relative rheometers. Relative rheometers often are called viscometers. However, the term *viscometer* should be reserved for a subset of rheometers that measure only steady shear flow and the corresponding Newtonian viscosity.

Temperature control during the course of measurement is critical to the rheological evaluation of non-Newtonian fluids. An Arrhenius-type equation has often been invoked to characterize Newtonian and non-Newtonian flow properties as a function of temperature:

$$\frac{\eta}{\eta_{ref}} = A \cdot e^{\left(\frac{E_0}{R}\left(\frac{1}{T} - \frac{1}{T_{ref}}\right)\right)} \quad (9)$$

$\eta$ = Newtonian or non-Newtonian viscosity at some absolute temperature $T$
$\eta_{ref}$ = Newtonian or non-Newtonian viscosity at some reference temperature $T_{ref}$
$A$ = constant
$E_0$ = energy for viscous flow
$R$ = universal gas constant

Energies for viscous flow and the constant $A$ are determined from experimental data. Energy dissipation by viscous flow is a function of measuring system geometry, temperature control, shear rate, and shear stress, but increased variability is observed in particular at high shear rates and for fluids that exhibit high apparent viscosity. Sample temperatures of non-Newtonian fluids should be controlled to ±0.1°, as is the case for Newtonian viscosity measurements.

**Measurement of Viscosity Using a Rotational Rheometer**

Rotational rheometers represent a more useful alternative to most capillary viscometers for measuring the rheological characteristics of non-Newtonian fluids as long as variations in shear rate, sample temperature, and edge or end effects can be minimized. The most common absolute rotational rheometer designs include concentric (coaxial) cylinder, cone-and-plate, and parallel-plate instruments. All of these are available in models that can provide absolute rheological data—that is, data that do not require substantial corrections for end or edge effects, viscous heating, or variations in shear rate or shear stress in the sample being evaluated. Rotating spindle rheometers—often described as viscometers—are relative rheometers that typically are used to assess apparent viscosity.

An additional factor with all rheometers/viscometers that must be taken into consideration, particularly with multiphase materials, is the potential formation of a thin, less-viscous layer of fluid at the wall of the instrument. When wall effects, or wall slip, occur, instrument measurements may be misleading because of the actual rheological behavior of the sample. Identification of wall effects is instrument specific. One useful method entails the comparison of results with a roughened vs. a smooth rotor. Instrument manufacturers generally provide recommendations for identification of and correction for wall slip.

Generally, calibration, operation, and cleaning of rheometers should be performed according to the instrument manufacturer's recommendations.

General chapter *Viscosity—Rotational Methods* ⟨912⟩ describes the procedures for the most common types of rheometers: spindle rheometers (viscometers) and concentric (coaxial) cylinder, cone-and-plate, and parallel-plate (parallel disk) instruments.

**Calculation of shear rate, shear stress, and viscosity using a concentric (coaxial) cylinder rheometer:**

For non-Newtonian liquids, it is essential to specify the shear stress, $\sigma$, or the shear rate, $\dot{\gamma}$, at which the viscosity is measured. Under narrow gap conditions (conditions satisfied in absolute rheometers), the shear rate $\dot{\gamma}$ in $s^{-1}$, and the shear stress $\sigma$, in Pa ($N \cdot m^{-2}$ or $kg \cdot m^{-1} \cdot s^{-2}$), are calculated using the following equations:

$$\dot{\gamma} = \left(\frac{R_o^2 + R_I^2}{R_o^2 - R_I^2}\right)\omega \quad (10)$$

$$\sigma = \left(\frac{1}{4\pi h R_o^2} + \frac{1}{4\pi h R_I^2}\right)M \quad (11)$$

$R_o$ = radius of the outer cylinder (m)
$R_I$ = radius of the inner cylinder (m)
$\omega$ = angular velocity (radian/s)
$M$ = torque acting on the cylinder surface ($N \cdot m$)
$h$ = height of immersion of the inner cylinder in the liquid medium (m)

Generally, the angular viscosity can be calculated using the equation:

$$\omega = \left(\frac{2\pi}{60}\right)n \quad (12)$$

$n$ = rotational speed, in revolutions per min (rpm)

For laminar flow, the viscosity $\eta$ (or apparent viscosity $\eta_{App}$), in Pa · s, is given by the following equation: [NOTE—1 Pa · s = 1000 mPa · s.]

$$\eta \text{ or } \eta_{\text{App}} = \frac{1}{4\pi h}\left(\frac{1}{R_I^2} - \frac{1}{R_o^2}\right)\frac{M}{\omega} = k\frac{M}{\omega} \quad (13)$$

$k$ = constant of the apparatus (radians/m³)

**Calculation of shear rate, shear stress, and viscosity using a cone-and-plate rheometer:**
The shear rate $\dot{\gamma}$ in $s^{-1}$, and the shear stress $\sigma$, in Pa, are calculated by the following equations:

$$\dot{\gamma} = \left(\frac{1}{\alpha}\right)\omega \quad (14)$$

$$\sigma = \left(\frac{1}{\frac{2}{3}\pi R^3}\right)M \quad (15)$$

$\alpha$ = angle between the flat plate and the cone (radians)
$R$ = radius of the cone (m)
$\omega$ = angular velocity (radian/s)
$M$ = torque acting on the cylinder surface (N · m)

For laminar flow, the viscosity $\eta$ (or apparent viscosity $\eta_{App}$), in Pa · s, is given by the following equation:

$$\eta \text{ or } \eta_{\text{App}} = \left(\frac{3\alpha}{2\pi R^3}\right)\left(\frac{M}{\omega}\right) = k\frac{M}{\omega} \quad (16)$$

$k$ = constant of the apparatus (radians/m³)

**Measurement of Rheological Properties Using a Nonrotational Rheometer**

Alternative nonrotational rheometer procedures for measuring rheological properties of non-Newtonian fluids include slit rheometers, small- and large-amplitude oscillatory shear-based rheometers, and capillary-breakup elongational rheometers. Equipment manufacturers generally provide detailed procedures, and these instruments and methods may be appropriate for use after users complete characterization and validation studies for both the equipment and the material under test. These types of rheometers are not described in *Viscosity—Rotational Methods* ⟨912⟩, as these are not rotational rheometers.

# ⟨1912⟩ MEASUREMENT OF ▲YIELD STRESS▲ (USP 1-Dec-2023) OF SEMISOLIDS

## ▲BACKGROUND

Semisolids are viscoelastic materials that exhibit a yield stress. The yield stress for a raw material or dosage form[1] is the applied stress at which a change in the viscoelastic properties of a semisolid is observed: below the yield stress the material response is dominated by completely reversible elastic deformation, whereas above the yield stress the material response is changing to irreversible elastic behavior (as the material remains a viscoelastic semisolid) or is dominated by viscous flow behavior. Often, the yield stress is identified as the applied stress below which a material appears to not show any motion or flow (i.e., where the shear rate is near-zero).

This observation can be dependent on the sample preparation, methods of testing and analysis, the time scale of the measurement, the scan rate used to locate the change in the behavior, and the direction from which the transition is approached. Most rotational measurement techniques identify the yield stress by locating the onset of flow; however, penetrometry, which is another rheological technique, looks for the yield stress where the semisolid stops yielding. Although the yield stress for various materials is expected to correlate when measured with different techniques, the values should not be considered to be independent of the method of testing and analysis. Yield stress is reported with units of shear stress [Pascals (Pa)].

Characterizing and monitoring the viscoelastic properties of semisolids is not straightforward because the properties can be dominated by either solid- or liquid-like behavior depending on how much deformation or stress is applied to the material. If the quality of a raw material or dosage form is primarily dependent on the behavior under high-shear conditions, then viscosity may be an appropriate parameter to monitor. In this case, efforts should be made to avoid wall slip and make measurements where the applied shear stress is much greater than the yield stress. However, if the properties of the raw material or dosage form are critical to quality at low shear or at rest (e.g., uniformity and stability of an ointment suspension or residence time at site of application), then measurement of the yield stress using one or more of the methods described below may be required.

For temperature-sensitive materials, viscoelastic properties at both ambient conditions (i.e., storage conditions) and physiological conditions [i.e., skin surface temperature (32°) or body temperature (37°)] are useful. For example, an anesthetic topical cream may require characterization at 32°, whereas a vaginal cream may require characterization at 37° (*1*–*2*).

A brief summary of the mathematical models used to quantify the viscoelastic properties of semisolids is presented below, followed by a summary of the most common experimental methods for assessing the viscoelastic properties and determining the yield stress for semisolids. [NOTE—Additional models for viscosity versus shear rate are also discussed in *Rheometry* ⟨1911⟩, see *Figure 3*).]

### Hooke's Elasticity Law and Newton's Viscosity Law

For elastic materials, Hooke's Elasticity Law applies,

$$\sigma = G\gamma \quad \text{Equation 1}$$

where $\sigma$ is the shear stress (= force/surface area, in units of pascals, Pa), $G$ is the shear modulus that represents the rigidity of a material, and $\gamma$ is the shear strain or shear deformation (= displacement/distance or shear gap, dimensionless).

For viscous materials, Newton's Viscosity Law applies,

$$\sigma = \eta\dot{\gamma} \quad \text{Equation 2}$$

where $\sigma$ is the shear stress, $\eta$ is the shear viscosity that represents the resistance of the material to flow, and $\dot{\gamma}$ is the shear rate (or strain rate = velocity/distance or shear gap, in units of $s^{-1}$).

Semisolid raw materials and dosage forms will have both viscous and elastic properties and, hence, are categorized as viscoelastic materials.

### Herschel–Bulkley Equation

The Herschel–Bulkley equation is suitable for parameterizing the observed shear stress versus shear rate information for a wide range of viscoelastic materials including semisolids exhibiting a yield stress. The Herschel–Bulkley equation is:

$$\sigma = \kappa\dot{\gamma}^{\eta} + \sigma_{\gamma} \quad \text{Equation 3}$$

where, $\sigma$ is the shear stress, $\kappa$ is the proportionality constant (formerly also referred to as consistency), $\dot{\gamma}$ is the shear rate, $\eta$ is the exponent, and $\sigma_{\gamma}$ is the yield stress according to Herschel–Bulkley.

The exponent, $n$, is less than 1 for shear-thinning fluids and is greater than 1 for shear-thickening fluids.

When $n = 1$, the Herschel–Bulkley equation simplifies to the Bingham equation with $\kappa$ referred to as the Bingham viscosity. When $n = 0.5$, the Herschel–Bulkley equation simplifies to the Casson equation with $\kappa$ typically referred to as the Casson viscosity.

[1] [NOTE—Throughout this chapter, the use of the term "raw material or dosage form" refers to its semisolid state.]

### Oscillatory Measurements of Viscoelastic Properties

If a sinusoidal oscillating shear strain (shear deformation) is applied to a material,

$$\gamma(t) = \gamma_0 \sin(\omega t) \quad \text{Equation 4}$$

where $\gamma(t)$ is the amplitude at time ($t$), $\gamma_0$ is the amplitude at time zero, and $\omega$ is the angular frequency of the shear strain, the corresponding shear rate is calculated as follows.

$$\dot{\gamma}(t) = \gamma_0 \omega \cos(\omega t) = \dot{\gamma_0} \cos(\omega t) \quad \text{Equation 5}$$

According to Hooke's Elasticity Law, the ideal elastic response to this applied shear strain will be sinusoidal:

$$\sigma(t) = \gamma_0 G \sin(\omega t) \quad \text{Equation 6}$$

which indicates that the ideal elastic response is in-phase with the strain ($G$ is the shear modulus).

According to Newton's Viscosity Law, the ideal viscous response will also be sinusoidal:

$$\sigma(t) = \eta \gamma_0 \omega \cos(\omega t) \quad \text{Equation 7}$$

which indicates that the ideal viscous response is out-of-phase (shifted by 90°, showing the phase shift angle of $\delta = 90°$) relative to the shear strain.

For a viscoelastic material, the response will be sinusoidal with a phase shift angle, $\delta$ (also referred to as the loss angle) of $0° \leq \delta \leq 90°$.

$$\sigma(t) = \sigma_0 \sin(\omega t + \delta) \quad \text{Equation 8}$$

The response of a viscoelastic material to an applied sinusoidal shear strain is used to determine the values of the loss angle, $\delta$, and the amplitude of the response, $\sigma_0$. This response can be separated into a viscous and elastic component according to *Equation 9* and *Equation 10*,

$$G' = \frac{\sigma_0}{\gamma_0} \cos\delta \quad \text{Equation 9}$$

$$G'' = \frac{\sigma_0}{\gamma_0} \sin\delta \quad \text{Equation 10}$$

where $G'$ is called the elastic (storage) modulus and $G''$ is called the viscous (loss) modulus. The dimensionless loss factor (or damping factor) as the ratio of the viscous and the elastic portions is defined as: $\tan\delta = G''/G'$ (unit: 1).

Therefore, the sinusoidal response of a viscoelastic material to an oscillatory shear strain (or shear stress) can be used to separate the viscous and elastic responses for a semisolid material in the range of low strains and low stresses without requiring the material to actually flow.

When the elastic response of a material is dominant ($G' > G''$), the material is referred to as a viscoelastic solid or a gel. When the viscous response of a material is dominant ($G' < G''$), the material is referred to as viscoelastic liquid or a sol. The point where $G' = G''$ ($\tan\delta = 1$) is referred to as the sol–gel transition.

## EXPERIMENTAL METHODS

### Yield Stress via the Viscosity Maximum

A viscosity maximum is performed by presetting a constant, very low ("near-zero") shear rate (e.g., of 0.01 or 1 $s^{-1}$) or a very low rotational speed (e.g., of 0.01 or 1 rpm). The relationship between rotational speed $n$ (in rpm) and angular velocity $\omega$ (in rad/s or 1/s) is: $\omega = (2\pi/60) \times n$. As a result, the yield stress corresponds to the maximum viscosity (or shear stress or torque), which can be displayed in a diagram showing one of these parameters on the $y$-axis and time (or shear strain) on the $x$-axis. The following applies according to Newton's Viscosity Law (see *Equation 2*): Because this experiment is run at a constant shear rate (or speed), the shear viscosity and the shear stress are proportional. The shape of the plots of the shear viscosity and shear stress (or torque) are identical. The resulting viscosity (or shear stress or torque) values will begin to increase with time (transient viscosity function, i.e., time-dependent). When approaching the yield stress, the increase in the values will slow, and thus, the curve will become flatter. There are two possible results:

- The plot will clearly show a maximum (or peak). The yield point (in Pa) is read off as the shear stress value appearing at the maximum point of the curve (see *Figure 1A*).
- The plot will steadily approach to a (constant) plateau value. The yield point (in Pa) is read off as the shear stress value when first reaching the plateau value (see *Figure 1B*).

Official

The experimental parameters that influence this measurement method include the sample loading technique, the placement of the measurement geometry (often a vaned rotor) in the sample cup, and the sample history. Because air pockets may be of concern, ideally, the sample should be loaded gently, without significant shearing and without introducing any air, and the sample cup should be large enough that the vane or cylinder can be placed at least $2H$ above the bottom of the sample cup (where $H$ is the height of the vane or cylinder) and at least a distance $D$ away from the side of the sample cup (where $D$ is the diameter of the vane or cylinder). To avoid end effects at the top of the vaned rotor or cylinder, either the top should be at least $H/2$ below the air interface, or the geometry should be positioned so that the top is at or above the air interface. After carefully immersing the geometry into the sample, an equilibration time may be required to relieve any stresses developed during the loading of the sample. The yield stress may be affected by the shear rate (or speed) used. When comparing different raw materials or dosage forms, it is important and recommended to use the same measurement speed.

## Yield Stress via Shear Rate Ramps or Shear Stress Ramps (flow curves)

The yield stress of a material can be estimated in two ways:

- Using a non-linear regression approach based on the Herschel–Bulkley equation (*Equation 3*), see *Figure 2*.
- Reading the plateau value at low shear rate. As shown in *Figure 3*, a material with a yield stress will exhibit a plateau on this log–log plot and the yield stress will correspond to this asymptotic value at low shear rate. If the plateau is not apparent, then fitting to the Herschel–Bulkley equation will provide a better estimate of the yield stress.

https://pharmacopeia.cn/v-download/

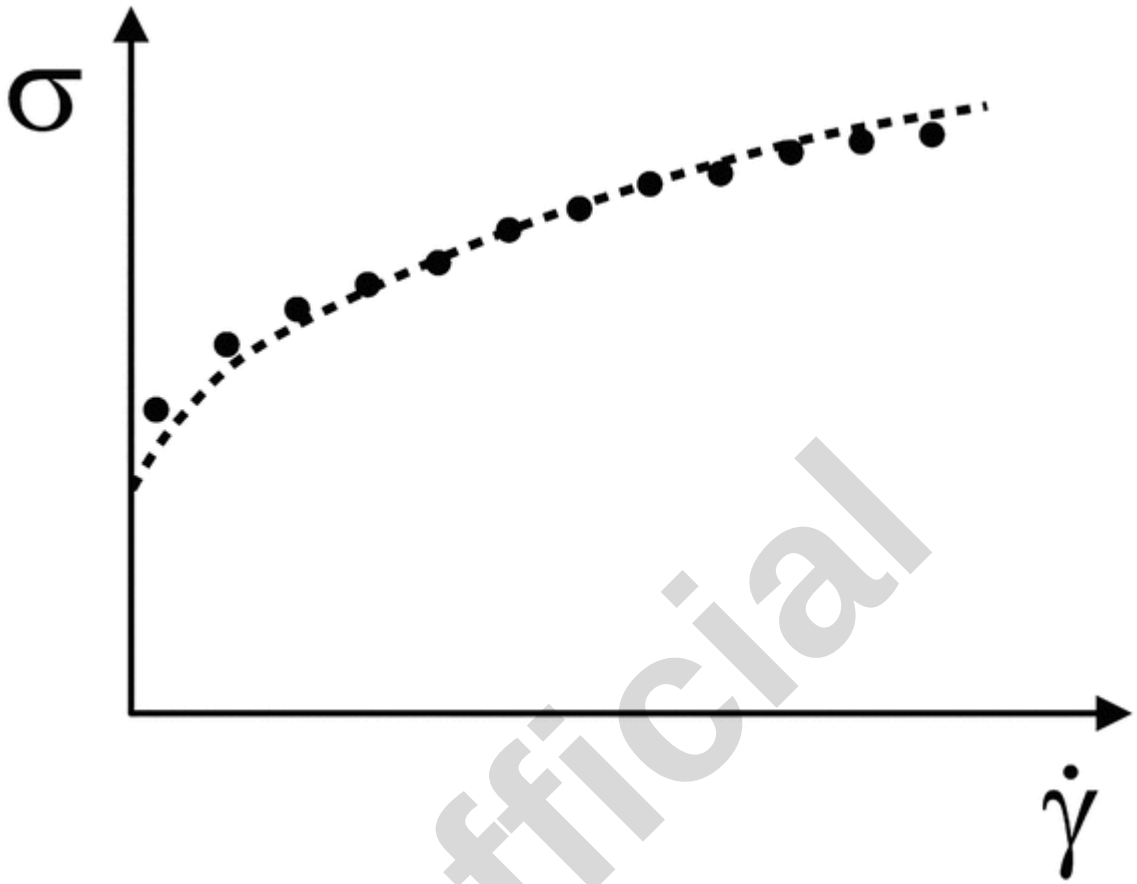

Figure 2. Yield stress determination using a curve-fitting function (e.g., according to the model of Herschel–Bulkley). Here, the individual measuring points of a flow curve measurement are shown (on a linear scale for both axes) as dots and the fitting curve as dotted line. The yield stress is read off at the intersection of the fitting curve and the σ-axis, or is calculated for the shear rate at the value zero, respectively.

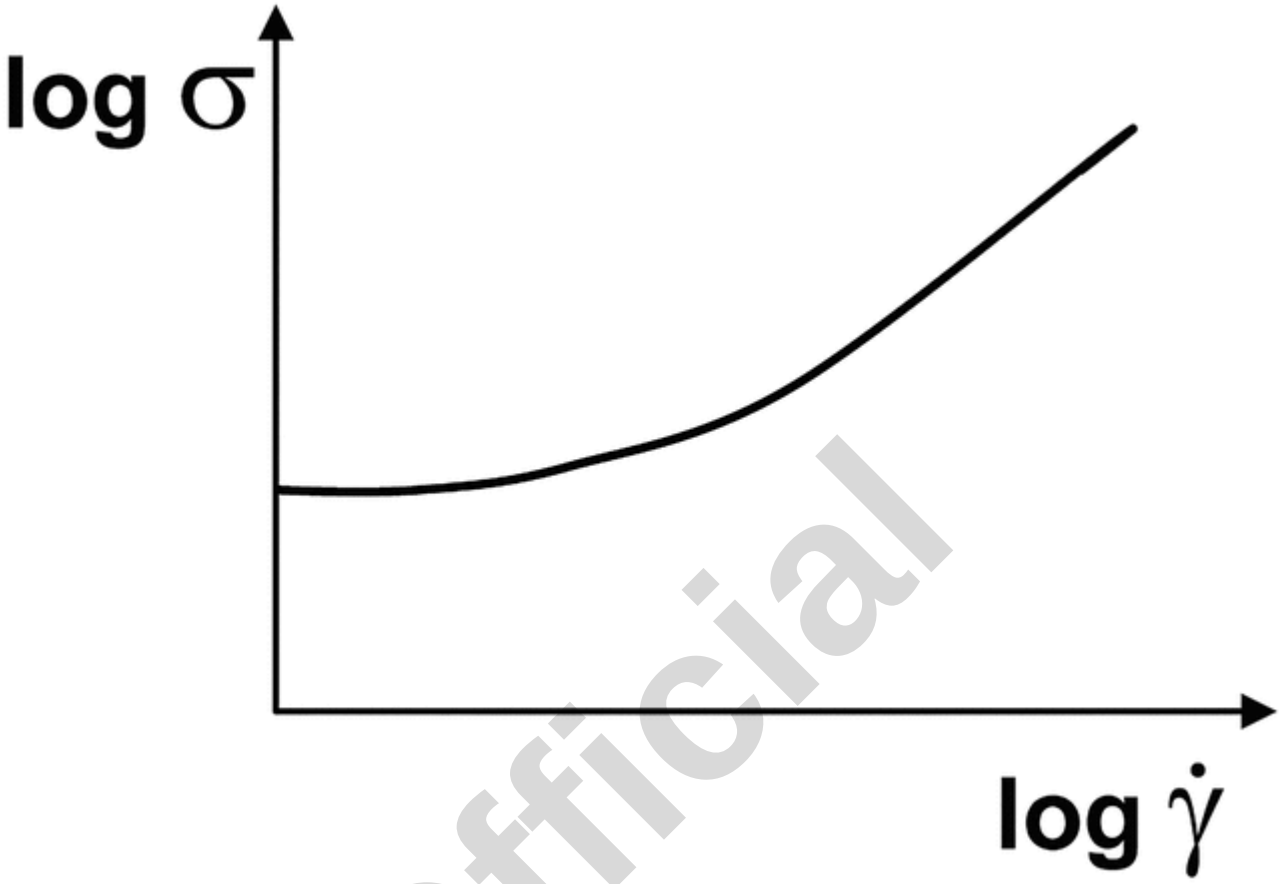

Figure 3. Flow curve diagram on a logarithmic scale for both axes. The yield stress is read off as the plateau value of the shear stress curve in the low-shear range.

Modern rotational rheometers can perform flow curve measurements using two modes of operation: 1) controlled shear rate (CSR) and 2) controlled shear stress (CSS). For CSR, typical examples for testing include: a) on a linear scale, preset of 20 measuring points from shear rate 0 to 1000 $s^{-1}$; and b) on a logarithmic scale, preset of 10 measuring points per decade between 0.01 $s^{-1}$ (or 1 $s^{-1}$) and 1000 $s^{-1}$.

For these experiments, wall slip at low shear rates will significantly affect the results. It is highly recommended that either a vaned rotor or a roughened (e.g., cross-hatched) parallel plate (PP) measurement geometry be used. In extreme cases of wall slip, a material with a yield stress may appear to switch to a state of flow and may lead to the incorrect conclusion that the material does not exhibit any yield stress at all. One benefit of dynamic oscillation stress or strain sweep tests is that it provides a lower probability of wall slippage.

## Yield Stress by Amplitude Sweep

For oscillatory measurements in the form of amplitude sweeps, the amplitude of the shear strain (or shear stress) is increased from low to high on a logarithmic scale (e.g., shear strain from 0.01%–100% or shear stress from 1 to 1000 Pa, preset on a log scale, with 10 points per decade). Users often perform amplitude sweeps at $\omega$ = 10 rad/s (or, alternatively, at frequency ($f$) = 1 Hz). This test may be used to evaluate the viscoelastic behavior and the stiffness (rigidity) of a gel in the linear viscoelastic range (LVR) . The LVR is the low shear range where the response of a sample behaves predominantly according to Hooke's Elasticity Law, the shear strain (shear deformation) is reversible, and the resulting parameters ($G'$ and $G''$) are constant, both showing plateau values with $G' > G''$ within this region. The LVR limit typically is determined in terms of the shear strain or shear stress value when the $G'$ curve deviates from the plateau value by 5% (see ISO 3219-3 for more information), usually downward.

The yield stress value is correlated with the storage modulus drop that occurs beyond the limit of the LVR. The limit of the LVR may be considered the onset of yielding or, alternatively, the onset point for yielding may be located as the intersection of an initial tangent line (from the LVR) with a final tangent line (where the $G'$ curve or complex viscosity drops rapidly). Additionally, the $G'$ and $G''$ crossover point may be considered a transition from elastic to viscous behavior. A yield point or yield stress may be identified from these plots in multiple ways.

Because the oscillatory tests do not require the measuring sample to flow, wall slip may not be a significant concern for these experiments, although vaned rotor and roughened measurement geometries may still be used.

Each amplitude sweep is performed at a single frequency. [For the conversion between the angular frequency $\omega$ (in rad/s) and the frequency (in Hz): $\omega = 2\pi \times f$.] The frequency selected for the amplitude sweep will affect the value of $G'$ in the LVR and

may affect the location of the crossover point of the curves of *G′* and *G″*.Frequency sweeps may be performed to determine the significance of the frequency (or time) dependence of the results.

*Figure 4* shows an example of an amplitude sweep of a typical semisolid. In the LVR, the *G′* value of the material is constant and may be used as a measure of the stiffness of the material. At the limit of the LVR, the value of *G′* begins to depart from the plateau, typically by sloping downward, and at even higher strain (or stress) amplitudes, the material exhibits the crossover point of *G′* and *G″*. Both the limit of the LVR and the crossover point of *G′* and *G″* represent significant changes in the viscoelastic properties of the material that sometimes are selected as a yield stress value. This can be interpreted as follows:

- The limiting shear stress, or $\sigma_L$, is the shear stress at the limit of the LVR. At this limit, the semisolid begins to yield but *G′* still dominates *G″*, and thus the elastic (solid) behavior over the viscous (liquid) one.
- The shear stress at the crossover point (also known as the flow point), or $\sigma_{co}$, is the point where *G″* dominates *G′*, and thus, the viscous (liquid) behavior over the elastic (solid) one. In other words, at this point the material is predominantly in a flowing state. Many practical users prefer the crossover point for two reasons: It can be located more precisely as it occurs clearly as a single point in the diagram, and it has been found to correlate particularly with the yield stress values resulting from rotational tests. [NOTE—However, for amplitude sweeps, the values of the crossover point (*G′* = *G″*) in terms of the shear strain and shear stress are clearly measured outside of the LVR.]

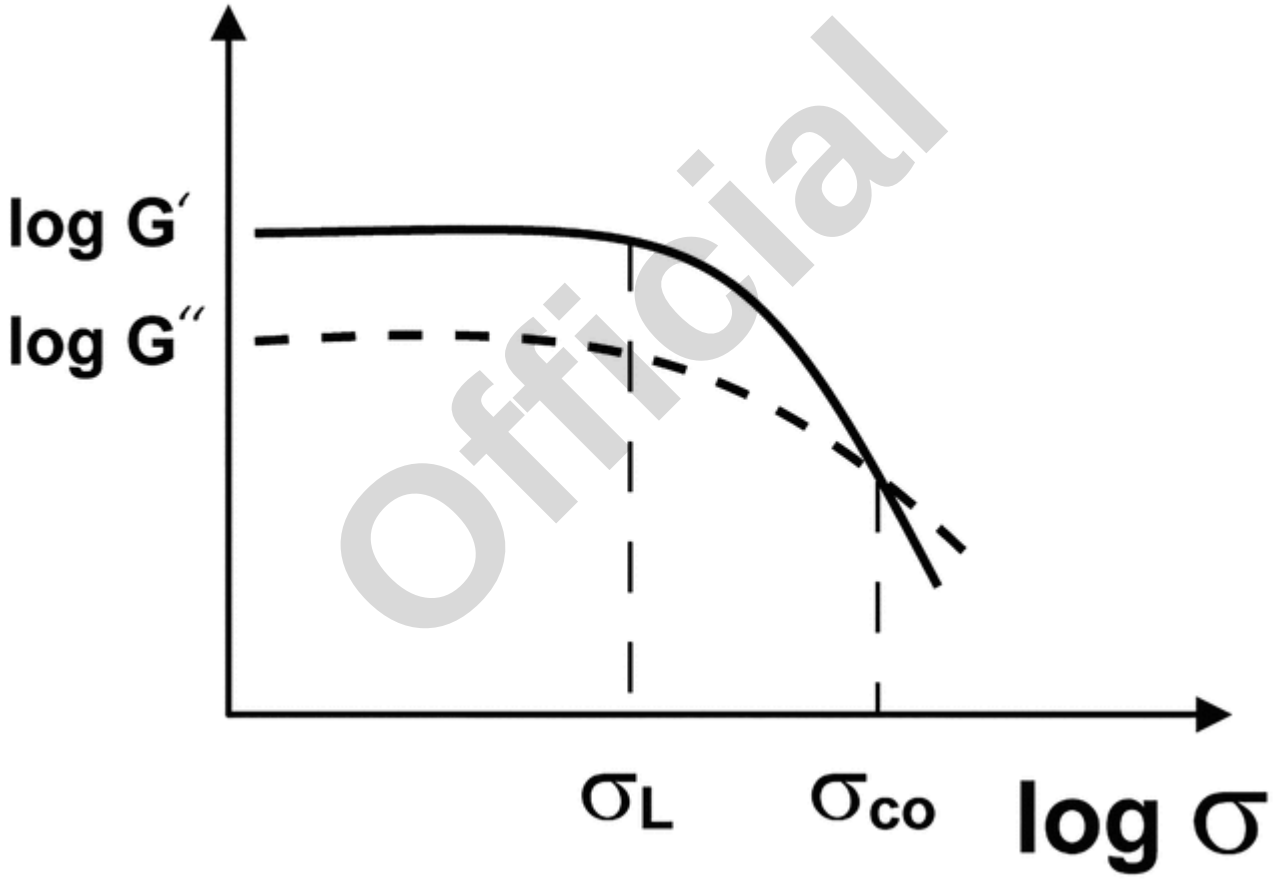

Figure 4. Amplitude sweep: in the LVR, the curves of *G′* and *G″* show plateau values. The LVR ends at the limiting value of the shear stress ($\sigma_L$), which is often also used for the yield stress. The shear stress value ($\sigma_{co}$) at the crossover point of the curves of *G′* and *G″* is the point where the viscoelastic behavior of the measuring sample changes from predominantly elastic (or solid) to predominantly viscous (or liquid); therefore, this point is often referred to as the flow stress (or flow point).

## Penetrometry Measurements

In the penetrometry experiment, a cone with an angle of 2α is driven into the semisolid by gravity. The most widely used penetrometer is a gravity-driven instrument (*Figure 5*), which is typically used to perform a penetrometry experiment according to ASTM D217, ASTM D937, the *European Pharmacopoeia*, 2.9.9 *Measurement of Consistency by Penetrometry*, or *Measurement of Structural Strength of Semisolids by Penetrometry* ⟨915⟩. These methods require measurement of the sample at 23.5 ± 2.0°.

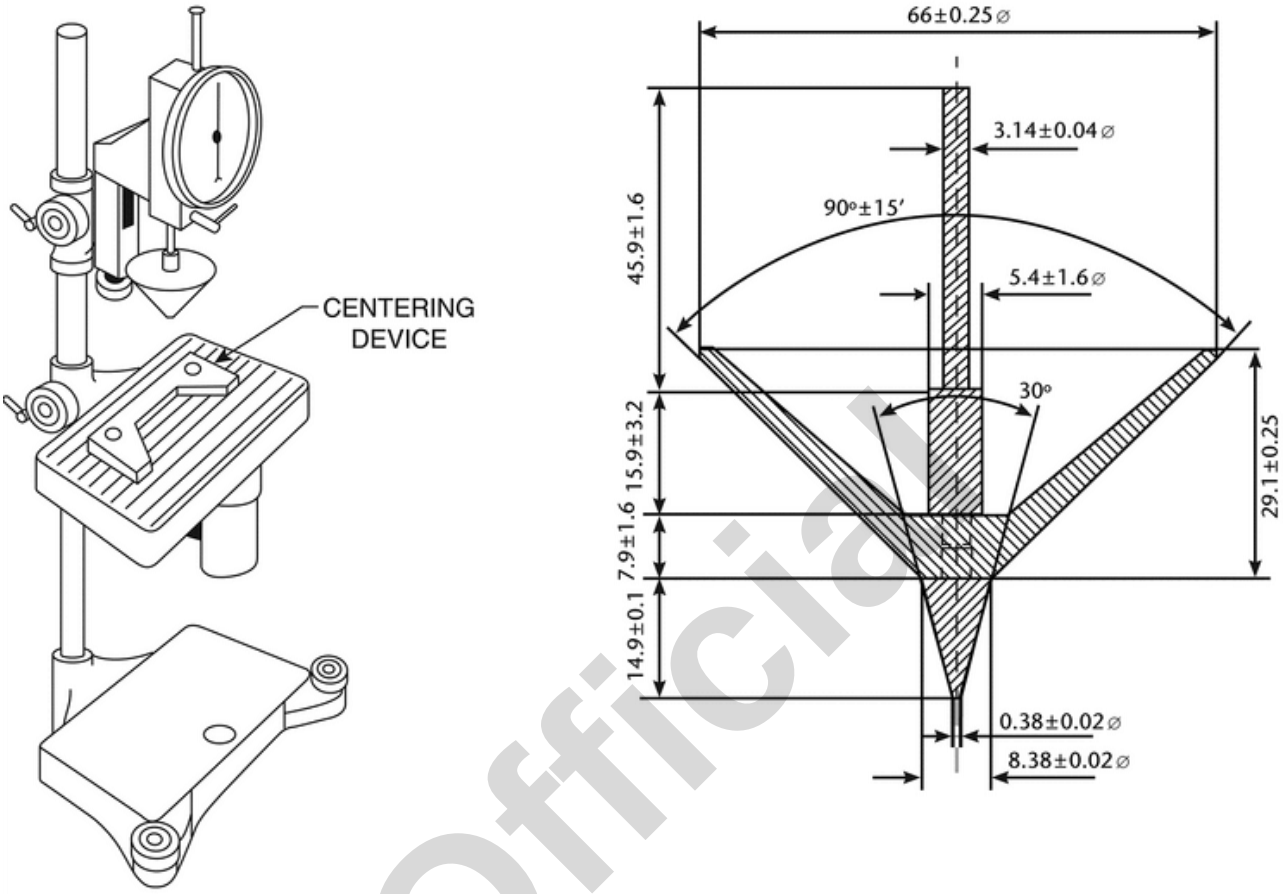

Figure 5. Typical penetrometer and cone used in hardness measurements. (Adapted with permission from *Pharmeuropa*, Vol. 9, No. 8, July 2019. ©Council of Europe, 2019.)

Briefly, the penetrometer cone positioned just above the surface of the semisolid is released and allowed to drop freely into the sample for 5 s. The penetration depth is recorded and reported in units of 0.1 mm. The penetration unit is decimillimeter (dmm). Three or more determinations are made, and the results are averaged to give the reported result. These penetrometry methods require the use of a two-piece cone (a small 30° cone attached to a larger 90° cone) that has a total effective mass of 150.0 ± 0.1 g. For this cone, gravity drives the cone into the semisolid with 1471 millinewtons (mN) of force.[2] The effective penetration force (the total force minus the buoyancy force) results in the application of a shear stress to the semisolid at the surface of the penetrating cone. In general, the semisolid will respond to this applied shear stress according to the Herschel–Bulkley equation (*Equation 3*).

The cone will continue to penetrate until the applied shear stress is equal to the yield stress of the semisolid. At this point, the cone will stop penetrating and the shear rate will go to zero. It can be shown that, at this point, the yield stress will be a function of the penetration depth, *h*, according to *Equation 11* below:

$$\sigma_0 = \left(\frac{\cos^2\alpha}{\pi \tan\alpha}\right)\frac{1}{h^2}\left(W - \frac{\rho_f g \pi h^3 \tan^2\alpha}{3}\right) \quad \text{Equation 11}$$

where $\alpha$ is the half-angle of the cone, $W$ is the weight of the penetrating cone, $\rho_f$ is the density of the semisolid, and $g$ is the acceleration from gravity. If the buoyancy correction is negligible, this equation simplifies as shown in *Equation 12*, indicating that the yield stress is essentially equal to the weight of the cone over the square of the penetration depth multiplied by a cone constant.

$$\sigma_0 = \left(\frac{\cos^2\alpha}{\pi\tan\alpha}\right)\frac{W}{h^2} \quad \text{Equation 12}$$

[2] Force (mN) = 1000 × m × g = 0.15 kg × 9.80665 m $s^{-2}$ = 1471 mN.

@2024 USPC

The term "hardness" (*H*) has been defined by several authors as shown in *Equation 13*,

$$H = C\frac{W}{h^n}$$ Equation 13

where *C* is a constant dependent on the cone geometry, *W* is the weight of the penetrating cone, *h* is the penetration depth, and *n* is an exponent. If *n* = 2, then *H* will be equivalent to the yield stress and have the same units (Pa).

The monographs for petrolatum and white petrolatum each require the result of the penetrometry measurement to be in the 100–300-dmm range (NLT 10.0 mm and NMT 30.0 mm). *Figure 6* shows the calculated yield stress for the standard 150-g, two-piece cone as a function of penetration depth.

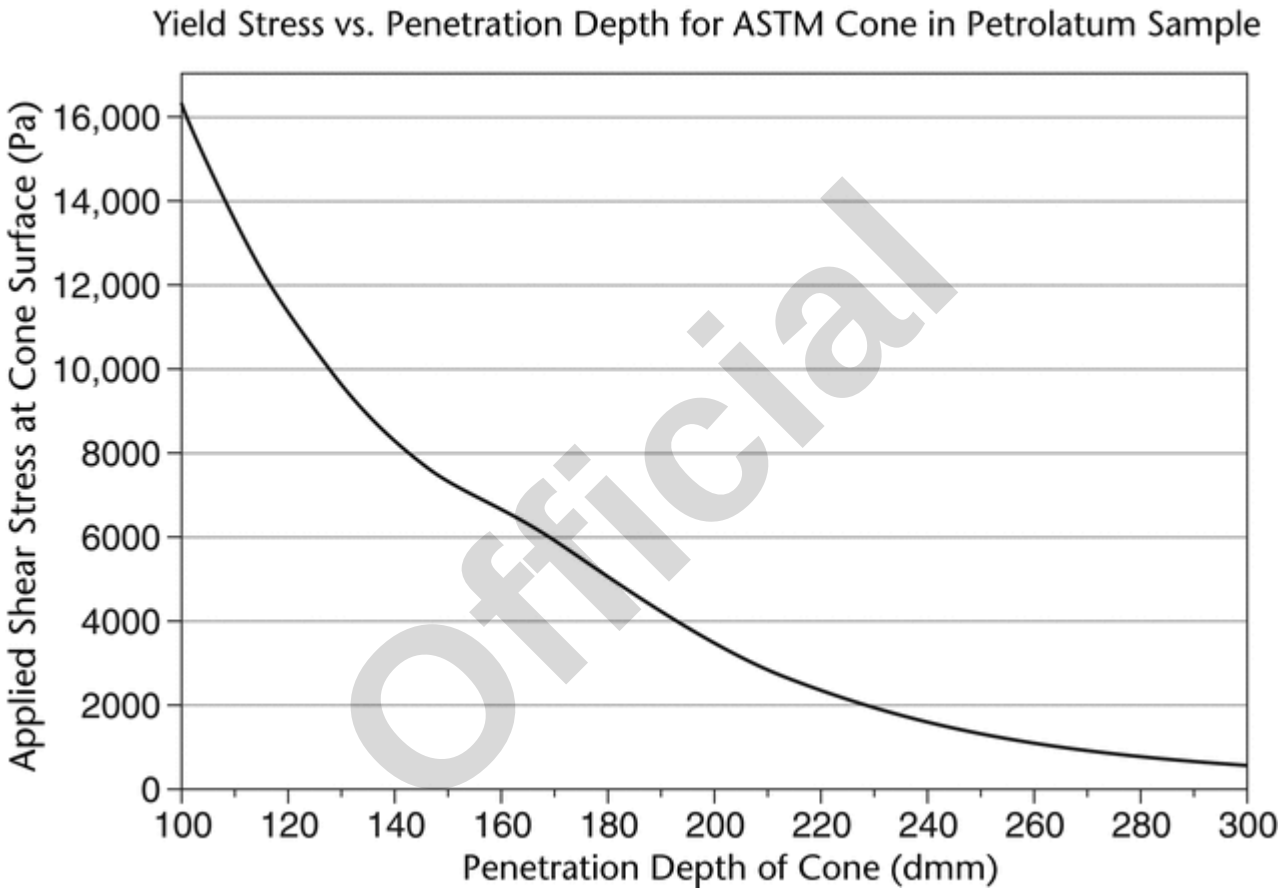

Figure 6. Yield stress (hardness) as a function of penetration depth for the two-piece, 150-g standard cone (from ⟨915⟩, *Procedure, Determination of Penetration, Method I*). This calculation uses *Equation 3* for penetration into sample with a density of 0.85 g/cm$^3$ and includes the buoyancy correction. Based on the ideal geometry, the smaller cone is truncated at the tip (by 7 dmm) and the two cones are joined at 150 dmm where they have the same diameters. This penetration depth corresponds to yield stresses in the 200–16,000 Pa range. The plot shows that there is a slight inflection point near 150 dmm where the two cones are joined.

## GLOSSARY

Note that the following definitions are provided to clarify the use of these terms in the context of this chapter. These definitions are not intended to supersede or contradict definitions found elsewhere in *USP–NF*.

**Consistency:** See Structural strength.

**Gel and Sol:** A gel is defined as a material for which $G' > G''$. A sol is defined as a material for which $G' < G''$. The behavior of a gel is dominated by its elastic response to strain (shear deformation). The behavior of a sol is dominated by its viscous response to strain. The point where $G' = G''$ is called the sol–gel transition. Rheology is used to characterize the continuous phase of a dosage form to classify it as either a gel or sol based on which behavior dominates the viscoelastic properties.

**Hardness:** Hardness is a term used synonymously with tensile stress, and yield stress is a type of tensile stress. Hardness is proportional with yield stress—a harder semisolid also exhibits a larger yield stress. In penetrometry, hardness has been more specifically defined as $H = C \times W/p^n$, where *C* is a constant dependent on the cone geometry, *W* is the weight of the penetrating cone, *p* is the depth of penetration, and *n* is an exponent. When *n* = 2, hardness has the same units as yield stress (Pa).

**Penetrometry:** A method for quantifying the yield stress of semisolid materials in which a metal cone, with standardized dimensions and weight, penetrates into a semisolid until the buoyancy of the cone and the yield stress of the semisolid exactly balances the gravity-applied force driving the penetrating object into the semisolid. See ⟨915⟩ for more details.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M10935_03_01
@2024 USPC

**Semisolids:** Materials that exhibit viscoelastic properties that are classified as more solid-like at rest and at room temperature. Typically, these materials will transition to more fluid-like behavior under applied stress or as a result of temperature changes. This transition from a sol to a gel is identified as a yield stress. When used as dosage forms semisolids may be further classified as gels, ointments, or creams.

**Strain:** The shear deformation of a material. If a cubic volume of material is deformed by moving the top plane of the cube relative to the bottom plane of the cube, the strain is equal to the linear displacement of the top plane divided by the height of the cube (distance between the planes). This strain that results from the shear deformation of the viscoelastic material is unitless as it has units of distance (displacement) over distance. It is sometimes multiplied by 100 and reported as a percentage strain.

**Structural strength (Consistency):** Consistency is sometimes used synonymously with "viscosity", albeit incorrectly. Viscosity represents the proportionality of the shear stress to the shear rate for a Newtonian fluid, whereas consistency is the term for this proportionality for semisolids that exhibit non-Newtonian rheological behavior. Because the term consistency may be confused with uniformity or homogeneity, the term structural strength is now the preferred term.

**Surface area:** The surface area of the sheared fluid volume on which the shear force is acting or the cross-sectional area of material with area parallel to the applied force vector.

**Wall slip:** Term describing the shear-thinning of a semisolid dosage form at the wall of a measurement system. When shear stress is applied to a dosage form, the material at the wall of the measurement system will yield and shear thin before the remaining bulk material. This slipping of the material at the wall of the measurement system results in incomplete transfer of the shear stress into the bulk. Wall slip will result in erroneously low viscosity results for shear thinning and yield stress fluids and will result in erroneously high shear rate for a given applied shear stress. Wall slip is most significant for low shear measurements and can be reduced by using plate-plate measurement systems with roughened surfaces or by using a vaned rotor rather than a cylinder.

**Yield stress:** The applied stress at which a change in the viscoelastic properties of a semisolid is observed. Below the yield stress the material response is dominated by completely reversible elastic deformation, whereas above the yield stress, the material response is changing to irreversible elastic behavior (as the material remains a viscoelastic semisolid) or is dominated by viscous flow behavior.

# ⟨2021⟩ MICROBIAL ENUMERATION TESTS—NUTRITIONAL AND DIETARY SUPPLEMENTS

## INTRODUCTION

This chapter provides tests for the estimation of the number of viable aerobic microorganisms present in nutritional supplements of all kinds, from raw materials to the finished forms. Alternative methods may be substituted for the tests, provided that they have been properly validated as giving equivalent or better results. In preparing for and in applying the tests, observe aseptic precautions in handling the specimens. The term "growth" is used in a special sense herein, i.e., to designate the presence and presumed proliferation of viable microorganisms.

## PREPARATORY TESTING

The validity of the results of the tests set forth in this chapter rests largely upon the adequacy of a demonstration that the test specimens to which they are applied do not, of themselves, inhibit the multiplication, under the test conditions, of microorganisms that may be present. Therefore, preparatory to conducting the tests on a regular basis and as circumstances require subsequently, inoculate diluted specimens of the material to be tested with separate viable cultures of the challenge microorganisms.

For the *Soybean–Casein Digest Agar Medium* used for *Total Aerobic Microbial Count*, inoculate duplicate plates with 25–250 cfu of *Staphylococcus aureus* (ATCC[1] No. 6538), *Escherichia coli* (ATCC No. 8739), and *Bacillus subtilis* (ATCC No. 6633) to demonstrate a greater than 70% bioburden recovery in comparison to a control medium. For the *Sabouraud Dextrose Agar Medium* used for *Total Combined Molds and Yeasts Count*, inoculate duplicate plates with 25–250 cfu of *Candida albicans* (ATCC No. 10231) and *Aspergillus brasiliensis* (ATCC No. 16404) to demonstrate a greater than 70% bioburden recovery in comparison to a control medium. For *Enterobacterial Count (Bile-Tolerant Gram-Negative Bacteria)*, appropriate dilutions of *Escherichia coli* (ATCC No. 8739) and *Salmonella typhimurium* (ATCC No. 13311) are used. Failure of the organism(s) to grow in the relevant medium invalidates that portion of the examination and necessitates a modification of the procedure by (1) an increase in the volume of diluent, the quantity of test material remaining the same, or by (2) the incorporation of a sufficient quantity of suitable inactivating agent(s) in the diluents, or by (3) an appropriate combination of modifications to (1) and (2) so as to permit growth of the inoculum.

The following are examples of ingredients and their concentrations that may be added to the culture medium to neutralize inhibitory substances present in the sample: soy lecithin, 0.5%; and polysorbate 20, 4.0%. Alternatively, repeat the test as described in the preceding paragraph, using *Fluid Casein Digest–Soy Lecithin–Polysorbate 20 Medium* to demonstrate neutralization of preservatives or other antimicrobial agents in the test material. Where inhibitory substances are contained in the product and the latter is soluble, a suitable, validated adaptation of a procedure set forth under *Procedure* using the *Membrane Filtration Method* may be used.

If, in spite of the incorporation of suitable inactivating agents and a substantial increase in the volume of diluent, it is still not possible to recover the viable cultures described above, and where the article is not suitable for the employment of membrane filtration, it can be assumed that the failure to isolate the inoculated organism is attributable to the bactericidal or bacteriostatic activity of such magnitude that treatments are not able to remove the activity. This information serves to indicate that the article is not likely to allow proliferation or contamination with the given species of microorganism. Monitoring should be continued in order to determine the inhibitory range and bactericidal activity of the article.

## BUFFER SOLUTION AND MEDIA

Culture media may be prepared as follows, or dehydrated culture media may be used provided that, when reconstituted as directed by the manufacturer or distributor, they have similar ingredients and/or yield media comparable to those obtained from the formulas given herein.

In preparing media by the formulas set forth herein, dissolve the soluble solids in the water, using heat if necessary to effect complete solution, and add solutions of hydrochloric acid or sodium hydroxide in quantities sufficient to yield the desired pH in the medium when it is ready for use. Determine the pH at 25 ± 2°.

Where agar is called for in a formula, use agar that has a moisture content of NMT 15%. Where water is called for in a formula, use *Purified Water*.

### pH 7.2 Phosphate Buffer

Prepare a stock solution by dissolving 34 g of monobasic potassium phosphate in about 500 mL of water contained in a 1000-mL volumetric flask. Adjust to a pH of 7.2 ± 0.1 by the addition of sodium hydroxide TS (about 175 mL), add water to volume, and mix. Dispense and sterilize. Store under refrigeration. For use, dilute the stock solution with water in the ratio of 1–800, dispense as desired, and sterilize.

[1] Available from ATCC, 10801 University Boulevard, Manassas, VA 20110-2209. Equivalent microorganisms, provided that they are from a national collection repository, can be used in lieu of ATCC strains. However, the viable microorganisms used in the test must not be more than five passages removed from the original ATCC or national collection culture.

https://pharmacopeia.cn/v-prod/

## Media

Prepare media for the tests as described below. Alternatively, dehydrated formulations may be used provided that, when reconstituted as directed by the manufacturer or distributor, they meet the requirements of *Growth Promotion Testing*. Unless otherwise indicated elsewhere in this chapter, media are sterilized in autoclaves using a validated process. The exposure time within the autoclave at 121° will depend on the volume of media to be sterilized. Thus, for example, a 500-mL volume would need to be autoclaved using a temperature and time relationship that will ensure that the medium has attained at least an $F_0$ of 12–15 in the sterilization process. However, the appropriate time and temperature duration for sterilizing prepared media at any given volume should be confirmed by a thermal penetration study using a thermocouple or thermoprobe placed within the liquid medium.

### FLUID CASEIN DIGEST–SOY LECITHIN–POLYSORBATE 20 MEDIUM

| | |
|---|---|
| Pancreatic Digest of Casein | 20 g |
| Soy Lecithin | 5 g |
| Polysorbate 20 | 40 mL |
| Water | 960 mL |

Dissolve *Pancreatic Digest of Casein* and *Soy Lecithin* in 960 mL of water, heating in a water bath at 48°–50° for about 30 min to effect solution. Add 40 mL of *Polysorbate 20*. Mix, dispense as desired, and sterilize.

### SOYBEAN–CASEIN DIGEST–AGAR MEDIUM

| | |
|---|---|
| Pancreatic Digest of Casein | 15.0 g |
| Papaic Digest of Soybean Meal | 5.0 g |
| Sodium Chloride | 5.0 g |
| Agar | 15.0 g |
| Water | 1000 mL |

pH after sterilization: 7.3 ± 0.2.

### FLUID SOYBEAN–CASEIN DIGEST MEDIUM

| | |
|---|---|
| Pancreatic Digest of Casein | 17.0 g |
| Papaic Digest of Soybean Meal | 3.0 g |
| Sodium Chloride | 5.0 g |
| Dibasic Potassium Phosphate | 2.5 g |
| Dextrose | 2.5 g |
| Purified Water | 1000 mL |

Dissolve the solids in the water, heating slightly to effect a solution. Cool the solution to room temperature, and adjust the pH with 1 N sodium hydroxide so that after sterilization it will have a pH of 7.3 ± 0.2. Filter, if necessary, and dispense into suitable containers. Sterilize at a temperature and time relationship that will ensure that the medium has attained at least an $F_0$ of 12–15 in the sterilization process, or by a validated filtration process.

### SABOURAUD DEXTROSE–AGAR MEDIUM

| | |
|---|---|
| Dextrose | 40.0 g |
| Mixture of Peptic Digest of Animal Tissue and Pancreatic Digest of Casein (1:1) | 10.0 g |
| Agar | 15.0 g |
| Water | 1000 mL |

Mix, and boil to effect solution.
pH after sterilization: 5.6 ± 0.2.

### VIOLET-RED BILE AGAR WITH GLUCOSE AND LACTOSE

| | |
|---|---|
| Yeast Extract | 3.0 g |

@2024 USPC

| | |
|---|---|
| Pancreatic Digest of Gelatin | 7.0 g |
| Bile Salts | 1.5 g |
| Lactose | 10.0 g |
| Sodium Chloride | 5.0 g |
| D-Glucose Monohydrate | 10.0 g |
| Agar | 15.0 g |
| Neutral Red | 30 mg |
| Crystal Violet | 2 mg |
| Water | 1000 mL |

Adjust the pH so that it is 7.4 ± 0.2 after heating. Heat to boiling, but do not heat in an autoclave. Pour onto plates.

MOSSEL–ENTEROBACTERIACEAE ENRICHMENT BROTH

| | |
|---|---|
| Pancreatic Digest of Gelatin | 10.0 g |
| D-Glucose Monohydrate | 5.0 g |
| Dehydrated Ox Bile | 20.0 g |
| Monobasic Potassium Phosphate | 2.0 g |
| Dibasic Potassium Phosphate | 8.0 g |
| Brilliant Green | 15 mg |
| Water | 1000 mL |

Suspend the solids in water, and heat to boiling for 1–2 min. Transfer 120-mL portions to 250-mL volumetric flasks or 9-mL portions to test tubes, all being capped with cotton plugs or loose-fitting caps. Heat on a steam bath for 30 min. Adjust the pH so that it is 7.2 ± 0.2 after heating.

GROWTH PROMOTION TESTING

Each lot of dehydrated medium bearing the manufacturer's identifying number or each lot of medium prepared from basic ingredients must be tested for its growth-promoting qualities. Cultures of *Staphylococcus aureus* (ATCC No. 6538), *Escherichia coli* (ATCC No. 8739), *Bacillus subtilis* (ATCC No. 6633), *Candida albicans* (ATCC No. 10231), and *Aspergillus brasiliensis* (ATCC No. 16404) are used. A $10^{-3}$ dilution of a 24-hour broth culture of the microorganism to the first dilution (in *pH 7.2 Phosphate Buffer* or *Fluid Soybean–Casein Digest Medium*) may be used as the inocula. Serially streak plates of the media with the appropriate inocula to obtain isolated colonies to demonstrate the growth-promotion qualities of the *Soybean–Casein Digest Agar* and *Sabouraud Dextrose Agar* media. Inoculate the *Fluid Soybean–Casein Digest Medium* and *Mossel–Enterobacteriaceae Enrichment Broth* with 10–100 cfu of the appropriate challenge organisms to demonstrate their growth-promotion qualities.

## SAMPLING

Provide 10-mL or 10-g specimens for the tests called for in the individual monograph.

## PROCEDURE

Prepare the specimen to be tested by a treatment that is appropriate to its physical characteristics and that does not alter the number and kind of microorganisms originally present, in order to obtain a solution or suspension of all or part of it in a form suitable for the test procedure(s) to be carried out.

For a solid that dissolves to an appreciable extent but not completely, reduce the substance to a moderately fine powder, suspend it in the vehicle specified, and proceed as directed under *Total Aerobic Microbial Count*.

For a fluid specimen that consists of a true solution, or a suspension in water or a hydroalcoholic vehicle containing less than 30% of alcohol, and for a solid that dissolves readily and practically completely in 90 mL of *pH 7.2 Phosphate Buffer* or the media specified, proceed as directed under *Total Aerobic Microbial Count*.

For water-immiscible products, prepare a suspension with the aid of a minimal quantity of a suitable, sterile emulsifying agent (such as one of the polysorbates), using a mechanical blender and warming to a temperature not exceeding 45°, if necessary, and proceed with the suspension as directed under *Total Aerobic Microbial Count*.

## Total Aerobic Microbial Count

For specimens that are freely soluble, use the *Membrane Filtration Method* or *Plate Method*. For specimens that are sufficiently soluble or translucent to permit use of the *Plate Method*, use that method; otherwise, use the *Multiple-Tube Method*. With either method, first dissolve or suspend 10.0 g of the specimen if it is a solid, or 10 mL, accurately measured, if the specimen is a liquid, in *pH 7.2 Phosphate Buffer, Fluid Soybean–Casein Digest Medium*, or *Fluid Casein Digest–Soy Lecithin–Polysorbate 20 Medium* to make 100 mL. For viscous specimens that cannot be pipeted at this initial 1:10 dilution, dilute the specimen until a suspension is obtained, i.e., 1:50 or 1:100, etc., that can be pipeted. Perform the test for absence of inhibitory (antimicrobial) properties as described under *Preparatory Testing* before the determination of *Total Aerobic Microbial Count*. Add the specimen to the medium NMT 1 h after preparing the appropriate dilutions for inoculation.

### MEMBRANE FILTRATION METHOD

Dilute the fluid further, if necessary, so that 1 mL will be expected to yield 30–300 colonies. Pipet 1 mL of the final dilution into 5–10 mL of *pH 7.2 Phosphate Buffer, Fluid Soybean–Casein Digest Medium*, or *Fluid Casein Digest–Soy Lecithin–Polysorbate 20 Medium*. Wash each membrane with an appropriate amount of one of the above diluents. Transfer each membrane to a Petri dish containing *Soybean–Casein Digest–Agar Medium*, previously solidified at room temperature. Incubate the plates at a temperature 30°–35° for 48–72 h. Following incubation, examine the plates for growth, count the number of colonies, and express the average for the two plates in terms of the number of microorganisms per g or per mL of specimen. If no microbial colonies are recovered from the dishes representing the initial 1:10 dilution of the specimen, express the results as “less than 10 microorganisms per g or per mL of specimen”.

### PLATE METHOD

Dilute the fluid further, if necessary, so that 1 mL will be expected to yield 30–300 colonies. Pipet 1 mL of the final dilution onto each of two sterile Petri dishes. Promptly add to each dish 15–20 mL of *Soybean–Casein Digest–Agar Medium*, previously melted and cooled to about 45°. Cover the Petri dishes, mix the sample with agar by gently tilting or rotating the dishes, and allow the contents to solidify at room temperature. Invert the Petri dishes and incubate for 48–72 h. Following incubation, examine the plates for growth, count the number of colonies, and express the average for the two plates in terms of the number of microorganisms per g or per mL of specimen. If no microbial colonies are recovered from the dishes representing the initial 1:10 dilution of the specimen, express the results as “less than 10 microorganisms per g or per mL of specimen”.

### MULTIPLE-TUBE METHOD

Into each of 14 test tubes of similar size, place 9.0 mL of sterile *Fluid Soybean–Casein Digest Medium*. Arrange 12 of the tubes in four sets of three tubes each. Put aside one set of three tubes to serve as the controls. Into each of three tubes of one set (“100”) and into a fourth tube (A) pipet 1 mL of the solution or suspension of the specimen, and mix. Pipet 1 mL from tube A into the one remaining tube (B), not included in a set, and mix. These two tubes contain 100 mg or 100 µL and 10 mg or 10 µL of the specimen, respectively. Into each of the second set (“10”) of three tubes pipet 1 mL from tube A, and into each tube of the third set (“1”) pipet 1 mL from tube B. Discard the unused contents of tubes A and B. Close well, and incubate all of the tubes. Following incubation, examine the tubes for growth: the three control tubes remain clear, and the observations in the tubes containing the specimen, when interpreted by reference to *Table 1*, indicate the most probable number of microorganisms per g or per mL.

**Table 1. Most Probable Count by Multiple-Tube Method**

| Observed Combinations of Numbers of Tubes Showing Growth in Each Set | | | Most Probable Number of Microorganisms per g or per mL |

## Total Combined Molds and Yeasts Count

PROCEDURE

Proceed as directed for *Membrane Filtration Method* or *Plate Method* under *Total Aerobic Microbial Count*, except to use the same amount of *Sabouraud Dextrose–Agar Medium* instead of *Soybean–Casein Digest–Agar Medium* and to incubate the plates for 5–7 days at 20°–25°.

RETEST

For the purpose of confirming a doubtful result by any of the procedures outlined in the foregoing tests following their application to a 10-g specimen, a retest on an additional 10-g specimen from the original sample and a 10-g specimen from the new sample of the nutritional supplement may be conducted. Proceed as directed under *Procedure*.

## Enterobacterial Count (Bile-Tolerant Gram-Negative Bacteria)

Dissolve or suspend the sample in a sufficient volume of *pH 7.2 Phosphate Buffer* or *Fluid Soybean–Casein Digest Medium* and dilute with *Fluid Soybean–Casein Digest Medium* to 100 mL. Pre-incubate for 2–5 h at 20°–25° in soybean–casein digest broth diluent; inoculate suitable quantities of *Mossel–Enterobacteriaceae Enrichment Broth* to contain 0.1, 0.01, or 0.001 g or mL of the product. Incubate at 30°–35° for 24–48 h. Subculture onto a plate of *Violet-Red Bile Agar with Glucose and Lactose*, and incubate at 30°–35° for 18–24 h. Growth of well developed, generally red or reddish, colonies of Gram-negative bacteria reveal the presence of enterobacteria. Determine the most probable number of microorganisms per g or per mL by reference to *Table 2*.

**Table 2. Most Probable Enterobacterial Count**

| Observed Presence of Enterobacteria | | | Most Probable Number of Enterobacteria per g or per mL |
|---|---|---|---|
| Number of g or mL of specimen per tube | | | |
| 0.1 | 0.01 | 0.001 | |
| + | + | + | More than $10^3$ |
| + | + | – | Fewer than $10^3$ but more than $10^2$ |
| + | – | – | Fewer than $10^2$ but more than $10^1$ |
| – | – | – | Fewer than $10^1$ |

# ⟨2022⟩ MICROBIOLOGICAL PROCEDURES FOR ABSENCE OF SPECIFIED MICROORGANISMS—NUTRITIONAL AND DIETARY SUPPLEMENTS

## INTRODUCTION

Good manufacturing practices require that objectionable organisms be absent from nonsterile nutritional and dietary products. A microorganism can be considered objectionable if it represents a potential health hazard to the user who is using the product as directed, or if it is capable of growing in the product. Objectionable microorganisms are defined as contaminants that, depending on the microbial species, number of organisms, dosage form, intended use, and patient population, would adversely affect product safety. Additionally, microorganisms may be deemed objectionable if they adversely affect product stability or if they may damage the integrity of the container closure system.

This chapter describes the testing of nutritional and dietary articles for specified microorganisms, which are specified in the individual monographs or whose absence is recommended by the guidance under *Microbiological Attributes of Nonsterile Nutritional and Dietary Supplements* ⟨2023⟩. When objectionable microorganisms are not specified in the individual monograph, it is the manufacturers' responsibility to determine which microorganisms in their products are objectionable. It is not intended that all nonsterile nutritional and dietary articles be tested for the absence of all of the microorganisms mentioned in this chapter, nor is the testing of relevant microorganisms restricted to those presented in this chapter.

Alternative microbiological, physicochemical, and biotechnological methods, including automated methods, may be substituted for these tests, provided they have been validated as being equivalent in their suitability for determining compliance.

***Change to read:***

## BUFFER AND MEDIA

### General Considerations

See *Buffer Solution and Media* under *Microbial Enumeration Tests—Nutritional and Dietary Supplements* ⟨2021⟩. The appropriateness of each medium for the intended purpose is to be assessed. Control sets of *Fluid Soybean–Casein Digest Medium* for *Preparatory Testing* are also used to assess the appropriateness of these media in the growth promotion of the specified microorganisms. For other media, streak agar plates to obtain isolated colonies of appropriate microorganisms, and inoculate the fluid media with the appropriate microorganisms at a final concentration of less than 100 cfu per mL. Observe the growth to establish the appropriateness of the media.

### Buffer

#### BUFFER STOCK SOLUTION and pH 7.2 PHOSPHATE BUFFER

Proceed as directed under *Microbial Enumeration Tests—Nutritional and Dietary Supplements* ⟨2021⟩.

### Media

#### FLUID SOYBEAN–CASEIN DIGEST MEDIUM

Prepare as directed under *Microbial Enumeration Tests—Nutritional and Dietary Supplements* ⟨2021⟩.

#### MANNITOL–SALT–AGAR MEDIUM

| | |
|---|---|
| Pancreatic Digest of Casein | 5.0 g |
| Peptic Digest of Animal Tissue | 5.0 g |
| Beef Extract | 1.0 g |
| D-Mannitol | 10.0 g |
| Sodium Chloride | 75.0 g |
| Agar | 15.0 g |
| Phenol Red | 0.025 g |
| Water | 1000 mL |

Mix, then heat with frequent agitation, and boil for 1 minute to effect solution.
pH after sterilization: 7.4 ± 0.2.

## FLUID TETRATHIONATE MEDIUM

| | |
|---|---|
| Pancreatic Digest of Casein | 2.5 g |
| Peptic Digest of Animal Fat | 2.5 g |
| Bile Salts | 1.0 g |
| Calcium Carbonate | 10.0 g |
| Sodium Thiosulfate | 30.0 g |
| Water | 1000 mL |

Heat to boiling. Do not autoclave; use the same day. Immediately before use, add a solution prepared by dissolving 5 g of potassium iodide and 6 g of iodine in 20 mL of water. Then add 10 mL of a solution of brilliant green (1 in 1000), and mix. Do not heat after adding the brilliant green solution.

## BRILLIANT GREEN–AGAR MEDIUM

| | |
|---|---|
| Yeast Extract | 3.0 g |
| Peptic Digest of Animal Tissue | 5.0 g |
| Pancreatic Digest of Casein | 5.0 g |
| Lactose | 10.0 g |
| Sodium Chloride | 5.0 g |
| Sucrose | 10.0 g |
| Phenol Red | 80.0 g |
| Agar | 20.0 g |
| Brilliant Green | 12.5 mg |
| Water | 1000 mL |

Boil for 1 minute. Sterilize just prior to use, melt, pour into Petri dishes, and allow to cool.
pH after sterilization: 6.9 ± 0.2

## XYLOSE–LYSINE–DESOXYCHOLATE–AGAR MEDIUM

| | |
|---|---|
| Xylose | 3.5 g |
| L-Lysine | 5.0 g |
| Lactose | 7.5 g |
| Sucrose | 7.5 g |
| Sodium Chloride | 5.0 g |
| Yeast Extract | 3.0 g |
| Phenol Red | 80 mg |
| Agar | 13.5 g |
| Sodium Desoxycholate (as Bile Salts) | 2.5 g |
| Sodium Thiosulfate | 6.8 g |
| Ferric Ammonium Citrate | 800 mg |
| Water | 1000 mL |

Heat, with swirling, just to the boiling point. Do not overheat or sterilize. Transfer at once to a water bath maintained at about 50°, and pour into Petri plates as soon as the *Medium* has cooled.
Final pH: 7.4 ± 0.2.

## HEKTOEN ENTERIC AGAR MEDIUM

| | |
|---|---|
| Protease Peptone | 12.0 g |
| Yeast Extract | 3.0 g |
| Lactose | 12.0 g |

https://pharmacopeia.cn/v29240/

| | |
|---|---|
| Sucrose | 2.0 g |
| Salicin | 9.0 g |
| Bile Salts No. 3 | 9.0 g |
| Sodium Chloride | 5.0 g |
| Sodium Thiosulfate | 5.0 g |
| Ferric Ammonium Citrate | 1.5 g |
| Acid Fuchsin | 0.1 g |
| Bromothymol Blue | 65 mg |
| Agar | 14.0 g |
| Water | 1000 mL |

Mix, and allow to stand for 10 minutes. Heat gently, and allow to boil for a few seconds to dissolve the agar. Do not sterilize. Cool to 60°, and pour into Petri dishes.
Final pH: 7.5 ± 0.2.

### TRIPLE SUGAR–IRON–AGAR MEDIUM

| | |
|---|---|
| Pancreatic Digest of Casein | 10.0 g |
| Pancreatic Digest of Animal Tissue | 10.0 g |
| Lactose | 10.0 g |
| Sucrose | 10.0 g |
| Dextrose | 1.0 g |
| Ferrous Ammonium Sulfate | 200 mg |
| Sodium Chloride | 5.0 g |
| Sodium Thiosulfate | 200 mg |
| Agar | 13.0 g |
| Phenol Red | 25 mg |
| Water | 1000 mL |

pH after sterilization: 7.3 ± 0.2.

### MACCONKEY AGAR MEDIUM

| | |
|---|---|
| Pancreatic Digest of Gelatin | 17.0 g |
| Pancreatic Digest of Casein | 1.5 g |
| Peptic Digest of Animal Tissue | 1.5 g |
| Lactose | 10.0 g |
| Bile Salts Mixture | 1.5 g |
| Sodium Salts Mixture | 5.0 g |
| Agar | 13.5 g |
| Neutral Red | 30 mg |
| Crystal Violet | 1.0 mg |
| Water | 1000 mL |

Boil for 1 minute to effect solution.
pH after sterilization: 7.1 ± 0.2.

### LEVINE EOSIN–METHYLENE BLUE–AGAR MEDIUM

| | |
|---|---|
| Pancreatic Digest of Gelatin | 10.0 g |
| Dibasic Potassium Phosphate | 2.0 g |
| Agar | 15.0 g |

Official

https://pharmacopeia.cn/v29240/

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Nov-2019
DOI Ref: d303e

DOI: https://doi.org/10.31003/USPNF_M99966_02_01
@2024 USPC

| | |
|---|---|
| Lactose | 10.0 g |
| Eosin Y | 400 mg |
| Methylene Blue | 65 mg |
| Water | 1000 mL |

Dissolve pancreatic digest of gelatin, dibasic potassium phosphate, and agar in water, with warming, and allow to cool. Just prior to use, liquefy the gelled agar solution, and add the remaining ingredients, as solutions, in the following amounts: for each 100 mL of the liquefied agar solution, add 5 mL of lactose solution (1 in 5), 2 mL of the eosin Y solution (1 in 50), and 2 mL of methylene blue solution (1 in 300). Mix. The finished *Medium* may not be clear.

pH after sterilization: 7.1 ± 0.2.

### BAIRD–PARKER AGAR MEDIUM

| | |
|---|---|
| Pancreatic Digest of Casein | 10.0 g |
| Beef Extract | 5.0 g |
| Yeast Extract | 1.0 g |
| Lithium Chloride | 5.0 g |
| Agar | 20.0 g |
| Glycine | 12.0 g |
| Sodium Pyruvate | 10.0 g |
| Water | 950 mL |

Heat with frequent agitation, and boil for 1 minute. Sterilize, cool to between 45° and 50°, and add 10 mL of sterile potassium tellurite solution (1 in 100) and 50 mL of egg yolk emulsion prepared as follows. Disinfect the surface of whole-shell eggs, aseptically crack the eggs, transfer intact yolks to a sterile graduated cylinder, add sterile saline TS to obtain a 3 to 7 ratio of egg yolk to saline, add to a sterile blender cup, and mix at high speed for 5 seconds. Mix all ingredients well but gently, and pour into plates.

pH after sterilization: 6.8 ± 0.2.

### VOGEL–JOHNSON AGAR MEDIUM

| | |
|---|---|
| Pancreatic Digest of Casein | 10.0 g |
| Yeast Extract | 5.0 g |
| Mannitol | 10.0 g |
| Dibasic Potassium Phosphate | 5.0 g |
| Lithium Chloride | 5.0 g |
| Glycine | 10.0 g |
| Agar | 16.0 g |
| Phenol Red | 25.0 mg |
| Water | 1000 mL |

Boil for 1 minute. Sterilize, cool to between 45° and 50°, and add 20 mL of sterile potassium tellurite solution (1 in 100).

pH after sterilization: 7.2 ± 0.2.

### FLUID SELENITE–CYSTINE MEDIUM

| | |
|---|---|
| Pancreatic Digest of Casein | 5.0 g |
| Lactose | 4.0 g |
| Sodium Phosphate | 10.0 g |
| Sodium Acid Selenite | 4.0 g |
| L-Cystine | 10.0 ▲mg▲ (ERR 1-Nov-2019) |
| Water | 1000 mL |

Mix, and heat to effect solution. Then heat in flowing stream for 15 minutes. Do not sterilize.

Final pH: 7.0 ± 0.2.

REINFORCED MEDIUM FOR CLOSTRIDIA

| | |
|---|---|
| Beef Extract | 10.0 g |
| Peptone | 10.0 g |
| Yeast Extract | 3.0 g |
| Soluble Starch | 1.0 g |
| Glucose Monohydrate | 5.0 g |
| Cysteine Hydrochloride | 0.5 g |
| Sodium Chloride | 5.0 g |
| Sodium Acetate | 3.0 g |
| Agar | 0.5 g |
| Water | 1000 mL |

Dissolve agar in water by heating to boiling, while stirring continuously. Adjust the pH if necessary, and sterilize.
pH after sterilization: 6.8 ± 0.2.

COLUMBIA AGAR

| | |
|---|---|
| Pancreatic Digest of Casein | 10.0 g |
| Meat Peptic Digest | 5.0 g |
| Heart Pancreatic Digest | 3.0 g |
| Yeast Extract | 5.0 g |
| Cornstarch | 1.0 g |
| Sodium Chloride | 5.0 g |
| Agar | 15.0 g |
| Water | 1000 mL |

Dissolve agar in water by heating to boiling and with continuous stirring. If necessary, adjust the pH. Sterilize, and allow to cool to 45° to 50°. Add, when necessary, gentamicin sulfate, equivalent to about 20 mg of gentamicin base, and pour into Petri dishes.
Pre-reduction of the medium is recommended.
pH after sterilization: 7.3 ± 0.2.

RAPPAPORT VASSILIADIS SALMONELLA ENRICHMENT BROTH

| | |
|---|---|
| Soya Peptone | 4.5 g |
| Magnesium Chloride Hexahydrate | 29.0 g |
| Sodium Chloride | 8.0 g |
| Dipotassium Phosphate | 0.4 g |
| Potassium Dihydrogen Phosphate | 0.6 g |
| Malachite Green | 0.036 g |
| Purified Water | 1000 mL |

Dissolve, warming slightly. Sterilize in an autoclave using a validated cycle, at a temperature not exceeding 115°.
The pH is 5.2 ± 0.2 at 25° after heating and autoclaving.

## PREPARATORY TESTING

Proceed as directed for *Preparatory Testing* under *Microbial Enumeration Tests—Nutritional and Dietary Supplements* ⟨2021⟩.
For enrichment broth, selective media, and differential media use an inoculating loop to transfer the inoculum of each test organism to the plated or liquid media being tested. If a plated medium is being tested, streak the surface of plate with the loop in four directions to obtain a pattern of isolated colonies. Incubate the media, and examine the plated or liquid media for the characteristic growth of the inocula (See *Tables 1*, *2*, *3*, and *4*).

## SAMPLING

Proceed as directed for *Sampling* under *Microbial Enumeration Tests—Nutritional and Dietary Supplements* ⟨2021⟩.

## TEST PROCEDURES

**Test Preparation—**Prepare as directed for *Sampling.* Transfer to a suitable container with 100 mL of *Fluid Soybean–Casein Digest Medium (FSCD).* Mix by shaking gently. [NOTE—On the basis of results for *Preparatory Testing,* modify the *Test Preparation* as appropriate.]

### Test for Absence of *Staphylococcus aureus*

Incubate at 30° to 35° for 18 to 24 hours. Streak a loopful from *FSCD* onto the surface of one or more of the following media: *Vogel–Johnson Agar Medium (VJ Agar), Mannitol–Salt–Agar Medium (MS-Agar),* and *Baird-Parker Agar Medium (BP Agar).* Cover the Petri plates, invert them, and incubate at 30° to 35° for 24 to 48 hours.

Examine the plates of *VJ Agar, MS-Agar,* and/or *BP Agar*, and interpret the results with reference to *Table 1:* if no plate contains colonies having the characteristics described, the test specimen meets the requirement for the absence of *Staphylococcus aureus.* If characteristic colonies are present, perform coagulase test as follows. Transfer representative colonies to separate tubes containing 0.5 mL of rabbit plasma, horse plasma, or any other mammalian plasma. Incubate in a water bath at 37°. Examine for coagulation after 3 hours of incubation and at suitable intervals up to 24 hours. Comparing with positive and negative controls, the absence of a coagulase reaction indicates the absence of *Staphylococcus aureus* in the tested article.

**Table 1. Characteristics of *Staphylococcus aureus* on Specified Agar Media**

| Agar Medium | Colonial Morphology | Gram Stain |
|---|---|---|
| *Vogel–Johnson* | Black surrounded by yellow zone | (+), cocci |
| *Mannitol–Salt* | Yellow colonies with yellow zone | (+), cocci |
| *Baird–Parker* | Black, shiny surrounded by 2–5-mm clear zones | (+), cocci |

### Test for Absence of *Salmonella* Species

Incubate at 30° to 35° for 18 to 24 hours. From *FSCD,* pipet a 1-mL aliquot into 10 mL of *Rappaport Vassiliadis Salmonella Enrichment Broth,* mix, and incubate at 30° to 35° for 18 to 24 hours. Streak a loopful from both incubated media onto individual surfaces of one or more of following media: *Brilliant Green Agar Medium (BG-Agar), Xylose–Lysine–Desoxycholate–Agar Medium (XLDC-Agar),* and *Hektoen Enteric Agar Medium (HE Agar).* Cover, invert the plates, and incubate at 30° to 35° for 24 to 48 hours. Examine the inoculated plates of *BG-Agar, XLDC-Agar,* and/or *HE Agar,* and interpret the results with reference to *Table 2*: if no colonies having the characteristics described are observed, the test specimen meets the requirement for the absence of *Salmonella* species. If colonies with characteristics described in *Table 2* are present, the suspect colonies are transferred to a slant of *Triple Sugar–Iron–Agar Medium (TSI)* using an inoculating wire, by first streaking the surface of the slant, and then stabbing the wire well beneath the surface. Incubate at 30° to 35° for 24 to 48 hours. If the tubes do not have red alkaline slants and yellow acid butts, with or without concomitant blackening of the butts from hydrogen sulfide production, the test specimen meets the requirement for the absence of *Salmonella* species.

**Table 2. Characteristics of *Salmonella* Species on Specified Agar Media**

| Agar Medium | Colonial Morphology | Gram Stain |
|---|---|---|
| *Brilliant Green* | Small, transparent and colorless; or opaque, pink or white (often surrounded by pink to red zone) | (–), rods |
| *Xylose–Lysine–Desoxycholate* | Red, with or without black centers | (–), rods |
| *Hektoen Enteric* | Blue-green, with or without black centers | (–), rods |

### Test for Absence of *Escherichia coli*

Incubate at 30° to 35° for 24 to 48 hours. From *FSCD,* pipet a 1-mL aliquot into a container containing 10 mL of *MacConkey Broth,* mix, and incubate at 42° to 44° for 24 to 48 hours. Streak a loopful from both incubated media onto individual surfaces of *MacConkey Agar Medium (MC Agar),* and incubate at 30° to 35° for 18 to 24 hours. Examine the inoculated *MC Agar* plate, and interpret the results with reference to *Table 3*: if no colonies having the characteristics described are observed, the test specimen meets the requirement for the absence of *Escherichia coli.* Suspect colonies showing the characteristics described in *Table 3* are transferred individually, using an inoculating loop, to the surface of a plate with *Levine Eosin–Methylene Blue–Agar Medium (LEMB-Agar).* If a large number of suspect colonies are to be transferred, divide the surface of each plate into quadrants, each quadrant being inoculated with a different colony. Cover the plates, invert, and incubate at 30° to 35° for 24 to 48 hours. If none of the colonies exhibit a characteristic metallic sheen under reflected light, and if none exhibit a blue-black appearance under transmitted light, the test specimen meets the requirement for the absence of *Escherichia coli.*

**Table 3. Characteristics of *Escherichia coli* on *MacConkey Agar Medium***

| Colonial Morphology | Gram Stain |
|---|---|
| Brick red, may have surrounding zone of precipitated bile | (–), rods |

## Test for Absence of *Clostridium* Species

### Test Preparation

Prepare as directed for *Sampling.* [Note—On the basis of results for *Preparatory Testing,* modify the *Test Preparation* as appropriate.]

Procedure—Take two equal portions of the *Test Preparation,* heat one to 80° for 10 minutes, and cool rapidly. Transfer 10 mL of each portion to separate containers, each containing 100 mL of *Reinforced Medium for Clostridia,* and incubate under anaerobic conditions at 35° to 37° for 48 hours. After incubation, subculture each specimen on *Columbia Agar Medium* to which gentamicin has been added, and incubate under anaerobic conditions at 35° to 37° for 48 hours. Examine the plates, and interpret with reference to *Table 4*: if no growth of microorganisms is detected, the test specimen meets the requirement for the absence of *Clostridium* species.

**Table 4. Characteristics of *Clostridium* Species on Specified Media**

| Medium | Gram Stain | Catalase |
|---|---|---|
| *Reinforced Medium for Clostridia* | (+), rods | Negative |
| *Columbia Agar* | (+), rods | |

If growth occurs, subculture each distinct colony on *Columbia Agar Medium,* and separately incubate in aerobic and in anaerobic conditions at 35° to 37° for 48 hours. The occurrence of only anaerobic growth of gram-positive bacilli, giving a negative catalase reaction, indicates the presence of *Clostridium sporogenes.* To perform the catalase test, transfer discrete colonies to glass slides, and apply a drop of dilute hydrogen peroxide solution: the reaction is negative if no gas bubbles evolve. If the test specimen exhibits none of these characteristics, it meets the requirement for the absence of *Clostridium* species.

### Retest

For the purpose of confirming a doubtful result by any of the procedures outlined in the foregoing tests following their application to a 10 g specimen, a retest on a 25 g specimen of the nutritional or dietary supplement may be conducted. Proceed as directed under *Procedure,* but make allowances for the larger specimen size.

# ⟨2023⟩ MICROBIOLOGICAL ATTRIBUTES OF NONSTERILE NUTRITIONAL AND DIETARY SUPPLEMENTS

## INTRODUCTION

The raw materials, pharmaceutical ingredients, and active ingredients used in the manufacture of nutritional and dietary articles may range from chemically synthesized vitamins to plant extracts and animal byproducts, and these ingredients are typically not sterile. Considerable experience has accrued with these highly refined plant- and animal-derived pharmaceutical ingredients, such as microcrystalline cellulose, modified starch, lactose, and magnesium stearate, and their microbiological attributes are well established. Botanicals may be microbiologically contaminated at any point during cultivation, harvesting, processing, packing, and distribution. Major sources of microbial contamination are associated with human or animal feces used as plant manure; contaminated irrigation water and/or process water; and poor worker hygiene and sanitation practices during harvesting, sorting, processing, packaging, and transportation. Furthermore, it is essential that microbiological contamination be minimized during the manufacture of nonsterile dietary supplements. To achieve this, Good Manufacturing Practices are employed and adequate microbiological specifications are established.

Microbiological process control, control of the bioburden of raw materials, and control of the manufacturing process to minimize cross-contamination are necessary to guarantee acceptable microbial quality in the final dosage forms. Because nonaqueous or dry dosage forms do not support microbial growth because of low water activity, the microbial quality of such articles is a function of the microorganisms introduced through ingredients or during processing. In addition to considering the intended use of the product, the frequency of microbial testing for the finished nonsterile dietary supplement would be a function of the historical microbial testing database of that product, knowledge of the manufacturing processes, the susceptibility of the formulation to microbial proliferation, and the demonstrated effectiveness of programs controlling the raw materials.

## FORMULATION AND PROCESS DESIGN

From a microbiological perspective, the development of the formulation of nutritional or dietary supplements includes an evaluation of raw materials and their suppliers and the contribution made to the products by each ingredient and the manufacturing processes. Characterization of these elements allows the adequacy of the manufacturing process to be demonstrated. For example, if a product is formulated with an ingredient of botanical or animal origin known to possess a high, variable, or unpredictable level of microbiological contamination, it is necessary to ensure that the microbiological monitoring identifies ingredients that have an inappropriate bioburden level and that a premanufacturing process such as drying, extraction, heat treatment, irradiation, or gaseous sterilization treatment will inactivate or remove any objectionable contaminant possibly present.

However, the selected treatment technique should not have any adverse effects. The treatment of raw materials by irradiation and ethylene oxide may cause unwanted changes affecting the safety and efficacy of the raw material. For instance, when treated by ethylene oxide, crude extracts containing alkaloids have shown reduced contents of alkaloids. Dry heat treatment has been used for inactivation as well, but requires further evaluation because it may adversely affect stability and degradation of the raw material. With regard to the design of the manufacturing process, appropriate consideration should be given to the microbiological effect of wet granulation manufacturing processes. Wetting of a dry powder can result in increased levels of microorganisms if the granulation is stored prior to drying. However, it is recognized that the pressure and temperature associated with compression of tablets will decrease microbial counts. Antimicrobial activity is also achieved, especially with aqueous preparations, by the addition of chemicals that have known antimicrobial properties and that are compatible with the formulation.

However, antimicrobial preservation is not a substitute for Good Manufacturing Practices. A process has to be designed to minimize the microbiological population. Operating procedures, temperatures, and time limits, including holding times, are established to protect the product from microbiological contamination and growth. All processes have to be validated for their intended purposes. Moreover, in-process manufacturing and testing controls necessary for microbiological quality should be identified and implemented.

## FACILITIES, EQUIPMENT, WATER, AND SANITIZATION

### Facilities

The facilities, including the building and the heating, ventilation, and air-conditioning (HVAC) systems, should be designed to minimize microbiological contamination. The design of facilities used for the manufacture of supplements and their operating parameters should be documented, and the documentation should include, when appropriate, HVAC filter types, space pressure differentials, temperature, and relative humidity and air changes. Dry products processed in a dry environment do not possess a high potential for increased microbial levels. However, some control is warranted to minimize microbiological and chemical contamination. Potentially problematic areas are those that utilize *Purified Water* for wet granulation, batching liquid products, and film-coating tablets, because water encourages microbial growth.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99967_01_01
@2024 USPC

## Equipment

Equipment used for the processing of semisolid and dry supplements should be designed to promote sanitary conditions, to be self-drying, and to be easy to clean. Dryers, ovens, wet granulation equipment, bulk tanks, and equipment for preparation of coating solutions are periodically evaluated to ensure that cleaning procedures are adequate.

## Water

As one of the major components in nutritional and dietary supplement manufacturing processes, water deserves a special consideration in the microbiological control of these articles. It is a growth medium for a variety of microorganisms that present a threat to product quality, safety, preservation, and stability. Water may even act as a carrier of objectionable microorganisms. In view of this, water used in manufacturing is *Purified Water*. For the manufacture of raw materials, process water that meets specific microbiological objectives and U.S. Environmental Protection Agency National Drinking Water standards or equivalent European and Japanese standards may be used.

## Cleaning and Sanitization

Detailed and specific cleaning and sanitization procedures should be evaluated, developed, and validated, with special attention given to product contact surfaces. Personnel should possess sufficient knowledge of these procedures.

# SUPPLEMENT COMPONENTS

Raw materials, excipients, and active substances as components of nutritional and dietary supplements can be a primary source of microbiological contamination. Specifications should be developed and sampling plans and test procedures should be employed to guarantee the desired microbiological attributes of these materials. The nature and extent of microbiological testing should be based upon a knowledge of the material's origin, its manufacturing process, use, historical data, and experience. For instance, materials of animal or botanical origin that are not highly refined might require special, more frequent testing than synthetic products.

Since members of the family Enterobacteriaceae are a major component of the normal epiphytic and endophytic microflora (e.g., members of genera *Klebsiella, Enterobacter*, and *Erwinia*) and have been associated with the seeds, pods, roots, leaves, and stems of plants of economic importance, coliform or Enterobacteriaceae counts will not be an appropriate general microbiological criterion for botanicals. However, when it is considered advantageous, coliform or Enterobacteriaceae counts may be included in the individual monographs. Typically on new leaves, bacteria predominate in the microflora, while yeast and filamentous fungi succeed bacteria and become dominant late in the growing season. With dried botanicals, the bacterial population will tend to change from Gram-negative bacteria to Gram-positive spore formers and fungi. Refinement of botanicals from chopped or powdered plant material to powdered extracts using alcoholic, alkaline, acid hydro-alcoholic, or aqueous extracting materials will reduce the likelihood of vegetative microorganisms within the botanical material. The classification of botanical materials is contained in *Table 1*.

**Table 1. Definitions of a Range of Botanical Materials**

| Botanical Preparation | Definition |
|---|---|
| Chopped or Powdered Botanicals | Hand-picked portions of the botanical (e.g., leaves, flowers, roots, tubers, etc.) that are air dried, chopped, flaked, sectioned, ground, or pulverized to the consistency of a powder. |
| Botanical Extracts | Extracts are solids or semisolid preparations of a botanical that are prepared by percolation, filtration, and concentration by evaporation of the percolate. The extracting material may be alcoholic, alkaline, acid hydro-alcoholic, or aqueous in nature. Typically, an extract is 4–10 times as strong as the original botanical. The extracts may be semisolids or dry powders termed powdered extracts. |
| Tinctures | Tinctures are solutions of botanical substances in alcohol obtained by extraction of the powdered, flaked, or sectioned botanical. |
| Infusions | Infusions are solutions of botanical principles obtained by soaking the powdered botanical in hot or cold water for a specified time and straining. Typically, infusions are 5% in strength. |
| Decoctions | Decoctions are solutions of botanicals prepared by boiling the material in water for at least 15 min and straining. Typically, decoctions are 5% in strength. |
| Fluidextracts | A fluidextract is an alcoholic liquid extract made by percolation of a botanical so that 1 mL of the fluidextract represents 1 g of the botanical. |
| Botanicals to be treated with boiling water before use | Dried botanicals to which boiling water is added immediately prior to consumption. |

# MICROBIOLOGICAL TESTING

## Frequency of Sampling and Testing

Microbiological attribute sampling and testing plans vary widely. In some cases, no sampling or testing is necessary; in other cases, periodic monitoring is warranted; and yet for some articles, each batch requires sampling and testing. The design of the sampling and testing plans and the kind of attributes examined depend on the application and the type of the product, the potential for contamination from components and processing, the growth promotion or inhibition properties of the formulation, and the target population for the supplement. For example, a powdered botanical may have highly variable microbiological attributes so that an incoming batch would be sampled and composite testing would not be advised, while a highly refined botanical extract may not require routine microbial testing. Similarly, products with a low water activity will not be susceptible to microbial growth during their shelf life provided they are protected from elevated humidity by their containers.

## Microbial Enumeration Tests

See the *Introduction* under *Microbial Enumeration Tests—Nutritional and Dietary Supplements* ⟨2021⟩. These tests provide meaningful information regarding the microbiological acceptability of excipients, active substances, and nonsterile supplement formulations. If the individual monograph does not specify microbial enumeration limits, the guidance provided in this chapter is used. Acceptable general limits of microbial levels for raw materials, excipients, and botanical products are shown in *Table 2*; and those for raw materials, excipients, active ingredients, and other nonsterile finished articles that are nutritional supplements, but do not contain botanicals, are shown in *Table 3*.

**Table 2. Recommended Microbial Limits for Botanical Ingredients and Products**

| Material | Recommended Microbial Limit Requirements (cfu/g or mL) |
|---|---|
| Dried or Powdered Botanicals | Total aerobic microbial count NMT $10^5$ |
| | Total combined yeasts and molds count NMT $10^3$ |
| | Bile-tolerant Gram-negative bacteria NMT $10^3$ |
| | Absence of *Salmonella* spp. and *E. coli* in 10 g |

## Absence of Objectionable Microorganisms

See *Introduction* under *Microbiological Procedures for Absence of Specified Microorganisms—Nutritional and Dietary Supplements* ⟨2022⟩. Absence of one or more species of objectionable microorganisms is required in some individual monographs.

## Test for Aflatoxins

Dietary and nutritional articles containing botanical products with a history of mycotoxin contamination are also typically tested for aflatoxins, especially if the material is obtained from roots or rhizomes. See *Articles of Botanical Origin* ⟨561⟩ for the details of a test for aflatoxins. Where necessary, this test is included in the individual monograph.

## Solid Oral Dosage Forms

Among all dosage forms, solid oral dosage forms present the lowest microbiological risk because of their method of manufacture, low water activity, and route of administration. When justified, reduced microbiological testing may be appropriate.

## Other Concerns

The presence of some microorganisms in articles can be an indicator of processes that are not under microbiological control. For example, *Purified Water* used at some stage of the manufacture of these products might contain a typical flora of Gram-negative microorganisms. As with pharmaceutical products, inadequate processing of water and poor maintenance of water systems may result in the contamination of processed formulations by Gram-negative microorganisms.

# ⟨2030⟩ SUPPLEMENTAL INFORMATION FOR ARTICLES OF BOTANICAL ORIGIN

This general chapter provides information about several aspects of botanical articles not covered in *USP* standards monographs. Although the standards in the monographs address the quality issues associated with botanical plant materials, extracts, and preparations of Pharmacopeial articles, there is a need to develop appropriate information to optimize the pre-harvest conditions for appropriate growth and the post-harvest handling to achieve consistent quality with minimum variations in the composition of chemical constituents.

## PROTOCOL CONTENTS

**Black Cohosh** (*Actaea racemosa* L.)
**Ginger** (*Zingiber officinale* Roscoe)
**Valerian** (*Valeriana officinalis* L.)
**Elm** (*Ulmus rubra* Muhlenberg)

## GENERAL GUIDANCES

It is recommended that, at a minimum, growers and others involved in the handling and distribution of botanical products should become familiar with and follow the WHO Guidelines on Good Agricultural and Collection Practices (GACP) for Medicinal Plants (found at http://apps.who.int/medicinedocs/pdf/s4928e/s4928e.pdf).

Commercial trade in natural products occurs in a global market. Material of domestic origin must be produced in compliance with all federal laws of the United States. Material of foreign origin, imported into the U.S., must be produced and transported in compliance with the laws of the U.S., the country of origin, and relevant international treaties. These include, but may not be limited to, the following:

1. The Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) is an international agreement between governments. Its aim is to ensure that international trade in specimens of wild animals and plants does not threaten their survival. Information about CITES is available at http://www.cites.org.
2. The Convention on Biological Diversity (CBD) establishes three main goals: the conservation of biological diversity, the sustainable use of its components, and the fair and equitable sharing of the benefits from the use of genetic resources. Each country that has ratified and is a party to the Convention is responsible for implementation by means of national enabling legislation that can differ from country to country.
3. The Endangered Species Act (ESA) was originally adopted in 1973. The ESA is a law that aims to protect species of fish, wildlife, and plants believed to be threatened with extinction. The ESA is administered primarily by the U.S. Fish and Wildlife Service. Full text of the act is available at: http://epw.senate.gov/esa73.pdf.

Provided below is additional information not covered in the compendial specifications: compendial history; sources; collection and cultivation, including common adulterants; and drying, storing, and shipping. This information is provided to complement the standards for quality control in the monographs for botanical articles.

**Compendial History—**The focus in this section is on historical compendial use that has strong validity, with only brief reference to anecdotal use. This is important information because traditional use is one of the elements taken into consideration to support the safety and the presumptions of benefits of botanical dietary supplements.

**Sources—**Included here is the point of origin of the botanical; it also encompasses cultivation (defined as agricultural growing) and wildcrafting (defined as collected in the wild), along with a listing of the primary geographical (native) areas of production.

**Collection and Cultivation—**This section discusses wildcrafting, the conservation of restricted and rare species, and the trend to cultivation as an ecological alternative; such optimal harvesting and collection practices serve to preserve the integrity of species and botanical products. It is divided into three subsections:

1. Collection (conservation and ecology)
2. Cultivation Practices
3. Optimal Times for Harvest

**Post-Harvest Handling (Optimal Handling and Processing Practices, Drying, Storage, and Shipping)—**Important factors regarding storage of herbal products and how they should be maintained include the following.

1. *Light:* Protection from light is important for botanical articles. Light accelerates numerous chemical processes that may lead to degradation or changes in the constituents of the articles.
2. *Temperature:* Storage temperatures in this *Pharmacopeia* are defined in *Packaging and Storage Requirements* ⟨659⟩*, Storage Conditions*. Excessive heat may affect the content of volatile constituents (essential oils) and accelerate degradation processes. However, heat treatments are sometimes useful in the maintenance of the article's quality and can be used in drying, reducing microbial load, and inhibiting certain enzymes. Heat application during these processes must be carefully controlled to achieve the desired balance between degradation and quality conservation.
3. *Humidity:* Moisture in the articles may allow certain enzymes such as glycosidases to become active, hence degrading constituents. High humidity also increases the danger of microbial proliferation. As a rule, it is advisable to store botanical

@2024 USPC

articles below 60% relative humidity. Although controlled humidity and temperature warehouses are now required in many good manufacturing practices for natural products, much of the world still lacks access to these facilities.

4. *Degree of Comminution:* The degree of comminution plays a role in determining the stability of the botanical articles during storage. The increased surface area in fine powders allows oxidation and other degradation processes to occur more extensively and rapidly than in the case of a whole article. Plants containing tannins, bitter substances, and essential oils are particularly sensitive to the degree of comminution. In general, dried crude botanicals should be stored in a minimally processed form.
5. *Containers:* Appropriate containers are defined in this *Pharmacopeia* in *Packaging and Storage Requirements* ⟨659⟩*, General Definitions*.

**Constituents—**Where known, the substances mainly responsible for the activity of the product are listed, along with other compounds contained in the plant.

## SUPPLEMENTAL INFORMATION AND GENERAL GUIDANCE PROTOCOLS

### **Black Cohosh** *Actaea racemosa* L.[*Cimicifuga racemosa* (L.) Nutt.] (Fam. Ranunculaceae)

#### BOTANICAL IDENTIFICATION

*Actaea racemosa* L. Herbaceous perennial from rhizome.
**Stem:** Erect, solitary, to 2.5 m tall, glabrous.
**Leaves:** Basal and cauline, alternate, 2–4-ternately compound, petioles 15 to 60 cm long, bases clasping stem; leaflets 20 to 70; terminal leaflet of central division 3-lobed, 6 to 15 cm long, 6 to 16.5 cm wide, with 3 prominent veins arising from base; subterminal leaflets with blades ovate-lanceolate to obovate, 4 to 12 cm long and 3 to 8 cm wide; margins toothed to deeply incised; green above, paler below; glabrous or rarely pubescent along veins of undersurface.
**Inflorescence:** Terminal panicle of 4 to 9 slender branches, each 7 to 60 cm long, pubescent; 1 bract subtending each pedicel.
**Flowers:** Perfect, radially symmetric; sepals 4, greenish-white, caducous; petals 0; staminodes (1–) 4 (–8), petaloid, cream-colored, 2 to 3 mm long, clawed, apex bifid; stamens 55 to 110; pistils 1 (–3), glabrous to pubescent, ovary superior, style short, stigma 0.5 mm wide.
**Fruit:** Many-seeded follicle, 5 to 10 mm long, ovoid, laterally compressed with curved, stout beak (peristent style), pubescent; seeds hemispheric, brown, scales lacking.
**Chromosome number:** n = 8.

There are currently two varieties of *A. racemosa* recognized on the basis of differences in leaf morphology: var. *racemosa* and var. *dissecta*. The former variety has triternate-pinnate leaves with serrate margins, while the latter has quadriternate-pinnate leaves that are deeply incised with serrate lobes. Variety *dissecta* is only known from very few herbarium specimens, all of which were collected well over 100 years ago, making this taxon of uncertain taxonomic significance.

#### COMPENDIAL HISTORY

Black cohosh appeared on the secondary list of substances in the first *United States Pharmacopoeia (USP)* of 1820, where it was listed as an anti-inflammatory and antispasmodic. It soon rose to the primary list in 1830, a position it held until the 10th decennial revision of 1920. Black cohosh appeared in the first edition of the *United States Dispensatory (USD)* in 1833 and remained through 1955 for a total of 122 years. Carrying forward the traditional Native American use of black cohosh for women's ailments and Barton's use for throat complaints, current therapeutics finds the plant used in a number of preparations for coughs and for gynecological disorders. In 2001, both the rhizome and the dry rhizome extract of black cohosh were proposed once again for inclusion in the *United States Pharmacopeia–National Formulary (USP–NF).* (See revised proposal on page 1455 of *PF* 28(5) [Sept.–Oct. 2002].) The monograph became official in the *Second Supplement* to *USP 30–NF 25*.

#### CONSTITUENTS

Major constituents of black cohosh are triterpene glycosides principally as beta-xylopyranosides and alpha-arabinopyranosides. The aglycones are mostly derived from acteol and cimigenol. The nomenclature of these compounds is quite confusing in the literature, with different names often given to the same compounds. A cyclopropane ring is a common feature of these compounds, which are structurally related to cycloartenol. The isoflavone formononetin has been reported in some publications; however, recent evidence indicates its absence in the roots and rhizomes of *Actaea racemosa.* Other constituents include tannins, resin, fatty acids, starch, sugars, and aromatic acids including ferulic acid, isoferulic acid, caffeic acid, and salicylic acid.

#### SOURCES AND DISTRIBUTION

**Sources**—Black cohosh can be found in moist deciduous forests, ravines, moist meadows, creek margins, and mountainous terrain. Black cohosh flowers from June to September and is native to eastern North America from Ontario south to Georgia and west to Missouri. The entire supply of black cohosh comes from the United States. The major producers of black cohosh are Kentucky and Tennessee, with additional supplies coming from Georgia, Michigan, North Carolina, Ohio, South Carolina, Virginia, West Virginia, and Wisconsin. Although there are reports of black cohosh being grown in China and India for export, the true identity of the cultivated material has not been verified and may well be an Asian species of *Actaea* such as *A. cimicifuga* (syn. *Cimicifuga foetida*). The vast majority of the commercial black cohosh is wild harvested. Concern over the conservation of black cohosh due to increasing demand makes this species a good candidate for cultivation.

**Distribution**—North America (Ontario; Georgia, Kentucky, Michigan, Missouri, North Carolina, Ohio, South Carolina, Tennessee, Virginia, West Virginia, and Wisconsin); China; and India.

## COLLECTION AND CULTIVATION

**Collection (Conservation and Ecology)**—Traditionally, black cohosh has been harvested after plants become reproductive, which occurs anywhere from 2 to 8 years of age in cultivated plants, depending on growing techniques (see *Cultivation Practices*). A portion of the rhizome with a visible bud on it should be left in the ground to resprout the following year. There is no published information on the relationship between the constituent profile of the rhizome and its age, growing conditions, or place of origin, although such studies are underway. The impact of harvest on wild populations of black cohosh is currently unknown, and sources differ in their opinion about it. Whereas some maintain that current levels of harvest threaten the viability of wild populations, others feel that sustainable harvesting is possible at current levels of demand. A study of sustainable harvest limits is currently underway. The regulatory status regarding the trade of black cohosh is under review by CITES. Refraining from harvesting plants until after they have set seed and leaving a portion of the rhizome in the ground to resprout are key components to sustainable harvesting.
**Cultivation Practices**—Black cohosh is grown from rhizome cuttings or seeds and requires some shading, depending on altitude and other environmental conditions. If grown from rhizome cuttings, a plant takes 2 to 3 years to become reproductive; grown from seed sown in the greenhouse and then planted, takes 4 to 6 years; direct-seeded may take from 6 to 8 years. Preliminary work indicates that black cohosh can be propagated successfully using in vitro techniques.
**Optimal Times for Harvest**—Rhizomes and roots should be harvested in autumn when the plant is dormant. At that time the underground portions of the plant have lower moisture content than in other seasons. Fall harvesting also allows plants to produce mature seeds before being uprooted.

## POST-HARVEST HANDLING

**Optimal Handling and Processing Practices**—Rhizomes with roots may be processed fresh or dried. They should be thoroughly washed directly after harvest and then laid out to dry. Freshly harvested roots should be solid but not woody.
**Drying**—Rhizomes with roots are cut and air-dried at 35° to 45°. They are fully dried when they are brittle and snap easily and when no moisture is evident in cross section, either visibly or to the touch.
**Storage**—Follow general guidelines for storage by packing in airtight containers protected from light, heat, moisture, and insect infestation.

## ADULTERANTS AND CONTAMINANTS

Other species of *Actaea,* especially yellow cohosh (*A. podocarpa* syn. *Cimicifuga americana*), have commonly been mixed with *A. racemosa* because of similarity in aboveground appearance and common growing habitat between species. The two species can be distinguished by differences in their freshly harvested underground parts: the fresh rhizome of *A. podocarpa* has a distinct yellowish hue, whereas that of *A. racemosa* is black. The rhizomes of both species are far more difficult to tell apart when dry because *A. podocarpa* darkens upon drying. The underground portions of baneberry *(Actaea pachypoda* and *A. rubra)* occur as occasional adulterants of black cohosh supplies. Fruiting plants of baneberry may be distinguished from black cohosh by their fleshy white or red poisonous berries, which contrast with the dry follicles of black cohosh. No information was available on how to distinguish the underground portions of black cohosh and baneberry from each other. According to one herb dealer, the roots of baneberry are smaller than those of black cohosh, and therefore are not often harvested by wildcrafters. In the Pacific Northwest, *Actaea elata* (syn. *Cimicifuga elata*) is collected for medicinal use.

# **Ginger** *Zingiber officinale* Roscoe (Fam. Zingiberaceae)

## BOTANICAL IDENTIFICATION

*Zingiber officinale* Roscoe. Herbaceous perennial from tuberous rhizome, aromatic because of the presence of volatile oils.
**Stem:** Erect, unbranched pseudostem formed by the tight overlap of sheathing leaf bases; 0.9 to 1.5 m tall.
**Leaf:** Simple, alternate and two-ranked, sessile or petioles short with bases sheathing the stem and a ligule where the leaf base meets the stem; blade linear to narrowly lanceolate, 15 to 25 cm long, 1.5 to 3 cm wide; margin entire; glabrous to pubescent.
**Inflorescence:** Terminal spike, 3.5 to 8 cm long, 1.5 to 2 cm wide, with conspicuous spirally arranged primary bracts; usually borne on specialized leafless stems.
**Flower:** Perfect, bilaterally symmetric; calyx tubular with 3 lobes; corolla tube 2 to 2.5 cm long with lanceolate apical lobes, 1.5 to 2 cm long, 2 to 3.5 mm wide, greenish yellow; stamen 1, anther cream-colored with dark purple, elongated connective grasping upper part of style; staminodes 4, petaloid, 2 fused into an erect, ovate-oblong lip that is dull purple with cream mottling; ovary inferior; style 1, slender, exerted beyond connective.
**Fruit:** Loculicidal capsule; seeds shiny black with a white aril.
**Chromosome number:** n = 11.
There are several different varieties and forms of ginger. The varying morphological characteristics of these are displayed in *Table 1*.

**Table 1. Morphological and Key Characteristics of Ginger from Different Areas of Production**

| Source | Form | Aroma | Color (External) |
|---|---|---|---|
| **Africa** | Flat surfaces, mostly peeled, starchy and fibrous; 9 cm long, 1.5 cm wide | Poor quality is recognized by its camphoraceous aroma | Uncut surface dark grayish-brown; cut surface brownish-black |
| **Australia** | | Citrus-like | Buff |
| **Bengal** | Flat surfaces, scraped | | Gray-brown |
| **China** | Short stumpy lobes, unscraped, mostly sliced | Strong, floral to citrus | Pale brown |
| **Cochin** | Lateral surfaces lacking cork | Strong, floral to citrus | Cream color with numerous black resin dots |
| **Jamaica (unbleached)** | Up to 12 cm long, 1 cm wide; surfaces completely peeled; starchy and fibrous thin cortex | Delicate, citrus-like | All surfaces yellow-brown |
| **Japan** | Up to 7 cm long, 12 mm wide; flat surfaces usually completely peeled; starchy and fibrous thick cortex | Bergamot-like | Externally gray-white to light grayish-brown, often with white powder from being coated with lime |
| **Malabar (Cochin and Calcutta)** | Cork layer completely removed, mostly treated with chalk | Citrus-like | Almost white |
| **Nigeria** | Smaller in size than other varieties, rather less deeply scraped | Delicate | Somewhat darker than other varieties |

## COMPENDIAL HISTORY

Ginger was official in the *United States Pharmacopoeia* from the first edition of 1820 through the fourteenth revision of 1950, often appearing in multiple preparations. It also appeared in all editions of the *United States Dispensatory* from 1833 through the final edition of 1973, where it was described as "a stimulant and carminative that has been used for treatment of dispepsia and flatulent colic".

## CONSTITUENTS

The essential oils and the pungent principles make up some of the major components of the rhizome of ginger: 4.0% to 10.0% of the rhizome consists of an oleoresin composed of nonvolatile, pungent principles (phenols such as gingerols and their related dehydration products, shogaols); nonpungent fats and their waxes. The essential oil (1% to 3%) contains sesquiterpenes and monoterpenes, mainly geranial and nerals. Generally, but not always, sesquiterpenes predominate (30% to 70%), such as zingiberene, sesquiphellandrene, and beta-bisabolene, which decompose on drying and storage. The nonvolatile pungent principles include the phenylalkanones, the gingerols, and the phenylalkanonols, shogaols with varying chain lengths.

## SOURCES AND DISTRIBUTION

**Sources**—Ginger is cultivated in most tropical and subtropical countries to greater or lesser degrees. The world production is estimated to be 100,000 tons. China and India are reported to be the primary areas of production. Approximately 5000 tons of ginger are imported into the United States. An estimated 80% of this comes from China. In China, Sichuan and Guizhou provinces reportedly produce the largest quantities and highest quality. It is also produced in Guangdong, Hubei, Shandong, Shanxi, and Zhejian provinces. Most of the dried ginger from China available in the United States has had the cortex scraped or rubbed off before it is dried. This gives it a whitish appearance. The freshly dug root is soaked overnight in water, scraped with a knife to remove the outer cortex, and then sun-dried. It has been reported that high arsenic levels in the soil of Changning County of Hunan Province, China, has negatively affected ginger yields.

In India, ginger is grown on a large scale in the warm, moist regions of Madras and Cochin, and to a lesser extent in Bengal and the Punjab. Varieties grown in Bengal are reportedly the highest quality material in India. Other areas of production include Africa (Nigeria and Sierra Leone), Australia, the East Indies, Fiji, Hawaii, and Jamaica. The morphological characteristics of ginger cultivated in these different areas are outlined in *Table 1*.

In older literature, Jamaican ginger is reported to be the highest quality and the most aromatic, though supplies are limited.
**Distribution**—Most tropical and subtropical countries, such as Australia, China (Guangdong, Guizhou, Hubei, Shandong, Shanxi, Sichuan, and Zhejian provinces), India (Bengal, Cochin, Malabar), the East Indies, Fiji, Jamaica, Japan, Nigeria, and Sierra Leone. Hawaii in the United States.

## COLLECTION AND CULTIVATION

**Collection (Conservation and Ecology)**—When the stems wither and are white, the rhizomes are ready for collection. Usually ginger is harvested after 6 months of growth at the earliest, and sometimes not until as late as 20 months; or to obtain larger roots, it is harvested in January or February of the second year of growth. In tropical and subtropical areas, roots are harvested

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M1132_02_01
@2024 USPC

as early as 4 months of growth, because they tend to become fibrous and tough as they get older. As ginger matures, it becomes more fibrous and stronger in flavor. Ginger harvest can be described in three stages:

1. Ginger that has been harvested early is known as green ginger and is traded as fresh ginger. It is succulent and tender, mellow, and mildly aromatic with a floral or lemony aroma and mild flavor.
2. Ginger harvested a few months later is more fibrous and drier and is collected for drying and may be sold as a full-flavored, pungent dried whole ginger.
3. The last harvest is usually around 9 months and yields the strongest ginger, which is quite dry and also richest in pungent components. This ginger is dried and then ground into powder.

**Cultivation Practices**—Ginger is a perennial herb that grows well at subtropical temperatures where the rainfall is at least 1.98 meters per year. The plant is sterile and is grown by vegetative means. Selected pieces of rhizome ("seed pieces" or "setts"), each bearing a bud, are planted in holes or trenches. Ideally the soil should be well-drained, rich clay loam. The growing conditions resemble those of potato cultivation. Mulching or manuring is necessary because the plant rapidly exhausts the soil of nutrients.

Ginger is susceptible to waterlogging and root rot. Preventive methods include using only the cleanest ginger for planting and washing it with fungicide before planting. A study growing ginger hydroponically yielded up to 125 tons per hectare in 6 to 7 months compared to 35 tons per hectare when grown in soil.

**Optimal Times for Harvest:** typically in December or January.

### POST-HARVEST HANDLING

**Optimal Handling and Processing Practices**—After harvesting, the rhizome is cleaned and stripped of its stems and roots. Each area processes its ginger differently after harvest. This results in the different quality and commercial grades available on the market. Green ginger consists of the rhizomes sent to market without drying. Unscraped or partially scraped varieties are traded as coated or black ginger. These roots have been scalded with boiling water and dried quickly. When dry, black ginger breaks with a horny, blackish, somewhat diaphanous fracture, due to the pasty condition of the starch. White ginger is bleached, usually by rubbing with chalk or lime, to lighten its color and to prevent insect infestation. Preserved ginger consists of soft, yellowish-brown pieces obtained by steeping the fresh ginger in hot syrup and carefully bottling. It is soft, brown-yellow and translucent. When baked, ginger loses its pungency and acquires a bitter taste.

**Drying**—In general, after harvest, the fresh roots are washed, and the whole dark outer skin, consisting of cork and a little underlying parenchyma, is scraped away. Scraping speeds up the drying time of the crude drug. However, excessive scraping can result in lower concentrations of essential oil that is lost with the discarded epidermal tissue. After scraping, the rhizomes are then laid out on clean floors and dried in the sun for 7 to 10 days. During this time they are occasionally turned and are piled up every night. If the fresh rhizomes are too fleshy or moist, drying will take longer and the product will end up looking shriveled. To obtain a whiter product, the ginger is moistened after 5 or 6 days and dried for another 2 days, at which time it is ready for export. Dried ginger is more pungent and stronger in taste than fresh ginger.

**Storage**—Store in a tightly closed container, protected from light and moisture, in a cool area. A study was done on ginger harvested after 8, 9.5, 11, or 12 months. Samples were stored at 10° to 15° and 45% to 55% relative humidity or 25° to 30° and 75% relative humidity for 0, 4, or 8 weeks. Oil and oleoresin yields increased with the age of the ginger. Room temperature storage had adverse effects, but refrigerated storage for up to 4 weeks had no effect on quality. When stored for extended periods of time, ground ginger loses its pungency.

### ADULTERANTS

Because ginger is so characteristic, unintentional adulterants are rare. However, in East Asia sometimes the much larger *Zedoary cassumer* and *Zedoary zerumbet*, along with *Alpinia allughas*, are used and found in European commerce. They are easy to distinguish because of their characteristic aromas. Occasionally, Chinese sugar-candied "ginger" is prepared from *Alpinia galangal*.

In older literature, other herbs have reportedly been used as adulterants. These include various species of *Curcuma, Capsicum,* and Grains of Paradise *(Amomum melegueta)* added to exhausted material in order to enhance color and pungency.

Ginger powder is sometimes adulterated with plant starches such as those from wheat middlings, potatoes, corn, barley, rice, legumes, acorns, flaxseed meal, mannihot, oil cakes from linseed, rapeseed, mustard, almond meal, palm kernel or olives, hazelnut shells, and mineral additives. These may be easily identified microscopically. The extent of this type of adulteration in trade is unknown.

Exhausted material should be considered an adulterant.

## **Valerian** *Valeriana officinalis* L. (Fam. Valerianaceae)

### BOTANICAL IDENTIFICATION

*Valeriana officinalis* L. Herbacious perennial, rhizomatous.

**Stem:** Solitary, hollow, 15 to 150 cm.

**Leaf:** Basal and cauline, opposite, oddly once pinnately lobed, lobes 11 to 21 lanceolate, entire or dentate, basal leaves petiolate, cauline leaves subsessile to clasping.

**Inflorescence:** Compound cyme, terminal or axillary, many pale pink to white, strongly scented flowers.

**Flower:** Calyx 5-lobed, lobes inconspicuous in flower, becoming elongate and pappus-like in fruit, corolla funnel-form, slightly saccate at the base, 5-lobed, tube 4 mm, lobes 1 mm, stamens 3, filaments attached to corolla tube alternate to corolla lobes, ovary inferior, triloculate, uniovulate, only 1 locule fertile, stigma tripartite.

@2024 USPC

**Fruit:** Achene crowned by persistent calyx, lanceolate-oblong, 4.5 to 5 mm, hairy or glabrous. Populations of *V. officinalis* range in ploidy level from diploid to tetraploid or octaploid. British *V. officinalis* is usually octaploid, and central European supplies are tetraploid.

There are three subspecies of *V. officinalis*: ssp. *officinalis,* ssp. *collina* (Wallr.) Nyman, and ssp. *sambucifolia* (Mikan fil.) Celak. All three of these subspecies, as well as the other European species of valerian, *V. repens* Host, have been considered acceptable source material for medicinal preparations.

**Macroscopic Identification**—Various chemotypes will have slightly different characteristics. When dried, the whole rhizome is up to 50 mm long and up to 30 mm in diameter, obconical to cylindrical, with an elongated or compressed base. It has a yellowish-brown to dark brown exterior with a circular stem and leaf scars. The rhizome contains numerous thick, light to dark brown rootlets that are located around a thin ligneous cord. The root is longitudinally wrinkled, approximately 100 mm long and 1 to 3 mm in diameter, almost cylindrical, and almost the same color as the rhizome. In longitudinal section, the pith exhibits a central cavity transversed by septa. The stolons are 20 to 50 mm long, pale yellowish grey with prominent nodes separated by longitudinally striated internodes. It is commonly sliced in half for ease of cleaning. The rootlets, which contain the majority of the essential oil, are brittle and break in short, horny fractures and are whitish or yellowish internally. Aroma: when dried properly, *V. officinalis* L., s.l. has only a very faint characteristic, valeric acid–like aroma that becomes stronger as it ages. Improperly dried or old material possesses a strong and characteristic odor due to the enzymatic hydrolysis of esters of the valepotriates (isovaleric acid and hydroxyvaleric acid). Taste: mildly sweet and camphoraceous with a slightly bitter and spicy aftertaste.

## COMPENDIAL HISTORY

Valerian was official in the *United States Pharmacopoeia* from the first edition of 1820 through the eleventh revison of 1930, often appearing in multiple preparations. At its peak from 1850 through 1880 it appeared six to seven times in different preparations. Valerian is among the top 30 most listed botanicals in the history of the *USP*. The root of valerian has been used as a sedative and spasmolytic in Europe since the 16th century.

## CONSTITUENTS

Major constituents of valerian have been identified as sesquiterpenes of volatile oils and iridoids (epoxy-triesters) known as valepotriates. The total content of volatile oil varies widely within a single species and between different species. European *Valeriana officinalis* L. usually contains 0.1% to 2.8% volatile oil. The oil consists of mixtures of monoterpene and sesquiterpene derivatives. The amount of valepotriates present also varies widely between species and genera and even within a species, generally ranging from 0.5% to 1.2%. Valepotriates are particularly unstable; they decompose easily under the effect of moisture, temperatures above 40°, or acidity (pH <3).

Valerian also contains small amounts of aliphatic acids, alkaloids, amino acids, phenolic acids, flavonoids, free fatty acids, sugars, and salts. Valerian constituents that have possible sedative effects include acetoxyvalerenic acid, 1-acevaltrate, baldrinal, didrovaltrate, hydroxyvalerenic acid, kessane derivatives, valeranone, valerenal, valerenic acid, and valtrate.

## SOURCES AND DISTRIBUTION

**Sources**—Valerian is found in damp or dry meadows, scrub, or woods in most of Europe, although rare in the south, and it is cultivated and naturalized in North America. Valerian is cultivated in Belgium, Britain, Eastern Europe, France, Germany, Japan, the Netherlands, North America, and Russia. The majority of standardized extract products and crude cut and sifted material on the domestic market are prepared from European supplies. A large number of liquid extracts are prepared from domestically cultivated material. Many species other than *V. officinalis* are reported to be traded as medicinal valerian. These include *V. edulis* Nutt. ex Torr. & A. Gray, *V. corneana* Briq. k, *V. stubendorfi* Kreyer ex Kom., *V. amurensis* P. Smirn. ex Kom., *V. hardwickii* Wall., *V. exaltata* Mikan, and *V. wallichi* DC. syn. *V. jatamansi* Jones.* The most frequently used North American species include *V. sitchensis* Bong and *V. edulis* Nutt.* = *V. edulis* Nutt. ex Torr. & Gray ssp. *procera.* Other species reported to be used locally include *V. arizonica* Gray, *V. capitata* Pall ex Link., *V. diocia* L., and *V. scouleri* Rydb. Detailed chemical analyses of most American species are lacking. A limited number of assays of material cultivated in the Pacific Northwest show varying levels of essential oil ranging from 0.4% to 1.3%. Valerenic acid and valepotriates have been found to be present in fresh and dry samples of *V. sitchensis* Bong. *V. sitchensis* Bong exhibits a strong pungency when fresh. High quality material is reported to contain from 1.0% to 1.5% essential oil, ≥30% extractable matter, and ≥0.5% valerenic acid.

**Distribution**—Europe (Belgium, Britain, Eastern Europe, France, Germany, the Netherlands), Japan, North America, and Russia.

## COLLECTION AND CULTIVATION

**Collection (Conservation and Ecology)**—The majority of valerian in trade comes from cultivated material. Harvest times will vary geographically. The composition of the essential oil varies greatly among different populations of the same subspecies and even between the same population of plants from year to year. Essential oil content also varies with genotypes, harvest times, growing conditions, age of root, drying techniques, and method of analysis. It has been reported that valerian harvested in higher elevations, grown in dryer regions, or cultivated in phosphate-rich soil yields relatively high levels of essential oil.

Older literature reports that valerian should be harvested in the fall, between August and September, preferably in the second year of growth. Analyses of material cultivated in the Netherlands report that the majority of constituents, including the essential oil and valerenic acid, were highest in roots harvested in the first year of growth, with essential oil being highest in September and November (1.2% to 2.1%). The next highest level of essential oil was reported for material harvested in March (0.9% to 1.6%). Valerenic acid and its derivatives were found to be highest in February and March (0.7% to 0.9%), followed by material

* *V. wallichi* DC. and *V. edulis* Nutt. reportedly are lacking in valerenic acid and its derivatives.

@2024 USPC

harvested in September (0.5% to 0.7%) and then in January (0.3% to 0.4%). From a commercial standpoint, it is more cost effective to harvest the roots in the same year the plants are sown than in the second year.
**Cultivation Practices**—Sowing seeds has been reported to be preferred over planting of seedlings. Best results were achieved by flat field planting at row spacings of 50 cm and a seed rate of 3 kg per hectare. Cutting off the flowering tops before the plant has set seed causes the rhizome to develop more fully.
**Optimal Times for Harvest**—Wagner reports that harvest should take place in the morning during relatively cool weather, a general recommendation for roots rich in essential oils.

### POST-HARVEST HANDLING

**Optimal Handling and Processing Practices**—The essential oil is located in the hypodermis of the rhizome in large thin-walled cells. Therefore, care must be taken not to damage these cells during handling. Excess washing of the roots can result in a significant reduction of extractive matter. Because of the sensitivity of volatile oils to heat, it is necessary to minimize the amount of time generated in the grinding or powdering process by doing small lots at a time, with frequent interruptions in run times, or by using a cryogenic grinder.
**Drying**—For maximum preservation of the essential oils, valerian should be dried at 40° with a flow rate of 0.05 kg per sec per $m^2$. Alternatively, drying at 20° for approximately 10 days, shade drying at approximately 45°, low temperature vacuum-drying, and freeze-drying are also reported to be appropriate drying techniques.

Careless or prolonged drying produces a darker color in the roots and results in the hydrolysis of the isovalerianic esters and the liberation of isovaleric and hydroxyisovaleric acid. This produces the characteristic valerianic aroma. Properly dried valerian will produce this same aroma over time.
**Storage**—Store in closed containers protected from light, air, and moisture. Hydroxyvalerenic acid, a decomposition product of acetoxyvalerenic acid, is formed when the herb is stored at too high humidity.

Improper storage conditions can cause significant deterioration of the material. Although the essential oil is relatively stable, it can evaporate with excessive exposure to air. The essential oil can degrade quickly in powdered material. In powdered root, the essential oil content can decrease by 50% within 6 months.

Valepotriates are sensitive to humidity, temperatures above 40°, and acid media (pH <3) and are generally not detected in commercial products after 60 days.

### ADULTERANTS

Other species of valerian: An unidentified *Apiaceae* species may be found in valerian trade. Adulteration of valerian in the American market is not common. Many species other than *V. officinalis* are reported to be traded as medicinal valerian. These include *V. edulis* Nutt. ex Torr. & A. Gray, *V. coreana* Briq. k, *V. stubendorfi* Kreyer ex Kom., *V. amurensis* P. Smirn. ex Kom., *V. hardwickii* Wall, *V. exaltata* Mikan, and *V. wallichi* DC. syn. *V. jatamansi* Jones.

## **Elm** *Ulmus rubra* Muhlenberg [*Ulmus fulva* Michaux] (Fam. Ulmaceae)

### BOTANICAL IDENTIFICATION

*Ulmus rubra* Muhlenberg; tree to 35 m high, with spreading branches and open flat crown; preparations derived from inner bark. *U. rubra* appears to be more closely related to the introduced Asian species *U. pumila* L. than to other native American species of *Ulmus*; where the two co-occur, interbreeding is common.
**Trunk:** 18 to 35 m high, to 1 m in diameter; the trunk rises free of branches until about 5 to 6 m.
**Branches:** Erect, spreading; young twigs are scabrous-pubescent.
**Bark:** Dark brown to reddish-brown, deeply furrowed. Inner bark is whitish (outer surface yellow-orange; inner surface pale yellow), fragrant (upon powdering, a distinctive fenugreek-like odor) and very mucilaginous upon chewing or moistening.
**Leaves:** Alternate; simple; petiolate with petiole (3–)5–7(–9) mm long; 7–18(–23) cm long, 5–10(–15) cm broad; elliptical to ovate, oblong, or obovate with oblique base and acuminate apex; margins serrate toward base, elsewhere doubly serrate; upper surface scabrous, rough; lower surface tomentose; secondary veins parallel, slightly curved, running to tips of marginal teeth.
**Inflorescence:** Axillary fascicles, roughly hemispherical, to 1.5(–2.5) cm in diameter.
**Flowers:** Small, perfect; pedicels 1–2(–3) mm long; calyx campanulate, 5–9-lobed at apex, about 2.6–3.5 mm in diameter, reddish-pubescent; petals absent; stamens 5–9, exserted at flowering; styles 2. Flowers occur before the leaves from March through early May.
**Fruit:** Winged samara, yellowish, irregularly suborbicular or occasionally broadly elliptical or obovate, 10–20 mm in diameter, reddish-pubescent over seed; wing papery-textured.

### COMPENDIAL HISTORY

Slippery elm (Ulmus) inner bark appeared in the list of materia medica in the first *United States Pharmacopoeia (USP)* of 1820 and remained official until it was removed from *USP XI* (1936). The *USP 1820* included instructions for the preparation of *Infusion of Slippery Elm: "Take of Slippery elm, sliced, one ounce. Boiling water, one pint. Infuse for twelve hours in a covered vessel, near the fire with frequent agitation, and strain."* Immediately following its removal from *USP XI* (official: June 1, 1936), *Slippery Elm Bark* became an official monograph in the sixth edition of the *National Formulary* (*NF*; official: June 1, 1936) until its elimination from the 11th edition (official: October 1, 1961). It became official again, as *Elm,* on November 15, 1995, in the *USP* section of the *Third Supplement* to the *United States Pharmacopeia–National Formulary* (*USP 23–NF 18*). A revision was published in the *Seventh Supplement* on November 15, 1997.

In 1982, Elm Bark appeared in the Food and Drug Administration (FDA) Advance Notice of Proposed Rulemaking (ANPR) for the establishment of a therapeutic monograph for oral health care drug products for over-the-counter (OTC) human use.

In the ANPR (1982) as well as in the subsequent tentative final monograph of 1988 and in the amendment to the monograph of 1991, Elm bark was classified as a Category I (Generally Recognized as Safe and Effective (GRASE)) OTC oral demulcent active ingredient, and appropriate standards were urged to be developed in the official compendia.

Aside from *USP–NF*, the monograph of *Elm* had already appeared in the second edition of *The Dispensatory of the United States of America* (1834), and its last appearance was in the 25th edition, 1960.

## CONSTITUENTS

Constituents of relevance for conformance to *Identification A* under *Elm* are mucilaginous substances. Elm inner bark mucilage is readily extractable by water and consists principally of a polysaccharide which on hydrolysis yields D-galactose, D-methyl galactose, L-rhamnose, and glucose. Borohydride reduction of the periodate-oxidized polysaccharide affords, on partial hydrolysis with hot acid, three oligosaccharides:
*O*-(3-*O*-methyl-β-D-galactopyranosyl)-(1→4)-*O*-(3-*O*-methyl-β-D-galactopyranosyl)-(1→4)-L-rhamnose,
*O*-(3-*O*-methyl-β-D-galactopyranosyl)-(1→4)-L-rhamnose, and *O*-(3-*O*-methyl-β-D-galactopyranosyl)-(1→4)-3-*O*-methyl-D-galactose.

Other Elm constituents are traces of tannins, including proanthocyanidins, some starch, traces of oxalate salts, beta-sitosterol, and minerals.

## SOURCES AND DISTRIBUTION

**Sources**—Slippery elm bark is harvested from wild populations in eastern Canada and the United States, from southern Quebec west to North Dakota, south to south-central Texas, and Florida. It is common throughout eastern, southern, and midwestern U.S., and it grows in more than 25 states. An increasing amount of the commercial supply is being collected according to sustainable wild resource management plans as a condition of organic certification for wild crops. Conversely, Dutch elm disease has had a significant negative impact on elm populations, from 1930 when it was first found in the United States affecting over 50% of elm trees in the northern states.

**Distribution**—Canada (New Brunswick, Ontario, Quebec), the United States (Alabama, Arkansas, Connecticut, Delaware, the District of Columbia, Florida, Georgia, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maine, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, Missouri, New Hampshire, New Jersey, New York, North Carolina, North Dakota, Ohio, Oklahoma, Pennsylvania, Rhode Island, South Carolina, South Dakota, Tennessee, Texas, Virginia, Vermont, Wisconsin, and West Virginia).

## COLLECTION AND CULTIVATION

**Collection (Conservation and Ecology)**—"Natural" (both inner and outer bark) and "rossed" (inner bark only) are harvested, but only the rossed bark will conform to the standards of the *USP* monograph. Harvesting should occur on dry, preferably warm days with no chance of precipitation, and it usually commences in late morning after the morning dew and humidity pass. This is because post-harvest processing (rossing) generally takes place at the collection site outdoors and humidity can damage the quality of the inner bark. Because the inner bark contains polysaccharide mucilage, when it comes in contact with moisture, it begins to gel.

The bark, from trees of a minimum age of 10 years (some harvesters recommend selecting at least 12- to 15-year-old trees) is obtained mainly by pruning or trimming the lower limbs and branches, but can also be obtained from the bole (trunk) and, very rarely, even from the roots in cases where the entire tree is felled. While the inner bark of the root reportedly contains more mucilage than that of the trunk or branches, sustainable wild resource management dictates harvesting only the branches of mature trees. In practice, commercial bark collectors are more likely to select branches from trees that are at least 30 to 50 years old in order to obtain a high enough yield. After pruning, the tree will heal over where harvested and continue to grow, but the trunk and/or branches should never be girdled, because this will kill the tree. Girdling is the stripping away of bark from the trunk or a branch all the way around. In practice, the most sustainable method of harvest from mature healthy trees is to prune off entire lower branches in a way that will not harm the tree. If sawn properly so that rainwater will not drop directly into the exposed cut area, the tree will grow over the cut area within a couple of years. The proper cut, which is made just outside the branch collar and the branch bark ridge, does the least amount of damage to the trees.

Although elm bark should not be gathered from already dead trees, selective collection from dying trees—for example, those affected with Dutch elm disease—is feasible. The fungus that causes Dutch elm disease, *Ophiostoma ulmi* and *Ophiostoma novo-ulmi* (syn: *Graphium ulmi* or *Ceratocystis ulmi*), is carried from tree to tree by the European elm bark beetle (*Scolytus multistriatus*), which arrived in North America on a ship carrying logs from Europe around 1930, and to a much lesser extent by the native elm bark beetle (*Hylurgopinus rufipes*). Elms appear to succumb to the disease at about 10 years of age and then die off in a two-year period. Once a tree is diagnosed with Dutch elm disease, healthy bark can still be harvested for about two years, up until the tree is near death. To monitor how long harvesting can continue, one can use a drawknife to take samples. Once the inner bark is showing increasingly noticeable black streaking, and as more and more limbs die and debarking is evident, the tree is near death. The near-dead tree can be dropped, and the remaining healthy bark can be stripped from the entire tree. Discolored (black-streaked) inner bark should be separated out and discarded. Pruning lower limbs from healthy trees and/or selectively harvesting entire older trees that are near death can both be acceptable methods as part of a sustainable resource management plan for a specific area of forest under organic supervision.

Following organic production system rules (e.g., for harvest site selection, absence of prohibited substances, testing of soil and water, disallowed inputs, periodic residue testing, documentation control, independent inspection) will more likely result in botanical raw material that meets the general requirements for pesticide residue and heavy metals limits, among other potential contaminants. Certified organic production of wild elm bark requires producers to promote ecological balance and conserve biodiversity. Wild collected elm bark that is to be certified organic must be harvested from a designated area that has had no prohibited substance applied to it for a period of 3 years immediately preceding the harvest, and must be harvested

@2024 USPC

in a manner that ensures that such harvesting or gathering will not be destructive to the environment and will sustain the growth and production of the wild crop. Wild crop producers must comply with the same organic system plan requirements and conditions, as applicable to their operation, as their counterparts who produce cultivated crops. The producer of organic wild harvested elm bark must initiate practices to support biodiversity and avoid, to the extent practicable, any activities that would diminish it. Production practices must maintain or improve the natural resources of the operation, including soil, water, wetlands, woodlands, and wildlife. This is accomplished, in part, by developing and executing a resource management plan that requires wild harvest from stable populations, minimizing disruption of priority species/sensitive habitats, avoiding erosion, allowing reestablishment, and monitoring wild crop sustainability.

**Cultivation Practices**—Even though the commercial supply is harvested from wild populations, slippery elm trees can be propagated by cuttings or by seed. For propagation by seed, the ripe seeds are collected from April to June from healthy and successful (dominant) trees from an area similar to the proposed planting site. A ripeness indicator is when the samaras (fruits) are green. It is best to collect seed from trees within 160 km north or south of the planting site, as potential for success is optimal within this range from the parents. Twenty-five seeds per square foot can be scattered, 0.6 cm deep. Slippery elm may be sown as in its normal cycle in the spring in a raised peat moss soil and sand bed. The seedbeds may need a wire top to protect young seedlings. Germination rate is 10% to 25%, with light germination in summer and increased germination the following spring. The young trees can be transplanted into tree tubes within the first month of germination and field planted after one or two years, depending on the size of the tree tube. The tree saplings must be watered during times of drought and routinely checked for insect predation and indications of fertilization needs.

**Optimal Times for Harvest**—Harvest should preferably occur in the spring (March to May), but can also take place in the autumn. In the spring, bark is harvested from mature trees (minimum 10 years) when the sap begins to rise.

## POST-HARVEST HANDLING

**Optimal Handling and Processing Practices**—To produce pharmacopeial quality elm inner bark, the outer corky layer of bark must be removed, exposing the inner bark. If post-harvest processing occurs at the wild collection site, the pruned limbs and branches should be placed onto clean tarps and not directly on the ground. The very small branches with leaves are stripped off the pruned limbs by hand and discarded. To optimize conformance to standards for composition, identity, purity, and quality (e.g., NMT 2% of adhering outer bark, NMT 2% foreign organic matter, NMT 10% total ash, and NMT 0.65% acid-insoluble ash), a clean bark rosser (hand tool with handle and knife blade) should be used to shave off the outer bark. The rough, scaly matter on the surface of the bark is called *ross*, and to ross bark is to scrape or shave the outer bark from the limb. An experienced rosser can visually discern that at least 98% of the outer bark has been shaved off. The inner bark is white in color (in the spring; reddish later in the season) in obvious visible contrast to the brown outer bark layer. After most of the outer bark is rossed off, greater care must be exercised to very carefully slice off the remaining thin layer of outer bark so as not to waste any of the inner bark in the process. After removal of the outer bark, the inner bark can then be removed in strips, squares, or chips. An incision is made with a clean knife down the center of the limb. Then a clean crowbar is slipped underneath the incision in order to lift and peel the inner bark off from the cambium. The strips of inner bark are stacked on a clean tarp and later bundled for transport to the drying facility.

**Drying**—*Elm USP* requires a loss on drying limit of NMT 12%. So long as rain is not expected, fresh elm inner bark can be sun-cured within a temperature range of 32° to 60°. Drying can also be carried out in a warm room with airflow or in a greenhouse. Greenhouse drying takes about 3 to 4 days. Drying indoors can take 5 to 7 days, depending on the heat source. Drying at commercial scale, however, is done typically in enclosed drying chambers, in which time and temperature can be better controlled. The strips of elm bark are placed onto a clean screen floor and dried over about 2 days' time at about 50° with fan-forced heat through the floor. Because of additional phytosanitary requirements for export of tree barks to Europe, higher heat exposure is necessary, usually at least 65° but up to 93° for up to two days. Post-drying, the strips of inner bark can be cut or sawn into pieces of equal length and bound into bundles with wire. The bundles usually consist of flat, oblong pieces, about 30 cm in length and from 10 to 15 cm in width. The bark strips can be stored this way until further processing (e.g., cutting or powdering) is scheduled.

**Storage**—To maintain pharmacopeial purity and quality (e.g., to prevent accumulation of excess moisture), dried elm inner bark should be preserved in well-closed containers, and stored in a cool, dry place.

## ADULTERANTS AND CONTAMINANTS

Common contaminants that could cause a material not to conform with the identification tests in the *Elm* monograph in *USP* would include other plant parts: for example, greater than 2% outer bark, which lacks mucilage. Insufficient shaving or rossing of outer bark could cause the material to exceed the monograph limit of NMT 2% of adhering outer bark. Other possible contaminants would include visible discolored inner bark, although no maximum limit has been established (for example, inner bark with visible black streaking obtained from a diseased tree). Powdered bark can also be adulterated with cornmeal, rice flour, starch, or other starchy substances. Consequences of contamination with outer bark or adulteration with flour or starch are lower mucilage content, lower swelling index value, and correspondingly less of a therapeutic demulcent effect that is mucilage-dependent. Excess outer bark could also cause the material to fail the quantitative standard of NMT 10% total ash. Methods to determine the presence of adulterants include microscopic examination in order to determine the presence of excess outer bark or any other adulterant and the concentration of mucilage cells. The *Elm* mucilage test (*Identification A*) as well as a modified swelling volume test (based on the test in the *USP* monograph *Psyllium Husk*) may also be useful to investigate if adulteration is suspected.

# ⟨2040⟩ DISINTEGRATION AND DISSOLUTION OF DIETARY SUPPLEMENTS

## INTRODUCTION

This general chapter is provided to determine compliance with the disintegration and dissolution standards for dietary supplements where stated in the individual monographs.

For the purposes of this chapter, dietary supplement dosage forms have been divided into three categories: *Vitamin–Mineral Dosage Forms*, *Botanical Dosage Forms*, and *Dietary Supplements Other Than Vitamin–Mineral and Botanical Dosage Forms*. *Vitamin–Mineral Dosage Forms* include articles prepared with vitamins, minerals, or combinations of these dietary ingredients, as described in *Table 1*. *Botanical Dosage Forms* comprise formulations containing ingredients of botanical origin, including plant materials and extracts. *Dietary Supplements Other Than Vitamin–Mineral and Botanical Dosage Forms* encompass dietary supplements formulated with lawfully recognized dietary ingredients that are different from those pertaining to the two foregoing categories (e.g., amino acids, chondroitin, and glucosamine).

Where a dietary supplement represents a combination of the categories mentioned above, and there is a difference between the requirements for the individual categories, the more stringent requirement applies. [NOTE—"More stringent requirement" means stricter acceptance criteria and/or milder operational conditions.]

Disintegration and dissolution tests as described in this chapter are quality-control tools to assess performance characteristics of dietary supplement finished dosage forms. These performance standards are intended to detect problems that may arise due to use or misuse, or changes in coatings, lubricants, disintegrants, and other components. These performance tests are also intended to detect manufacturing process issues, such as overcompression and overdrying, that would affect the release characteristics of the final dosage forms. These tests are not intended to be used as a demonstration or as a surrogate for in vivo absorption, bioavailability, or effectiveness, unless an in vitro–in vivo correlation (IVIVC) has been established.

### DISINTEGRATION

This test is provided to determine whether dietary supplement capsules or tablets disintegrate within the prescribed time when placed in a liquid medium at the experimental conditions presented below. Compliance with the limits on *Disintegration* stated in the individual monographs for dietary supplements is required, except where the label states that the products are intended for use as troches, are to be chewed, or are designed as extended-release dosage forms. Dietary supplements claiming to be extended-release dosage forms must comply with standards other than disintegration to verify that the release of the dietary ingredients from the dosage form is for a defined period of time. Dietary supplements claiming to be extended-release dosage forms must not be labeled as in compliance with USP unless a *USP* monograph exists for such product. Determine the type of dosage form under test from the labeling and from observation, and apply the appropriate procedure to 6 or more units.

For purposes of this test, disintegration does not imply complete solution of the unit or even of its active constituent. Complete disintegration is defined as that state in which any residue of the unit, except fragments of insoluble coating or capsule shell, remaining on the screen of the test apparatus or adhering to the lower surface of the disk (if used) is a soft mass having no palpably firm core.

- **APPARATUS**

**Apparatus A:** Use the *Apparatus* described in *Disintegration* ⟨701⟩*, Apparatus* for capsules or tablets that are NMT 18 mm long. For larger capsules or tablets, use *Apparatus B*.

**Apparatus B:** The apparatus consists of a basket-rack assembly, a 1000-mL low-form beaker for the immersion fluid, a thermostatic arrangement for heating the fluid between 35° and 39°, and a device for raising and lowering the basket in the immersion fluid at a constant frequency rate between 29 and 32 cycles/min through a distance of 53–57 mm. The volume of the fluid in the vessel is such that at the highest point of the upward stroke, the wire mesh remains at least 15 mm below the surface of the fluid and descends to NLT 25 mm from the bottom of the vessel on the downward stroke. At no time should the top of the basket-rack assembly become submerged. The time required for the upward stroke is equal to the time required for the downward stroke, and the change in stroke direction is a smooth transition rather than an abrupt reversal of motion. The basket-rack assembly moves vertically along its axis. There is no appreciable horizontal motion or movement of the axis from the vertical.

**Basket-rack assembly:** The basket-rack assembly (see *Figure 1*) consists of three open-ended transparent tubes, each 77.5 ± 2.5 mm long and having an inside diameter of 32.0–34.6 mm and a wall 2.0–3.0 mm in thickness; the tubes are held in a vertical position by two plastic plates, each 97 ± 2 mm in diameter and 7.5–10.5 mm in thickness, with three holes, 36.0–40.6 mm in diameter, equidistant from the center of the plate and equally spaced from one another. Attached to the undersurface of the lower plate is 10-mesh No. 23 (0.025-inch) W- and M-gauge woven stainless-steel wire cloth having a plain square weave. The parts of the apparatus are assembled and rigidly held by means of three bolts passing through the two plastic plates. A suitable means is provided to suspend the basket-rack assembly from the raising and lowering device, using a point on its axis. The design of the basket-rack assembly may be varied somewhat, provided that the specifications for the glass tubes and the screen mesh size are maintained.

**Beaker:** Low form, 1000 mL; the difference between the diameter of the plastic plates, which hold the tubes in a vertical position, and the inside diameter of the beaker should be NMT 6 mm.[1]

**Disks:** Each tube is provided with a perforated cylindrical disk 15.3 ± 0.15 mm in thickness and 31.4 ± 0.13 mm in diameter. The disk is made of a suitable, transparent plastic material having a specific gravity of between 1.18 and 1.20. Seven holes 3.15 ± 0.1 mm in diameter extend between the ends of the cylinder, one of the holes being in

[1] 1000-mL low-form beakers, designed in compliance with the current ASTM E 960 Type I or Type II or ISO 3819 specifications, meet the size requirements.

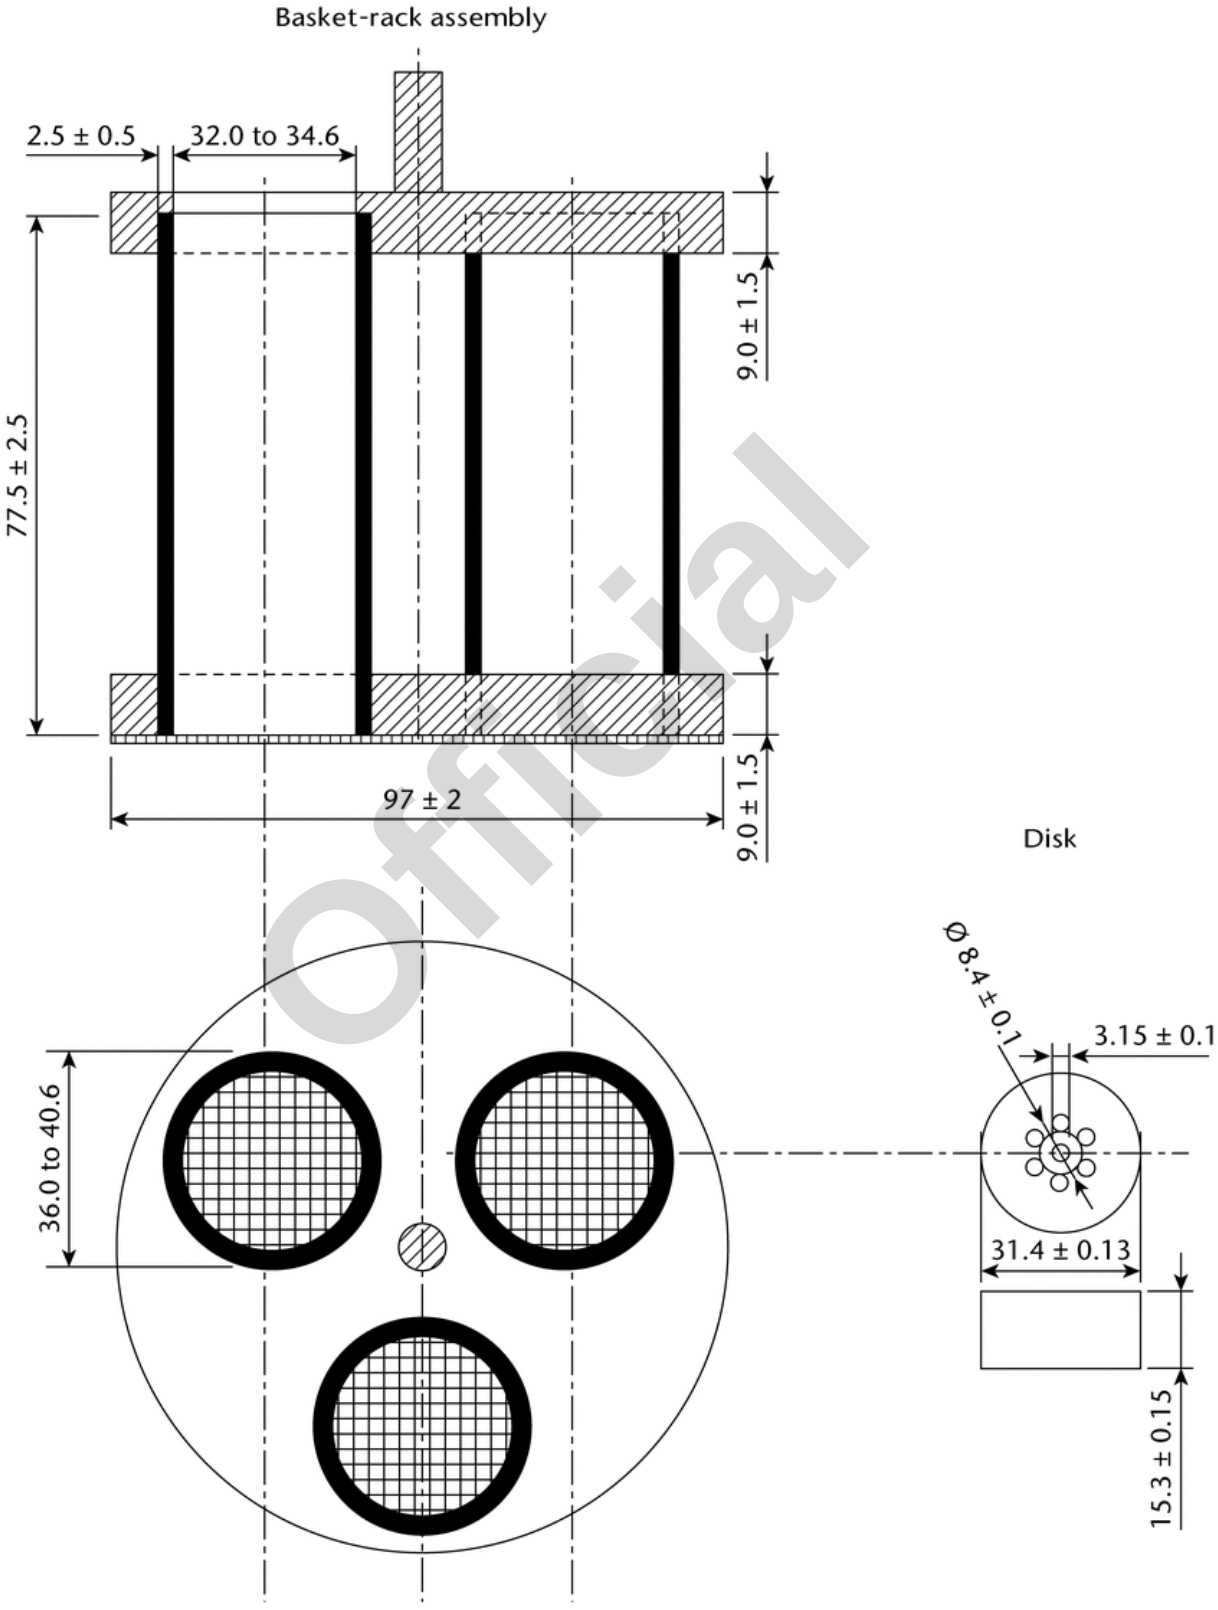

Figure 1. Basket-rack assembly, *Disintegration, Apparatus B* (dimensions in mm).

Official

https://pharmacopeia.cn/

- **PROCEDURE:** Test 6 dosage units as described below for each type of dosage form. [NOTE—Two basket arrangements for a total of six tubes are necessary for *Apparatus B*.] If 1 or 2 dosage units fail to disintegrate completely, repeat the test on 12 additional dosage units.

  **Uncoated tablets:** Place 1 tablet in each of the tubes of the basket and, if prescribed, add a disk to each tube. Operate the apparatus, using water or the specified medium as the immersion fluid, maintained at 37 ± 2°. At the end of 30 min, lift the basket from the fluid and observe the tablets.

  **Plain-coated tablets:** Place 1 tablet in each of the tubes of the basket and, if the tablet has a soluble external sugar coating, immerse the basket in water at room temperature for 5 min. Then, if prescribed, add a disk to each tube and operate the apparatus, using water or the specified medium as the immersion fluid, maintained at 37 ± 2°. At the end of 30 min, lift the basket from the fluid and observe the tablets.

  **Delayed-release (enteric-coated) tablets:** Omit the use of a disk. Place 1 tablet in each of the six tubes of the basket, and if the tablet has a soluble external sugar coating, immerse the basket in water at room temperature for 5 min. Then operate the apparatus using simulated gastric fluid TS, maintained at 37 ± 2°, as the immersion fluid. After 1 h of operation in simulated gastric fluid TS, lift the basket from the fluid and observe the tablets: the tablets show no evidence of disintegration, cracking, or softening. Operate the apparatus using simulated intestinal fluid TS, maintained at 37 ± 2°, as the immersion fluid for the time specified in the monograph. Lift the basket from the fluid and observe the tablets.

  **Delayed-release (enteric-coated) soft-shell capsules:** Place 1 softgel capsule in each of the six tubes of the basket. Omit the use of a disk. Operate the apparatus using simulated gastric fluid TS, maintained at 37 ± 2°, as the immersion fluid. After 1 h of operation in simulated gastric fluid TS, lift the basket from the fluid and observe the softgels: the softgels show no evidence of disintegration or rupture that would permit the escape of the contents. Operate the apparatus with disks using simulated intestinal fluid TS, maintained at 37 ± 2°, as the immersion fluid for NMT 60 min. Lift the basket from the fluid and observe the capsules.

  **Hard-shell capsules:** Apply the test for *Uncoated tablets* using, as the immersion fluid, maintained at 37 ± 2°, a 0.05 M acetate buffer prepared by mixing 2.99 g of sodium acetate trihydrate and 1.66 mL of glacial acetic acid with water to obtain a 1000-mL solution with a pH of 4.50 ± 0.05. Attach a removable wire cloth, as described in *Basket-rack assembly*, to the surface of the upper plate of the basket-rack assembly. At the end of 30 min, lift the basket from the fluid and observe the capsules.

  **Soft-shell capsules:** Proceed as directed in the *Rupture Test for Soft-Shell Capsules*.

- **USE OF DISKS**

  **Vitamin–mineral dosage forms:** Add a disk to each tube unless otherwise specified in the *Procedure* above or in the individual monograph.

  **Botanical dosage forms:** Omit the use of disks unless otherwise specified in the *Procedure* above or in the individual monograph.

  **Dietary supplements other than vitamin–mineral and botanical dosage forms:** Omit the use of disks unless otherwise specified above or in the individual monograph.

- **TOLERANCES:** All of the 6 dosage units initially tested or NLT 16 of a total of 18 dosage units tested disintegrate completely.

**RUPTURE TEST FOR SOFT-SHELL CAPSULES**

**Medium:** Water; 500 mL

**Apparatus:** Use *Apparatus 2* as described in *Dissolution* ⟨711⟩, *Apparatus*, operating at 50 rpm.

**Time:** 15 min

- **PROCEDURE:** Place 1 capsule in each vessel, and allow the capsule to sink to the bottom of the vessel before starting rotation of the blade. Use sinkers if the capsules float. Observe the capsules throughout the test and at the end of the test. The capsule shell is considered ruptured if breached, exposing or allowing the fill contents to escape.
- **TOLERANCES:** The requirements are met if all of the capsules tested rupture in NMT 15 min. If 1 or 2 of the capsules rupture in >15 min but NMT 30 min, repeat the test on 12 additional capsules: NMT 2 of the total of 18 capsules tested rupture in >15 min but NMT 30 min. For soft gelatin capsules that do not conform to the above rupture test acceptance criteria, repeat the test with the addition of papain to the *Medium* in the amount that results in an activity of NMT 550,000 units/L of *Medium* or with the addition of bromelain in the amount that results in an activity of NMT 30 gelatin-digesting units (GDU)/L of *Medium*. [NOTE—Determine papain activity using the *Assay* in the monograph for *Papain* and bromelain activity using the procedure in bromelain, in the *Reagent Specifications* section.]

**DISSOLUTION**

This test is provided to determine compliance with the *Dissolution* requirements where stated in the individual monographs for dietary supplements. The operative assumption inherent in this test is that if the index vitamin or mineral or marker compound(s) for a botanical is dissolved within the time frame and under conditions specified, the dosage form does not suffer from formulation- or manufacturing-related problems affecting the adequate release of the active ingredients.

- **FOR DOSAGE FORMS CONTAINING OR COATED WITH GELATIN**

For hard or soft gelatin capsules and gelatin-coated tablets that do not conform to the dissolution specification because of the presence of cross-linking, the dissolution procedure should be repeated with the addition of enzymes to the medium, as described below.

**Dissolution medium with pH ≤4.0**

**Enzyme:** Pepsin, activity determined by the procedure in pepsin, in the *Reagent Specifications* section

**Amount:** A quantity of pepsin that results in an activity of NMT 750,000 units/L of dissolution medium

**Dissolution medium with pH >4.0 and <6.8**

**Enzyme:** Papain, activity determined by the *Assay* in the monograph for *Papain*; or bromelain, activity determined by the procedure in bromelain, in the *Reagent Specifications* section

**Amount:** A quantity of papain that results in an activity of NMT 550,000 units/L of dissolution medium, or a quantity of bromelain that results in an activity of NMT 30 GDU/L of dissolution medium

**Dissolution medium with pH ≥6.8**

**Enzyme:** Pancreatin, protease activity determined by the procedure in *Assay for protease activity* (*Casein digestive powder*) in the monograph for *Pancreatin*

**Amount:** A quantity of pancreatin that results in a protease activity of NMT 2,000 units/L of dissolution medium

**Dissolution medium containing surfactants or other components known to denature the enzyme:** If the dissolution medium contains surfactants or other components known to denature the enzyme to be used, a pretreatment step should be applied. The pretreatment step is performed under the same dissolution conditions (apparatus, rotation, and flow rate), except to use a medium with the corresponding amount of enzyme as directed in the preceding section and without the surfactant or component known to denature the enzyme. To achieve the final specified volume of medium, the pretreatment step may be conducted with a smaller volume of medium without the surfactant or component in such a manner that the final specified volume is achieved after the addition of the surfactant or component at the end of the pretreatment step. Perform the pretreatment step until capsule rupture, but for NMT one-half of the total dissolution time specified in the procedure. The pretreatment time is included in the total dissolution time specified in the procedure.

- **Apparatus:** See ⟨711⟩ for a description of the apparatus used, apparatus suitability test, and other related information. Where the procedure specifies the use of a stationary basket, use the quadrangular basket of stainless steel wire gauze as shown in *Figure 2a* and *Figure 2b*.

The capsule is placed in a basket, soldered in one of its upper, narrow sides to the end of a steel rod (see *Figure 2a*). The capsule cover is placed in the horizontal diagonal of the basket. The rod assembly is inserted vertically through the cover of the dissolution vessel, and fixed by means of two teflon nuts, 3.2 cm from the center of the vessel, or by any other appropriate means. The lower edge of the bottom of the basket is adjusted to about 1 cm above the top of the paddle blade (see *Figure 2b*).

Of the types of apparatus described in ⟨711⟩, use the one specified in the individual monograph.

- **Vitamin–Mineral Dosage Forms**

All dietary supplement capsules, tablets, or chewable gels containing folic acid are subject to the dissolution test and criteria for folic acid described in this chapter. This test is required because of the importance of the relationship between folate deficiency and the risk of neural tube defects. Dietary supplement capsules, tablets, or chewable gels containing water-soluble vitamins, minerals, or their combination are subject to the dissolution test and criteria for index vitamins, index minerals, or both, described in this chapter. Dietary supplement tablets, chewable gels, and hard-shell capsules with solid content dosage forms containing vitamin A are subject to the dissolution test and criteria for vitamin A described in this chapter. Dissolution standards were not established and therefore are not applicable to vitamin A in dietary supplement soft-shell capsules filled with liquids. *Table 1* summarizes the dissolution requirements for the assigned USP classes of dietary supplements. Vitamin–mineral combinations that do not belong to any of the USP classes listed in *Table 1* are subject to the *Dissolution* test and criteria specified in the individual monographs.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99970_04_01

**Table 1. Dietary Supplements—Vitamin–Mineral Dosage Forms**

| USP Class | Ingredients | Dissolution Requirements for Tablets, Chewable Gels, and Hard-Shell Capsules with Solid Contents | Dissolution Requirements for Soft-Shell Capsules Filled with Liquids |
|---|---|---|---|
| I | Oil-soluble vitamins | Vitamin A (if present) | Not applicable |
| II | Water-soluble vitamins | One index water-soluble vitamin and folic acid (if present) | One index water-soluble vitamin and folic acid (if present) |
| III | Water-soluble vitamins with minerals | One index water-soluble vitamin, one index element, and folic acid (if present) | One index water-soluble vitamin, one index element, and folic acid (if present) |
| IV | Oil- and water-soluble vitamins | Vitamin A (if present), one index water-soluble vitamin, and folic acid (if present) | One index water-soluble vitamin and folic acid (if present) |
| V | Oil- and water-soluble vitamins with minerals | Vitamin A (if present), one index water-soluble vitamin, one index element, and folic acid (if present) | One index water-soluble vitamin, one index element, and folic acid (if present) |
| VI | Minerals | One index element | One index element |
| VII | Oil-soluble vitamins with minerals | Vitamin A (if present) and one index element | One index element |

**Selection of index water-soluble vitamins and index elements:** Compliance with the dissolution requirements for dietary supplements representing combinations of water-soluble vitamins and combinations of oil- and water-soluble vitamins is determined by measuring the dissolution of a single index vitamin from the water-soluble vitamins present. Riboflavin is the index vitamin when present in the formulation. For formulations that do not contain riboflavin, pyridoxine is the index vitamin. If neither riboflavin nor pyridoxine is present in the formulation, the index vitamin is niacinamide (or niacin), and in the absence of niacinamide (or niacin), the index vitamin is thiamine. If none of these four water-soluble vitamins are present in the formulation, the index vitamin is ascorbic acid.

Compliance with the dissolution requirements for dietary supplements representing combinations of minerals is determined by measuring the dissolution of only one index element. Iron is the index element when present in the formulation. For formulations that do not contain iron, the index element is calcium. If neither iron nor calcium is present, the index element is zinc. In the absence of all three of these elements, magnesium is the index element.

Compliance with the dissolution requirements for dietary supplements representing combinations of water-soluble vitamins and minerals and combinations of oil- and water-soluble vitamins and minerals is determined by measuring the dissolution of one index water-soluble vitamin and one index element, designated according to the respective hierarchies described above.

**Dissolution conditions for vitamin A:** [NOTE—Perform this test under light conditions that minimize photodegradation.]
**Medium:** 1% (w/v) sodium ascorbate and 1% (w/v) octoxynol 9 in 0.05 M phosphate buffer, pH 6.8; 900 mL
**Apparatus 2:** 75 rpm
**Time:** 45 min

**Dissolution conditions for folic acid:** [NOTE—Perform this test under light conditions that minimize photodegradation.]
**Test 1**
**Medium:** Water; 900 mL
**Apparatus 1:** 100 rpm, for capsules
**Apparatus 2:** 75 rpm, for tablets
**Time:** 1 h
If the units tested do not meet the requirements for dissolution in water, use the following conditions:
**Buffer:** Mix 95 mL of 0.1 M citric acid monohydrate and 405 mL of 0.1 M sodium citrate dihydrate, dilute with water to 1000 mL, mix, and adjust to a pH of 6.0 by using either 0.1 M hydrochloric acid or 0.1 M sodium hydroxide solution.
**Medium:** Buffer; 900 mL
**Apparatus 1:** 100 rpm, for capsules
**Apparatus 2:** 75 rpm, for tablets
**Time:** 1 h
**Test 2** (for lipid-filled soft-shell capsules): Proceed as directed for *Test 2* under *Dissolution conditions for index water-soluble vitamins and index minerals*. If the article complies with this test, the labeling indicates that it meets USP *Dissolution Test 2*.
**Test 3** (for lipid-filled soft-shell capsules): Proceed as directed for *Test 3* under *Dissolution conditions for index water-soluble vitamins and index minerals*. If the article complies with this test, the labeling indicates that it meets USP *Dissolution Test 3*.
[NOTE—Compliance with the dissolution requirements for folic acid does not exempt the article from compliance with the dissolution requirements of the pertinent index vitamin or the corresponding index mineral.]

**Dissolution conditions for index water-soluble vitamins and index minerals**
**Test 1**
**Medium:** 0.1 N hydrochloric acid; 900 mL
**Apparatus 1:** 100 rpm, for capsules
**Apparatus 2:** 75 rpm, for tablets
**Time:** 1 h

@2024 USPC

For formulations containing 25 mg or more of the index vitamin, riboflavin, use the following conditions:
**Medium:** 0.1 N hydrochloric acid; 1800 mL
**Apparatus 1:** 100 rpm, for capsules
**Apparatus 2:** 75 rpm, for tablets
**Time:** 1 h

**Test 2** (for lipid-filled soft-shell capsules)**:** If the article complies with this test, the labeling indicates that it meets USP *Dissolution Test 2*.
**Medium:** 0.25% (w/v) octoxynol 9, 0.02% (w/v) ascorbic acid, and 0.04% (w/v) simethicone in simulated gastric fluid TS; 250 mL
**Apparatus 3:** 15 dpm
**Screen** (top and bottom)**:** 20-mesh
**Time:** 1 h

**Test 3** (for lipid-filled soft-shell capsules)**:** If the article complies with this test, the labeling indicates that it meets USP *Dissolution Test 3*.
**Medium:** 0.25% (w/v) octoxynol 9 and 0.02% (w/v) ascorbic acid in simulated gastric fluid TS; 500 mL
**Apparatus 2:** 125 rpm; dosage unit placed in stationary basket (*Figure 2a* and *Figure 2b*)
**Time:** 1 h

[NOTE—Compliance with dissolution requirements for the pertinent index vitamin or index mineral does not exempt the article from compliance with the dissolution requirements for folic acid, if present.]

**Procedures:** In the following procedures, combine equal volumes of the filtered solutions of the six individual specimens withdrawn, and use the pooled sample as the test specimen. Determine the average amount of vitamin A, folic acid, or the index vitamin or element dissolved in the pooled sample. Make any necessary modifications, including concentration of the analyte in the volume of *Sample solution* taken. Use the *Medium* for preparation of the *Standard solution* and dilution, if necessary, of the *Sample solution*.

**Vitamin A:** Determine the percentage of retinyl acetate or retinyl palmitate dissolved by using the following procedure.
**Standard solution:** Dissolve a suitable amount of USP Retinyl Acetate RS or USP Retinyl Palmitate RS in isopropyl alcohol, and dilute with *Medium* to obtain a concentration similar to that expected in the *Sample solution*. [NOTE—The amount of isopropyl alcohol should be 5%–10%.]
**Sample solution:** Withdraw a portion of the solution under test, pass through a suitable filter of 0.45-µm pore size, and use the pooled sample as the test specimen.
**Solution A:** Methanol and water (90:10)
**Solution B:** Methanol and isopropyl alcohol (55:45)
**Mobile phase:** See *Table 2*.

**Table 2**

| Time (min) | Solution A (%) | Solution B (%) |
|---|---|---|
| 0 | 100 | 0 |
| 8 | 0 | 100 |
| 13 | 0 | 100 |
| 13.1 | 100 | 0 |
| 15 | 100 | 0 |

**Chromatographic system**
(See *Chromatography* ⟨621⟩*, System Suitability*.)
**Mode:** LC
**Detector:** UV 325 nm
**Column:** 4.6-mm × 10-cm; 3-µm packing L1
**Flow rate:** 1.0 mL/min
**Injection volume:** 50 µL

**System suitability**
**Sample:** *Standard solution*
**Suitability requirements**
**Tailing factor:** NMT 1.5 for retinyl acetate; NMT 2.0 for retinyl palmitate
**Relative standard deviation:** NMT 2.0%

**Analysis**
**Samples:** Appropriate *Standard solution* and *Sample solution*

$$\text{Result} = (r_U/r_S) \times (C_S \times V/L) \times 100$$

$r_U$ = peak area of the all-*trans*-retinyl ester from the *Sample solution*
$r_S$ = peak area of the all-*trans*-retinyl ester from the appropriate *Standard solution*
$C_S$ = concentration of retinol in the appropriate *Standard solution* (µg/mL)
$V$ = volume of *Medium*, 900 mL
$L$ = label claim of vitamin A, as retinol (µg/tablet)

Official

https://pharmacopeia.cn/

**Folic acid:** Determine the amount of folic acid ($C_{19}H_{19}N_7O_6$) dissolved by using the procedure set forth in the assay for folic acid in the individual monograph. Make any necessary modifications.

**Niacin or niacinamide, pyridoxine, riboflavin,** and **thiamine:** Determine the amount of the designated index vitamin dissolved by using the procedure set forth in the assay for niacin or niacinamide, pyridoxine hydrochloride, riboflavin, and thiamine in the individual monographs. Make any necessary modifications.

**Ascorbic acid:** Determine the amount of ascorbic acid ($C_6H_8O_6$) dissolved by using the procedure set forth in the assay for ascorbic acid in the individual monograph. Make any necessary modifications.

**Iron, calcium, magnesium,** and **zinc:** Determine the amount of the designated index element dissolved by using the procedure set forth in the appropriate assay in the individual monographs. Make any necessary modifications.

**Tolerances:** The requirements are met if NLT 75% of the labeled content of vitamin A, NLT 75% of the labeled content of folic acid, and NLT 75% of the labeled content of the index vitamin or the index element from the units tested is dissolved.

- **Botanical Dosage Forms**

Compliance with dissolution requirements necessitates the testing of 6 dosage units individually, or testing 2 or more dosage units in each of the six vessels of the dissolution apparatus, and measuring the dissolution of one or more index/marker compound(s) or the extract specified in the individual monograph.

**Procedures:** Combine equal volumes of the filtered solutions of the six or more individual specimens withdrawn, and use the pooled sample as the *Sample solution*. Determine the average amount of index or marker compound(s) or the extract dissolved in the pooled sample by the procedure specified in the individual monograph. Make any necessary modifications, including concentration of the analyte in the volume of the *Sample solution* taken. Use the *Medium* for preparation of the *Standard solution* and dilution, if necessary, of the *Sample solution*.

**Tolerances:** Unless otherwise specified in the individual monograph, the requirements are met if NLT 75% of the labeled content of the index or marker compound(s) or the extract from the units tested is dissolved in 1 h.

- **Dietary Supplements Other Than Vitamin–Mineral and Botanical Dosage Forms**

Unless otherwise stated in the individual monographs for dietary supplement dosage forms in this category, compliance requires the testing of 6 individual units, measuring the dissolution of the dietary ingredient as the average of the 6 units tested.

**Procedures:** Combine equal volumes of the filtered solutions of the six specimens withdrawn, and use the pooled sample as the *Sample solution*. Determine the average amount of the dietary ingredient dissolved in the pooled sample by the procedure specified in the individual monograph. Make any necessary modifications, including concentration of the analyte in the volume of the *Sample solution* taken. Use the *Medium* for preparation of the *Standard solution* and for dilution, if necessary, of the *Sample solution*.

**Tolerances:** Because of the diversity of chemical characteristics and solubilities of dietary ingredients pertaining to this category, general tolerances cannot be established. See individual monographs for *Tolerances*.

# ⟨2091⟩ WEIGHT VARIATION OF DIETARY SUPPLEMENTS

***Change to read:***

## INTRODUCTION

The following tests provide limits for the permissible variations in the weights of individual tablets, capsules, ▲or chewable gels▲ (USP 1-Dec-2019) expressed in terms of the allowable deviation from the average weight of a sample. Separate procedures and limits are described herein for capsules, uncoated tablets, coated tablets, ▲and chewable gels▲ (USP 1-Dec-2019) that are intended for use as dietary supplements.

## CAPSULES

Capsules meet the requirements of the following test with respect to variation in weight of contents.

### Hard Shell Capsules

Weigh 20 intact capsules individually, and determine the average weight. The requirements are met if each of the individual weights is within the limits of 90% and 110% of the average weight.

If not all of the capsules fall within the aforementioned limits, weigh the 20 capsules individually, taking care to preserve the identity of each capsule, and remove the contents of each capsule with the aid of a small brush or pledget of cotton. Weigh the emptied shells individually, and calculate for each capsule the net weight of its contents by subtracting the weight of the shell from the respective gross weight. Determine the average net content from the sum of the individual net weights. Then determine the difference between each individual net content and the average net content: the requirements are met if (a) NMT 2 of the differences are greater than 10% of the average net content and (b) in no case is the difference greater than 25%.

If more than 2 but NMT 6 capsules deviate from the average between 10% and 25%, determine the net contents of an additional 40 capsules, and determine the average content of the entire 60 capsules. Determine the 60 deviations from the new average: the requirements are met if (a) NMT 6 of the 60 capsules have differences that are greater than 10% of the average net content and (b) in no case does the difference exceed 25%.

### Soft Shell Capsules

Proceed as directed under *Hard Shell Capsules*, but determine the net weight of the contents of individual capsules as follows. Weigh the intact capsules individually to obtain their gross weights, taking care to preserve the identity of each capsule. Then cut open the capsules by means of a suitable clean, dry cutting instrument, such as scissors or a sharp open blade, and remove the contents by washing with a suitable solvent. Allow the occluded solvent to evaporate from the shells at room temperature over a period of about 30 min, taking precautions to avoid uptake or loss of moisture. Weigh the individual shells, and calculate the net contents. The requirements are as stated under *Hard Shell Capsules*.

## TABLETS

Tablets conform to the criteria given in *Table 1*.

### Uncoated Tablets and Film-Coated Tablets

Weigh 20 whole tablets individually, and calculate the average weight. The requirements are met if the weights of NMT 2 of the tablets differ from the average weight by more than the percentage listed in *Table 1*, and no tablet differs in weight by more than double that percentage.

### Coated Tablets (Other Than Film-Coated Tablets)

Weigh 20 whole tablets individually, and calculate the average weight. If the coated tablets do not conform to the criteria in *Table 1*, place 20 tablets in a beaker of water at 37° and swirl gently for NMT 5 min. Examine the cores for evidence of disintegration and repeat the procedure for a shorter time if disintegration has begun. Dry the cores at 50° for 30 min. Accurately weigh 20 individual tablet cores, and calculate the average weight.

The requirements are met if the weights of NMT 2 of the tablets differ from the average weight by more than the percentage listed in *Table 1* and no tablet differs in weight by more than double that percentage.

Official

https://pharmacopeia.com/

## Acceptance Criteria

**Table 1. Weight Variation Tolerances for Uncoated Tablets, Film-Coated Tablets, and Coated Tablets (Other Than Film-Coated Tablets)**

| Average Weight of Tablet (mg) | Difference (%) |
|---|---|
| 130 or less | 10 |
| From 130 through 324 | 7.5 |
| More than 324 | 5 |

***Add the following:***

## ▲CHEWABLE GELS

Chewable gels meet the requirements of the following test with respect to weight variation. Individually weigh an equal number of units of each color and shape to obtain a total of NLT 20 and NMT 30 individual weights, and calculate the average weight.

The requirements are met if no individual weight deviates from the average weight by more than 7.5%. If more than 1 unit exceeds the specified limit, the test fails.

If 1 unit falls outside of the limits, repeat the procedure with an additional set of NLT 20 and NMT 30 individual chewable gels. The requirements are met if none of the units tested in the second set differ from their average weight by more than 10%.▲ (USP 1-Dec-2019)

# ⟨2232⟩ ELEMENTAL CONTAMINANTS IN DIETARY SUPPLEMENTS

The objective of this general chapter is to limit the amounts of elemental contaminants in finished dietary supplement dosage forms labeled as conforming to *USP* or *NF* standards. This general chapter is not intended to set limits for dietary ingredients. Those limits are set in the corresponding individual monographs.

The focus of this general chapter is on the four major elements of toxicological concern: arsenic, cadmium, lead, and mercury. The extent of testing can be determined using a risk-based approach that takes into account the likelihood of contamination. Manufacturers should consider the presence of unexpected elemental contaminants to determine compliance.

## LIMITS OF ELEMENTAL CONTAMINANTS

The levels of elemental contaminants should be restricted as shown in *Table 1* unless otherwise stated in the individual monograph. Specific monographs may provide different limits for articles that need to be consumed in large quantities.

**Table 1**

| Element | PDE (µg/day)[a] |
|---|---|
| Arsenic (inorganic) | 15 |
| Cadmium | 5 |
| Lead | 5 |
| Mercury (total) | 15 |
| Methylmercury (as Hg) | 2 |

[a] Permitted Daily Exposure (PDE) is derived from the Provisional Tolerable Weekly Intake (PTWI) that is recommended by the Food and Agriculture Organization of the United Nations and World Health Organization (FAO/WHO) by subtracting the daily exposure (µg/day) to each elemental contaminant from air, food, and drinking water. A body weight of 50 kg and a safety factor are used to calculate the PDE. Other regulations (e.g., Proposition 65 in California) may require different limits; manufacturers are responsible for compliance with applicable local requirements differing from these PDE values.

Arsenic may be measured using a nonspeciation procedure under the assumption that all arsenic contained in the supplement is in the inorganic form. Where the limit is exceeded using a nonspeciation procedure, compliance with the limit for inorganic arsenic shall be demonstrated on the basis of a speciation procedure. Methylmercury determination is not necessary when the content for total mercury is less than the limit for methylmercury.

## OPTIONS FOR COMPLIANCE WITH THE LIMITS OF ELEMENTAL CONTAMINANTS

In order for a dietary supplement finished dosage form to comply with the limits for elemental contaminants as described in this chapter, the level of elemental contaminant in the finished dietary supplement should be NMT the PDE. The following three options are available for determining compliance with the limits for elemental contaminants in dietary supplements.

- **Dietary Supplement Analysis Option**

  This option is generally applicable. In this option the finished dietary supplement dosage form is analyzed according to the procedures in the general chapter *Elemental Impurities—Procedures* ⟨233⟩ or the speciation procedures given in this chapter. The results obtained from the analysis of a typical serving size, scaled to a maximum daily intake, are compared to the PDE, as stated in *Table 1*.

  **Analysis:** Proceed as directed below in this chapter.

  Calculate the measured amount of each elemental contaminant, in µg/daily intake, as:

  $$\text{Result} = MVSS \times N$$

  $MVSS$ = measured amount of each elemental contaminant (µg/serving size)

  $N$ = maximum daily intake of the supplement recommended in the labeling (servings/day)

  **Acceptance criteria:** The measured amount/daily intake is NMT the PDE value given in *Table 1*.

- **Individual Component Option**

  This option is applicable to finished dietary supplement dosage forms with a maximum daily intake of NMT 10 g of the dietary supplement finished product.

  **Analysis:** Unless otherwise specified in the individual monograph, proceed with the individual ingredient as directed below in this chapter.

  **Acceptance criteria:** The product meets the requirements when each component used to prepare the finished dietary supplement meets the limits given in *Table 2*.

**Table 2**

| Element | Individual Component Limits (µg/g)[a] |
|---|---|
| Arsenic (inorganic)[b] | 1.5 |
| Cadmium | 0.5 |
| Lead | 0.5 |
| Mercury (total) | 1.5 |
| Methylmercury (as Hg)[c] | 0.2 |

DOI: https://doi.org/10.31003/USPNF_M5291_02_01

@2024 USPC

[a] The limits for individual components are based on a maximum daily intake of 10 g of a dietary supplement and are intended for use only with *Options for Compliance with the Limits of Elemental Contaminants*, *Individual Component Option*.
[b] Arsenic may be measured using a nonspeciation procedure under the assumption that all arsenic contained in the supplement is in the inorganic form. Where the limit is exceeded using a nonspeciation procedure, compliance with the limit for inorganic arsenic shall be demonstrated on the basis of a speciation procedure.
[c] Methylmercury determination is not necessary when the content for total mercury is less than the limit for methylmercury.

[NOTE—If all components in a formulation meet the limits given for the *Individual Component Limits*, these components can be used in any proportion. No further calculation is necessary.]

- **SUMMATION OPTION**

This option can be used for finished dietary supplement dosage forms that are consumed in quantities greater than 10 g/day or where the acceptance limit for any contaminant in any component of the dietary supplement exceeds the applicable *Individual Component Limits*.

**Analysis:** Unless otherwise specified in the individual monograph, proceed with the individual ingredient as directed below in this chapter.

Calculate the amount of each elemental contaminant, in µg/daily intake, present in the finished dietary supplement dosage form:

$$\text{Result} = \Sigma(C_i \times W_i) \times N$$

$C_i$ = elemental contaminant concentration in the individual component (µg/g)

$W_i$ = weight of each individual component per serving of the dietary supplement (g/serving)

$N$ = maximum daily intake of the supplement recommended in the labeling (servings/day)

**Acceptance criteria:** The calculated amount of each elemental contaminant/daily intake is NMT the PDE value given in *Table 1*.

***Change to read:***

## ANALYTICAL PROCEDURES FOR TOTAL ELEMENTAL CONTAMINANTS

Performance-based methodology for analysis of total elemental contaminants in general chapter *Elemental Impurities—Procedures* ⟨233⟩ is applicable for dietary supplements. The validation necessity will vary depending on the situation. In all three options described in the section *Options for Compliance with the Limits of Elemental Contaminants*, the use of *Validation of Limit Procedures* (see *Elemental Impurities—Procedures* ⟨233⟩) may be appropriate. However, for the *Summation Option*, acceptable levels of validation must be determined on a case-by-case basis. Validation of a procedure using the *Validation of Quantitative Procedures* (see *Elemental Impurities—Procedures* ⟨233⟩) is acceptable for all options under all circumstances and is generally preferred. The determination of the level of validation necessity is at the discretion of the manufacturer and the competent regulatory authority.

- **ANALYTICAL PROCEDURE FOR INORGANIC ARSENIC**

Where the level of total arsenic exceeds the limit recommended in this chapter, speciation may be used to determine the amount of inorganic arsenic present. The following procedure is suggested for determination of inorganic arsenic, but any validated procedure shown to give equivalent or better results can be used.

**Apparatus:** See *Figure 1*.

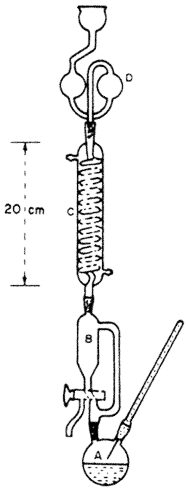

Figure 1. Special apparatus for the determination of inorganic arsenic (A, 250-mL distillation flask; B, receiver chamber, approximately 50-mL capacity; C, reflux condenser; D, splash head or security funnel).

**Reagents**

**Distillation-reducing solution:** 30.0 g of potassium iodide in 100 mL of water. [NOTE—Prepare fresh on the day of use.]

**Control:** 6.0 µg of arsenic (As) (6.0 mL of *Standard Arsenic Solution*). [NOTE—Use this amount rather than the 3.0 mL specified for *Standard Preparation* in the general chapter ▲*Arsenic* ⟨211⟩, *Procedures, Procedure 1*▲ (CN 1-Jun-2023).]

Official

https://pharmacopeia.com/

**Sample solution:** Transfer a 2.00-g sample that has previously been ground to pass through a 60-mesh screen to a distillation flask (A). To the flask add 35 mL of hydrochloric acid 6.6 N and 15 mL of *Distillation-reducing solution*, let stand for 5 min to ensure reduction of arsenic [As(V)], connect the flask to the receiver chamber (B), complete the assembly of the apparatus, and begin circulating tap water through the condenser (C). Half-fill the lower two bulbs of the splash head (D) with water. Maneuver the stopcock to cause the contents of the receiver chamber to drain into the distillation flask, heat the flask until the temperature above the solution reaches 100°–110°, and continue refluxing at this temperature for 15 min. Close the stopcock, continue heating at 108°–110°, and collect 30–33 mL of distillate in the receiver chamber. Remove the heating source, and allow the temperature to drop to about 80°.

Close the stopcock, and add a second 35-mL portion of 6.6 N hydrochloride (HCl) and 15 mL of the *Distillation-reducing solution* through the thermometer opening to the distillation flask. Replace the thermometer, increase the temperature to 100°–110°, and collect a second 30- to 33-mL portion of distillate in the receiver chamber. Drain the second distillate into the beaker containing the first portion, and cool the combined distillate to room temperature. Remove the splash head, and wash its contents into the beaker. Also, wash down the inside of the condenser and receiver chamber with water, collecting the washings into the beaker. Transfer to a 100-mL volumetric flask, and complete with water to volume.

**Analysis:** Determine the arsenic content by the ICP-MS procedure in *Elemental Impurities—Procedures* ⟨233⟩. Alternatively, add 2 mL of potassium iodide TS and 0.5 mL of stronger acid stannous chloride TS to the *Sample solution* contained in the Erlenmeyer flask, and proceed as directed in ▲*Arsenic* ⟨211⟩*, Procedures, Procedure 1*▲ (CN 1-Jun-2023)*, Procedure*, beginning with "Allow to stand at room temperature for 30 minutes."

- **Analytical Procedure for Methylmercury**

Where methylmercury determination is required, the following procedure is suggested. However, any validated procedure shown to give equivalent or better results can be used.

**Procedure 1**

This procedure uses an aqueous extraction of the mercury species with an L-cysteine solution, HPLC separation of the derivatized mercury species with a mobile phase also containing L-cysteine, and ICP-MS detection.

**Cysteine solution:** 1% L-cysteine hydrochloride monohydrate in water

**Mobile phase:** 0.1% L-cysteine hydrochloride monohydrate and 0.1% L-cysteine free base in water

**Standard stock solution:** 1 µg/mL of mercury (Hg) as methylmercury chloride, and 1 µg of mercury (Hg) as mercury chloride in 5% hydrochloric acid containing 0.2 mg/mL of L-cysteine hydrochloride monohydrate

**Standard solution:** 2 ng/mL of mercury as methylmercury from *Standard stock solution* in *Cysteine solution*

**Sample solutions**

**For supplements in tablet form:** Weigh, and finely powder a counted number of tablets. Transfer an accurately weighed portion of the powder equivalent to 0.5 times the daily recommended intake to a tared vial. Add 50.0 mL of *Cysteine solution* accurately weighed, cap the vial, and shake vigorously. Place the vial in a water bath at 60° for 60 min. Shake the vial again, and return to the water bath for another period of 60 min. Shake the vial again, and allow to cool at room temperature for about 20 min. Filter through a 0.45-µm polyethylene membrane. [NOTE—Prepare fresh on the day of use.]

**For supplements in capsule form:** Weigh accurately NLT 20 capsules, and determine the average weight. Place a number of capsules equivalent to about 5 times the daily recommended intake in a blender, add 500.0 mL of *Cysteine solution* and blend to obtain a homogenous analytical suspension. Transfer 50.0 mL of this analytical suspension to a vial, cap the vial, and shake vigorously. Place the vial in a water bath at 60° for 60 min. Shake the vial again, and return to the water bath for another period of 60 min. Shake the vial again, and allow to cool at room temperature for about 20 min. Filter through a 0.45-µm polyethylene membrane.

[NOTE—Prepare fresh on the day of use.]

**For supplements in liquid form:** Weigh accurately an amount of the liquid equivalent to 0.5 times the daily recommended intake into a vial, and add 50.0 mL of *Cysteine solution*. Cap the vial, and shake vigorously. Place the vial in a water bath at 60° for 60 min. Shake the vial again, and return to the water bath for another period of 60 min. Shake the vial again, and allow to cool at room temperature for about 20 min. Filter through a 0.45-µm polyethylene membrane.

[NOTE—Prepare fresh on the day of use.]

**Chromatographic system**

(See *Chromatography* ⟨621⟩*, System Suitability*.)

**Mode:** LC

**Detector:** ICP-MS at a mass-to-charge ratio of 202

**Column:** 4.6-mm × 15-cm; 4-µm packing L1

**Flow rate:** 1 mL/min

**Injection volume:** 50 µL

**System suitability**

**Sample:** *Standard solution*

**Suitability requirements**

**Resolution:** NLT 3 between the peak representing mercury ($Hg^{2+}$) species at a relative retention time of about 0.56 and the peak representing methylmercury ($MeHg^{+}$) species at a relative retention time of 1.0

**Relative standard deviation:** NMT 10.0%, *Standard solution*

**Analysis**

**Samples:** *Standard solution* and the appropriate *Sample solution*

Determine the peak area of the peak representative of methylmercury in the chromatograms of the *Sample solution* and *Standard solution*.

**Acceptance criteria:** 0.2 µg/daily intake: The peak area for methylmercury in the chromatogram of the *Sample solution* is NMT the peak area for methylmercury in the chromatogram of the *Standard solution*.

# ⟨2250⟩ DETECTION OF IRRADIATED DIETARY SUPPLEMENTS

## INTRODUCTION

Federal regulations do not permit irradiation of dietary ingredients or dietary supplements for sanitation purposes. Under section 201(s) of the Federal Food, Drug, and Cosmetic Act [21 USC 321(s)], irradiation is considered an additive, and as such it requires FDA approval. Foods that are irradiated should be adequately labeled according to international and national guidelines with statements such as "Treated with radiation" or "Treated by irradiation" in addition to information required by other regulations, including the irradiation logo, the Radura [21 USC 321(s)]. Overexposure to irradiation may have negative effects on product quality. Currently, several independent methods are used to identify irradiated foodstuffs, including dietary supplements. These methods have been validated and are recognized worldwide.

Procedures based on luminescence are widely applied and include screening by photostimulated luminescence (PSL), which is a rapid, simple preliminary screening method to detect irradiation, and a subsequent thermoluminescence (TL) procedure to confirm that the sample has been irradiated. PSL is less time consuming than TL because the inorganic/silicate mineral source of luminescence does not need to be isolated from any organic components present. Both PSL and TL signal intensities are affected by irradiation dose as well as by the nature and amount of inorganic material. TL analysis is one of the detection methods used for confirming the presence of irradiated foods, herbs, spices, vegetables, and fruits, although it has certain limitations: for example, samples must contain sufficient amounts of silicates that can be successfully separated from the samples. The lengthy preparation and need for irradiation in all cases limits TL to a small number of laboratories.

The procedures described in this chapter can be used both by regulatory authorities and by producers and suppliers of foods, including dietary supplements, to detect undeclared irradiated products in the market for purposes of determining compliance with regulations.

## PRINCIPLES OF PHOTOSTIMULATED LUMINESCENCE AND THERMOLUMINESCENCE

Most of the natural dietary ingredients that are either cultivated or wild contain silicate minerals, calcite, or hydroxyapatite. Exposure to ionizing radiation from gamma rays ($^{60}Co$ or $^{137}Cs$), electron beams (up to 10 MeV), or x-rays (up to 5 MeV) stimulates electrons in those types of crystals, resulting in energized electrons being stored in the crystal lattice. Trapped high-energy electrons can be released by stimulation with light or controlled heat, leaving electron holes in the crystal lattice. The energy thus released is detected as luminescence. PSL occurs if light is applied to the system, and TL occurs when heat is applied to the system. The recorded luminescence intensity is proportional to the initial radiation dose absorbed.

Samples for both PSL and TL measurements must be taken from a light-protected position of the bulk samples, and exposure to high temperature and light must be avoided after the samples are taken from the bulk. Sample preparation and subsequent PSL or TL measurement must be conducted under subdued lighting conditions when possible.

TL has been widely used for detection of irradiation in food and dietary ingredients from which silicate minerals can be isolated. In this chapter, PSL and TL are described as the most appropriate detection methods for the materials typically used as dietary ingredients. The two methods are both radiation-specific phenomena, based on the observation that photon counts of irradiated samples usually are higher than those of nonirradiated samples. However, all available methods have some limitations in terms of their specific application range, product-to-product variation, complexity of or interference from the food matrix, and low concentration of radiation-induced markers.

## GENERAL PROCEDURE FOR DETECTION OF IRRADIATION IN DIETARY INGREDIENTS AND DIETARY SUPPLEMENTS

### Screening Using Photostimulated Luminescence

PSL, also known as optically stimulated luminescence, is based on the emission of light in the 300–600 nm range from irradiated samples when illuminated at longer wavelengths in the near-IR region. PSL analysis allows multiple measurements to be performed without sample pretreatment in a short period of time. PSL is also a nondestructive method that does not require separation of inorganic minerals and organic compounds. PSL is based on optical stimulation of mineral debris, typically silicates, and bioinorganic materials such as calcite, feldspar, or hydroxyapatite, and its sensitivity depends on the quantities and types of minerals present in the sample. Before the measurement of PSL, two thresholds are set: the lower typically is set at 700 counts/min (T1), and the upper typically is set at 5000 counts/min (T2). These two thresholds serve to classify the samples. After initial screening of PSL intensity from the samples is performed, the results are classified into negative (counts/ min less than T1), intermediate (counts/min NLT T1 and NMT T2), or positive (counts/min more than T2). A second measurement after a known irradiation dose, known as calibrated PSL (CalPSL), is applied in cases of poorly defined sample matrices whose luminescence sensitivities are not well established. By comparing the screening PSL measurement against its CalPSL response, analysts can take into account variation in detection sensitivity due to variable amounts and different types of minerals present in a given sample. CalPSL measurements are recommended to rule out false negative results due to low mineral content.

#### INSTRUMENTATION

The PSL system consists of pulsed IR sources for photostimulation, a single-photon counting system for highly sensitive detection of luminescence, a sample chamber, and a computer for data analysis.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M8186_01_01
@2024 USPC

The instrumental setup procedure includes checks of irradiated and nonirradiated materials, as well as establishing measurement parameters (cycle time, thresholds, and data-recording conditions). Measurement of initial background counts and periodic measurement of counts in the empty chamber should be conducted in subdued lighting to confirm lack of instrument contamination. The PSL signals (photon counts) emitted from the sample/second are automatically accumulated in the computer and are reported as counts/min. [NOTE—All experiments should be conducted under subdued lighting. In order to minimize the risk of cross-contamination, all preparations are performed in a laminar-flow cabinet.]

### PHOTOSTIMULATED LUMINESCENCE MEASUREMENT

**Procedure**

*PSL screening*—Dispense and weigh two portions of the sample (5–10 g, depending on the density of the product) into two separate 50-mm disposable Petri dishes to cover the Petri base in a thin layer. Dispense samples in subdued lighting to minimize bleaching and under a laminar-flow cabinet to minimize cross-contamination. Measure the PSL of the sample for 1 min on the duplicate aliquots, and calculate the mean.

CALIBRATED PSL (CALPSL)— [NOTE—CalPSL testing may be done only once as part of the validation of the procedure for each material.]

Dispense and weigh two portions of the sample (5–10 g, depending on the density of the product) into 50-mm disposable Petri dishes to cover the Petri base in a thin layer. Measure the PSL of the sample for 1 min on duplicate aliquots, and for each sample calculate the mean. Irradiate the sample to a known dose of 1 kGy after the initial screening. Repeat the PSL measurement (CalPSL).

*Evaluation*—Classify results in the following manner:

<T1: negative, no evidence of PSL

>T1 and <T2: intermediate, weak PSL signal

>T2: positive, stronger signal.

ACCEPTANCE CRITERIA—Nonirradiated samples produce negative results in the PSL screening and are known to produce positive results in the CalPSL. [NOTE—Negative signals in the PSL screening are generally associated with nonirradiated material but can result from low-sensitivity irradiated materials. To evaluate whether a sample is a low-sensitivity material, assessment of the signals using the CalPSL option is necessary. Positive signals in the PSL screening are associated with irradiated material. Samples that are classified as intermediate require further investigation by the TL method to determine their irradiation status.]

## Confirmatory Analysis Using Thermoluminescence

The TL analysis is based on physical changes in silicate minerals that are present in many food samples and dietary ingredients. The silicate minerals are able to store the absorbed radiation energy. A TL reader measures the amount of light that is emitted during controlled heating. The TL of the sample ($TL_1$) is compared to that of the same sample following irradiation at 1 kGy ($TL_2$). If the TL ratio ($TL_1/TL_2$) is greater than 0.1, the sample is considered to be irradiated. In order to use the TL method for the detection of irradiated foods or dietary ingredients, silicate minerals must be isolated from the samples.

### INSTRUMENTATION

TL measurements can be performed with a TL detector that meets the specifications in *Table 1*.

**Table 1. Thermoluminesence Detector Specifications[a]**

| | |
|---|---|
| Radiation[b] | Photon: energies >5 keV<br>Neutron: thermal to 100 MeV<br>Electron/beta: energies >70 keV |
| Measurement ranges | 10 µGy to 1 Gy (1 mrad to 100 rad) linear<br>1 Gy to 20 Gy (100 rad to 2000 rad) supralinear |
| Repeatability | For 1 mGy (100 mrad) $^{137}$Cs doses, <2% standard deviation of 10 sequential measurements |
| Heating plate | 50° to approximately 500°,<br>approximately 6°/s |

[a] Harshaw TLD 3500 (Thermo Fisher Scientific, Waltham, MA) and Nanogray TL2000 (Nanogray, Osaka, Japan) are suitable.
[b] Gamma rays from $^{60}$Co or 10-MeV electron beams are suitable radiation sources.

### PROCEDURE FOR SAMPLE PREPARATION

**Sodium polytungstate solution:** Prepare a solution of sodium polytungstate in water with a final density of 2 g/mL.
**Mineral extraction:** Suspend 3–20 g of sample with 50–100 mL of pure water, and sonicate for about 5 min. Sieve through a 250-µm nylon mesh, rinsing the mesh with water each time by using a strong jet from a wash bottle into a larger beaker (500–1000 mL). Allow the minerals to settle for 5 min and decant most of the water, leaving the minerals in <50 mL of water. Transfer the mineral fraction to a centrifuge tube, and centrifuge for 1 min at 1000 × g. Discard the water layer.
**Preconcentration density separation:** Add 5 mL of the *Sodium polytungstate solution* to the minerals in the centrifuge tube. Shake or mix on a vortex mixer, then sonicate for 5–15 min. Centrifuge for 2 min at 1000 × g. Silicate minerals (density 2.5–2.7 g/mL) precipitate, whereas organic components float. Carefully overlay a layer of water on the *Sodium polytungstate solution*, and discard the water layer and the organic materials by decantation or vacuum suction, leaving the minerals behind in the polytungstate layer. Carefully remove the *Sodium polytungstate solution* layer, and wash the minerals twice with water

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Dec-2014
DOI Ref: 28yrc
DocId: GUID-3DCD3164-527B-4283-A8B6-C9CBE3245CBE_1_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M8186_01_01

(centrifuge at 1000 × g briefly). Add 1–2 mL of 1 M hydrochloric acid, shake, and leave for 10 min in the dark to dissolve carbonates adhering to the silicate materials. Neutralize the acid with 1 M ammonium hydroxide. Fill the tube with water. Allow the minerals to settle, and centrifuge. Discard the water, and wash the minerals twice with water.

**Fixing the minerals on disc for TL measurement:** Add 3 mL of acetone to the preconcentrated minerals, and shake to displace residual water. Use a stainless steel disc suitable for the TL reader in use. [NOTE—Discs typically are 9–10 mm in diameter and 0.25–0.50 mm in thickness] . Carefully clean the disc by rinsing in water, wash two to three times with acetone, and dry in an oven. Store under dust-free conditions. Record the weight of the clean disc immediately before use. Transfer the minerals (in acetone), and dry the disc at 50° overnight (lab oven). Weigh the disc, and calculate the mass of minerals. Repeat the extraction, if necessary, to meet the system suitability requirements. [NOTE—The mineral sample amount is typically between 0.1 mg and 5 mg] . The deposited minerals can be fixed on the disc by using silicone spray (or by layering with 0.2% carboxymethylcellulose) and drying at 50° overnight.

**Blank discs:** Use clean discs.

## TL MEASUREMENT

TL measurements are performed using a TL reader. Register the TL emission as a function of temperature (glow curves).

**Minimum detectable integrated TL intensity level (MDL):** Integrate the TL intensity of the first glow of the blank discs, and calculate the standard deviation. The MDL is three times the standard deviation of the integrated TL intensity of the blank discs.

**System suitability:** The integrated TL intensity of the irradiated sample ($TL_2$) should be at least 10 times the MDL.

**Measurement of $TL_1$**

*First-glow $TL_1$ measurement*—Set the instrument to an initial temperature of 70°, a heating rate of 6°/s, and a final temperature of 350°. Flush the chamber with nitrogen. Place the sample disc on the heating plate of the TL reader, and measure the glow curve. Determine $TL_1$ as the integrated TL signal between 150° and 250°. Measure the background glow for the sample ($BG_1$) after cooling the sample to 50°. After measuring $TL_1$ and $BG_1$, measure the weight of the sample ($BW_1$).

*Irradiation*—Irradiate the disc with the minerals, with a defined radiation dose of about 1 kGy. [NOTE—A source of $^{60}Co$ gamma rays is suitable.] Store at 50° overnight.

**Measurement of $TL_2$**

*Second-glow $TL_2$ measurement*—Measure the TL for the irradiated sample ($TL_2$) as described for $TL_1$. Measure the background glow for the irradiated sample ($BG_2$) after cooling the sample to 50°, and record the weight of the sample plate with the sample ($BW_2$). Measure the blank levels for process control (without the sample), following the procedures at each stage. Calculate the MDL as the integrated TL intensity of the blank plus three standard deviations.

**TL glow ratio:** The TL glow ratio per sample weight is calculated as described below:

$$\text{TL glow ratio} = [(TL_1 - BG_1)/BW_1]/[(TL_2 - BG_2)/BW_2]$$

$TL_1$ = irradiated sample for the first-glow measurement
$BG_1$ = background glow for the irradiated first-glow sample
$BW_1$ = weight of the irradiated first-glow sample
$TL_2$ = irradiated sample for the second-glow measurement
$BG_2$ = background flow for the irradiated second-glow sample
$BW_2$ = weight of the irradiated second-glow sample

**Evaluation:** TL glow ratios from irradiated samples are typically greater than 0.1. The ratios from nonirradiated samples are below 0.1.

**Acceptance criteria:** The temperature that gives the maximum glow from $TL_1$ measurement must be equal to or higher than the one from a nonirradiated sample. The TL glow ratio must be NMT 0.1 for nonirradiated materials.

# ⟨2251⟩ SCREENING FOR UNDECLARED DRUGS AND DRUG ANALOGUES

## INTRODUCTION

The illegal addition of undeclared synthetic compounds to products marketed as dietary supplements[1] (DS) is an issue of universal concern. This fraud is practiced to impart therapeutic effects that cannot be achieved by the dietary ingredients alone. Increasingly, synthetic intermediates and structural analogues of the pharmaceuticals and drugs that have been discontinued or withdrawn from the market are being used as adulterants. Multiple adulterating compounds may be added to a single product, frequently in erratic amounts.

The proposed test methodologies facilitate screening for synthetic adulterants. No individual technique is capable of addressing all potential analytes; thus, a combination of orthogonal approaches adds certainty to the analytical outcome. Mass spectrometric techniques provide strong substantiation of the analytical findings. In some cases, e.g., with hormonal drugs, the amounts of physiologically relevant adulterants may be so low that GC-MS or LC-MS may be the only fitting analytical options.

The express purpose of assembling the procedures recommended herein is their suitability for screening. The level of evidence achievable by application of one or several of the recommended procedures is ultimately dictated by the specific requirements of the end-user. It should be noted that structure elucidation and quantitative assessment are beyond the scope of this chapter.

This chapter is meant to be updated regularly, as new concealment methodologies for the adulterants are introduced, or improvements to the methods of analysis are realized.

## ADULTERATION CATEGORIES

The following major categories of adulterated products are recognized:

- **Sexual Enhancement:** This category is also referred to as the Erectile Dysfunction (ED) category. It encompasses a functionally coherent group of adulterants, including several approved drugs, their numerous approved and unapproved analogues, and synthetic intermediates. Their functionality is manifested by inhibition of phosphodiesterase type 5 enzyme (PDE5), which hydrolyzes cyclic guanosine 3′,5′-monophosphate (cGMP); this group of compounds is frequently identified as PDE5 inhibitors. Screening methods for products adulterated with ED compounds are presented in *Appendix A*.
- **Weight Loss (WL):** This category comprises a functionally and chemically diverse collection of compounds that include stimulants, laxatives, diuretics, anorexiants, and psychoactive drugs. Although stimulants constitute an important segment of WL adulterants, the oral anorexiant sibutramine dominates this category, frequently in combination with phenolphthalein, a laxative. Methods for analysis of products adulterated with WL compounds will be addressed in *Appendix B* (to come).
- **Sports Performance Enhancement (SPE):** These compounds constitute the third major category of adulteration. Professional and amateur athletes are targeted with designer anabolic steroids and stimulants, which are systematically banned by the World Anti-Doping Agency. Functional and structural diversity, synthetic proclivity of the adulterators, and the generally small amounts of the infringing substances required to elicit a therapeutic effect make this category especially challenging to address. These supplements are customarily formulated in protein- and fat-rich matrices, thereby further complicating detection. For these reasons, GC- and LC-$MS^n$ techniques constitute primary analytical methodologies within this category. Analysis of products adulterated with SPE compounds will be addressed in *Appendix C* (to come).

## BULK INGREDIENTS AND DOSAGE FORMS

Adulteration may occur either at the level of bulk ingredients or at any subsequent stage of the finished product manufacturing. Analysts should be mindful of the possibility of adulterants physically associated with the finished dosage matrix or excipients, as well as components. In the latter, synthetic compounds have been found embedded into the capsule shell body. This underscores the need for deliberate adjustment to the laboratory procedures that typically focus on the capsule contents alone. Appropriate sampling practices for powders and finished dosage forms should be exercised, particularly when only a limited amount of sample is available.

## RECOMMENDED ANALYTICAL METHODOLOGIES

Adulteration analysis may be broadly categorized into targeted and nontargeted methods. The distinction between these types may be subtle, and a minor adjustment to the methodology will transform a nontargeted method into a targeted method.

### Targeted

These techniques are warranted when the analytes are known. An example of a targeted approach would be monitoring a chromatographic run at a particular wavelength (or mass), and quantifying the analyte that appears within a predefined retention time window. Targeted analysis is conceptually straightforward, because it relies on pre-existing knowledge of the analyte and allows optimization of test methodology for its reliable detection. The targeted approach also is a rarity in the adulterated products analysis, where the nature of the analyte may be anticipated only tentatively, and variable amounts of multiple adulterants belonging to several functional categories are commonplace.

[1] In the United States, dietary supplements are defined as substances that are ingested, in agreement with 21 U.S. Code §321(ff)(2)(A)(i). Definitions of dietary supplements, nutritional supplements, functional foods, and bioactive food additives may vary extensively, depending on local or national legislation. In the marketplace, there is a trend toward expanding the mode of delivery of the adulterating compounds to routes not covered by the regulatory definition for dietary supplements, i.e., topical oils, creams, lotions, e-cigarettes, chewing gums, sprays, and others. Such novel delivery systems present unique challenges, particularly from the standpoint of sample preparation, and are not considered for the purposes of this chapter to be dietary supplements. However, recognizing the emerging threat, USP chooses to highlight the existence of these products. In no way should mention of these products be interpreted as a comment on their legal status or be perceived as an expansion of the definition of DS.

**Nontargeted**

These methods are better suited to a broad-spectrum detection requirement presented by adulterated products. Nontargeted screening trades precise knowledge of the analyte identity, along with specificity and accuracy, for a wider detection scope. Examples of nontargeted chromatographic screening include acquisition of photodiode array data and full mass-spectral scanning following a chromatographic separation. The procedures in this chapter are written with an eye toward applying all techniques in a nontargeted mode, even the ones considered to be inherently targeted, thereby facilitating detection of a suspect adulterant even in the absence of a matching reference compound.

It is generally recommended to apply a broadly nontargeted methodology first, followed by a targeted procedure. It is crucial to clearly define the end-purpose of analysis, and only then decide on the appropriate instrumentation and assemble a logical testing strategy from the procedures provided. Thus, application of a nontargeted screening method may satisfy the requirements of a manufacturer for the purposes of monitoring bulk raw materials. Conversely, a laboratory requiring a higher level of evidence to enact an enforcement action may opt for a two-step procedure: a preliminary screen, followed by confirmatory analysis of suspect samples.

USP Reference Standards recommended for screening are listed at the end of each relevant *Appendix*. However, considering the rate of propagation of structural analogues and proliferation of newly developed "designer" molecules, establishing and maintaining an all-inclusive catalog of reference materials is both challenging and impractical. Several commercial sources of the compounds of interest exist.[2] Please note that mention of the external reference materials suppliers does not in any way constitute their endorsement, as neither does the listing of reagents, supplies, and instrumentation.

## APPENDIX

- **Appendix A. Screening Methodologies for PDE5 Inhibitors**

### 1. HPLC with Photodiode Array Detection

**Solution A:** 0.1% Formic acid in water
**Solution B:** 0.1% Formic acid in acetonitrile
**Mobile phase:** See *Table 1*.

**Table 1**

| Time (min) | Solution A (%) | Solution B (%) |
|---|---|---|
| 0 | 95 | 5 |
| 15 | 5 | 95 |
| 23 | 5 | 95 |
| 24 | 95 | 5 |
| 31 | 95 | 5 |

**Diluent:** Acetonitrile and water (50:50)
**Standard solution:** 100 µg/mL each of USP Sildenafil Citrate RS, USP Tadalafil RS, and USP Vardenafil Hydrochloride RS in *Diluent*
**Sample solution:** Combine one-fifth of the dosage unit, 10–20 mg of bulk material, or a small fragment of the capsule shell (3 mm × 3 mm) with 10 mL of *Diluent*, sonicate for 30 min, and pass through a 0.2-µm PTFE syringe filter.
**Chromatographic system**
(See *Chromatography* ⟨621⟩, *System Suitability*.)
**Mode:** LC
**Detector:** Photodiode array, 200–400 nm
**Analytical wavelength:** 290 nm
**Column:** 2.1-mm × 15-cm; 5-µm packing L1[3]
**Column temperature:** 40°
**Flow rate:** 0.2 mL/min
**Injection volume:** 1 µL
**System suitability**
**Sample:** *Standard solution*
**Suitability requirements**
**Column efficiency:** NLT 3000 theoretical plates
**Tailing factor:** NMT 1.5
**Analysis**
**Sample:** *Sample solution*
Examine the UV spectra of the prominent peaks for similarity to those in the *Standard solution* or other known PDE5 inhibitor compounds (*Figure 1* and *Table 5*). Typical retention times of several PDE5 inhibitors are provided in *Table 5*. However, neither retention time match nor the absorbance spectrum similarity should be construed as sufficient confirmation of the chemical identity of an adulterant.

[2] CacheSyn (http://www.cachesyn.com/); Santa Cruz Biotechnology, Inc. (http://www.scbt.com); TLC Pharmachem (http://www.tlcpharmachem.com/); and Toronto Research Chemicals (http://www.trc-canada.com/) are some of the potential sources of rare and hard-to-find adulterant reference materials.
[3] The procedure was developed on the Agilent Technologies Zorbax SB-C18 column.

**2. HPLC with Mass-Spectrometric Detection**

Preferably, a mass-spectrometric detector is connected in sequence to the UV-Vis detector. The settings below apply to an ion-trap mass spectrometer. Other MS detectors are suitable; however, it is advisable to use spectrometers that possess MS/MS capability.

**Solution A:** 0.1% Formic acid in water

**Solution B:** 0.1% Formic acid in acetonitrile

**Mobile phase:** See *Table 2*.

**Table 2**

| Time (min) | Solution A (%) | Solution B (%) |
|---|---|---|
| 0 | 95 | 5 |
| 15 | 5 | 95 |
| 23 | 5 | 95 |
| 24 | 95 | 5 |
| 31 | 95 | 5 |

**Diluent:** Acetonitrile and water (50:50)

**Standard solution:** 5 µg/mL each of USP Sildenafil Citrate RS, USP Tadalafil RS, and USP Vardenafil Hydrochloride RS in *Diluent*

**Sample solution:** Combine one-fifth portion of the dosage unit, 10–20 mg of bulk material, or a small fragment of the capsule shell (3 mm × 3 mm) with 10 mL of *Diluent*, sonicate for 30 min, and pass through the 0.2-µm PTFE syringe filter. Dilute the filtrate 20-fold with *Diluent* before injection.

**Chromatographic system**

(See *Chromatography* ⟨621⟩, *System Suitability*.)

**Mode:** LC

**Detector:** UV 290 nm

**Column:** 2.1-mm × 15-cm; 5-µm packing L1[4]

**Column temperature:** 40°

**Flow rate:** 0.2 mL/min

**Injection volume:** 1 µL

**Mass spectrometric system**[5]

(See *Mass Spectrometry* ⟨736⟩.)

**Ionization:** ESI

**Polarity:** Positive or negative

**Sheath gas:** 35 mL/min

**Sweep gas:** 5 mL/min

**Capillary temperature:** 300°

**Source voltage:** 5 kV

**Collision:** 45 meV

**Scanning:** *m/z* 90–1050 and dependent scan on the most intense ion

**System suitability**

**Sample:** *Standard solution*

**Suitability requirements**

**Resolution:** NLT 2.0 between vardenafil and sildenafil peaks

**Tailing factor:** NMT 1.5

**Analysis**

**Sample:** *Sample solution*

Compare mass-to-charge ratios of the molecular ions $[M+H]^+$ or $[M-H]^-$ and fragments to those of the *Standard solution* or other known analytes listed in *Table 4*. Typical retention times of several common PDE5 inhibitors are provided in *Table 5*.

**3. High Performance Thin-Layer Chromatography (HPTLC) with Visual, UV, and/or MS Detection**

**Standard solution:** A composite of 0.2-mg/mL each of USP Sildenafil Citrate RS, USP Tadalafil RS, and USP Vardenafil Hydrochloride RS in methanol, with sonication if necessary. Additional reference materials may be available commercially.

**Sample solution:** Comminute 1 dosage unit, including the capsule shell and tablet coating, or about 500 mg of raw material; combine with 10 mL of methanol, and subject to ultrasonication for 30 min. Centrifuge or filter the solution, and use the supernatant. [NOTE—Upon development, if the chromatographic bands appear too saturated and UV densitometric spectra are distorted, dilute the *Sample solution* 10-fold with methanol.]

**Developing solvent system:** *tert*-Butyl methyl ether, methanol, and 28.0% (w/w) ammonium hydroxide (20:2:1). [NOTE—Strength of ammonium hydroxide was found to be crucial for adequate method performance. It is therefore

[4] The procedure was developed on the Agilent Technologies Zorbax SB-C18 column.

[5] The settings were found appropriate for ThermoElectron LTQ XL Linear Ion Trap Mass Spectrometer. Users will need to optimize their respective instrumentation according to the manufacturer's recommendations.

advisable to establish the titer of higher-concentration ammonia[6] and to adjust the latter to exactly 28.0% immediately before the experiment.]

**Chromatographic system**

(See *HPTLC for Articles of Botanical Origin* ⟨203⟩.)

**Adsorbent:** Chromatographic silica gel with an average particle size of 5 µm

**Application volume:** 3 µL, as 8-mm bands

**Relative humidity:** Condition the plate to a relative humidity of 47% using a suitable device in the presence of a saturated solution of potassium isothiocyanate.

**Temperature:** Ambient

**Saturation:** 20 min, with paper

**Developing distance:** 6 cm

**Derivatization reagent:** None

**Drying:** 5 min in a current of cold air

**Detection 1:** Visual, under illumination with 254- and 365-nm UV light

**Detection 2:** UV-Vis spectrometry (scanning densitometer), 190–550 nm

**Detection 3:** Mass spectrometry, *m/z* 90–1050

**Mass spectrometric system**[7]

(See *Mass Spectrometry* ⟨736⟩.)

**Ionization:** ESI

**Polarity:** Positive, negative, or rapid switching

**Desolvation gas ($N_2$):** 300 L/h

**Cone gas ($N_2$):** 80 L/h

**Temperatures**

**ESI probe:** 105°

**Desolvation:** 150°

**Capillary voltage:** 3.0 kV

**Cone voltage:** 50 V

**Scanning:** *m/z* 90–1050

**System suitability**

**Sample:** *Standard solution*

**Suitability requirements:** Under UV light at 254 nm, sildenafil, tadalafil, and vardenafil appear as dark bands against the fluorescent background. Under UV light at 365 nm, sildenafil, tadalafil, and vardenafil appear as blue fluorescent bands.

**Analysis:** Inspect the plate under short-wave (254 nm) and long-wave (365 nm) UV light. PDE5 inhibitors appear as dark bands against the fluorescent background at 254 nm and typically exhibit different shades of blue fluorescence under 365 nm. Note the similarities in $R_F$ values between the bands in the *Standard solution* and *Sample solution*; these may be informative, however they do not constitute sufficient proof of identity. Relative intensities of the bands permit approximation of the amounts. Using scanning densitometry, obtain UV spectra of the prominent bands in the *Sample solution*, and compare them to those of the PDE5 inhibitors in the *Standard solution* and those provided in *Table 5* and *Figure 1*. Mass-spectrometric interface, if available, may facilitate more definitive assignment of the analyte bands: compare mass-to-charge ratios of the molecular ions $[M+H]^+$ or $[M-H]^-$ and fragments to those of the common adulterants listed in *Table 4*.

**4. Ambient Ionization Mass Spectrometry**

**Diluent:** Acetonitrile and water (50:50), with 0.1% formic acid

**Standard solution:** A composite solution containing 20 µg/mL each of USP Sildenafil Citrate RS, USP Tadalafil RS, and USP Vardenafil Hydrochloride RS in *Diluent*. Additional reference materials may be available commercially.

**Sample solution:** Grind the entire dosage form, including the capsule shell and tablet coating, to a fine powder. Weigh about 50 mg of the resulting powder, or about 50 mg of bulk material, and combine with 5 mL of *Diluent*. Cap tightly, subject to ultrasonication for 2 min, and vortex thoroughly. Centrifuge or filter the resulting solution, and dilute an aliquot of the supernatant or filtrate 100-fold with *Diluent*.

**Mass spectrometric system**

(See *Applications of Mass Spectrometry* ⟨1736⟩*, Mass Spectrometers, Ionization Procedures, Ambient Ionization Procedures*.)

**Ionization:** Ambient with thermal desorption

**Mode:** Thermal profile

**Polarity:** Positive, negative, or rapid switching

**Gas temperature:** 150°, 250°, 350°, and 450°

**Scanning:** *m/z* 90–1050

**System suitability:** Deposit 3-µL aliquots of the *Standard solution* onto the disposable sample cards. Set the compatible mass spectrometer to a 30-s acquisition of 90–1050 Da. Using one sample card for each temperature setting, acquire mass spectra at each of the following desorption gas temperatures: 150°, 250°, 350°, and 450° in positive ionization mode. Switch polarity, and re-acquire spectra at the same four temperatures in the negative ionization mode. [NOTE—If the mass spectrometer permits rapid polarity switching, both positive and negative spectra may be acquired

[6] 32% Ammonia solution is available from EMD Millipore.

[7] Procedure was developed using Expression CMS mass spectrometer from Advion, equipped with a TLC-MS interface available from CAMAG. If other mass spectrometers are used, relevant settings will have to be optimized. The bands were directly eluted with a mixture of water and acetonitrile (80:20) containing 0.1% formic acid.

@2024 USPC

simultaneously using a single sample.] Confirm that the $[M+H]^+$ or $[M-H]^-$ ions of sildenafil, tadalafil, and vardenafil are observed as listed in *Table 4*.

**Analysis:** Deposit 3-µL aliquots of the *Sample solution* onto the disposable sample cards, and follow the procedure outlined above for the *Standard solution*. In the event that a single ion dominates the mass spectrum at every temperature setting, dilute the *Sample solutions* 10-fold with *Diluent* and re-analyze. Compare mass-to-charge ratios of the molecular ions $[M+H]^+$ or $[M-H]^-$ and fragments to those of the known analytes listed in *Table 4*.

**5. NMR Spectroscopy–Low-Field and High-Field**

(See *Nuclear Magnetic Resonance Spectroscopy* ⟨761⟩*, Qualitative and Quantitative NMR Analysis*.) [NOTE—Deuterated acetonitrile ($CD_3CN$) should be NLT 99.8 atom % D, and should contain 0.05% tetramethylsilane (TMS) as a chemical shift reference. Use of solvents in sealed ampules is recommended. NMR tubes should be suitable for use at the selected magnetic field strength.]

**Standard solutions:** Dissolve 10 mg of USP Sildenafil Citrate RS, USP Tadalafil RS, or USP Vardenafil Hydrochloride RS in separate 1-mL aliquots of $CD_3CN$, and transfer 700-µL aliquots of the resulting solutions into individual NMR tubes. Additional reference materials are available commercially.

**Sample solution:** Grind the entire dosage form, including the capsule shell and tablet coating, to a fine powder. Transfer 100–200 mg of the ground material, or an equivalent amount of bulk raw material powder, into a 5-mL sealable glass vial. Add 1 mL of $CD_3CN$, vortex thoroughly, and allow the solids to settle. Transfer about 700 µL of the supernatant to an NMR tube, taking care to minimize transfer of solids.

**Instrument performance qualification**

(See *Nuclear Magnetic Resonance Spectroscopy* ⟨761⟩.)

**Magnetic field strength:** NLT 42.5 MHz ($^1H$ operating frequency)

**Data collection:** Use the parameters specified in *Table 3*; perform 90° pulse width calibration before the analysis according to the recommendations of the equipment manufacturer.

**Table 3**

| Parameter | $^1H$-NMR Qualitative Measurement |
|---|---|
| Pulse program | Single pulse $^1H$ |
| Spectral width | 14 ppm (–1 to 13 ppm) |
| Transmitter offset | Center of spectral width |
| Relaxation delay | 5–10 s |
| Acquisition time | 2–5 s |
| Number of data points per FID[a] | NLT 16,000 |
| Temperature | 25° |

[a] Free induction decay.

**System suitability:** Acquire a $^1H$ spectrum of the *Standard solution* using the settings outlined in *Data collection*. Record a sufficient number of scans to ensure that signal-to-noise ratio of the TMS signal is NLT 10.

**Analysis:** Acquire a $^1H$ spectrum of the *Sample solution* under the conditions outlined in *Data collection*. Record a sufficient number of scans to ensure that the signal-to-noise ratio of the TMS signal is NLT 10. Reference all acquired spectra to the $^1H$ signal of TMS (0 ppm). Measure and record the chemical shift and multiplicity of the NMR signals in the spectra of the *Standard solutions* and *Sample solution*. Compare the $^1H$ NMR spectrum of the *Sample solution* to those of the *Standard solutions*, paying particular attention to the aromatic region (5–9 ppm). Determine whether the chemical shift and multiplicity of the NMR signals in the *Sample solution* exhibit sufficient similarity to those found in the *Standard solutions*.

**6. Bioassay**[8]

**PDE5 enzyme**[9] **stock solution:** Prepare a concentration of approximately 3000 Units/µL. If necessary, dilute with 40 mM tris(hydroxymethyl)aminomethane hydrochloride (tris-HCl), pH 8.0, 110 mM sodium chloride (NaCl), 2.2 mM potassium chloride (KCl), 3 mM dithiothreitol, and 20% glycerin. Vortex gently to mix.

**PDE5 working solution** (100 Units per 6.5 µL)**:** Combine 400 µL of PDE-Glo™ Reaction Buffer 5X, 10 µL of *PDE5 enzyme stock solution*, and 1590 µL of water. Vortex gently to mix.

**cGMP solution:** Combine 400 µL of PDE-Glo™ Reaction Buffer 5X, 40 µL of 1-mM cGMP stock solution, and 1560 µL of water. Mix thoroughly by vortexing.

**100-mM IBMX stock solution in DMSO:** Prepare a 22.2-mg/mL solution of 3-isobutyl-1-methylxanthine (IBMX) in dimethylsulfoxide (DMSO), e.g., dissolve 100 mg of IBMX in 4.5 mL of DMSO. Mix thoroughly by vortexing.

**Reaction buffer:** Combine 400 µL of PDE-Glo™ Reaction Buffer 5X and 1600 µL of water. Mix thoroughly by vortexing.

**Reaction buffer with 4% DMSO:** Combine 400 µL of PDE-Glo™ Reaction Buffer 5X, 80 µL of DMSO and 1520 µL of water. Mix thoroughly by vortexing.

[8] The procedures were developed using commercial Promega PDE-Glo™ Phosphodiesterase Assay Kit, Catalog # V1361. It includes the following reagents: PDE-Glo™ Reaction Buffer 5X (Catalog # V133A); PDE-Glo™ Detection Buffer 5X (Catalog # V134A); Protein Kinase A Solution (Catalog # V135A); PDE-Glo™ Termination Buffer 5X (Catalog # V136A); cGMP Stock Solution, 1 mM (Catalog # V641A); cAMP, 1 mM (Catalog # V642B); Kinase-Glo™ Substrate (Catalog # V672A); and Kinase-Glo™ Buffer (Catalog # V673A). Kits from alternative suppliers may also be used, e.g., BPS Science, Catalog # 60350, although re-optimization of test procedures will be required.

[9] The procedures were developed using human phosphodiesterase 5A from BPS Bioscience Catalog # 60050. The enzyme is available from numerous suppliers, e.g., Sigma-Aldrich Catalog # E9034.

@2024 USPC

**Termination buffer:** Combine 400 µL of PDE-Glo™ Termination Buffer 5X, 40 µL of *100-mM IBMX stock solution in DMSO*, and 1560 µL of water. Mix thoroughly by vortexing.

**Detection buffer:** Combine 400 µL of PDE-Glo™ Detection Buffer 5X, 16 µL of Protein Kinase A Solution, and 1584 µL of water. Vortex gently to mix.

**Kinase-Glo™ reagent:** Add 10 mL of Kinase-Glo™ Buffer to the vial of Kinase-Glo™ Substrate, and vortex gently.

**Standard solution** (400 nM)**:** Dissolve 5 mg of USP Sildenafil Citrate RS in 3.0 mL of DMSO to obtain a 2.5-mM stock solution. Combine a 10-µL aliquot of the resulting solution with 240 µL of DMSO, and mix thoroughly (100 µM). Combine a 10-µL aliquot of the resulting solution with 90 µL of DMSO, and mix thoroughly (10 µM). Combine a 10-µL aliquot of the resulting solution with 240 µL of *Reaction buffer*, and mix thoroughly (400 nM); the last dilution is the *Standard solution*.

**Control solution:** Combine 10 µL of DMSO with 240 µL of *Reaction buffer*, and mix thoroughly by vortexing.

**Sample solution:** Grind the entire dosage form, including the capsule shell and tablet coating, to a fine powder. Transfer 100 mg of the ground material into a 5-mL polypropylene vial. Add 3.0 mL of DMSO, and vortex for 60 s. Allow solids to settle, combine 50 µL of the clear supernatant with 200 µL of DMSO, and mix thoroughly by vortexing. Combine a 10-µL aliquot of the resulting solution with 90 µL of DMSO, and mix thoroughly by vortexing. Combine a 10-µL aliquot of the resulting solution with 240 µL of *Reaction buffer*, and mix thoroughly by vortexing; the last dilution is the *Sample solution*.

**Analysis**

1. Dispense 12.5-µL aliquots of the *Standard solution*, *Control solution*, and *Sample solution* into microplate wells, in triplicate. Use a white, flat-bottom, opaque polystyrene, nontreated, 96-well microtiter plate.[10] [NOTE—Do not use treated plates, black plates, or clear plates.]
2. Add 6.5 µL of *PDE5 working solution* to each well. Incubate for 5 min.
3. Add 6.0 µL of *cGMP solution* to effect a 5-µM cGMP concentration in a 25-µL volume. Incubate for 30 min.
4. Add 12.5 µL of *Termination buffer*. Incubate for 5 min.
5. Add 12.5 µL of *Detection buffer*. Incubate for 20 min.
6. Add 50 µL of *Kinase-Glo™ reagent*. Incubate for 10 min.
7. Record luminescence at 560 nm with a microplate luminometer at 0.5 s/well.

[NOTE—Incubate the plate at room temperature, preferably using a plate shaker.]

Calculate average luminescence values for the replicate preparations. Assess the degree of PDE5 inhibition in the *Sample solution* relative to that observed in the *Standard solution* and *Control solution*. Inhibition of PDE5 is manifested as reduction of luminescence: the samples that exhibit suppression of luminescent output comparable to or in excess of that observed with the *Standard solution* are likely adulterated with synthetic PDE5 inhibitors.

- **USP REFERENCE STANDARDS** ⟨11⟩

USP Sildenafil Citrate RS

# 1. GENERAL PROVISIONS

This general information chapter provides recommended minimum good manufacturing practices for the methods to be used in and the facilities and manufacturing controls to be used for the manufacture, holding, packaging, labeling, and distribution of dietary ingredients. These principles are set forth to assist manufacturers as well as auditors in establishing whether the facilities and controls used for the manufacture of dietary ingredients are adequate and whether the dietary ingredients possess the identity, strength, and meet the quality and purity characteristics that they purport to possess.

The requirements pertaining to dietary ingredients apply to determining whether or not a dietary ingredient is adulterated within the meaning of §402(a)(3) of the US Federal Food, Drug, and Cosmetic Act (FD&C Act) in that the dietary ingredient has been manufactured under such conditions that is unfit for food; or §402(a)(4) of the FD&C Act in that the food has been prepared, packed, or held under insanitary conditions whereby it may have become contaminated with filth, or whereby it may have been rendered injurious to health; and in violation of §361 of the Public Health Service Act (42 USC §264). The operation of a facility that manufactures, processes, packs, or holds food for sale in the United States if the owner, operator, or agent in charge of such facility is required to comply with, and is not in compliance with, §418 of the FD&C Act or Subpart C, D, E, or F of this part is a prohibited act under §301(UU) of the FD&C Act.

A production and in-process control system must be designed and implemented to cover all stages of manufacturing, packaging, labeling, holding, and distribution of the dietary ingredient and that is designed to ensure quality as specified in the batch production, packaging control record, and dietary ingredient specification.

An overall scheme of quality systems adopted in the chapter consists of the following:

1. *Quality management system*—This system assures overall compliance with current good manufacturing practices (cGMPs) and internal procedures and specifications. This system includes the quality control (QC) unit and all of its review and approval duties (e.g., change control, deviations and material reviews, batch release, product quality review, validation protocols, and reports, etc.). It also includes Hazard Analysis and Risk-Based Preventive Controls (HARPC) or the Hazard Analysis Critical Control Points (HACCP) which details the food safety plan (FSP), food allergen controls, sanitation controls, supply-chain program, and HARPC implementation records. The quality management system must define the quality unit's obligations and authorities to ensure that all material use and disposition decisions are independent of any conflict of interest.
2. *Physical plant and equipment system*—This system includes the measures and activities that provide an appropriate physical environment and resources used in the manufacture of dietary ingredients. It includes buildings and facilities along with maintenance, equipment qualifications, calibration and preventative maintenance, computerized systems, and utilities that are not intended to be incorporated into the product such as water systems.
3. *Materials management system*—This system includes measures and activities to control dietary ingredients including specifications and determining compliance with specifications. It also includes the procedures and process for receiving and release of materials and collecting representative and reserve samples along with storage, distribution controls, and records. The materials management system also includes electronic systems that are used to quarantine and control the movement of physical inventory to ensure that only approved and released materials are allocated to a production order.
4. *Production operations and controls system*—This system includes measures and activities to control the manufacture of dietary ingredients, including batch and continuous production and control records, production and process controls, and operation and control documentation. This system also includes an evaluation of automatic electronic weighing and control systems that are designed to minimize the potential for errors in production.
5. *Packaging and labeling operations and controls system*—This system includes measures and activities that control the packaging and labeling of dietary ingredients. It includes written procedures, label examination and usage, on-site label printing, label storage and issuance, packaging and labeling operations controls, and validation of these operations.
6. *Laboratory control system*—This system includes measures and activities related to laboratory procedures, testing, analytical methods development and validation or verification, and the stability program.

# 2. QUALITY MANAGEMENT

## 2.1 General Principles

Quality unit operations must be implemented in manufacturing, packaging, labeling, laboratory, and holding operations for producing the dietary ingredients to ensure the quality of the dietary ingredient and that the dietary ingredient is packaged and labeled as specified in the master manufacturing and packaging control record.

Quality should be the responsibility of all persons involved in manufacturing, testing, packaging, labeling, and holding dietary ingredients. An effective system for managing quality that involves the active participation of management and appropriate manufacturing personnel must be established, documented, and followed. Management oversight of quality should encompass the organizational structure, procedures, processes, resources, and activities necessary to ensure that the dietary ingredient will meet its intended specifications for quality. All quality-related activities must be defined and documented.

There must be a quality unit(s) that is independent of production and that fulfills both quality assurance (QA) and QC responsibilities. This can be in the form of separate QA and QC units or a single individual or group, depending on the size and structure of the organization.

All quality- and manufacturing-related activities must be recorded and reviewed contemporaneously, and then signed and dated.

https://pharmacopeia.cn/v-cn/

## 2.2 Organization and Personnel

### 2.2.1 GENERAL

The owner, operator, or facility in charge and the management of the establishment must take reasonable measures and precautions to ensure all individuals who manufacture, process, pack, or hold dietary ingredients are qualified to perform their assigned duties.

Written procedures must be established and followed for creating and maintaining job position descriptions, listing job responsibilities and required qualifications for education, training and experience. There must be an organizational chart clearly delineating the structure of the organization and the relationships and relative ranks of its parts and job positions.

### 2.2.2 RESPONSIBILITIES OF THE QUALITY UNIT

A quality unit must be established that is involved in all quality-related matters and that must review and approve all appropriate quality-related documents. Quality unit personnel must ensure that manufacturing, packaging, labeling, and holding operations ensure the quality of the dietary ingredient and that the dietary ingredient is packaged and labeled as specified in the master production and control record.

The primary responsibilities of the independent quality unit(s) should not be delegated and these responsibilities must be described in writing. The quality unit(s) must have the primary responsibility and authority for the following:

- Establishing the HARPC and FSP
- Approving or rejecting (i.e., making a disposition decision for) the release of all dietary ingredients for distribution or of in-process materials for use outside the control of the manufacturer
- Establishing a system to approve or reject the release of raw materials, other ingredients, in-process materials, packaging materials, labeling materials, and the finished dietary ingredient
- Reviewing and approving or rejecting the release of products manufactured, packaged, labeled, or held under contract by another company
- Reviewing and approving all specifications and master production, packaging, and labeling records
- Reviewing and approving all procedures affecting the quality of in-process materials and dietary ingredients
- Reviewing completed production records to ensure that no errors have occurred or, if errors have occurred, that they have been investigated and resolved
- Ensuring that all deviations are properly documented and that deviations are investigated and resolved
- Ensuring that corrective and preventive actions as a result of investigations (deviations or complaints) and internal audits are implemented in a timely manner
- Ensuring that internal audits (self-inspections) are performed
- Establishing a supply chain control system to evaluate and approve suppliers of raw materials, other ingredients, packaging materials and labeling, and suppliers of manufacturing and laboratory services (i.e., contract manufacturers and contract laboratories)
- Establishing a system to evaluate and approve changes that potentially impact the quality of dietary ingredients
- Reviewing and approving test method validation protocols and reports
- Establishing a system to handle complaints and ensure that quality-related complaints are investigated and resolved
- Establishing effective systems for maintaining and calibrating equipment and instruments
- Ensuring that materials are properly tested and the results are reported
- Ensuring that there is stability data to support the retest or expiry date and labeled storage conditions of dietary ingredients
- Performing product quality reviews and trend analysis, as needed

The QC unit (i.e., QC laboratory) must have the responsibility for approving or rejecting all laboratory processes, procedures, specifications, controls, tests, examinations, and deviations from or modifications to them that may affect the identity, strength, quality, and purity of the dietary ingredient. All responsibilities and procedures applicable to the QC unit must be in writing.

The quality unit personnel must be identified and qualified to perform QA and/or QC operations and have responsibilities related to performing quality unit operations distinct and separate from responsibilities that person otherwise has when not performing such operations.

The designated QC personnel who conducts a material review and makes the disposition decision must, at the time of performance, document any material review and disposition decisions.

### 2.2.3 RESPONSIBILITIES OF THE PREVENTIVE CONTROLS-QUALIFIED INDIVIDUAL AND QUALIFIED AUDITOR

One or more preventive controls-qualified individuals must do or oversee the following:

- Preparing the HARPC and FSP
- Validating the preventive controls
- Writing justification for validation to be performed in a time frame that exceeds the first 90 calendar days of production of the applicable dietary ingredient
- Determining that validation is not required with written justification
- Reviewing records
- Writing justification for review of records of monitoring and corrective actions within a time frame that exceeds 7 working days
- Re-analyzing the FSP

Official

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:38:53 AM(EST)
Printed by: USP NF
Do Not Distribute

- Determining that re-analysis can be completed, and additional preventive controls validated as appropriate to the nature of the preventive control and its role in the facility's food safety system, in a time frame that exceeds the first 90 calendar days of production of the applicable dietary ingredient

To be a preventive controls-qualified individual, the individual must have successfully completed training in the development and application of risk-based preventive controls at least equivalent to that received under a standardized curriculum recognized as adequate by the FDA or be otherwise qualified through job experience to develop and apply a food safety system. Job experience may qualify an individual to perform these functions if that experience has provided knowledge at least equivalent to that provided through the standardized curriculum. The preventative controls-qualified individual may be, but is not required to be, an employee of the facility.

A qualified auditor must conduct an on-site audit. To be a qualified auditor, a qualified individual must have technical expertise obtained through education, training, or experience (or a combination thereof) necessary to perform the auditing function.

All applicable training in the development and application of risk-based preventive controls must be documented in records, including the date of the training, the type of training, and the person(s) trained.

### 2.2.4 RESPONSIBILITIES FOR PRODUCTION OPERATIONS

The responsibilities for production operations must be documented in writing and should include the following:

- Preparing, reviewing, approving and distributing the instructions for the production of in-process materials and dietary ingredients according to written procedures
- Reviewing all production batch records and ensuring that they are completed and signed
- Ensuring that production facilities are clean and sanitized, if needed
- Ensuring that HVAC, dust collection, and other systems are appropriately designed to minimize the potential for cross-contamination
- Ensuring that physical and spatial separation are used in combination to minimize the potential for cross-contamination and to prevent mix-ups, when appropriate
- Ensuring that the premises and equipment are maintained and records are kept
- Ensuring that manufacturing process validation protocols and reports are reviewed and approved
- Evaluating proposed changes in product, process, or equipment
- Ensuring that new and any modified facilities and equipment are qualified through an appropriate documented change control system

### 2.2.5 PERSONNEL QUALIFICATIONS

Each person engaged in the manufacture of dietary ingredients (including temporary and seasonal personnel) or in the supervision thereof must be a qualified individual having the proper education, training, and experience (or any combination thereof) needed to perform the assigned functions.

Responsibility for ensuring compliance by individuals with the requirements of this general information chapter must be clearly assigned to supervisory personnel. Each person responsible for supervising the manufacture of dietary ingredients must have the proper education, training, and experience (or any combination thereof) to perform assigned functions in such a manner as to provide assurance that the dietary ingredient has the safety, identity, strength, quality, and purity that it is represented to possess.

An adequate number of qualified personnel to perform and supervise the manufacture of dietary ingredients should be provided.

Personnel qualifications apply equally to contractors, consultants, and temporary employees. Records should be maintained stating the name, address, qualifications, and type of service provided by contractors and consultants.

### 2.2.6 TRAINING

Training should be regularly conducted by qualified persons and should cover, at minimum, the particular operation(s) that the employee performs and cGMPs as it relates to the employee's functions. Training must also cover the principles of food hygiene and food safety, including the importance of employee health and personal hygiene, and, as appropriate to the dietary ingredient, the facility and the employee's assigned duties.

Training requirements should be specified (e.g., read and understand documents, instruction with trainer, on-the-job training). Training effectiveness should be periodically assessed. Training programs including on the job training should be re-assessed. Appropriate documentation of any training must be retained by the company, including the date of the training, the type of training, the name of trainer if applicable, the person trained, and any assessment results (e.g., test results).

### 2.2.7 PERSONNEL RESPONSIBILITIES

The company management must take all reasonable measures and precautions to ensure the prevention of microbial contamination and to maintain hygienic practices.

**2.2.7.1 Preventing microbial contamination:** Any person who, by medical examination, by the person's acknowledgment, or by supervisory observation, is shown to have, or appears to have, an illness, infection, or open lesion, or has been exposed to communicable disease or any other abnormal source of microbial contamination that could result in microbial contamination of raw materials, other ingredients, in-process materials, dietary ingredients, or contact surfaces, must be excluded from working in any operations that may result in such contamination until the health concern no longer exists or unless conditions such as

@2024 USPC

open lesions, boils, and infected wounds are adequately covered (e.g., by an impermeable cover). Personnel must be instructed to report such health conditions to their supervisors.

**2.2.7.2 Hygienic practices:** All persons working in an operation in direct contact with raw materials, other ingredients, in-process materials, dietary ingredients, or food-contact surfaces must conform to hygienic practices to the extent necessary to protect against allergen cross-contact, microbial contamination, and other types of contamination of the dietary ingredient. These practices include the following:

- Wearing outer garments in a manner that protects against the contamination of raw materials, other ingredients, in-process materials, or dietary ingredients, or any food-contact surfaces
- Maintaining adequate personal cleanliness
- Removing cosmetics from parts of the body that may contact raw materials, other ingredients, in-process materials, dietary ingredients, or food-contact surfaces during performances of their duties
- Washing hands thoroughly (and sanitizing, if necessary, to protect against contamination with undesirable microorganisms) in an adequate hand-washing facility before starting work, as well as at any other time when the hands may have become soiled or contaminated
- Removing all unsecured jewelry and other objects that might fall into raw materials, other ingredients, in-process materials, dietary ingredients, equipment, or packaging materials, and removing hand jewelry that cannot be adequately sanitized during periods in which raw materials, other ingredients, in-process materials, or dietary ingredients are manipulated by hand. If hand jewelry and cosmetics cannot be removed, they must be covered by material that is maintained in an intact, clean, and sanitary condition, and that effectively protects against contamination of raw materials, other ingredients, in-process materials, dietary ingredients, or food-contact surfaces
- Maintaining gloves used in handling raw materials, other ingredients, in-process materials, or dietary ingredients in an intact, clean, and sanitary condition; the gloves must be of impermeable material if bare hands or gloves have the potential to come in contact with these materials during the performances of a person's duties
- Wearing hair nets, caps, beard covers, or other hair restraints when appropriate, such as when the raw material, in-process material, or ingredient is exposed, and in an effective manner
- Storing clothing or other personal belongings in areas separate from where raw materials, other ingredients, in-process materials, dietary ingredients, or any food-contact surface are exposed or where food-contact surfaces are washed
- Not eating food, chewing gum, drinking beverages, taking personal medication, or using tobacco products in areas where raw materials, other ingredients, in-process materials, dietary ingredients, or food-contact surfaces are exposed or where food-contact surfaces are washed
- Taking any other precautions necessary to protect against allergen cross-contact and contamination of raw materials, other ingredients, in-process materials, dietary ingredients, or food-contact surfaces with microorganisms, allergens, filth, foreign substances, or other extraneous materials, including perspiration, hair, cosmetics, tobacco, chemicals, and medicines applied to the skin. These precautions may include restricting individuals working in unit operations with known allergens from moving to non-allergen production areas, and/or color-coding of in-process allergen containing materials to differentiate them from non-allergen containing materials

## 2.3 Documentation and Records

### 2.3.1 GENERAL

Documentation can be viewed as the foundation of all quality systems, because clear, complete, and accurate records are essential to all operations and procedures. A guiding cGMP principle is that if it is not written down, it is not done. *Good Documentation Guidelines* ⟨1029⟩, which provides guidelines on good documentation practices for cGMP-regulated industries, should be followed.

All documents related to the manufacture of dietary ingredients must be initiated, prepared, reviewed, approved, distributed, and archived according to written procedures. Such documents can be in paper or electronic form.

When entries are made in records, these must be made legibly and indelibly in spaces provided for such entries, directly after performing the activities. Entries should identify the person making the entry, as well as the day and time when the entry was made. All dates must include the day, month, and year in a consistent and unambiguous format such as establishing a date format (e.g., DD-MM-YYYY) or spelling out the month. Numerical results must have appropriate numerical units, and calculations must be made with appropriate rounding and significant figures. Corrections to entries must be dated and signed and leave the original entry still legible. If the reason for the correction is not obvious (e.g., date transcription error), then a statement should be made to provide clarity for the correction.

### 2.3.2 CONTROL OF DOCUMENTATION

The issuance, revision, superseding, and withdrawal of all documents must be controlled by the maintenance of revision histories. A procedure should be established for retaining all appropriate documentation (e.g., procedures and records). There should be proper control over the following:

- Forms: content, revision, review
- Spreadsheets: spreadsheet for specific project (accuracy checked by reviewer), spreadsheet for routine use (validated, access/revision controlled)
- External documents: proprietary documents, guidance documents issued by outside agency
- Uncontrolled documents
- "For reference only" documents

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

- Employee notes and memos

A formal documentation filing system (paper and electronic) should be established with appropriate security, and documentation should be readily retrievable.

#### 2.3.3 RECORDS RETENTION

The retention periods for these documents must be specified. Written records must be kept, at minimum, for 1 year past the retest or expiry date of the dietary ingredient associated with those records. Records must be kept as original records, as accurately reproduced copies (e.g., photocopies, microfilm, compact disc), or as electronic copies. All electronic records must comply with 21 CFR Part 11 (*Electronic Records; Electronic Signatures*).

All records or copies of records required by this general information chapter must be readily available during the retention period for inspection by the FDA when requested. If reduction techniques such as microfilming are used, suitable reader and photocopying equipment must be made readily available to the FDA.

## 2.4 Change Control

A formal change control system must be established to evaluate all changes that may affect the production and quality of dietary ingredients. Written procedures should provide for the identification, documentation, appropriate review, and approval of changes to raw materials, other ingredients, packaging materials, labeling material specifications, analytical methods, facilities, utility systems, equipment, computer systems, production operations, and packaging and labeling operations.

Any proposals for cGMP-relevant changes should be drafted, reviewed, and approved by the appropriate manufacturing units, as well as reviewed and approved by the quality unit(s).

The potential impact of the proposed change on the quality of the dietary ingredient should be evaluated. A classification procedure may help in determining the level of testing, validation, and documentation needed to justify changes to a validated process. Changes can be classified (e.g., as minor or major) depending on the nature and extent of the changes, and the effects these changes may impart on the process. Scientific judgment should determine what additional testing and validation studies are appropriate to justify a change in a validated process. When implementing approved changes, measures should be taken to ensure that all documents affected by the change are revised.

The potential for critical changes to affect established retest or expiry dates (e.g., changes to product manufacturing process or formulation) should be evaluated. If necessary, the dietary ingredient produced by the change should be placed on an accelerated stability program and/or added to the stability monitoring program.

Dietary ingredient manufactures should require their raw material suppliers or packagers to notify them of changes from established production process controls that can affect the quality of the dietary ingredient.

## 2.5 Deviations and Material Reviews

#### 2.5.1 DEVIATIONS

Written procedures must be established and followed for documenting all deviations and for investigating deviations. Any deviation from established procedures and standards should be documented and explained. Deviations should be investigated, and the investigation and its conclusions should be documented. The investigation should extend to any and all batches of material that may have been associated with the specific failure or deviation. The quality unit must ensure that deviations are investigated and resolved.

#### 2.5.2 MATERIAL REVIEW

Written procedures must be established and followed for conducting material reviews and making disposition decisions, and for the quality unit to approve or reject any treatment or in-process adjustment of a raw material, other ingredient, in-process material that is rejected, or reprocessing of a dietary ingredient that is rejected.

Quality unit personnel must conduct all required material reviews and make all required disposition decisions. Quality unit personnel must conduct a material review and make a disposition decision if one of the following occurs:

- A specification is not met for a raw material, other ingredient, in-process material, packaging, labeling, dietary ingredient, a dietary ingredient received for packaging and labeling, or finished packaged and labeled dietary ingredient
- A batch deviates from the master production and control record, including when any step is not completed and any deviation from specifications occurs
- Any unanticipated occurrence during manufacturing operations adulterates or could lead to adulteration of the raw material, other ingredient, in-process material, dietary ingredient, or packaging, or could lead to the use of a label not specified in the master production and control record
- Calibration of an instrument or control suggests a problem may have resulted in a failure to ensure the quality of a batch or batches of a dietary ingredient
- A dietary ingredient is returned

Quality unit personnel must reject the raw material, other ingredient, in-process material, dietary ingredient, packaging, or labeling when an established specification is not met or when a deviation or unanticipated occurrence during the batch production and in-process control system results in or could lead to adulteration of the product. However, the quality unit can approve a treatment, an in-process adjustment, or a reprocessing to correct the deviation or occurrence, ensuring that the quality of the final dietary ingredient and that its packaging and labeling meets the specifications of the master production and control record.

Official

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:38:53 AM(EST)
Printed by: USP NF
Do Not Distribute
Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-May-2022
DOI Ref: 3a0hm
DocId: GUID-DE5DE10D-9550-4D57-8933-7B9B1C922698_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

The quality unit personnel and each qualified individual who provides information relevant to the material review and disposition decision and subsequent approval or rejection of the treatment, in-process adjustment, or reprocessing of the subject material must document performance of the review by signing and dating in the deviation investigation and material review report at the time of performance.

Deviation investigation and material review reports must include the following:

- Description of the specific deviation or unanticipated occurrence
- Description of the root cause investigation
- Evaluation of whether the deviation or unanticipated occurrence has resulted in or could lead to a failure to ensure the quality of the dietary ingredient or failure to package and label the dietary ingredient as specified in the master production and control record
- Identification of corrective action(s) and preventive action(s) taken with timelines
- Description of any material reviews and a scientifically valid reason for any treatment, in-process adjustment, or reprocessing so as to correct the applicable deviation or unanticipated occurrence, along with the quality unit personnel's approval signature and date when performed
- Conclusion(s), including the explanation of the final disposition decision (approval or rejection) made for the subject article
- Signatures of individual(s) who are designated to perform quality unit operations and who conducted the material review and made the disposition decision, and of each qualified individual who provides information relevant to that material review and disposition decision

Documentation of any material review and disposition decision or reference to the deviation investigation and material review report must be included in the appropriate batch production and control record.

## 2.6 Corrective and Preventative Actions

Corrective Actions and Preventative Actions (CAPA) programs are important to continuous improvement of the quality management system. The CAPA operating system is an essential governance document by which personnel plan and implement control to mitigate and control failures within the quality management systems. CAPAs may rise from many sources, including deviations, customer complaints, investigations, internal audit findings, and external audit findings.

The quality unit must establish, monitor, and maintain a CAPA program. The CAPA program should include a tracking system for deviations and nonconformities, including out-of-specification (OOS) laboratory results, and corrective and/or preventive action(s). All persons must identify deviations and nonconformities and notify management and/or the quality unit. Supervisors must determine root causes and develop and implement appropriate remedial, corrective, and/or preventive action(s). The quality unit must monitor CAPAs and manage the CAPA program to assist with adequate development, implementation, and closure of CAPAs. See *2.7.4.2 Corrective actions and correction procedures* for further details regarding corrective actions and correction procedures as they apply to the FSP.

A *Glossary* that includes CAPA terms (i.e., corrective action, preventive action, remedial (short-term) action, nonconformity, deviation, root cause) is presented at the end of the chapter.

## 2.7 Hazard Analysis and Risk-Based Preventive Controls (HARPC)

### 2.7.1 FOOD SAFETY PLAN (FSP)

The HARPC include the requirement to prepare and implement a written FSP that is overseen by one or more preventive controls-qualified individuals. The scope of HARPC/FSP includes evaluating hazards that could affect food safety; implementing preventive steps or controls to minimize or prevent hazards; monitoring the controls to ensure that they work; maintaining records of monitoring; and specifying what actions will be taken to correct problems that arise, including a recall plan for the dietary ingredient. The FDA's draft guidance *Hazard Analysis and Risk-Based Preventive Controls for Human Food: Guidance for Industry* should be consulted.

The contents of the written FSP must include the following:

- Hazard analysis
- Preventive controls
- Supply chain controls
- Recall plan
- Monitoring implementation of preventive controls
- Corrective actions and correction procedures
- Verification and validation procedures
- Associated records

### 2.7.2 HAZARD ANALYSIS

A hazard analysis must be conducted to identify and evaluate known or reasonably foreseeable hazards for each type of dietary ingredient manufactured, processed, packed, or held at the facility to determine whether there are any hazards requiring preventive control. This hazard analysis is based on experience, illness data, scientific reports, and other information.

Hazard identification must include known or reasonably foreseeable hazards, such as the following:

- Biological hazards, including microbiological hazards such as parasites, environmental pathogens, and other pathogens
- Chemical hazards, including radiological hazards, substances such as pesticides and drug residues, natural toxins, decomposition, unapproved or color additives, and food allergens

Official

https://pharmacopeia.cn/v-cn/

- Physical hazards, such as stones, glass, and metal fragments
- Hazards that may be present in the dietary ingredient for any of the following reasons:
  - The hazard occurs naturally
  - The hazard may be introduced unintentionally
  - The hazard may be introduced intentionally for the purpose of economic gain

The identified hazards must be evaluated to assess the severity of the illness or injury if the hazards were to occur and the probability that the hazard will occur in the absence of preventive controls. Hazard evaluation must include environmental pathogens whenever a dietary ingredient is exposed to the environment prior to packaging and the packaged dietary ingredient does not receive a treatment or another control measure, such as formulations with antimicrobial properties that would significantly minimize or reduce the likelihood for the presence of pathogenic microorganisms. The hazard evaluation analysis also must consider the effect of the following factors on the safety of the finished dietary ingredient for the intended consumer:

- Physical and chemical properties of the dietary ingredient (e.g., water activity, pH)
- Formulation of the dietary ingredient
- Condition, function, and design of facility and equipment
- Raw materials and other ingredients
- Transportation practices
- Manufacturing/processing procedures
- Packaging activities and labeling activities
- Storage and distribution
- Intended or reasonably foreseeable use
- Sanitation, including employee hygiene
- Any other relevant factors, such as the temporal (e.g., weather-related) nature of some hazards (e.g., levels of some natural toxins)

### 2.7.3 PREVENTIVE CONTROLS

Preventive controls must be identified and implemented to provide assurances that any hazards requiring a preventive control will be significantly minimized or prevented and the dietary ingredient manufactured, processed, packed, or held by the facility will not be adulterated or misbranded. Preventive controls must be written. Preventive controls include controls at any critical control points (CCPs) and other controls appropriate for food safety.

Preventive controls include the following, as appropriate to the facility:

- Process controls
- Food allergen controls
- Sanitation controls
- Supply-chain controls
- Recall plan

**2.7.3.1 Process controls:** These include procedures, practices, and processes to ensure the control of parameters during operations such as heat processing, acidifying, irradiating, and refrigerating foods. As appropriate to the nature of the applicable control and its role in the facility's food safety system, process controls must include parameters associated with the control of the hazard and the maximum or minimum value, or combination of values, to which any biological, chemical, or physical parameter must be controlled to significantly minimize or prevent a hazard. Where practical, dietary ingredient manufacturers should employ process analytical technologies such as electronic metal detection to mitigate the risk of hazards.

**2.7.3.2 Food allergen controls:** These include procedures, practices, and processes to control food allergens. As appropriate, food allergen controls must include those procedures, practices, and processes employed for ensuring the protection of food from allergen cross-contact, including during storage, handling, and use; and labeling the finished food, including ensuring that the finished food is not misbranded.

**2.7.3.3 Sanitation controls:** These include procedures, practices, and processes to ensure that the facility is maintained in a sanitary condition adequate to significantly minimize or prevent hazards such as environmental pathogens, biological hazards due to employee handling, and food allergen hazards. As appropriate to the facility and the dietary ingredient, sanitation controls must include procedures, practices, and processes for the cleanliness of food-contact surfaces, including food-contact surfaces of utensils and equipment, and prevention of allergen cross-contact and cross-contamination from insanitary objects, from personnel to food, food packaging material, and other food-contact surfaces, and from raw product to processed product.

**2.7.3.4 Supply-chain controls:** When dietary ingredient manufacturers who receive the raw materials and other ingredients identify a hazard that requires a supply-chain-applied control, a written risk-based supply-chain control program must be established and implemented for those raw materials and other ingredients. The supply-chain program must provide assurance that a hazard requiring a supply-chain-applied control has been significantly minimized or prevented.

If the receiving facility is an importer that is in compliance with the foreign supplier verification program requirements in 21 CFR Part 1, Subpart L, and that has documentation of verification activities conducted in 21 CFR 1.506(e) (which provides assurance that the hazards requiring a supply-chain-applied control for the raw material or other ingredient have been significantly minimized or prevented), it does not need to conduct supplier verification activities for that raw material or other ingredient.

When a supply-chain-applied control is applied by an entity other than the dietary ingredient manufacturer's supplier (e.g., a raw material or other ingredient manufacturer applies controls under different management than the supplier), the dietary ingredient manufacturer must verify the supply-chain control or obtain documentation of appropriate verification activity from the entity, review and assess the entity's applicable documentation, and document that review and assessment. For the purposes of this section, "verification" means the application of methods, procedures, tests, and other evaluations, in addition to

Official

Printed by: USP NF
Do Not Distribute

monitoring, to determine whether a control measure or combination of control measures is or has been operating as intended and to establish the validity of the FSP.

The supply-chain control program must include the following:

- Using approved suppliers and documenting that approval before receiving raw materials and other ingredients from those suppliers
  - Written procedures for receiving raw materials and other ingredients must be established and followed and must ensure that raw materials and other ingredients are received only from approved suppliers (or, when necessary and appropriate, on a temporary basis from unapproved suppliers whose raw materials and other ingredients are subjected to adequate verification activities before acceptance for use)
  - Use of the written procedures for receiving raw materials and other ingredients must be documented
- Determining appropriate supplier verification activities, including determining the frequency of conducting the activity by considering the following:
  - The hazard analysis of the raw material or other ingredient, including the nature of the hazard controlled before receipt of the raw material or other ingredient
  - The entity or entities that will be applying controls for the hazards requiring a supply-chain-applied control
  - Supplier performance, including the following:
    - The supplier's procedures, processes, and practices inherent to the hazards associated with the raw material and other ingredients
    - Applicable FDA food safety regulations and information relevant to the supplier's compliance with those regulations, including an FDA warning letter or import alert relating to the safety of the raw material and other ingredients, and other FDA compliance actions related to food safety (or, when applicable, relevant laws and regulations of a country whose food safety system FDA has officially recognized as comparable or has determined to be equivalent to that of the United States, and information relevant to the supplier's compliance with those laws and regulations)
    - The supplier's food safety history relevant to the raw materials and other ingredients that the manufacturer receives from the supplier, including available information about results from testing raw materials and other ingredients for hazards, audit results relating to the safety of the raw material and other ingredients, and responsiveness of the supplier in correcting problems
  - Any other factors as appropriate and necessary, such as storage and transportation practices
- Conducting one or more supplier verification activities as determined to be appropriate for raw materials and other ingredients, and approving each supplier before using the raw materials and other ingredients
  - Risk-based supplier verification activities may include the following:
    - On-site audits
    - Sampling and testing of raw materials and other ingredients to verify the accuracy of information on the supplier certificate of analysis
    - Review of supplier's relevant food safety records
    - Other appropriate supplier verification activities based on supplier performance and the risk associated with the raw materials and other ingredients
  - When a hazard in a raw material or other ingredient will be controlled by the supplier and is one for which there is a reasonable probability that exposure will result in serious adverse health consequences or death to humans, the appropriate supplier verification activity is an on-site audit of the supplier, which must be conducted annually unless there is a written determination that other verification activities and/or less frequent on-site auditing of the supplier provide adequate assurance that the hazards are controlled
  - There must not be any financial conflicts of interests that influence the results of the verification activities, and payment must not be related to the results of the activity
- Taking and documenting prompt corrective measures to ensure that raw materials and other ingredients from the supplier do not cause the dietary ingredient to be adulterated or misbranded, if the manufacturer has identified through auditing, verification testing, document review, relevant consumers, and customer or other complaints that the supplier is not controlling hazards requiring a supply-chain-applied control
- Documenting supplier qualification activities

*2.7.3.4.1 On-site audit:* An on-site audit of a supplier must be performed by a qualified auditor. If the raw material or other ingredient at the supplier is subject to one or more FDA food safety regulations, an on-site audit must consider such regulations and include a review of the supplier's written plan (e.g., HACCP plan or other FSP), if any, and its implementation for the hazard being controlled (or, when applicable, an on-site audit may consider relevant laws and regulations of a country whose food safety system the FDA has officially recognized as comparable or has determined to be equivalent to that of the United States).

One of the following may be substituted for an on-site audit, provided that the inspection was conducted within 1 year of the date that the on-site audit would have been required to be conducted:

- The written results of an appropriate inspection of the supplier for compliance with applicable FDA food safety regulations conducted and reported by the FDA, by representatives of other federal agencies (such as the US Department of Agriculture), or by representatives of state, local, tribal, or territorial agencies
- For a foreign supplier, the written results of an inspection by the FDA or the food safety authority of a country whose food safety system the FDA has officially recognized as comparable or has determined to be equivalent to that of the Unites States

Official

https://pharmacopeia.cn/v29240/

- For inspections conducted by the food safety authority of a country, the raw material or other ingredient that is the subject of the on-site audit must be within the scope of the official recognition or equivalence determination, and the foreign supplier must be in and under the regulatory oversight of that country.

An on-site audit is not subject to the requirements in 21 CFR Part 1, Subpart M, if it is solely conducted to meet the requirements of the manufacturer's supply-chain control program by an audit agent of a certification body accredited in accordance with those regulations.

*2.7.3.4.2 Responsibilities of the receiving facility:* The receiving facility must approve suppliers. The receiving facility must determine and conduct appropriate supplier verification activities and satisfy all supply-chain-program documentation requirements.

An entity other than the receiving facility may do any of the following provided that the receiving facility reviews and assesses the entity's applicable documentation and documents that review and assessment:

- Establish written procedures for receiving raw materials and other ingredients by the entity
- Document that written procedures for receiving raw materials and other ingredients are being followed by the entity
- Determine and/or conduct the appropriate supplier verification activities with appropriate documentation

As a supplier verification activity for a particular lot of product, the supplier may conduct and document sampling and testing of raw materials and other ingredients for the hazard controlled by the supplier and provide such documentation to the receiving facility, provided that the receiving facility reviews and assesses that documentation and maintains a record of that review and assessment.

A receiving facility may not accept any of the following as a supplier verification activity:

- A determination by its supplier of the appropriate supplier verification activities for that supplier
- An audit conducted by its supplier
- A supplier-conducted review of that supplier's own relevant food safety records

The requirements of this section do not prohibit a receiving facility from relying on an audit provided by its supplier when the audit was conducted by a third-party qualified auditor.

*2.7.3.4.3 Supply-chain program documentation and records:* The manufacturer receiving raw materials and other ingredients must document and review the following records as applicable to its supply-chain program:

- The written supply-chain program
- Documentation that a receiving facility that is an importer is in compliance with the foreign supplier verification program requirements in 21 CFR part 1, subpart L, including documentation of verification activities in 21 CFR 1.506(e)
- Documentation of the approval of a supplier
- Written procedures for receiving raw materials and other ingredients
- Documentation demonstrating use of the written procedures for receiving raw materials and other ingredients
- Documentation of the determination of the appropriate supplier verification activities for raw materials and other ingredients
- Documentation of the conduct of an on-site audit, which must include:
  - The name of the supplier subject to the on-site audit
  - Documentation of audit procedures
  - The dates the audit was conducted
  - The conclusions of the audit
  - Corrective actions taken in response to significant deficiencies identified during the audit
  - Documentation that the audit was conducted by a qualified auditor
- Documentation of sampling and testing conducted as a supplier verification activity, which must include:
  - Identification of the raw material or other ingredient tested (including lot number) and the number of samples tested
  - Identification of the test(s) conducted, including the analytical method(s) used
  - The date(s) on which the test(s) were conducted and the date of the report
  - The results of the testing
  - Corrective actions taken in response to detection of hazards
  - Information identifying the laboratory conducting the testing
- Documentation of the review of the supplier's relevant food safety records, which must include:
  - The name of the supplier whose records were reviewed
  - The date(s) of the review
  - The general nature of the records reviewed
  - The conclusions of the review
  - Corrective actions taken in response to significant deficiencies identified during the review
- Documentation of other appropriate supplier verification activities based on the supplier performance and the risk associated with the raw material or other ingredient
- Documentation of any determination that verification activities other than an on-site audit and/or less frequent on-site auditing of a supplier provide adequate assurance that the hazards are controlled when the supplier controls a hazard in a raw material or other ingredient and that hazard is one for which exposure could probably result in serious adverse health consequences or death to humans
- The written results of an appropriate inspection of the supplier for compliance with applicable FDA food safety regulations by the FDA, by representatives of other federal agencies (such as the US Department of Agriculture), or by representatives

Official

https://pharmacopeia.cn/

from state, local, tribal, or territorial agencies, or the food safety authority of another country when the results of such an inspection is substituted for an on-site audit
- Documentation of actions taken with respect to supplier non-conformance
- Documentation of verification of a supply-chain-applied control applied by an entity other than the receiving facility's supplier
- When applicable, documentation of the receiving facility's review assessment, which could include:
  - Applicable documentation from an entity other than the receiving facility:
    - Of written procedures for receiving raw materials and other ingredients being followed
    - Of the determination of the appropriate supplier verification activities for raw materials and other ingredients
    - Of conducting the appropriate supplier verification activities for raw materials and other ingredients
    - Of the verification activities when a supply-chain-applied control is applied by an entity other than the receiving facility's supplier
  - Applicable documentation from its supplier:
    - Of the results of sampling and testing conducted by the supplier
    - Of the results of an audit conducted by a third-party qualified auditor

Supplier verification activities must be documented. Formal reports should be generated for each raw material or other ingredient from each supplier summarizing initial supplier verification activities and analyses, and plans and schedule for continuous monitoring. An approved list of raw materials, other ingredients, and suppliers should be readily available to staff. A unique material item code should be assigned for each material from each supplier; however, the manufacturer may identify equivalencies between the same raw materials and other ingredients from different suppliers as long as they meet the same critical specifications for identity, strength, purity, composition, and limits on contaminants.

Quality unit personnel must review and approve the documentation setting forth the basis for the qualification of any supplier.

**2.7.3.5 Recall plan:** For dietary ingredients with a hazard requiring a preventive control, the manufacturer must establish a written recall plan for the dietary ingredient. The written recall plan must include procedures that describe the steps to be taken and assign responsibility for taking those steps and to perform the following actions as appropriate to the facility:
- Directly notify the direct consignees of the dietary ingredient being recalled, including how to return or dispose of the affected dietary ingredient
- Notify the public about any hazard presented by the dietary ingredient when appropriate to protect public health
- Conduct effectiveness checks to verify that the recall is carried out
- Appropriately dispose of the recalled dietary ingredient (e.g., through reprocessing, reworking, diverting to a use that does not present a safety concern, or destroying the dietary ingredient)

A written procedure should define the circumstances under which recall of a dietary ingredient should be considered. The recall procedure should designate who should be involved in evaluating the information, how a recall should be initiated, who should be informed about the recall, and how the recalled dietary ingredient should be treated. If the event of a health hazard is not self-evident, then an independent health hazard assessment by a qualified individual or organization should be conducted to determine the depth and scope of a recall. In the event of a serious or potentially life-threatening situation, local, national, and/or international regulatory authorities should be informed, and their advice sought to ensure regulations are properly followed and executed for disposition of the recalled article.

Mock recalls should be performed annually.

**2.7.3.6 Other controls:** Other controls include any other procedure, practice, and process necessary to ensure that food will not be adulterated or misbranded; examples of other controls include hygiene training and other good cGMPs.

### 2.7.4 PREVENTIVE CONTROL MANAGEMENT

Preventive controls are subject to the following preventive control management components as appropriate to ensure the effectiveness of the controls while considering their nature and their role in the facility's food safety system:
- Monitoring
- Corrective actions and corrections
- Verification

The supply-chain program is subject to the following preventive control management component as appropriate to ensure the effectiveness of the supply-chain program while considering the nature of the hazard controlled before receipt of the raw material or other ingredient:
- Corrective actions and corrections that consider the nature of any supplier non-conformance:
  - Review of records
  - Re-analysis

**2.7.4.1 Monitoring:** As appropriate to the nature of the preventive controls and their role in the facility's food safety system, written procedures must be established and implemented and include the frequency with which they are to be performed for monitoring the preventive controls. Preventive controls must be monitored with adequate frequency to provide assurance that they are consistently performed. The monitoring of preventive controls must be documented in records that are subject to verification and records review.

**2.7.4.2 Corrective actions and correction procedures:** As appropriate to the nature of the hazard and the nature of the preventive controls, the manufacturer must establish and implement written corrective action procedures that must be taken if preventive controls are not properly implemented, including procedures to address, for the presence of the following hazards:
- The presence of a pathogen or appropriate indicator organism detected as a result of product testing

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M15255_02_01

@2024 USPC

- The presence of an environmental pathogen or appropriate indicator organism detected through environmental monitoring

The corrective action procedures must describe the steps to be taken to ensure that:

- Appropriate action is taken to identify and correct a problem that has occurred with implementation of a preventive control
- Appropriate action is taken when necessary to reduce the likelihood that the problem will reoccur
- All affected dietary ingredients are evaluated for safety
- All affected dietary ingredients are prevented from entering commerce, if the manufacturer cannot ensure that the affected dietary ingredient is not adulterated or misbranded

The manufacturer must follow these steps and, if appropriate, re-analyze the FSP to determine whether modification of the FSP is required if any of the following circumstances occur:

- A preventive control is not properly implemented and a corrective action procedure has not been established
- A preventive control, combination of preventive controls, or the FSP is found to be ineffective
- A review of records finds that the records are not complete, the activities conducted did not occur in accordance with the FSP, or appropriate decisions were not made about corrective actions

All corrective actions (and corrections, when appropriate) taken must be documented in records that are subject to verification and records review.

**2.7.4.3 Verification activities:** Verification activities must include the following preventive control management components as appropriate to the nature of the preventive controls and their role in the facility's food safety system:

- Validation
- Verification that monitoring is being conducted as required in *2.7.4.1 Monitoring*
- Verification that appropriate decisions about corrective actions are being made as required in *2.7.4.2 Corrective actions and correction procedures*
- Verification of implementation and effectiveness
- Re-analysis

All verification activities must be documented in records and are subject to review.

*2.7.4.3.1 Validation:* The manufacturer must validate that the preventive controls identified and implemented are adequate to control the hazard as appropriate to the nature of the controls and their role in the facility's food safety system. The validation of the preventive controls must be performed (or overseen) by a preventive controls-qualified individual at the following times:

- Prior to implementation of the FSP
- When necessary to demonstrate the control measures can be implemented as designed (within 90 calendar days, or within a reasonable justifiable time frame after production of the applicable dietary ingredient first begins)
- Whenever a change to a control measure or combination of control measures could affect whether the control measure or combination of control measures, when properly implemented, will effectively control the hazards
- Whenever a re-analysis of the FSP reveals the need to do so

The validation of the preventive controls must include obtaining and evaluating scientific and technical evidence (or, when such evidence is not available or is inadequate, conducting studies) to determine whether the preventive controls, when properly implemented, will effectively control the hazards.

The manufacturer does not need to validate the food allergen controls, the sanitation controls, the recall plan, the supply-chain controls, and other preventive controls if the preventive controls-qualified individual prepares (or oversees the preparation of) a written justification that validation is not applicable based on factors such as the nature of the hazard and the nature of the preventive control and its role in the facility's food safety system.

*2.7.4.3.2 Verification of implementation and effectiveness:* The manufacturer must verify that the preventive controls are consistently implemented and are effectively and significantly minimizing or preventing the hazards by conducting the following activities as appropriate to the facility, the dietary ingredient, and the nature of the preventive controls and their role in the facility's food safety system:

- Calibration of process monitoring instruments and verification instruments (or checking them for accuracy)
- Product testing for a pathogen (or appropriate indicator organism) or another hazard
- Environmental monitoring for an environmental pathogen or for an appropriate indicator organism
- Other activities appropriate for verification of implementation and effectiveness
- Review of the following records within the specified time frames by (or under the oversight of) a preventive controls-qualified individual to ensure that the records are complete, the activities reflected in the records occurred in accordance with the FSP, the preventive controls are effective, and appropriate decisions were made about corrective actions:
    - Records of monitoring and corrective action records within 7 working days after the records are created or within a reasonable time frame, provided that the preventive controls-qualified individual prepares (or oversees the preparation of) a written justification for a time frame that exceeds 7 working days. All records should be reviewed and approved by a qualified individual before the products are released in the market
    - Records of calibration, testing (e.g., product testing, environmental monitoring), supplier and supply-chain verification activities, and other verification activities within a reasonable time after the records are created

As appropriate to the facility, the food, the nature of the preventive control, and the role of the preventive control in the facility's food safety system, the manufacturer must establish and implement written procedures for the following activities:

- The method and frequency of calibrating process monitoring instruments and verification instruments (or checking them for accuracy)
- Product testing procedures that must:

Official

https://pharmacopeia.cn/

- Be scientifically valid
- Identify the test microorganism(s) or other analytes
- Specify the procedures for identifying samples, including their relationship to specific lots of product
- Include the procedures for sampling, including the number of samples and the sampling frequency
- Identify the test(s) conducted, including the analytical method(s) used
- Identify the laboratory conducting the testing
- Include the corrective action procedures

- Environmental monitoring procedures that must:
  - Be scientifically valid and based on risk management procedures
  - Identify the test microorganism(s)
  - Identify the locations from which samples will be collected and the number of sites to be tested during routine environmental monitoring (the number and location of sampling sites must be adequate to determine whether preventive controls are effective)
  - Identify the timing and frequency for collecting and testing samples (the timing and frequency for collecting and testing samples must be adequate to determine whether preventive controls are effective)
  - Identify the test(s) conducted, including the analytical method(s) used
  - Identify the laboratory conducting the testing
  - Include the corrective action procedures

*2.7.4.3.3 Re-analysis:* The manufacturer must conduct a re-analysis of the FSP in its entirety once every 3 years. In addition, the manufacturer must conduct a re-analysis either in its entirety or of the affected portion of the FSP when one of the following occurs:

- Whenever a significant change in the activities conducted at the facility creates a reasonable potential for a new hazard or creates a significant increase in a previously identified hazard
- Whenever the manufacturer becomes aware of new information about potential hazards associated with the dietary ingredient
- Whenever appropriate after an unanticipated food safety problem
- Whenever the manufacturer finds that a preventive control, combination of preventative controls, or the FSP in its entirety is ineffective
- Whenever the FDA determines it is necessary to respond to new hazards and developments in scientific understanding

The manufacturer must complete the re-analysis and validate as appropriate to the nature of the preventive controls and their role in the facility's food safety system any additional preventive controls needed to address the hazard identified in one of the following time frames:

- Before any change in activities (including any change in preventive control) at the facility is operative
- When necessary to demonstrate the control measures can be implemented as designed within one of the following:
  - 90 calendar days after production of the applicable dietary ingredient
  - A reasonable time frame, provided that the preventive controls-qualified individual prepares (or oversees the preparation of) a written justification for a time frame that exceeds 90 calendar days after production of the applicable dietary ingredient first begins

The manufacturer must either revise the written FSP if a significant change in the activities conducted at the facility creates a reasonable potential for a new hazard or a significant increase in a previously identified hazard, or document the basis for the conclusion that no revisions are needed. A preventive controls-qualified individual must perform (or oversee) the re-analysis and revisions to the FSP.

### 2.7.5 HARP IMPLEMENTATION RECORDS

The manufacturer must establish and maintain the following records documenting implementation of the FSP:

- Records that document the monitoring of preventive controls
- Records that document corrective actions
- Records that document verification, including, as applicable, those related to:
  - Validation
  - Verification of monitoring
  - Verification of corrective actions
  - Calibration of process monitoring and verification instruments
  - Product testing
  - Environmental monitoring
  - Records review
  - Re-analysis
- Records that document the supply-chain program
- Records that document applicable training for the preventive controls-qualified individual and the qualified auditor

Official

https://pharmacopeia.cn/v29240/

## 2.8 Contract Manufacturers and Contract Laboratories

All contract manufacturers and contract laboratories should comply with the requirements of this chapter. Special consideration should be given to the prevention of allergen cross-contact and cross-contamination and to maintaining traceability.

Contract manufacturers and contract laboratories should be evaluated by the contract giver to ensure cGMP compliance of the specific operations occurring at the contract sites.

A written and approved contract or quality agreement should define in detail the cGMP responsibilities, including the quality measures, of each party. The contract acceptor should permit the contract giver to audit the contract acceptor's facilities for compliance with cGMPs. When subcontracting is allowed, the contract acceptor should use a third party for any of the work entrusted to it under the contract without the contract giver's prior evaluation and approval of the arrangements.

Manufacturing and laboratory records should be kept at the site where the activity occurs and be readily available. Changes in the process, equipment, test methods, specifications, or other contractual requirements should not be made unless the contract giver is informed and approves the changes.

## 2.9 Complaints

All quality-related complaints, whether received orally or in writing, should be recorded and investigated according to written procedures.

Complaint records should include the following:

- Name, address, and phone number of complainant
- Name of dietary ingredient, item code, and lot number
- Nature of the complaint, including how the product was used if known
- Date complaint was received
- Investigation undertaken and initial findings, including dates and identity of person(s) conducting the investigation
- Action initially taken, including dates and identity of person(s) taking the action
- Any follow-up action taken
- Response provided to the complainant, including the date the response was sent
- Final findings and decision on product lot
- Quality unit personnel review and approval signature

A qualified person must review and investigate all product complaints to determine whether the product complaint involves a possible failure of a dietary ingredient to meet any of its specifications or any other requirements of this general chapter, including those specifications and other requirements that, if not met, may result in risk of illness or injury. Quality unit personnel must review and approve decisions about whether to investigate a product complaint and review and approve the findings and follow-up action of any investigation performed. The review of the product complaint and any investigation performed must extend to all relevant batches and records.

Records of complaints should be retained in order to evaluate trends, product-related frequencies, and severity with a view of taking additional and, if appropriate, immediate corrective action.

Official

## 2.10 Internal (Self-Inspection) Audits

To verify compliance with the requirements of this chapter, regular internal audits should be performed according to an approved schedule. Audit findings and corrective actions should be documented and brought to the attention of responsible management. Acceptable corrective action should be completed in a timely and effective manner. Internal audits also should verify that computer systems with an audit trail feature have it enabled.

## 2.11 Product Quality Reviews

Regular quality reviews of dietary ingredients should be conducted annually or by using a matrix and bracketing approach on a rotation cycle over a 3-year period with the objective of verifying the consistency of the manufacturing process.

Such review should normally include a review of the following:

- Critical dietary ingredient test results
- All batches that failed to meet established specification(s)
- Deviations or nonconformities and related investigations
- Adequacy of corrective actions
- Changes to the manufacturing process and analytical test methods
- Results of the stability monitoring program
- Quality-related returns, complaints, and recalls

The results of this review should be evaluated, and an assessment made of whether any additional corrective action or any revalidation should be undertaken. Reasons for such corrective actions should be documented. Acceptable corrective actions should be completed in a timely and effective manner.

## 2.12 Quality Management Documentation

The following documentation must be made and kept for fulfilling the requirements of the quality management system (see *1. General Provisions*).

### 2.12.1 WRITTEN PROCEDURES

Written procedures must be established and followed for the following:

- Creating and maintaining job position descriptions and listing job responsibilities and required qualifications for education, training, and experience
- Implementing a training program
- Implementing a documentation and records control management system
- Implementing a change control program
- Implementing a deviation management program
- Conducting material reviews
- Implementing a corrective action and preventive action management program
- Implementing an FSP
- Implementing a supplier-chain control program
- Handling recalls
- Implementing a contract (manufacturing and laboratory) services program
- Implementing a complaint handling program
- Conducting internal audits
- Conducting product quality reviews

### 2.12.2 RECORDS

Records must meet the following standards:

- Be kept as original records, true copies (e.g., photocopies, pictures, scanned copies, microfilm, microfiche, or other accurate reproductions of the original records), or electronic records including associated metadata
- Contain the actual values and observations obtained during monitoring and, as appropriate, during verification activities
- Be accurate, indelible, and legible
- Be created concurrently with performance of the activity documented
- Be as detailed as necessary to provide history of work performed
- Include the following information:
  - Information adequate to identify the plant or facility (e.g., the name and when necessary the location of the plant or facility)
  - The date and, when appropriate, the time of the activity documented
  - The signature or initials of the person performing the activity
  - When appropriate, the identity of the product and the lot code

Records must be made and kept for the following:

- Organizational chart, job position descriptions, and curriculum vitae for all key management staff in manufacturing and quality operations
- Training, including the date of the training, the type of training, name of trainer if applicable, the person(s) trained, content of the training or reference to a document that describes the content, and any assessment results (e.g., test results)
- List and copies of current standard operating procedures, manufacturing instructions, and standard test methods
- List and reports of changes that affect the production and quality of dietary ingredients
- List and reports of unanticipated occurrences and deviations from approved instructions or established standards
- List and reports of material reviews
- List and reports of corrective actions and preventative actions taken
- List of approved suppliers of raw materials, other ingredients, packaging materials and labeling, and corresponding supplier qualification evaluation reports
- List of approved suppliers of manufacturing and laboratory services, including any provided service such as pest control and metrology, and of corresponding evaluation reports and related quality agreements
- List of complaints and corresponding investigation reports
- Recall and mock recall reports
- Internal (self-inspection) audit schedule and reports
- Product quality review reports

The owner, operator, or agent in charge of the facility must sign and date the FSP upon initial completion and upon any modification.

All records must be retained at the plant or facility for at least 2 years after the date they were prepared. Records that relate to the general adequacy of the equipment or processes being used by a facility, including the results of scientific studies and evaluations, must be retained by the facility for at least 2 years after their use is discontinued (e.g., because the facility has updated the written FSP or records that document validation of the written FSP).

@2024 USPC

Except for the FSP, off-site storage of records is permitted if such records can be retrieved and provided on-site within 24 h of request for official review. The FSP must remain on-site, except when the plant or facility is closed for a prolonged period, in which case the FSP may be transferred to some other reasonably accessible location but must be returned to the plant or facility within 24 h for official review upon request. Electronic records are on-site if they are accessible from an on-site location.

Existing records (e.g., records kept to comply with other federal, state, or local regulations, or for any other reason) do not need to be duplicated if they contain all of the required information and satisfy applicable requirements. Existing records may be supplemented as necessary to include all required information and satisfy the applicable requirements. The information required does not need to be kept in one set of records. If existing records contain some of the required information, any new information required may be kept either separately or combined with the existing records.

# 3. PHYSICAL PLANT AND EQUIPMENT

## 3.1 Grounds Maintenance

The grounds around the physical plant must be kept in a condition that protects against the contamination of raw materials, other ingredients, in-process material, dietary ingredients, and food-contact surfaces. The methods for adequate ground maintenance include the following:

- Properly storing equipment, removing litter and waste, and cutting weeds or grass within the immediate vicinity of the physical plant so that it does not constitute an attractant, breeding place, or harborage for pests
- Maintaining roads, yards, and parking lots so that they do not become a source of contamination in areas where raw materials, other ingredients, in-process material, dietary ingredients, or food-contact surfaces are exposed
- Adequately draining areas that may contribute to the contamination of raw materials, other ingredients, in-process materials, dietary ingredients, or food-contact surfaces by seepage, filth, or any other extraneous materials, or by providing a breeding place for pests
- Adequately operating systems for waste treatment and disposal so that they do not constitute a source of contamination in areas where raw materials, other ingredients, in-process materials, dietary ingredients, or food-contact surfaces are exposed
- Exercising care if the physical plant grounds are bordered by grounds not under the operator's control and not maintained in the aforementioned manner, using inspection, extermination, or other means to exclude pests, dirt, filth, or any other extraneous materials that may be a source of contamination

## 3.2 Physical Plant Design

Any physical plant used in the manufacture of dietary ingredients must be of suitable size, construction, and design to facilitate maintenance, cleaning, and sanitizing operations. The physical plant must have adequate space for the orderly placement of equipment and holding of materials as is necessary for maintenance, cleaning, and sanitizing operations and to prevent contamination and mix-ups of materials.

The physical plant must take adequate precautions to reduce the potential for allergen cross-contact and for contamination of materials and food-contact surfaces with microorganisms, chemicals, filth, and other extraneous materials. The potential for allergen cross-contact and for contamination may be reduced by adequate food safety controls and operating practices or effective design, including the separation of operations in which allergen cross-contact and contamination are likely to occur, by one or more of the following means: location, time, partition, air flow systems, dust control systems, enclosed systems, or other effective means.

The flow of materials and personnel throughout the physical plant should be designed to prevent contamination and mix-ups of materials.

### 3.2.1 SEPARATE AND DEFINED AREAS

The physical plant must have and the manufacturer must use separate, defined areas of adequate size or other control systems, such as computerized inventory controls or automated systems of separation, physical and spatial to prevent contamination or allergen cross-contact and mix-ups of raw materials, other ingredients, in-process materials, dietary ingredients, and packaging materials and labels, during the following operations:

- Receiving, identifying, sampling, holding, and withholding from use materials to be used in manufacturing
- Separating materials to be used in manufacturing from materials awaiting material review and disposition (i.e., in quarantine)
- Performing production, packaging, labeling, and holding operations, as appropriate
- Physically separating allergen-containing materials from non-allergen-containing materials
- Holding rejected materials before further disposition (e.g., return, reprocessing, or destruction)
- Performing and separating the manufacturing, packaging, labeling, and holding of different product types, including different types of dietary ingredients and other foods, cosmetics, and pharmaceutical products
- Cleaning and sanitizing food-contact surfaces as necessary
- Performing and separating chemical and microbiological laboratory analyses and holding of laboratory samples and supplies

Laboratory areas/operations normally should be separated from production areas. Some laboratory areas, particularly those used for in-process controls, can be located in production areas, provided the operations of the production process do not

Official

https://pharmacopeia.cn/

adversely affect the accuracy of the laboratory measurements and the laboratory and its operations do not adversely affect the production process.

Dedicated production areas, which can include facilities, air-handling equipment, and/or process equipment should be considered when materials of an allergenic nature are involved, unless validated cleaning procedures are established and maintained.

#### 3.2.2 DESIGN AND CONSTRUCTION

The physical plant must be designed and constructed in a manner that prevents contamination of materials and contact surfaces by having the following:

- Floors, walls, and ceilings that can be adequately cleaned and kept in good repair
- Fixtures, ducts, and pipes that do not contaminate materials and contact surfaces by dripping or other leakage or by condensation
- Adequate ventilation or environmental control equipment such as airflow systems, including filters, fans, and other air-blowing equipment that minimize odors and vapors (including steam and noxious fumes) in areas where they may cause allergen cross-contact or contamination of materials or food-contact surfaces, and that are located and operated in a manner that minimizes the potential for allergens, microorganisms, and particulate matter to contaminate materials or food-contact surfaces
- Equipment that controls air pressure, temperature, and humidity as needed to ensure the quality of the dietary ingredient; attention should be given to areas where raw materials, other ingredients, in-process materials, and dietary ingredients are exposed to the environment
- Aisles or working spaces between equipment and walls that are adequately unobstructed and of adequate width to permit staff to perform their duties and to protect against contamination of materials or food-contact surfaces with clothing or personal contact
- Adequate lighting in all areas where material is examined, processed, or held, or where food-contact surfaces are cleaned, and in hand-washing areas, dressing and locker rooms, and bathrooms
- Safety-type light bulbs, fixtures, skylights, or other glass or glass-like materials when suspended over exposed materials in any step of manufacture
- Adequate screening or other protection against pests and insects, where necessary
- Adequate protection of materials in bulk fermentation vessels by using, for example, protective coverings; placement in areas where harborages for pests can be eliminated over and around the vessels and where staff can check regularly for pests, pest infestation, filth, or any other extraneous materials; or use of skimming equipment

### 3.3 Physical Plant Sanitation and Facilities

The physical plant must be kept clean and sanitary and maintained in repair adequate to prevent materials and contact surfaces from becoming contaminated. Cleaning and sanitizing of utensils and equipment must be conducted in a manner that protects against allergen cross-contact and against contamination of food, food-contact surfaces, or food-packaging materials.

Overall sanitation of the physical plant must be under the supervision of one or more competent individuals assigned responsibility for this function.

Written procedures should be established assigning responsibility for sanitation and describing the cleaning schedules, methods, equipment, and materials to be used in cleaning buildings and facilities.

The physical plant must be equipped with adequate sanitary facilities and accommodations including water supply, plumbing, sewage disposal, toilet facilities, hand-washing facilities, and rubbish and offal disposal.

Utilities that could affect dietary ingredient quality (e.g., steam, gases, compressed air, and heating, ventilation, and air conditioning) should be qualified and appropriately monitored and action should be taken when acceptance criteria are not met. Drawings for these utility systems should be made and available.

#### 3.3.1 CLEANING COMPOUNDS, SANITIZING AGENTS, PESTICIDES, AND OTHER TOXIC MATERIALS

Cleaning compounds and sanitizing agents must be free from undesirable microorganisms and must be safe and adequate under the conditions of use. All toxic materials should be purchased with a safety data sheet and supplier's guarantee or certification or with an examination of these substances for contamination. Toxic materials must not be used or held in the physical plant in which raw materials, other ingredients, in-process materials, dietary ingredients, and food-contact surfaces are manufactured and/or exposed, unless those materials are required to maintain clean and sanitary conditions, to conduct laboratory test procedures, to maintain or operate the physical plant or equipment, or for use in the physical plant's operations. Toxic materials must be identified and held in a manner that protects against contamination of raw materials, other ingredients, in-process materials, dietary ingredients, and food-contact surfaces. All relevant federal, state, and local government regulations for the use and holding of these toxic materials must be followed.

Any substances associated with the operation of equipment, such as lubricants, heating fluids, or coolants, should not contact in-process materials or dietary ingredients so as to alter their quality beyond established specifications. Any deviations from this should be evaluated to ensure that there are no detrimental effects upon the suitability for use of the material. When possible, food-grade lubricants and oils should be used.

#### 3.3.2 PEST CONTROL

No animals or pests must be allowed in any area of the physical plant. Guard, guide, or pest-detecting dogs may be allowed in some areas of a plant if the presence of the dogs is unlikely to result in the contamination of materials or food-contact surfaces.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

Effective measures must be taken to exclude pests from the physical plant and to protect against contamination of materials and food-contact surfaces on the premises by pests. The use of pesticides, such as insecticides, fumigants, fungicides, or rodenticides, is permitted only if precautions and restrictions are taken to protect against the contamination of raw materials, other ingredients, in-process materials, dietary ingredients, and food-contact surfaces. Pesticides should be registered and used in accordance with the Federal Insecticide, Fungicide, and Rodenticide Act (7 USC §136 et seq.).

### 3.3.3 SANITATION OF CONTACT SURFACES

All food-contact surfaces including utensils and equipment must be cleaned as frequently as necessary to protect against allergen cross-contact and against contamination of dietary ingredients.

Food-contact surfaces used for manufacturing/processing, packing, or holding low-moisture food must be in a clean, dry, and sanitary condition before use. When the surfaces are wet-cleaned, they must, when necessary, be sanitized and thoroughly dried before subsequent use.

In wet processing, when cleaning is necessary to protect against allergen cross-contact or the introduction of microorganisms into the dietary ingredient, all food-contact surfaces must be cleaned and sanitized before use and after any interruption during which food-contact surfaces may have become contaminated. When equipment and utensils are used in a continuous production operation, the utensils and food-contact surfaces of the equipment must be cleaned and sanitized, as necessary, to prevent contamination.

Single-service articles (e.g., utensils intended for one-time use, paper cups, and paper towels) must be stored, handled, and disposed of in a manner that protects against allergen cross-contact and against contamination of food and food-contact surfaces.

Non-food-contact surfaces of equipment used in the operation of the physical plant must be cleaned in a manner and as frequently as necessary to protect against allergen cross-contact and against contamination of food, food-contact surfaces, and food-packaging materials.

Cleaned and sanitized portable equipment with food-contact surfaces and utensils must be stored in a location and manner that protects food-contact surfaces from allergen cross-contact and contamination.

### 3.3.4 WATER SUPPLY

Potable water at a suitable temperature, and under pressure as needed, must be supplied in all areas where required for the processing of food; for cleaning of equipment, utensils, and food-packaging materials; or for staff sanitary facilities. The potable water must be supplied in a plumbing system free of defects and that protects against contamination or undesirable chemical reaction of raw materials, other ingredients, in-process materials, dietary ingredients, and food-contact surfaces. Any water that contacts food, food-contact surfaces, or food packaging materials must be safe and of adequate sanitary quality.

Potable water must meet, at minimum, all the requirements for drinking water promulgated in the US Environmental Protection Agency's National Primary Drinking Water Regulations (40 CFR Part 141), and any applicable state and local drinking water requirements that are more stringent. For manufacturers outside the United States, potable water meeting equivalent requirements may be acceptable with justification; for example, the drinking water regulations of the European Union (European Commission Directive 98/93/EC) or Japan Drinking Water Quality Standards. Water not meeting such requirements should not be permitted for use in the water purification system for *Purified Water*.

When water used in the manufacturing process is treated by the manufacturer to achieve a defined quality, the treatment process should be qualified and monitored with appropriate acceptance and action criteria.

### 3.3.5 PLUMBING

The plumbing in the physical plant must be of an adequate size and design and be adequately installed and maintained to do the following:

- Carry adequate amounts of water to the required locations throughout the physical plant
- Properly convey sewage and liquid disposable waste from the physical plant
- Avoid constituting a source of contamination to food, water supplies, and contact surfaces, or creating an unsanitary condition
- Provide adequate floor drainage in all areas where floors are subject to flooding-type cleaning or where normal operations release or discharge water or other liquid waste on the floor
- Not allow backflow from or cross connection between piping systems that discharge waste water or sewage and piping systems that carry water used for manufacturing dietary ingredients, for cleaning contact surfaces, or for use in bathrooms or hand-washing facilities

Permanently installed pipework should be appropriately identified. This can be accomplished by identifying individual lines with content and directional flow arrows, documentation of computer control systems, or alternative means.

### 3.3.6 SEWAGE AND TRASH DISPOSAL

Sewage, refuse, and other waste in and from buildings and the immediate surrounding area should be disposed of in a safe, timely, and sanitary manner. Sewage must be disposed of in an adequate sewage system or through other adequate means. Trash and hazardous waste must be conveyed, stored, and disposed of in a manner to minimize the development of odors; minimize the potential for the trash to attract, harbor, or become a breeding place for pests; and protect against contamination of materials, contact surfaces, water supplies, and grounds surrounding the physical plant. Containers and/or pipes for waste material should be clearly identified.

When raw materials, other ingredients, or refuse are unprotected, they must not be handled simultaneously in a receiving, loading, or shipping area if that handling could result in allergen cross-contact or contaminated food.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

#### 3.3.7 BATHROOMS AND HAND-WASHING FACILITIES

Adequate and readily accessible bathrooms and hand-washing facilities must be provided and kept clean and must not be a potential source of contamination of materials and contact surfaces. Hand-washing facilities must be designed to ensure that an employee's hands are not a source of contamination of materials and contact surfaces. The facilities must be designed to provide water at a suitable temperature, as well as soap and sanitizing agents, air driers, or single-service towels. Adequate facilities for showering and/or changing clothes should be provided, when appropriate.

#### 3.3.8 ALLERGEN CROSS-CONTAMINATION REDUCTION CONTROL

Adequate precautions must be taken to reduce the potential for allergen cross-contact of raw materials, other ingredients, in-process materials, dietary ingredients, and contact surfaces with adequate food safety controls and operating practices or effective design of the physical plant, including the separation of operations in which allergen cross-contact is likely to occur, by using one or more of the following means: location, time, partition, air-flow systems, dust-control systems, enclosed systems, or other effective means.

#### 3.3.9 SANITATION SUPERVISORS

One or more employees must be assigned to supervise overall sanitation and must be qualified by education, training, and/or experience to develop and supervise sanitation procedures, using appropriate risk-based assessments and preventative controls.

### 3.4 Equipment, Instruments, and Utensils

Equipment, instruments, and utensils used in the manufacture of dietary ingredients must be of appropriate design, construction, and workmanship to enable them to be suitable for their intended use, to be and suitably located to facilitate operations for their intended use, and to be adequately cleaned and properly maintained to protect against allergen cross-contact and contamination.

Equipment and utensils include but are not limited to the following: equipment used to hold or convey; equipment used to measure (i.e., instruments); equipment using compressed air or gas; equipment used to carry out processes in closed pipes and vessels.

Major equipment and permanently installed processing lines used during the production, packaging, and labeling of dietary ingredients should be appropriately identified. A set of current drawings and/or manuals should be maintained for equipment and critical installations (e.g., instrumentation and utility systems). Equipment should be identified as to its contents and its cleanliness status by appropriate means.

Equipment that is in areas where food is manufactured, processed, packed, or held and that does not come into contact with food must be so constructed that it can be kept in a clean and sanitary condition.

Holding, conveying, and manufacturing systems, including gravimetric, pneumatic, closed, and automated systems, must be of a design and construction that enables them to be maintained in an appropriate clean and sanitary condition.

#### 3.4.1 DESIGN AND CONSTRUCTION

Equipment and utensils must be appropriate in design and construction and used appropriately to do the following:

- Prevent contamination of dietary ingredient with lubricants, fuel, coolants, metal or glass fragments, filth or any other extraneous material, contaminated water, or any other contaminants
- Be corrosion-resistant and made of nontoxic materials if the equipment or utensils contact dietary ingredients
- Withstand the environment in which they are used in manufacturing, cleaning, and sanitizing
- Have seams that are smoothly bonded or maintained to minimize accumulation of dirt, filth, organic material, particles of dietary ingredient, or any other extraneous materials or contaminants, and thus minimize the opportunity for growth of microorganisms and allergen cross-contact
- Constructed so that surfaces that contact dietary ingredients are not corrosive, reactive, additive, or absorptive so as to alter the quality of the dietary ingredient beyond the established requirements
- Must be maintained to protect dietary ingredients from allergen cross-contact and from being contaminated by any source

Automated, mechanical, or electronic equipment that is used to manufacture, package, label, or hold a dietary ingredient must be designed or selected to ensure that the dietary ingredient specifications are consistently met. The suitability of the equipment must be determined by ensuring that the equipment is capable of operating satisfactorily within the operating limits required by the process.

#### 3.4.2 INSTALLATION AND MAINTENANCE

Equipment and utensils must be installed and/or maintained to facilitate cleaning the equipment and utensils and adjacent spaces and to protect dietary ingredients from being contaminated by any source. Equipment and utensils must be maintained in an adequate condition through appropriate cleaning and sanitizing, as necessary. Insofar as necessary, equipment must be taken apart for thorough cleaning.

Each freezer, refrigerator, and cold storage compartment used to store and hold dietary ingredients must do the following:

- Be fitted with an indicating thermometer, temperature-measuring device, or temperature-recording device that shows, indicates, and records or allows for recording by hand the temperature accurately within the compartment

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-May-2022
DOI Ref: 3a0hm
DocId: GUID-DE5DE10D-9550-4D57-8933-7B9B1C922698_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

- Have an automated device for regulating temperature or an automated alarm system to indicate a significant temperature change in a manual operation

Compressed air or other gases introduced mechanically into or onto dietary ingredients or dietary ingredient-contact surfaces, or that are used to clean food-contact surfaces, must be treated in such a way (e.g., proper filtration) that food is not contaminated.

Instruments or controls used in the manufacturing, packaging, labeling, or holding of a dietary ingredient, and instrument controls used to measure, regulate, or record temperatures, pH, water activity, or other conditions and to control or prevent the growth of microorganisms or other contamination, must be accurate and precise, periodically calibrated, adequately maintained, and adequate in number for their designated uses.

### 3.4.3 OPERATION AND CALIBRATION

Control, weighing, measuring, monitoring and test equipment (i.e., instruments and controls), which are critical for assuring the quality of dietary ingredients, must be calibrated according to written procedures and an established schedule. Equipment and instruments used in the manufacture of dietary ingredients must be used only within its qualified operating range. Equipment calibrations should be performed using standards traceable to certified standards, if available.

Instruments and controls used in manufacturing or testing raw materials, other ingredients, in-process material, or dietary ingredients must be calibrated before first use at a frequency specified in writing by the manufacturer of the instrument or control and at established intervals or as otherwise necessary to ensure the accuracy and precision of the instrument and control. Instruments or controls that cannot be adjusted to agree with the reference standard must be repaired or replaced.

Balances used to accurately weigh material should comply with *Balances* ⟨41⟩ and *Weighing on an Analytical Balance* ⟨1251⟩.

Automated, mechanical, or electronic equipment that is used to manufacture, package, label, or hold a dietary ingredient must be routinely calibrated, inspected, or checked to ensure proper performance. The quality unit must approve these calibrations, inspections, or checks. The appropriate controls for automated, mechanical, and electronic equipment (including software for a computer-controlled process) must be established and used to ensure that any changes to the manufacturing, packaging, labeling, holding, or other operations are approved by the quality unit and instituted only by authorized personnel. The appropriate controls must be established and used to ensure that the equipment functions in accordance with its intended use. These controls must be approved by the QC unit.

Deviations from approved standards of calibration on critical instruments should be investigated to determine if these could have had an effect on the quality of in-process materials or dietary ingredients using the equipment since the last successful calibration.

Quality unit personnel must do the following:

- Review and approve all processes for calibrating equipment and instruments
- Periodically review all records for calibration of equipment, instruments, and controls
- Periodically review all records for calibrations, inspections, and checks of automated, mechanical, or electronic equipment
- Review and approve controls to ensure that automated, mechanical, or electronic equipment functions in accordance with its intended use

### 3.4.4 CLEANING AND MAINTENANCE

Equipment, utensils, and any other contact surfaces used to manufacture, package, label, or hold raw materials, other ingredients, in-process materials, or dietary ingredients must be maintained, cleaned, and sanitized as necessary to protect against allergen cross-contact and contamination of raw materials, other ingredients, in-process materials, and dietary ingredients. Equipment and utensils must be taken apart as necessary for thorough maintenance, cleaning, and sanitizing.

Schedules and procedures, including assignment of responsibility, should be established for the preventative maintenance of equipment.

Written procedures should be established for the cleaning of equipment and its subsequent release for use in the manufacture of dietary ingredients. Cleaning procedures should contain enough details to enable operators to clean each type of equipment in a reproducible and effective manner. These procedures should include the following:

- Assignment of responsibility for cleaning of equipment
- Cleaning and sanitizing schedules as needed
- Complete description of the methods and materials, including dilution of cleaning agents used to clean equipment
- Instructions, as needed, for disassembling and reassembling each part of equipment to ensure proper cleaning
- Instructions for the removal or obliteration of previous batch identification
- Instructions for the protection of clean equipment from contamination prior to use, and the maximum time that may elapse between completion of cleaning and use in manufacturing
- Inspection of equipment cleanliness immediately before use
- Establishment of the maximum time that may elapse between the completion of manufacturing processing and equipment cleaning

All contact surfaces must be cleaned and sanitized as necessary before use and after any interruption during which the contact surfaces may have become contaminated. In consecutive operations involving batches of different dietary ingredients, the contact surfaces must be adequately cleaned, and sanitized as needed, to prevent cross-contamination. In consecutive operations involving different batches of the same dietary ingredient, the contact surfaces must be inspected and adequately cleaned and sanitized as necessary to prevent build-up and carry-over of contaminants (e.g., objectionable levels of microorganism). Acceptance criteria for residues and the choice of cleaning procedures and cleaning agents should be defined and justified. The cleaning status of equipment should be stated on the equipment or in close proximity to the equipment.

DocId: GUID-DE5DE10D-9550-4D57-8933-7B9B1C922698_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

Surfaces that do not come into direct contact with raw materials, other ingredients, in-process materials, or dietary ingredients must be cleaned as frequently as necessary to protect against contaminating raw materials, other ingredients, in-process materials, or dietary ingredients.

Effective systems should be used to reduce the potential of non-food-contact surfaces from becoming sources of contamination, such as the use of floor sticky pads between different production areas and a captive shoe policy and program or shoe covers in high-risk areas of operation.

Heat-treated pallets (or plastic pallets) must be used in areas where raw materials, other ingredients, in-process materials, dietary ingredients, and contact surfaces are exposed. An effective pallet cleaning, maintenance, inspection, and management program must be established, documented, and followed.

Contact surfaces used for manufacturing or holding low-moisture raw materials, other ingredients, in-process materials or dietary ingredients must be in a clean, dry, and sanitary condition before use. When the surfaces are wet-cleaned, they must be sanitized, when necessary, and thoroughly dried before subsequent use.

If wet processing is used during manufacturing, all contact surfaces must be cleaned and sanitized as necessary to protect against the introduction of microorganisms into raw materials, other ingredients, in-process materials, or dietary ingredients. When cleaning and sanitizing is necessary, all contact surfaces must be cleaned and sanitized before use and after any interruption during which the contact surface may have become contaminated. In a continuous production operation or in consecutive operations involving different batches of the same dietary ingredient, the contact surfaces must be adequately cleaned and sanitized, as necessary.

Single-service articles (e.g., utensils intended for one-time use, paper cups, and paper towels) must be stored in appropriate containers and handled, dispensed, used, and disposed of in a manner that protects against contamination of raw materials, other ingredients, in-process materials, dietary ingredients, or any contact surface.

Cleaning compounds and sanitizing agents must be adequate for their intended use and safe under their conditions of use.

The portable equipment and utensils that have contact surfaces must be cleaned, sanitized, and stored in a location and manner that protects them from contamination.

### 3.4.5 EQUIPMENT AND INSTRUMENT QUALIFICATION

"Fitness for purpose" must be demonstrated for equipment and instruments. There are many ways of demonstrating that equipment and instruments meet fitness for purpose and are under control, and these can include qualification, calibration, and maintenance. Equipment or instrument qualification activities necessary to establish fitness for purpose may be grouped into four phases: design qualification (DQ), installation qualification (IQ), operational qualification (OQ), and performance qualification (PQ). In order to ensure fitness for purpose, an integrated approach based on a risk assessment should be undertaken.

A variety of equipment and instruments ranging from a simple apparatus to complex computerized systems is used in the dietary ingredient industry to manufacture, package, label, test, and hold dietary ingredients. A risk assessment enables the classification of equipment and instruments to determine the extent of qualification and actions needed to demonstrate fitness for purpose. Generally, the more complex the equipment or instrument or the higher the criticality of its operation, the greater the amount of work required to ensure fitness for purpose.

Requirements for the intended use should be appropriately defined to ensure that the particular needs and technical and operational requirements are met. Qualification activities are described in *Analytical Instrument Qualification* ⟨1058⟩.

When an equipment or instrument undergoes major repairs or modifications, it should be evaluated using change control. Relevant equipment qualification should be repeated to verify that the equipment continues to operate satisfactorily. If equipment is moved to another location, an assessment should be made of what, if any, qualification stage should be repeated.

### 3.4.6 COMPUTERIZED SYSTEMS

Written procedures should be available for the operation and maintenance of computerized systems.

Appropriate IQ and OQ should demonstrate the suitability of the computer hardware and software to perform assigned tasks.

cGMP-related computerized systems must be validated. The depth and scope of validation depends on the diversity, complexity, and criticality of the computerized application. Commercially available software that has been validated may require an abbreviated level of testing. If an existing system was not validated at time of installation, a retrospective validation could be conducted if appropriate documentation is available.

When critical data are being entered manually, an additional check on the accuracy of the entry must be done, either by a second operator or by the system itself (e.g., barcode reader).

Changes to the computerized system must be made according to a change control procedure and should be formally authorized, documented, and tested. Records must be kept of all changes, including modifications and enhancements made to hardware and software. These records should demonstrate that the system is maintained in a validated state.

If system breakdowns or failures would result in the permanent loss of records, a back-up system should be provided. A means of ensuring data protection should be established for all cGMP-related computerized systems. Data can be recorded by a second means in addition to the computer system. Test records should not be written to erasable media not covered by an audit trail, such as thumb drives.

All electronic records must comply with 21 CFR Part 11 (*Electronic Records; Electronic Signatures*).

**3.4.6.1 Computer systems procedures and controls:** cGMP-related computerized systems used to create, modify, maintain, or transmit electronic records must employ procedures and controls designed to ensure the authenticity, integrity, and, when appropriate, the confidentiality of electronic records, and to ensure that the signer cannot readily repudiate the signed record as not genuine. Such procedures and controls must include but are not limited to the following:

- Validation of systems to ensure accuracy, reliability, consistent intended performance, and the ability to discern invalid or altered records

DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

- The ability to generate accurate and complete copies of records (including controls to prevent omissions in data, such as the system being turned off and data not being captured) for inspection, review, and copying
- Protection of records to enable their accurate and ready retrieval throughout the records retention period
- Limiting system access to authorized individuals to prevent unauthorized access or changes to data
- Use of secure, computer-generated, and time-stamped audit trails to independently record the date and time of operator entries and actions that create, modify, or delete electronic records
- Establishment of and adherence to written policies that hold individuals accountable and responsible for actions initiated under their electronic signatures in order to deter record and signature falsification
- Use of appropriate controls over systems documentation including distribution of, access to, and use of documentation for system operation and maintenance, and revision and change control procedures to maintain an audit trail that documents time-sequenced development and modification of systems documentation

**3.4.6.2 Electronic signatures:** Signed electronic records must contain information associated with the signing that clearly indicates the following: the printed name of the signer, the date and time when the signature was executed, and the meaning (e.g., review, approval, responsibility, or authorship) associated with the signature.

Each electronic signature must be unique to one individual and must not be reused by or reassigned to anyone else. Individuals responsible for electronic signatures must have a specific identification code and password. Persons who used electronic signatures must employ controls to ensure their security and integrity.

## 3.5 Physical Plant and Equipment Documentation

The following documentation must be made and kept for fulfilling the requirements of the physical plant and equipment quality system (see *1. General Provisions*).

### 3.5.1 WRITTEN PROCEDURES

Written procedures must be established and followed for the following:

- Maintaining, cleaning, and sanitizing as necessary, the physical plant and facilities
- Pest control
- Maintaining, cleaning, and sanitizing as necessary, equipment, utensils, and any other contact surfaces that are used to manufacture package, label, or hold raw materials, other ingredients, in-process materials, and dietary ingredients
- Use of cleaning compounds, sanitizing agents, pesticides, and other toxic materials
- Pallet inspection
- Equipment and instrument qualification
- Calibrating instruments and controls used in manufacturing or testing a raw material, other ingredient, in-process material, or dietary ingredient
- Calibrating, inspecting, and checking automated, mechanical, and electronic equipment and instruments
- Operating and maintaining cGMP-related computerized systems

### 3.5.2 RECORDS

Records must be made and kept for the following:

- List of approved cleaning compounds, sanitizing agents, and corresponding safety data sheets
- Drawings for utility systems (e.g., water, steam, gases, compressed air, and heating, ventilation, and air conditioning)
- Physical plant and facility maintenance, cleaning, and sanitizing schedules, and logs of the date of maintenance and any cleaning and sanitizing unless such documentation is kept with the batch record
- Pest control
- Demonstrating that water, when used as a component of a dietary ingredient, meets all federal, state, and local standards of potability. Some intended uses of water in dietary ingredients may require the use of compendial grade *Purified water*
- List of manufacturing equipment and instrumentation
- Drawings and/or manuals for equipment and critical installations
- Documentation in individual equipment logs of the date of use, maintenance, cleaning, and sanitizing of equipment, unless such documentation is kept with the batch record
- Documentation of the controls used to ensure that equipment and instruments function in accordance with their intended use
- Documentation of any calibration and each time the calibration is performed for instruments and controls used in manufacturing or testing a raw material, other ingredient, in-process material, or dietary ingredient
    - The documentation must identify the instrument or control calibrated and date of its calibration, identify the reference standard used including the certification of accuracy of the reference standard and history of recertification of accuracy, identify the calibration method used including appropriate acceptance limits for accuracy and precision of instruments and controls when calibrating, provide the calibration reading(s) found, identify the recalibration method used and reading(s) found if accuracy and/or precision acceptance limits were not met, and initials of the person who performed the calibration or recalibration
- Documentation of pallet inspection and disposition
- Documentation of equipment and instrument qualification

@2024 USPC

- Documentation of calibrations, inspections, and checks of automated, mechanical, and electronic equipment
- Back-up file(s) of current and outdated software, as necessary, for retrieval of records that are required to be kept, and of data entered into the computer system used to manufacture, package, label, and hold dietary ingredients

Back-up file(s) (e.g., a hard copy of data entered, tapes, compact disks, flash drives) must be an exact and complete record of the date entered and must be kept secure from alterations, inadvertent erasures, or loss.

# 4. MATERIALS MANAGEMENT OPERATIONS AND CONTROLS

The person(s) authorized to release raw materials, other ingredients, packaging materials, labeling, and dietary ingredients should be specified. No materials should be released or used before the satisfactory completion of evaluation by the quality unit(s) unless appropriate systems are in place to allow for such use (e.g., release under quarantine, see *4.5 Holding, Distribution, and Transportation*).

## 4.1 Establishing Material and In-Process Production Specifications

Specifications must be established for any point, step, or stage in the manufacturing process in which control is necessary to ensure the quality of the dietary ingredient and that the dietary ingredient is packaged and labeled as specified in the master manufacturing and packaging control record.

### 4.1.1 RAW MATERIAL AND OTHER INGREDIENT SPECIFICATIONS

Specifications must be established for each raw material and other ingredient that is used in the manufacture of a dietary ingredient to ensure that the specifications for its purity, strength, and composition are met. The specification for the raw materials and other ingredients should include test specifications for the following:

- Identity (i.e., identification)
- Purity, strength, or composition (i.e., content or assay)
- Limits on contaminants that may adulterate or may lead to adulteration of the finished batch of dietary ingredients
- Applicable specific tests (e.g., peroxide value, anisidine value for oil rancidity)
- Manufacturing processing quality tests (e.g., particle size, bulk density)

Starting materials and processing aids used to manufacture dietary ingredients should be of suitable quality to ensure that the finished dietary ingredient meets appropriate standards of identity, strength, purity, composition, and limits on contaminants.

Other ingredients used in manufacturing dietary ingredient preparations should meet *USP*, *NF*, or *Food Chemical Codex* standards. When such standards do not exist, other ingredients may be used in dietary ingredients if they have been shown to be of acceptable food grade quality using other suitable procedures.

Raw materials and other ingredients either must not contain levels of microorganisms that may render the food injurious to the health of humans, or must be pasteurized or otherwise treated during manufacturing operations so that they no longer contain levels that would cause the dietary ingredient to be adulterated.

Other ingredients may be added to dietary ingredients provided that the other ingredients comply with applicable regulatory requirements and do not interfere with the assay and tests prescribed for determining compliance with the dietary ingredient compendial specification.

Adequate documentation must be provided for the basis for why the raw material and other ingredient specifications will help ensure that the specifications are met for the identity, purity, strength, and composition of the dietary ingredients and for limits on those types of contamination that may adulterate or may lead to adulteration of the finished batch of the dietary ingredient.

Each raw material and other ingredient received from a supplier that is liable to contamination with microorganisms, filth, insect infestation, allergens, aflatoxins, other natural toxins, pesticides, organic impurities (e.g., residual solvents), inorganic impurities (e.g., elemental impurities), foreign substances, or other extraneous substances that may be a source of contamination that is objectionable in view of its intended use must be tested or examined against established specifications for such contamination. The following *USP* chapters should be consulted:

- *Residual Solvents* ⟨467⟩
- *Articles of Botanical Origin* ⟨561⟩, *Test for Aflatoxins* and *Pesticide Residue Analysis*
- *Microbial Enumeration Tests* ⟨2021⟩
- *Absence of Specified Microorganisms* ⟨2022⟩
- *Microbiological Attributes of Nonsterile Nutritional and Dietary Supplements* ⟨2023⟩
- *Elemental Contaminants in Dietary Supplements* ⟨2232⟩

Raw materials and other ingredients susceptible to contamination with aflatoxin or other natural toxins must comply with FDA regulations for poisonous or deleterious substances before these raw materials or other ingredients are incorporated into the dietary ingredient and ultimately finished food.

Raw materials, other ingredients, and rework susceptible to contamination with pests, undesirable microorganisms, or extraneous material must comply with applicable FDA regulations for natural or unavoidable defects if a manufacturer wishes to use the materials in manufacturing food.

#### 4.1.2 IN-PROCESS PRODUCTION SPECIFICATIONS

Specifications must be established for in-process production for any point, step, or stage in the master production and control record in which control is necessary to help ensure that the specifications are met for the identity, purity, strength, and composition of the dietary ingredients and, as necessary, for limits on those types of contamination that may adulterate or may lead to adulteration of the finished batch of the dietary ingredient.

Adequate documentation must be provided for the basis for why meeting the in-process specifications, in combination with meeting raw material and other ingredient specifications, will help ensure that the specifications are met for the identity, purity, strength, and composition of the dietary ingredients and for limits on those types of contamination that may adulterate or may lead to adulteration of the finished batch of the dietary ingredient. Quality unit personnel must review and approve this documentation.

#### 4.1.3 LABELING AND PACKAGING MATERIAL SPECIFICATIONS

Specifications must be established for labeling (see *Labeling* ⟨7⟩) and packaging materials that come in contact with dietary ingredients (see *Packaging and Storage Requirements* ⟨659⟩, *Containers—Glass* ⟨660⟩, *Plastic Packaging Systems and Their Materials of Construction* ⟨661⟩, *Plastic Materials of Construction* ⟨661.1⟩, *Plastic Packaging Systems for Pharmaceutical Use* ⟨661.2⟩, *Auxiliary Packaging Components* ⟨670⟩, *Containers—Performance Testing* ⟨671⟩). Packaging that may come into contact with dietary ingredients must be safe and suitable for its intended use and must not be reactive or absorptive or otherwise affect the safety or quality of the dietary ingredient.

#### 4.1.4 IN-PROCESS DIETARY INGREDIENT SPECIFICATIONS

Specifications must be established for each dietary ingredient that is manufactured. The specification for the dietary ingredient should include test specifications for the following:

- Identity (i.e., identification) should be established through a validated method that has a high degree of specificity to differentiate between similar dietary ingredients
- Purity, strength, or composition (i.e., content or assay)
- Limits on contaminants that may adulterate or may lead to adulteration of the finished batch of dietary ingredients
- Applicable specific tests (e.g., peroxide value, anisidine value for oil rancidity)
- Applicable performance tests (e.g., particle size)
- Applicable manufacturing quality tests (e.g., content uniformity)

Dietary ingredients that have a *USP* monograph should comply with the monograph standard and other applicable standards in that compendium.

**4.1.4.1 Defect action levels:** Some dietary ingredients, even when produced under cGMPs, contain naturally occurring unavoidable defects that at low levels present no health hazard. The FDA set defect action levels because it is economically impractical to grow, harvest, or process raw products that are totally free of non-hazardous, naturally, and unavoidable defects. Products harmful to consumers are subject to regulatory action whether or not they exceed the defect action levels. The manufacturer, packer, and holder of a dietary ingredient must at all times utilize quality unit operations that reduce natural or unavoidable defects to the lowest level currently feasible. The mixing of a dietary ingredient containing defects at levels that render that dietary ingredient adulterated with another lot of dietary ingredient is not permitted and renders the final dietary ingredient adulterated, regardless of the defect action level of the final dietary ingredient.

#### 4.1.5 RECEIVED IN-PROCESS DIETARY INGREDIENT SPECIFICATIONS

Specifications must be established for an in-process dietary ingredient received from a supplier for packaging and labeling and for its distribution rather than for return to the supplier. The specification must provide sufficient assurance that the in-process dietary ingredient received is adequately identified and consistent with the purchase order or supplier quality agreement.

#### 4.1.6 FINISHED DIETARY INGREDIENT SPECIFICATIONS

Specifications must be established for the packaging and labeling of the finished packaged and labeled dietary ingredients that ensure the correct packaging and labeling was used.

### 4.2 Determining Compliance with Specifications

#### 4.2.1 GENERAL

Quality unit personnel must determine whether the specifications set for raw materials, other ingredients, in-process materials, packaging materials, labeling, in-process dietary ingredients, received in-process dietary ingredients, and finished dietary ingredients are met.

QC (laboratory control) unit personnel must conduct the necessary tests to determine whether the specifications for raw materials, other ingredients, in-process materials, and dietary ingredients comply with specifications. On the basis of adequate process verification, in-process controls, and statistical confidence, a reduced testing (or sampling) plan can be used as an alternative to fully testing of contaminants in every batch of material.

Tests and examinations that are used to determine whether material specifications are met must be appropriate for their intended use, and scientifically validated methods according to *Validation of Compendial Procedures* ⟨1225⟩.

Official

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-May-2022
DOI Ref: 3a0hm
DocId: GUID-DE5DE10D-9550-4D57-8933-7B9B1C922698_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

The QC unit must conduct or review and approve an OOS investigation prior to making a material use and disposition decision on any dietary ingredients. Corrective action plans must be developed and implemented when a dietary ingredient is confirmed to be out-of-specification and a root cause has been identified.

### 4.2.2 RAW MATERIALS AND OTHER INGREDIENTS

Before any raw material or other ingredient is used in manufacturing, at least one appropriate test or examination must be conducted to verify the identity of the raw material or other ingredient and determine whether other applicable raw material and other ingredient specifications are met by doing one of the following:

- Conduct appropriate tests or examinations for all of the test specifications
- Rely on the certificate of analysis from the supplier of the raw material and other ingredient received, provided the following:
  - The supplier is qualified by establishing the reliability of the supplier's certificate of analysis through confirmation of the results of the supplier's tests or examinations, on-site audit, and other appropriate supplier qualification activities
  - The certificate of analysis includes a description of the specific tests or examination methods used (i.e., specific reference to a test procedure that can be performed by an experienced scientist), acceptance criteria for the tests or examinations, and actual results of the tests or examinations
  - Documentation is maintained of how the supplier was qualified
  - The reliability of the supplier's certificate of analysis is periodically re-confirmed (i.e., requalified)
  - Quality unit personnel have reviewed and approved the documentation setting forth the basis for qualification and requalification of the supplier

### 4.2.3 IN-PROCESS PRODUCTION

In-process points, steps, or stages where control is necessary to ensure the quality of the finished batch of dietary ingredients must be monitored to determine whether in-process specifications are met and to detect any deviation or unanticipated occurrence that may result in the failure of the dietary ingredient to meet specifications.

### 4.2.4 DIETARY INGREDIENTS

For every batch of dietary ingredients, the manufacturer must verify that the batch meets product specifications for identity, purity, strength, and composition. Reduced testing (i.e., reduced sampling) of contaminants that may adulterate or may lead to adulteration of the dietary ingredient can be applied to batches that have been identified through a sound statistical sampling plan:

- Established specifications for limits on those types of contamination that may adulterate or that may lead to adulteration of the dietary ingredient would verify that the production process control system is producing a dietary ingredient that meets product specifications
- Appropriate tests or examinations must be conducted to determine compliance with the applicable specifications
- Adequate documentation must be provided of the basis for determining how compliance with reduced testing of contaminants will ensure that the finished batch of dietary ingredients will meet all product specifications for the limits on those types of contamination that may adulterate or that may lead to adulteration of the dietary ingredient
- Quality unit personnel must review and approve all supporting documentation for reduced testing

### 4.2.5 RECEIVED IN-PROCESS DIETARY INGREDIENT

A product received for packaging or labeling as a dietary ingredient and for distribution rather than for return to the supplier must be visually examined and documentation must be provided or obtained through testing and examination to determine whether the in-process product specifications are met.

### 4.2.6 PACKAGING MATERIAL AND LABELING

Before packaging material is used, a visual identification of the containers and closures must be conducted and the supplier's invoice, guarantee, or certification must be reviewed to determine whether the packaging specifications are met, at a minimum.

Before labeling is used, at minimum, a visual identification of the labeling must be conducted and the supplier's invoice, guarantee, or certification must be reviewed to determine whether the labeling specifications are met.

### 4.2.7 FINISHED DIETARY INGREDIENTS

At minimum, a visual examination of the packaging and labeling of the finished dietary ingredient must be conducted to determine whether the packaging used and the label applied was specified in the master packaging control record.

### 4.2.8 DISPOSITION DECISION FOR MATERIALS

For raw materials, other ingredients, in-process materials, packaging materials, labeling, and dietary ingredients that meet specifications, the quality unit may approve the material for use in manufacturing.

For raw materials, other ingredients, in-process materials, packaging materials, labeling, and dietary ingredients that do not meet specifications, the quality unit must reject the material for use in manufacturing, unless quality unit personnel approve a

Do Not Distribute

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-May-2022
DOI Ref: 3a0hm
DocId: GUID-DE5DE10D-9550-4D57-8933-7B9B1C922698_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

treatment, an in-process adjustment, or reprocessing that will ensure the quality of the finished dietary ingredient, and that the dietary ingredient is packaged and labeled as specified in the master packaging record.

For raw materials and other ingredients that do not meet specification(s) for identity (i.e., identification), QC personnel must reject the raw material or other ingredient, which must not be used in manufacturing the dietary ingredient.

For a dietary ingredient received from a supplier for packaging and/or labeling as a dietary ingredient and for distribution rather than for return to the supplier that does not meet specifications, QC personnel must reject the product, which may not be packaged or labeled for distribution as a dietary ingredient.

The quality unit personnel must not approve and release for distribution any batch or reprocessed batch of dietary ingredient in the following situations:

- When any component in the batch does not meet its identity specification
- When all product specifications are not met
- When a dietary ingredient has not been manufactured, packaged, labeled, and held under conditions to prevent adulteration
- When a dietary ingredient was received from a supplier for packaging or labeling as a dietary ingredient and for distribution rather than return to the supplier, but without sufficient assurance provided to adequately identify the product and to determine that the product is consistent with its purchase order

#### 4.2.9 TREATMENTS, IN-PROCESS ADJUSTMENTS, AND REPROCESSING

A rejected dietary ingredient must not be reprocessed, and a rejected component, packaging material, or labeling must not undergo treatment or in-process adjustment to make it suitable for use in the manufacture of a dietary ingredient, unless the following is done:

- Quality unit personnel conduct a material review and make a disposition decision that is based on a scientifically valid reason and approves the reprocessing, treatment, or in-process adjustment
- The reprocessing, treatment, or in-process adjustment will ensure the quality of the finished dietary ingredient and that the dietary ingredient is packaged and labeled as specified in the master production and control record
- All raw materials and other ingredients in the batch met its identity (i.e., identification) specification

For a rejected dietary ingredient received from a supplier for packaging and/or labeling as a dietary ingredient and for distribution rather than for return to the supplier that does not meet specifications, QC personnel must reject the dietary ingredient and the dietary ingredient may not be packaged or labeled for distribution as a dietary ingredient.

Any batch of dietary ingredient that is reprocessed, that contains raw materials and other ingredients that have been treated, or to which in-process adjustments have been made to make them suitable for use in the manufacture of the dietary ingredient must be approved by quality unit personnel before release for distribution.

Prior to approving any batch of dietary ingredient for reprocessing or an in-process adjustment, the quality unit should determine what tests should be performed to verify the effectiveness of the reprocessing/in-process adjustment to ensure that specifications have not been compromised.

Quality unit personnel must not approve and release for distribution any batch or reprocessed batch of dietary ingredient in the following situations:

- When any component in the batch does not meet its identity specification
- When all product specifications have not been met
- When the dietary ingredient has not been manufactured, packaged, labeled, and held under conditions to prevent adulteration
- When the dietary ingredient was received from a supplier for packaging or labeling as a dietary ingredient and for distribution rather than return to the supplier, but without sufficient assurance provided to adequately identify the product and to determine that the product is consistent with its purchase order

### 4.3 Receiving and Release of Materials

#### 4.3.1 RAW MATERIALS, OTHER INGREDIENTS, PACKAGING MATERIALS, AND LABELS

The person responsible for receiving raw materials, other ingredients, packaging materials, or labels must visually examine each immediate container or grouping of immediate containers in a shipment that is received for the appropriate content label, container damage, or broken seals to determine whether the container condition may have resulted in contamination or deterioration of the raw materials, other ingredients, packaging materials, or labels. The person must visually examine the supplier's invoice, guarantee, or certification in a shipment that is received to ensure the raw materials, other ingredients, packaging materials, and labels are consistent with the purchase order.

Raw materials received via bulk truck or railcar must include verification that the vehicle is dedicated to that service or that the vehicle has been properly cleaned and the prior load does not pose a risk of contamination.

Raw materials and other ingredients must be inspected and segregated or otherwise handled as necessary to ascertain that they are clean and suitable for processing into a dietary ingredient and must be stored under conditions that will protect against allergen cross-contact, against contamination, and minimize deterioration. Raw materials must be washed or cleaned as necessary to remove soil or other contamination. Water used for washing, rinsing, or conveying food must be safe and of adequate sanitary quality (i.e., potable water).

The raw materials, other ingredients, packaging materials, and labels must be placed in quarantine before they are used in the manufacture of a dietary ingredient until the following occurs:

Official

https://pharmacopeia.cn/

Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-May-2022
DOI Ref: 3a0hm
DocId: GUID-DE5DE10D-9550-4D57-8933-7B9B1C922698_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

- Representative samples of each unique shipment of raw materials, other ingredients, packaging materials, and labels received are collected, as well as of each unique lot within each unique shipment of raw materials, other ingredients, packaging materials, and labels
- Quality unit personnel review and approve the results of any tests or examinations conducted on raw materials, other ingredients, packaging materials, and labels
- Quality unit personnel approve and release from quarantine the raw materials, other ingredients, packaging materials, and labels for use in the manufacture of a dietary ingredient, including approval of any treatment or in-process adjustments of raw materials, other ingredients, packaging materials, and labels to make them suitable for use in the manufacture of a dietary ingredient

Each unique lot within each unique shipment of raw materials, other ingredients, packaging materials, and labels that is received, and any lot of raw materials and other ingredients that are produced, must be identified in a manner that allows a person to trace the lot to the supplier by the date received; the name and status (e.g., quarantined, approved, or rejected) of the raw material, other ingredient, packaging material, and label; as well as to the dietary ingredient that was manufactured and distributed. This unique identifier must be used whenever recording the disposition of each unique lot within each unique shipment of raw materials, other ingredients, packaging materials, and labels that was received, and any lot of in-process material or dietary ingredient produced.

Raw materials, other ingredients, packaging materials, and labels must be held under conditions that will protect against contamination and deterioration and avoid mix ups.

#### 4.3.2 PRODUCT RECEIVED FOR PACKAGING AND LABELING AS A DIETARY INGREDIENT

The person responsible for receiving product for packaging and labeling as a dietary ingredient and for distribution rather than for return to the supplier must visually examine each immediate container or grouping of immediate containers in a shipment for appropriate content label, container damage, or broken seals to determine whether the container condition may have resulted in contamination or deterioration of the received product. That person must visually examine the supplier's invoice, guarantee, or certification in a shipment of received product to ensure the received product is consistent with the purchase order.

The received product must be placed in quarantine before it is used in the packaging and labeling of a dietary ingredient until the following occurs:

- Representative samples of each unique shipment of received product and of each unique lot within each unique shipment of received product are collected
- Quality unit personnel review and approve results of any tests or examinations conducted on the received product and review and approve the documentation supplied with the received product to determine whether it meets specifications
- Quality unit personnel approve the received product for packaging and labeling as a dietary ingredient and release the received product from quarantine

Each unique lot within each unique shipment of received product must be identified in a manner that allows a person to trace the lot to the supplier by the date received, the name of the received product, packaging material and label, the status of the received product (e.g., quarantined, approved, or rejected), as well as to the dietary ingredient that was packaged and labeled and distributed. This unique identifier must be used whenever recording the disposition of each unique lot within each unique shipment of received product.

Received product must be held under conditions that will protect against contamination and deterioration, and avoid mix-ups.

### 4.4 Representative Samples and Reserve Samples

#### 4.4.1 REPRESENTATIVE SAMPLES

Quality unit personnel must collect representative samples of the following:

- Each unique shipment and each unique lot within each unique shipment of raw materials, other ingredients, packaging material, and labels to be used in manufacturing to determine whether the material meet established specifications
- In-process materials for each manufactured batch at points, steps, or stages in the manufacturing process as specified in the master production and control record where control is necessary to ensure identity, purity, strength, and composition of dietary ingredients, to determine whether in-process materials meet specifications
- Each finished manufactured batch of dietary ingredient before releasing for distribution to verify that the finished batch of dietary ingredient meets specifications
- Each unique shipment and each unique lot within each unique shipment of product received for packaging or labeling as a dietary ingredient and for distribution rather than for return to the supplier to determine whether the received product meets established specifications
- Each lot of packaged and labeled dietary ingredients to determine whether the packaging used and the label applied was specified in the master packaging control record

The representative samples of dietary ingredients must be held in a suitable container–closure system that represents similar barrier properties to the container–closure system in which the dietary ingredient is ultimately sold to the user.

A sampling room or booth must be used to sample raw materials and other ingredients to protect material from allergen cross-contact and contamination.

Written procedures for sampling must be established and followed. The number of containers sampled and the amount of material to be sampled from each container should be based on appropriate criteria such as component variability, statistical

https://pharmacopeia.cn/

DocId: GUID-DE5DE10D-9550-4D57-8933-7B9B1C922698_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

confidence levels, degree of precision desired, the past quality history of the supplier, and the quantity of material needed for analysis and reserve, when required. Sampling procedures should include the following:

- Containers should be cleaned prior to opening
- Containers should be opened, sampled, and resealed in a manner designed to prevent contamination of their contents and contamination of other raw materials, other ingredients, product containers, or closures
- Containers should be identified so that the following information can be determined: name of the material sampled, the lot number, the container from which the sample was taken, the date on which the sample was taken, and the name of the person who collected the sample

Sampling of botanicals should be in compliance with the provisions in ⟨561⟩.

#### 4.4.2 RESERVE SAMPLES

Quality unit personnel must collect and hold reserve samples of each lot of packaged and labeled dietary ingredients that is distributed, which must be held using a container–closure system that provides essentially the same characteristics to protect against contamination or deterioration as the one in which it is distributed.

Reserve samples of dietary ingredients must be identified with the batch, lot, or control number. The reserve sample of each batch of dietary ingredients must consist of at least twice the quantity necessary for all tests or examinations to determine whether the dietary ingredient meets product specifications and must be collected and retained for at least 1 year past its retest or expiry date.

### 4.5 Holding, Distribution, and Transportation

Written procedures must be established and followed for holding or warehousing and distributing operations.

#### 4.5.1 HOLDING

Raw materials and other ingredients and dietary ingredients must be held under appropriate conditions of temperature, humidity, and light so that the identity, purity, strength, and composition of the raw materials and other ingredients and dietary ingredients are not affected. Raw materials and other ingredients, along with rework, must be held in bulk, or in containers designed and constructed so as to protect against contamination and must be held at such temperature and relative humidity and in such a manner as to prevent the food from becoming contaminated. Frozen raw materials and other ingredients must be kept frozen. If thawing is required prior to use, it must be done in a manner that prevents the raw materials and other ingredients from becoming contaminated. Liquid or dry raw materials and other ingredients received and stored in bulk form must be held in a manner that protects against allergen cross-contact and against contamination. Raw materials and other ingredients that are food allergens and rework that contains food allergens must be identified and held in a manner that prevents allergen cross-contact.

Storage of dietary ingredients must be under conditions that will protect against contamination, as well as the deterioration of the dietary ingredient and the container.

Packaging materials and labeling must be held under appropriate conditions so that they are not adversely affected. Raw materials, other ingredients, dietary ingredients, packaging materials, and labeling must be held under conditions that do not lead to the mix-up or contamination of raw materials, other ingredients, dietary ingredients, packaging materials, and labeling.

In-process material must be identified and held under appropriate conditions that protect against mix-up and contamination. In-process material must be held under appropriate conditions of temperature, humidity, and light to protect against deterioration.

Raw materials and other ingredients and in-process materials that contain food allergens must be clearly identified and held in a manner that prevents allergen cross-contact.

Reserve samples of dietary ingredients must be held in a suitable container–closure system that represents similar barrier properties to the container–closure system in which the dietary ingredient is ultimately sold to the user.

Reserve samples of dietary ingredients must be held in a manner that protects against contamination and deterioration. Reserve samples of dietary ingredients must be held under conditions consistent with the label conditions stated on the product labels. If no storage conditions are recommended on the label (e.g., for in-process dietary ingredients), they must be held under ordinary storage conditions consistent with expected storage conditions for the finished product. Reserve samples of dietary ingredients must be held using the same container–closure system in which packaged and labeled dietary ingredients are distributed. If distributing dietary ingredients that are to be packaged and labeled, a container–closure system that provides essentially the same characteristics to protect against contamination or deterioration must be used.

Reserve samples must be retained for 1 year past the retest or expiry date of the dietary ingredient for use in appropriate investigations.

#### 4.5.2 REJECTED MATERIALS

Any raw material, other ingredients, packaging material, labels, and products received for packaging and labeling as a dietary ingredient and for distribution rather than return to the supplier that is rejected and is unsuitable for use in manufacturing, packaging, and labeling operations must be clearly identified, held, and controlled under a quarantine system for appropriate disposition. The quarantine system for rejected materials must include physical segregation and conspicuous labeling of the material, in addition to any electronic controls.

@2024 USPC

#### 4.5.3 RETURNED DIETARY INGREDIENTS

Returned dietary ingredients must be identified and quarantined until quality unit personnel conduct a material review and make a disposition decision.

Returned dietary ingredients must be destroyed or otherwise suitably disposed of unless the outcome of a material review and disposition decision is that QC personnel do one of the following:

- Approve the salvage of the returned dietary ingredient for redistribution
- Approve the returned dietary ingredient for reprocessing

A returned dietary ingredient may be salvaged only if QC personnel conduct a material review and make a disposition decision to allow the salvage.

Any returned dietary ingredients that are reprocessed must meet all dietary ingredient specifications, and QC personnel must approve or reject the release for distribution any returned dietary ingredient that is reprocessed.

If the reason for a dietary ingredient being returned implicates other batches, an investigation of the manufacturing processes and each of those other batches must be conducted to determine compliance with specifications.

#### 4.5.4 DISTRIBUTION

Dietary ingredients must be distributed under conditions that will protect the dietary ingredient against contamination and deterioration. The first manufactured batch of a dietary ingredient should be distributed first. Distributing operations must be designed to facilitate recall of dietary ingredients, if necessary.

#### 4.5.5 TRANSPORTATION OPERATIONS

All transportation operations must be conducted under such conditions and controls necessary to prevent dietary ingredients from becoming adulterated and to protect against deterioration of the dietary ingredient and the container during transportation.

Vehicles and transportation equipment used in transportation operations must meet the following standards:

- Adequately designed and maintained in a sanitary condition for their intended use to prevent raw materials and other ingredients and dietary ingredients from becoming adulterated during transportation operations
- Designed, maintained, and equipped as necessary to provide adequate temperature control to prevent raw materials and other ingredients and dietary ingredients requiring temperature control from becoming adulterated during transportation
- Stored in a manner that prevents it from harboring pests or becoming contaminated in any other manner that could result in raw materials and other ingredients or dietary ingredients for which it will be used becoming adulterated during transportation operations

Responsibility for ensuring that transportation operations are carried out adequately must be assigned to competent supervisory personnel.

Shippers, receivers, loaders, and carriers engaged in transportation must conduct all transportation operations under such conditions and controls necessary to prevent raw materials and other ingredients and dietary ingredients from becoming unsafe during transportation. Such operations include taking the following effective measures:

- Segregation, isolation, or the use of packaging to protect raw materials and other ingredients and dietary ingredients from contamination from other articles in the same load
- Ensure that raw materials and other ingredients and dietary ingredients that require temperature control for safety and quality are transported under adequate temperature control
- Restrict the co-shipment with a non-food item, which might render the raw materials and dietary ingredients to become adulterated through cross-contamination

Shippers must specify to the carrier and the loader all necessary sanitary specifications for the carrier's vehicle and transportation equipment including any specific design specifications (e.g., temperature control) and cleaning procedures.

Considering specifications provided by the shipper when appropriate, loaders must determine if the vehicle or transportation equipment is in appropriate sanitary and operational condition for the transport of raw materials and other ingredients and dietary ingredients.

Upon receipt of raw materials and other ingredients and dietary ingredients, receivers must take steps to adequately assess whether the raw materials and other ingredients and dietary ingredients were not subjected to adverse conditions that may have caused them to become adulterated.

Carriers must ensure that vehicles and transportation equipment meet the shipper's specifications and are otherwise appropriate to prevent raw materials and other ingredients and dietary ingredients from becoming adulterated during transportation operations.

Measures to implement requirements and procedures may be accomplished by the shipper or the carrier or another party involved in transportation operations under a written agreement.

Records should be maintained regarding specifications, agreements, procedures, associated records related to transportation (maintenance, cleaning, previous cargoes, temperature control), and training.

### 4.6 Materials Management Operations and Control Documentation

The following documentation must be made and kept for fulfilling the requirements of the material management controls quality system (see *1. General Provisions*).

Official

DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

#### 4.6.1 WRITTEN PROCEDURES

Written procedures must be established and followed for the following:

- Preparing, reviewing, and approving material and in-process production specifications
- Supply chain control program
- Material receiving, sampling, testing, and making a disposition decision for materials to be used in manufacturing
- Warehousing maintenance, cleaning, and inventory controls
- Pallet inspection, cleaning, and maintenance
- Implementing a supply-chain control program
- Holding and distributing operations
- Receiving and conducting material reviews and making disposition decisions for returned dietary ingredients

#### 4.6.2 RECORDS

Records must be made and kept for the following:

- Specifications for raw materials, other ingredients, in-process production, packaging materials, labeling, in-process dietary ingredients, received in-process dietary ingredients, and finished dietary ingredients
- List of approved suppliers of raw materials, other ingredients, packaging materials and labeling, and corresponding supplier qualification evaluation reports for the purpose of relying on the supplier's certificate of analysis
- Documentation explaining why meeting in-process specifications, in combination with meeting component specifications, help to ensure that the dietary ingredient meets the specifications for identity, purity, strength, and composition, as well as for limits on those types of contamination that may adulterate or may lead to adulteration of the finished batch of the dietary ingredient
- Documentation explaining why the results of appropriate reduced tests or examinations for dietary ingredients ensure that the dietary ingredient meets all product specifications
- Receiving records (e.g., certificates of analysis, supplier's invoice, and supplier's guarantee) for materials
- Inventory control records documenting material history of use
- Documentation at the time of performance that demonstrates that QC unit personnel determined whether the specifications set for materials to be used in manufacturing were met (i.e, performed the required tests and made a disposition decision for materials)
- Dietary ingredient distribution
- Documentation of any material review and disposition decisions on a returned dietary ingredient
- The results of any testing or examination of returned dietary ingredients to determine compliance with product specifications
- Documentation of the re-evaluation by quality unit personnel of any dietary ingredient that is reprocessed and the determination by quality unit personnel of whether the reprocessed dietary ingredient meets in-process dietary ingredient specifications

## 5. PRODUCTION OPERATIONS AND CONTROLS

All dietary ingredient manufacturing, processing, packing, and holding must be conducted under such conditions and controls that are necessary to minimize the potential for the growth of microorganisms, allergen cross-contact, contamination of food, and deterioration of dietary ingredient. Equipment, containers, and utensils used to convey, hold, or store raw materials, other ingredients, work-in-process, rework, or dietary ingredients must be constructed, handled, and maintained during manufacturing, processing, packing, and holding in a manner that protects against allergen cross-contact and contamination.

### 5.1 Master Production Records

Written master production records must be prepared and followed for each unique formulation of dietary ingredients manufactured, and for each batch size to ensure batch-to-batch uniformity in the finished dietary ingredient. The master production record for each in-process material (i.e., intermediate) and dietary ingredient should be prepared, dated, and signed by one person in production, and then independently checked, dated, and signed by a person in the quality unit.

The master production record may include all manufacturing, packaging, and labeling directions and controls, or it may be separated into two records: one for manufacturing and another for packaging and labeling.

The master production record must do the following:

- Identify in-process production specifications for the points, steps, or stages in the manufacturing process where control is necessary to ensure the quality of the dietary ingredient and that the dietary ingredient is packaged and labeled as specified in the master production and control record
- Establish controls and procedures to ensure that each batch of dietary ingredient that is manufactured meets in-process specifications

The master production record must include the following:

- The name of the intermediate (i.e., in-process material) or dietary ingredient to be manufactured and an identifying document reference code
- The strength, concentration, weight, or measure of each raw material and other ingredient for each batch size

Official

- A complete list of raw materials and other ingredients to be used, designated by names and codes specific to identify any special quality characteristics
- An accurate statement of the weight or measure of each raw material and other ingredient to be used
  - When the quantity is not fixed, the calculation for each batch size or rate of production should be included
  - Variations to quantities should be included where they are justified
- The identity and weight or measure of each other ingredient and dietary ingredient that will be declared on the finished dietary ingredient (preparation) list of ingredients
- Detailed production instructions, including the following:
  - Sequences to be followed
  - Ranges of process parameters to be used
  - Sampling instructions and in-process controls with their acceptance criteria, when appropriate
  - Time limits for completion of individual processing steps and/or the total process, when appropriate
  - Expected yield ranges at appropriate phases of processing or time
- A statement of theoretical yield of a manufactured intermediate or dietary ingredient (preparation) expected at each point, step, or stage of the manufacturing process where control is needed to ensure the quality of the dietary ingredient, and of the expected yield at the end of manufacturing the dietary ingredient, including the maximum and minimum percentages of theoretical yield beyond which a deviation investigation of a batch is necessary and a material review is conducted and disposition is made
- Where appropriate, special notations and precautions to be followed, or cross-references to them
- The instructions for storage of the intermediate or finished dietary ingredient to assure its suitability for use, including a description of packaging materials and a representative label, or cross-reference to the physical location of the actual or representative label, and special storage conditions with time limits, when appropriate

The master production record must also include written instructions, including the following:

- Specifications for each point, step, or stage in the manufacturing process where control is necessary to ensure the quality of the dietary ingredient and that the dietary ingredient is packaged and labeled as specified in the master production and control record
- Procedures for sampling and cross-reference to procedures for tests and examinations
- Specific actions necessary to perform and verify points, steps, or stages in the manufacturing process where control is necessary to ensure the quality of the dietary ingredient and that the dietary ingredient is packaged and labeled as specified in the master production and control record
  - Such specific actions must include verifying the weight or measure of any raw material and other ingredient and verifying the addition of any raw material and other ingredient
  - For manual operations, such specific actions must include the following:
    - One person weighing or measuring a raw material and other ingredient and another person verifying the weight or measure
    - One person adding the raw material and other ingredient and another person verifying the addition
- Special notations and precautions to be followed
- Corrective action plans for use when a specification is not met

## 5.2 Executed Batch Production Records

An executed batch production record (paper or electronic) must be prepared or generated every time a batch of dietary ingredients is manufactured, and it must include complete information relating to the production and control of each batch. The executed batch production and control record must accurately follow the appropriate master production and control record, and each step in the production of the batch must be performed.

The executed batch production record must include the following:

- The batch, lot, or control number of the dietary ingredient, of each lot of packaged and labeled dietary ingredient from a finished batch of dietary ingredient, and of each lot of dietary ingredient from the finished batch of dietary ingredient that is distributed to another person for packaging or labeling
- The identity of equipment and processing lines used in producing the batch (exceptions can be noted when equipment is dedicated or the identity of the product or processing is self-evident)
- The date and time of the maintenance, cleaning, and sanitizing of the equipment and processing lines used in producing the batch, or a cross-reference to records, such as individual equipment logs, where this information is retained
- The unique identifier that was assigned to each raw material and other ingredient used or, when applicable, to a used product that was received from a supplier for packaging and labeling as a dietary ingredient, packaging, and labeling
- The identity and weight or measure of each raw material and other ingredient used
- A statement of the actual yield and a statement of the percentage of theoretical yield at appropriate phases of processing
- The actual results obtained during any monitoring operation
- The results of any testing or examination performed during the batch production, or a cross-reference to such results
- Documentation that the finished dietary ingredient meets the in-process dietary ingredient and finished dietary ingredient specifications

The executed batch production record must also include documentation at the time of performance of the manufacture of the batch, including the following:

- The date on which each step of the master production and control record was performed

Official

https://pharmacopeia.cn/

- The initials of the person performing each step, including initials of the persons responsible for the following:
  - Weighing or measuring each raw material and other ingredient used in the batch
  - Verifying the weight or measure of each raw material and other ingredient used in the batch
  - Adding the raw material and other ingredient to the batch
  - Verifying the addition of raw materials and other ingredients to the batch
- Documentation at the time of performance of packaging and labeling operations, including the following:
  - The unique identifier that was assigned to packaging and labels used, the quantity of the packaging and labels used, and, when label reconciliation is required, reconciliation of any discrepancies between issuance and use of labels
  - An actual or representative label, or a cross-reference to the physical location of the actual or representative label specified in the master manufacturing (or packaging and labeling) record
  - The results of any tests or examinations conducted on a packaged and labeled dietary ingredient, including repackaged or relabeled dietary ingredients, or a cross-reference to the physical location of such results
- Documentation at the time of performance that quality unit personnel did the following:
  - Reviewed the batch production record, including reviewing any monitoring operation required for determining compliance to material specifications and reviewing the results of any tests and examinations, including tests and examinations conducted on raw materials, other ingredients, in-process materials, finished batches of dietary ingredients, and packaged and labeled dietary ingredients
  - Approved or rejected any reprocessing or repackaging
  - Approved and released or rejected the batch for distribution, including any reprocessed batch
  - Approved and released or rejected the packaged and labeled dietary ingredient, including a repackaged or relabeled dietary ingredient
- Documentation at the time of performance of any required material review and disposition decision
- Documentation at the time of performance of any reprocessing

## 5.3 Manufacturing Operations Production and Process Controls

Written procedures must be established and followed for manufacturing operations. Manufacturing processes must be designed and selected to ensure that dietary ingredient specifications are consistently met.

All manufacturing operations must be conducted in accordance with adequate sanitation principles.

All necessary precautions must be taken during the manufacture of a dietary ingredient to prevent contamination of raw materials and other ingredients or dietary ingredients. These precautions include the following:

- Performing manufacturing operations under conditions and controls that protect against the potential for growth of microorganisms and the potential for allergen cross-contact and contamination
- Protecting dietary ingredients from contaminants that may drip, drain, or be drawn into the dietary ingredient
- Washing and cleaning raw materials and other ingredients that contain soil and other contaminants
- Using water that, at a minimum, complies with the applicable federal, state, and local requirements and does not contaminate the dietary ingredient when the water may be used as a raw material or may become another ingredient of the finished batch of dietary ingredient
- Performing chemical, microbiological, or other testing as necessary to prevent the use of contaminated raw materials and other ingredients
- Sterilizing, pasteurizing, freezing, refrigerating, controlling hydrogen-ion concentration (pH), controlling humidity, controlling water activity (aw), or using any other effective means to remove, destroy, or prevent the growth of microorganisms and prevent decomposition
- Washing, cutting, sorting and inspecting, mashing, dewatering, cooling, shredding, extruding, and drying performed in a manner that protects dietary ingredients against allergen cross-contact and against contamination
- Heat blanching when required in the preparation of dietary ingredients capable of supporting microbial growth, effected by heating the food to the required temperature, holding it at this temperature for the required time, and then either rapidly cooling the food or passing it to subsequent manufacturing without delay
  - Growth and contamination by thermophilic microorganisms in blanchers must be minimized by the use of adequate operating temperatures and by periodic cleaning and sanitizing, as necessary
- Treating or maintaining solutions and other similar preparations held and used repeatedly over time in such a manner that they are protected against allergen cross-contact and against contamination, and minimizing the potential for the growth of undesirable microorganisms
- Holding food at risk for the rapid growth of microorganisms of public health significance in a manner that prevents the food from becoming adulterated, such as keeping it at acceptable temperatures
- Processing and maintaining food that relies principally on the control of water activity for preventing the growth of undesirable microorganisms at a safe moisture level
- Monitoring and maintaining food that relies principally on the control of pH for preventing the growth of undesirable microorganisms at or below a pH of 4.6
- Identifying and holding any raw materials and other ingredients or dietary ingredients for which a material review and disposition decision is required and doing so in a manner that protects raw materials and other ingredients or dietary ingredients not under a material review against contamination and mix-ups with those that are under a material review

@2024 USPC

- Performing mechanical manufacturing steps (e.g., washing, peeling, trimming, cutting, sorting, inspecting, mashing, shredding, drying, grinding, blending, and sifting) by any effective means to protect the dietary ingredients against contamination, such as the following examples:
  - Cleaning and sanitizing contact surfaces
  - Using temperature controls
  - Using time controls
- Using effective measures to protect against the inclusion of metal or other foreign material in raw materials and other ingredients or dietary ingredients, such as filters or strainers, traps, magnets, or electronic metal detectors
- Segregating and identifying all containers for a specific batch of dietary ingredients to identify their contents and, when necessary, the phase of manufacturing
- Identifying all processing lines and major equipment used during manufacturing to indicate their contents, including the name of the dietary ingredient and the specific batch or lot number and, when necessary, the phase of manufacturing
- Protecting dietary ingredients transported by conveyor against allergen cross-contact and against contamination as necessary

## 5.4 Quality Unit Responsibilities for Production

Quality unit personnel must do the following:

- Review and approve all master production and control records and all modifications to them
- Review and approve all master packaging and labeling records (if separate from master production and control records) and all modifications to them
- Review and approve all batch production-related records
- Review all monitoring required for determining compliance to material specifications
- Conduct any material review and make any required disposition decisions
- Approve or reject any treatments, in-process adjustments, and reprocessing
- Determine whether all in-process production specifications are met
- Determine whether each finished batch of dietary ingredients conforms to its specifications
- Make a disposition decision (i.e., approving and releasing, or rejecting) each finished batch of dietary ingredients, including any reprocessed finished batch of dietary ingredients, for distribution

## 5.5 Disposition Decision for Production

For ingredients that meet specifications and that were manufactured, packaged, labeled, and held under conditions to ensure the quality of the dietary ingredient, the quality unit may approve and release the batch of dietary ingredients for distribution.

The quality unit personnel must not approve and release for distribution any batch or reprocessed batch of dietary ingredient in the following situations:

- Any raw material and other ingredient in the batch does not meet its identity specification
- It does not meet all product specifications
- It has not been manufactured, packaged, labeled, and held under conditions to prevent adulteration
- It was received from a supplier for packaging or labeling as a dietary ingredient and for distribution rather than return to the supplier, but without sufficient assurance to adequately identify the product and to determine that the product is consistent with its purchase order

For dietary ingredients, raw materials, and other ingredients that are adulterated, one of the following must be done:

- Disposed of in a manner that protects against the contamination of other ingredients
- If the adulterated dietary ingredients, raw materials, and other ingredients are capable of being reconditioned, one of the following must be done:
  - Recondition (if appropriate) using a method that has been proven to be effective; or
  - Recondition (if appropriate) and re-examine to find if it is not adulterated before being incorporated into other ingredients

## 5.6 Production Operations and Controls Documentation

The following documentation must be made and kept for fulfilling the requirements of the production operations and controls quality system (see *1. General Provisions*).

### 5.6.1 WRITTEN PROCEDURES

Written procedures for manufacturing operations must be established and followed for the following:

- Preparation and approval of master production and control records
- Cleaning and inspecting manufacturing facilities
- Manufacturing production operations
- Quality unit responsibilities and operations

Official

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:38:53 AM(EST)

DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

#### 5.6.2 RECORDS

Records must be made and kept for manufacturing operations, including the following:

- Executed batch production and control records
- Equipment and production suite cleaning record
- Quality unit operations

# 6. PACKAGING AND LABELING OPERATIONS AND CONTROLS

## 6.1 General

Written procedures must be established and designed to ensure that correct packaging materials and labels are used. Packaging and labeling operations must be designed to prevent mix-ups.

Written procedures should describe the receipt, identification, quarantine, sampling, examination and/or testing and release, and handling of packaging and labeling materials.

Packaging and labeling material should conform to established specifications. Food-packaging materials must be safe and suitable. Those that do not comply with such specifications should be rejected to prevent their use in operations for which they are unsuitable.

Records should be maintained for each shipment of labels and packaging materials that show receipt, examination, or testing, as well as whether the shipment accepted or rejected.

## 6.2 Packaging Materials

#### 6.2.1 GENERAL PROCEDURES

Necessary actions must be taken to determine whether packaging for dietary ingredients meets specifications so that the condition of the packaging will ensure the quality of the dietary ingredients. Containers must provide adequate protection against any deterioration or contamination of the dietary ingredient that may occur during transportation and recommended storage. Food containers must be maintained in an adequate condition through appropriate cleaning and sanitizing, as necessary.

General chapter ⟨659⟩ provides packaging definitions, auxiliary packaging information, and storage condition definitions relevant to the storage and distribution of dietary ingredients, and it should be consulted.

Containers must be clean and, where indicated by the nature of the product, sanitized to ensure that they are suitable for their intended use. These containers must not be reactive, additive, or absorptive so as to alter the quality of the dietary ingredient beyond specified limits.

If containers (e.g., for raw materials and other ingredients, in-process materials, or bulk material) are reused, they should be cleaned in accordance with documented procedures, and all previous labels should be removed or defaced.

#### 6.2.2 TAMPER-EVIDENT PACKAGING

Dietary ingredients should use tamper-evident packaging. A tamper-evident package is one that has an indicator or barrier to entry that, if breached or missing, can reasonably be expected to provide visible evidence to the customer (i.e., dietary supplement manufacturer) that tampering has occurred. To reduce the likelihood of substitution of a tamper-evident feature after tampering, the indicator or barrier to entry must be distinctive by design or by the use of an identifying characteristic (e.g., a pattern, name, registered trademark, logo, or picture). The term “distinctive by design” means that the packaging cannot be duplicated with commonly available materials or through commonly available processes. A tamper-evident package may involve a primary container–closure system, a secondary container or carton system, or any combination of systems intended to provide a visual indication of package integrity. The tamper-evident feature should be designed to remain intact when handled in a reasonable manner during holding, manufacture, and distribution.

## 6.3 Labeling

#### 6.3.1 GENERAL PROCEDURES

Labeling must comply with applicable federal and state labeling regulations for dietary ingredients.

Quantitative label claims for the product must be truthful and accurately reflect the contents of the declared dietary ingredients and/or their marker compounds. There are two classes for label claims:

- Class I (standardized): fortified or fabricated nutrients whose contents have been controlled in some fashion; must meet 100% of the quantitative label claim
- Class II (non-standardized): naturally occurring nutrients, whose constituents occur naturally in an ingredient and whose level is not controlled; must meet at least 80% of the quantitative label claim

Reference to the *USP–NF* on the label or labeling must be appropriate and completely accurate in accordance with *General Notices, 3.20 Indicating Conformance*. When the dietary ingredient monograph title appears on the label, the product must fully conform to the specified compendial standard.

Labeling must comply with applicable federal and state labeling regulations for dietary ingredients.

Official

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:38:53 AM(EST)
Printed by: USP NF
Do Not Distribute
Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-May-2022
DOI Ref: 3a0hm
DocId: GUID-DE5DE10D-9550-4D57-8933-7B9B1C922698_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

For botanicals, the common or usual name and/or the Latin binomial of the botanical species must be listed on the label. The current edition of the American Herbal Product Association's *Herbs of Commerce* should be consulted regarding the appropriate common or usual name of a botanical ingredient. Additionally, the proper Latin binomial name should be provided in parenthesis on the label, except that this name is not required when it is synonymous with the common or usual name for the botanical species. The label must include the plant part(s) used. The terms "whole", "root", "seed", "aerial", and "leaf" are all acceptable terminology.

Labeling for dietary ingredients must comply with applicable allergen labeling requirements as promulgated in the Food Allergen Labeling and Consumer Protection Act (FALCPA).

The label must include a statement of the necessary storage requirements for the dietary ingredient, and it must accurately state the country of origin for any product of foreign origin imported into the United States. The name and place (city, state, zip code) of business of the manufacturer, packer, or distributor also must be located on the label.

#### 6.3.2 RETEST OR EXPIRY DATE

Dietary ingredient labeling must state a retest date or expiry date that is indicative of the date after which the dietary ingredient can no longer meet applicable specifications of identity, strength, quality, and purity when stored under labeled conditions. The expiry date must be supported by suitable stability data.

A written procedure must be designed to ensure that the correct retest date or expiry date is printed on the finished dietary ingredient labeling.

### 6.4 Labeling Issuance and Control

Access to the label storage areas (i.e., label control room) must be limited to authorized personnel. Procedures should be implemented to ensure that labels are stored in a manner that prevents mix-ups and provides proper identification used to reconcile the quantities of labels issued, used, and returned, as well as to evaluate discrepancies found between the number of containers labeled and the number of labels issued and used. Such discrepancies should be investigated, and the investigation should be approved by the quality unit(s).

All excess labels bearing batch numbers or other batch-related printing should be destroyed. Returned labels should be maintained. Obsolete and outdated labels and incorrect labels should be destroyed to ensure that they are not used in any future packaging and labeling operations.

Printing devices used to print labels for packaging operations (e.g, for bulk packaging) should be controlled to ensure that all imprinting conforms to the print specified in the batch production and control record.

Labeling issuance must be designed to prevent mix-ups. Strict control must be exercised over the issuance of labeling for use in finished dietary ingredient labeling operations. Labels should be delivered to packaging lines in a secured container (e.g., locked box or cage).

Labeling materials issued for a batch should be carefully examined for proper identity and conformity to the labeling specifications in the batch packaging record. A printed label or copy of the printed label representative of those used must be included in the batch packaging record.

Procedures should be used to reconcile the quantities of labeling issued, used, and returned, and they should require evaluation of discrepancies found. If discrepancies are found between the quantity of product finished and the quantity of labeling issued and are outside the preset limits based on historical operating data, such discrepancies should be investigated. Label reconciliation is not required for cut or rolled labels if a 100% examination for correct labels is performed by appropriate electronic or electromechanical equipment during or after completion of finishing operations.

Returned labeling should be maintained and sorted in a manner to prevent mix-ups and provide proper identification. All excess labeling bearing lot or control numbers should be destroyed and documented.

### 6.5 Packaging and Labeling Operations

Filling, assembling, packaging, labeling, and other related operations must be performed in a manner that ensures the quality of the dietary ingredient; that the dietary ingredient is protected against allergen cross-contact, contamination, and the growth of undesirable microorganisms; and that the dietary ingredient is packaged and labeled as specified in the master packaging record. This must be done using any effective means, including the following:

- Cleaning and sanitizing all filling and packaging equipment, utensils, and dietary ingredient packaging, as appropriate
- Protecting manufactured dietary ingredients from contamination, particularly airborne contamination
- Using sanitary handling procedures
- Establishing physical or spatial separation of packaging and labeling operations from operations on other raw materials and other ingredients and dietary ingredients to prevent mix-ups
- Identifying filled dietary ingredient containers that are set aside and held in unlabeled conditions for future label operations in order to prevent mix-ups
- Assigning a batch, lot, or control number to each lot of a packaged and labeled dietary ingredient that came from a finished batch of dietary ingredient, as well as each lot of dietary ingredient distributed to another person for packaging or labeling
- Examining a representative sample of each batch of the packaged and labeled dietary ingredient to determine whether the finished dietary ingredient meets its specifications
- Suitably disposing of labels and packaging for dietary ingredients that are obsolete or incorrect to ensure that they are not used in any future packaging and labeling operations

Written procedures must be established and designed to ensure that correct packaging materials and labeling are used. Issuance and use of packaging and labels and reconciliation of any issuance and use discrepancies must be controlled. Before

Official

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

packaging and labeling operations begin, packaging and labeling for each batch of dietary ingredients must be examined to determine whether the packaging and labeling conforms to the batch packaging control record. Packaging and labeling materials must be identified by item control number and lot number.

Packaging and labeling facilities must be inspected immediately before use to ensure that all materials not needed for the next packaging operation have been removed, and that packaging and labeling facilities have been properly cleaned. Results of the inspection and cleaning should be documented in the batch packaging control records, the packaging facility log, or other documentation system.

Packaged and labeled dietary ingredients should be examined to ensure that containers and packages in the batch have the correct label. This examination should be part of the packaging operation. Results of these examinations must be recorded in the batch packaging control record.

A reserve sample of each batch of finished dietary ingredients, consisting of at least twice the quantity necessary for finished dietary ingredient specification tests and examinations, must be collected and retained for at least 1 year past its retest or expiry date.

In-process dietary ingredients transported outside the manufacturer's control must be sealed in a manner such that, if the seal is breached or missing, the recipient will be alerted to the possibility that the contents may have been altered.

Any packaged and labeled dietary ingredient that is rejected for distribution must be clearly identified, held, and controlled under a quarantine system for appropriate disposition.

The complete manufacturing history and control of the packaged and labeled dietary ingredient through distribution must be traceable.

## 6.6 Repackaging and Relabeling

Dietary ingredients may be repackaged or relabeled only after quality unit personnel have approved such repackaging or relabeling. A representative sample of each batch of repackaged or relabeled dietary ingredients must be examined to determine whether the repackaged or relabeled dietary ingredients meet all established specifications. Quality unit personnel must approve or reject each batch of repackaged or relabeled dietary ingredients prior to its release for distribution. Repackaged or relabeled ingredients should retain the original retest or expiry date.

*Good Repackaging Practices* ⟨1178⟩ should be consulted.

## 6.7 Packaging and Labeling Operations and Controls Documentation

The following documentation must be made and kept for fulfilling the requirements of the packaging and labeling operations and controls quality system (see *1. General Provisions*).

### 6.7.1 WRITTEN PROCEDURES

Written procedures for packaging and labeling operations must be established and followed for the following:

- Receipt, identification, quarantine, sampling, examination and/or testing and release, and handling of packaging and labeling materials
- Preparation and approval of packaging material and labeling specifications
- Preparation and approval and master batch packaging and labeling control records
- Cleaning and inspecting packaging and labeling facilities
- Filling, assembling, packaging, labeling, and other related operations
- Determination and issuance of finished dietary ingredient retest or expiry date to batch packaging and labeling control records

### 6.7.2 RECORDS

Records for packaging and labeling must be made and kept for the following:

- Packaging and labeling specifications
- Packaging and labeling facility cleaning and inspection records
- Executed batch packaging and labeling control records
- Executed batch repackaging and relabeling control records

# 7. LABORATORY OPERATIONS AND CONTROLS

## 7.1 General

Written procedures must be established and followed for laboratory operations, including written procedures for the tests and examinations to be conducted to determine whether specifications are met.

Adequate laboratory facilities must be used for whatever testing or examinations are necessary to determine whether raw materials, other ingredients, packaging materials, labeling, in-process materials, and dietary ingredients meet specifications.

Laboratory control processes must be established and followed that are reviewed and approved by quality unit personnel, including the following:

- Use of criteria for establishing appropriate specifications
- Use of sampling plans for obtaining representative samples of the following:

Official

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:38:53 AM(EST)
Printed by: USP NF
Do Not Distribute

- Raw materials, other ingredients, packing materials, and labels
- In-process materials
- Finished batches of dietary ingredients
- Product that is received for packaging or labeling as a dietary ingredient and for distribution rather than for return to the supplier
- Packaged and labeled dietary ingredients

- Use of criteria for selecting appropriate examination and testing methods
- Use of criteria for selecting standard reference materials used in performing tests and examinations
- Use of test methods and examinations in accordance with established criteria

QC personnel must verify that the laboratory examination and testing methodologies are appropriate for their intended use. QC personnel must identify and use appropriate scientifically validated methods for each established specification for which testing or examination is required to determine whether the specification is met.

Specifications, sampling plans, and test procedures, including changes or modifications to them, should be drafted by the appropriate QC unit personnel and reviewed and approved by the appropriate QA unit personnel. Specifications should be established in accordance with accepted standards and consistent with the manufacturing process.

There also must be documented procedures describing sampling, testing, approval and rejection of materials, and recording and storage of laboratory data.

## 7.2 Reagents and Reference Standards

Reagents and standard solutions should be prepared and labeled following written procedures. “Use by” dates should be established and applied as appropriate for analytical reagents and standard solutions.

Primary reference standards should be obtained as appropriate for the manufacture of dietary ingredients. The source of each primary reference standard must be documented. Records should be maintained of each primary reference standard’s storage and use in accordance with the supplier’s recommendations. Primary reference standards obtained from an officially recognized source (e.g., USP Reference Standard) may be used without testing if stored under conditions consistent with the supplier’s recommendations.

When a primary reference standard is not available from an officially recognized source, an in-house primary standard must be established. Appropriate testing needs to be performed to establish fully the identity and purity of the in-house primary reference standard. Appropriate documentation of this testing should be maintained.

Secondary reference standards should be appropriately prepared, identified, tested, approved, and stored. The suitability of each batch of secondary reference standard should be determined prior to first use by comparing it against a primary reference standard. Each batch of secondary reference standards should be periodically requalified in accordance with a written protocol.

## 7.3 Scientifically Validated Test Procedures

Tests and examinations used to determine whether material specifications are met must be appropriate for their intended use and be scientifically validated methods. Tests methods or procedures must meet proper standards of accuracy and reliability.

Chemical, microbial, or extraneous-material testing procedures must be used when necessary to identify sanitation failures or possible allergen cross-contact and food contamination.

### 7.3.1 VALIDATION OF TEST PROCEDURES

If the test procedure is not in an official compendium, the procedure must be validated according to ⟨1225⟩. Method performance characteristics include specificity, linearity, range accuracy, precision, detection limit, and quantitation limit, and those of interest may vary depending on the type of test: identification, assay, impurities, or performance.

For microbial test procedures, the following *USP* general information chapters should be consulted:

- *Biological Assay Validation* ⟨1033⟩
- *Validation of Alternative Microbiological Methods* ⟨1223⟩
- *Validation of Microbial Recovery from Pharmacopeial Articles* ⟨1227⟩

### 7.3.2 VERIFICATION OF OFFICIAL TEST PROCEDURES

If the test procedure is in an official compendium, such as *USP–NF* or AOAC International’s *Official Methods of Analysis*, the procedure only needs to be verified for its suitability under actual conditions of use, according to *Verification of Compendial Procedures* ⟨1226⟩. Verification requirements should be based on an assessment of the complexity of both the procedure and the material to which the procedure is applied. Verification is not required for basic compendial procedures, such as loss on drying and residue on ignition, or simple instrumental determinations, such as pH measurements.

## 7.4 Test Procedures

Test procedures must have clear and complete descriptions to provide an analyst with directions on how to reproducibly perform the given test. Test procedures should include the following information, as applicable:

- Purpose
- Safety information, if applicable
- Materials and equipment

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

- Procedures that include, as applicable:
  - System suitability
  - Preparation of solutions and reagents
  - Preparation of standards and samples
  - Instrumental parameters
  - Calculations and reporting
- Review and approval with approval dates
- Revision history

The tests and examinations can include gross organoleptic analyses, macroscopic analyses, microscopic analyses, chemical (inorganic and organic) analyses, microbiological analyses, DNA-based analyses, and other scientifically valid methods.

Test procedures should be followed and documented at the time of performance, and any departure from established test procedures should be documented and explained.

## 7.5 Transfer of Analytical Test Procedures

Testing materials for compliance to specifications is critical in establishing the quality of the dietary ingredient. The transfer of analytical procedures (TAP), also referred to as "method transfer", is the documented process that qualifies a laboratory (the receiving unit) to use an analytical test procedure that originated in another laboratory (the transferring unit), thus ensuring that the receiving unit has the procedural knowledge and ability to perform the transferred analytical procedure as intended. *Transfer of Analytical Procedures* ⟨1224⟩ summarizes the types of transfers that may occur and outlines the potential raw materials and other ingredients of a transfer protocol, and it should be consulted to qualify a laboratory (both internal and external to the manufacturer) to ensure it has the procedural knowledge and ability to perform the test procedure as intended.

## 7.6 Reduced Testing

### 7.6.1 GENERAL PROCEDURES

Reduced testing or inspection provides a way of reducing the testing or inspection effort on received raw materials, other ingredients, in-process material, and dietary ingredients of high quality, in which all batches are expected to be of the similar quality.

Reduced testing for contaminants should be based on one or more of the following:

- Statistical analysis of an adequate quantity of historical test data
- Statistical confidence in the capability of the manufacturing process as determined by suitable verification
- Ongoing monitoring of the process using recognized statistical process control (SPC) techniques

General control procedures should be established to monitor critical in-process manufacturing attributes that if not properly controlled, could cause a failure to meet identity, strength, purity, composition, or limits on contaminants. Special controls should be used to ensure content uniformity of blended, encapsulated, enrobed, or other specialized dietary ingredients.

The following terms are useful when describing reduced testing:

- "Lot-by-lot inspection" means full inspection of products submitted in a series of lots
- "Reduced sampling inspection" means a sampling inspection procedure in which some lots in a series are accepted without full testing when the sampling results for a stated number of immediately preceding lots meet stated criteria
- "Inspection sampling frequency" means the probability that a lot has been fully tested (e.g., every fifth lot)
- "Disqualification" means failure to qualify for reduced sampling inspection
- "Requalification" means qualification for a resumption of reduced sampling inspection
- "Supplier qualification" means assessment of the supplier's cGMP competence so as to implement reduced sampling inspection
- "Product qualification" means assessment of product (i.e., raw material, other ingredient, in-process material, or dietary ingredient) quality to determine its suitability for reduced sampling inspection

### 7.6.2 REDUCED TESTING REQUIREMENTS

Reduced sampling inspection may be used only when both the supplier's cGMP quality systems and product (i.e., the raw material, other ingredient, in-process material, or dietary ingredient) are qualified. The dietary ingredient certificate of analysis should clearly disclose when reduced testing principles are applied.

- Requirements for supplier qualification are the following:
  - The supplier must have established, documented, and followed effective and applicable cGMP quality systems for managing quality that involves the active participation of personnel
  - An assessment of the supplier's cGMP quality systems must be performed
  - Ongoing assessment of the supplier's cGMP quality systems should be performed on a specified frequency
  - The supplier must not have experienced changes in its cGMP quality systems that adversely affect product quality
- Requirements for product (i.e., raw material, other ingredient, in-process material, or dietary ingredient) qualification are the following:
  - An assessment for product qualification should not be made prior to the assessment of the supplier's cGMP quality systems

Official

https://pharmacopeia.cn/
Printed on: Fri Jan 05 2024 06:38:53 AM(EST)
Printed by: USP NF
Do Not Distribute

- The preceding 3 or more consecutive lots have been accepted, and results of resubmitted lots are not included

The following is an example of a typical reduced inspection and rotational testing approach that can be performed:

- Conduct lot-by-lot full inspection on the first 3 lots
- If successful, conduct reduced sampling inspection on every 5th lot for a set period of time
- If successful, reduce sampling inspection to every 10th lot, until there is a failure
- Test a minimum of 1 lot every year
- If a failure is encountered, disqualify the supplier and the product, conduct a root cause investigation, and return to full testing of the next 3 lots

#### 7.6.3 RECEIVED RAW MATERIALS, OTHER INGREDIENTS, IN-PROCESS MATERIALS, AND DIETARY INGREDIENTS

On the basis of adequate supplier qualification, process validation, in-process controls, and statistical confidence, a reduced testing plan is an alternative to fully testing every batch of raw materials and other ingredients received from a supplier provided that at least one identity (i.e., identification) test is conducted. Such identification tests must include sufficient specificity to determine the identity of the raw material and other ingredient.

Each batch of raw material and other ingredient received from a supplier must be tested or examined against established specifications for contamination if it is liable to be contaminated with microorganisms, filth, insect infestation, allergens, aflatoxins, other natural toxins, pesticides, organic impurities (e.g., residual solvents), inorganic impurities (e.g., foreign substances), or other extraneous substances that may be a source of contamination that is objectionable in view of its intended use. In such cases, reduced testing of examination must not apply until risk is mitigated by the supplier.

#### 7.6.4 IN-PROCESS MATERIALS AND DIETARY INGREDIENTS

On the basis of process validation, in-process controls, and statistical confidence, a reduced testing plan is an alternative to fully testing every batch of in-process material and dietary ingredients provided that at least one representative measure (i.e., rotational testing) is performed.

### 7.7 Out-of-Specification (OOS) Investigations

Written procedures must be established and followed for investigating deviations or the failure of a batch of material to meet specifications (i.e., OOS investigations), and corrective action plans must be established for use when an established specification is not met. The investigation should extend to other batches that may have been associated with the specific failure or deviation. The procedure should require analysis of the data, assessment of whether a significant problem exists, allocation of the tasks for corrective actions, and conclusions. Any resampling and/or retesting after OOS test results should be performed according to a documented procedure. Regulatory guidance for investigating OOS test results should be consulted.

### 7.8 Stability Testing

A documented on-going testing program must be designed to monitor the stability characteristics of dietary ingredients, and the results must be used to establish appropriate storage conditions and retest or expiry dates for the dietary ingredients. Test procedures used in stability testing must be validated and indicate stability. Stability samples should be stored in container–closure systems that simulate the packaging proposed to distribute the finished dietary ingredient in the marketplace. If multiple container–closure systems are used, stability and expiry date assignment can be satisfied by testing the container–closure system with the least desirable barrier properties. Stability studies should include testing of those attributes of the dietary ingredient that are susceptible to change during storage and that influence the quality of the dietary ingredient.

Ideally the first 3, but at minimum 1, production batches should be placed on the stability monitoring program to establish the product retest or expiry date. Thereafter, at least 1 batch per year of manufactured dietary ingredient (unless none are produced that year) should be added to the stability monitoring program.

As appropriate, the stability storage conditions for temperature and relative humidity (RH) should be as follows:

- Long term = 25 ± 2° and 60% ± 5% RH
- Intermediate = 30 ± 2° and 65% ± 5% RH
- Accelerated = 40 ± 2° and 75% ± 5% RH

Long-term studies also can be performed under the labeled storage conditions, such as at room temperature (ambient conditions) or in a cool, dry place (8°–15° and not more than 40% RH). Alternative storage conditions should be considered for products marketed outside the United States in different climatic zones.

The frequency of testing should be sufficient to establish the stability profile of the dietary ingredient. The following testing frequencies are recommended:

- Long term = 0, 3, 6, 9, 12, 18, 24, and 36 months
- Intermediate = 0, 3, 6, 9, and 12 months
- Accelerated = 0, 1, 2, 3, and 6 months

For long-term studies, the frequency of testing should be sufficient to establish the stability profile of the dietary ingredient. For ingredients intended for storage in a refrigerator, the storage conditions and minimum time period should be as follows:

- Long term = 5 ± 3°; 12 months
- Accelerated = 25 ± 2° and 60% ± 5% RH; 6 months

Accelerated stability studies are designed to increase the rate of chemical degradation or physical change and are intended to evaluate the effect of short-term excursions outside the labeled storage conditions, which might occur during shipping.

@2024 USPC

Although accelerated stability studies may not adequately reflect the stability of the product under labeled (e.g., long term) conditions, results from accelerated stability can be used to estimate a preliminary retest or expiry date for a dietary ingredient that should eventually be supported with data from long-term stability studies.

If significant change occurs between 3 and 6 months of testing at the accelerated storage condition, the proposed retest or expiry period should be based on the real time data available during the long-term storage condition. If significant change occurs within the first 3 months of testing at the accelerated storage condition, consideration should be given to address the effect of short-term excursions outside the label storage condition, such as during shipping and handling.

Preliminary shelf-life (expiry) dates can be based on pilot scale batches if the pilot batch is at least one-tenth the size of the commercial batch size and the pilot batches employs a manufacturing process that simulates the process to be used on a commercial manufacturing scale. Bench scale batches should not be used for stability studies.

In certain cases, dietary ingredients being closely related in composition may be grouped together using one representative dietary ingredient formulation with which to obtain stability data to support the retest or expiry date of all dietary ingredient formulations within that group. Under such circumstances, sufficient scientific justification should be provided as to support grouping of the dietary ingredients for stability purposes.

The design of the stability studies may also bracket dietary ingredients in a way that only dietary ingredients on the extremes of certain factors (e.g., strength, package size) are tested. This design assumes that the stability of any intermediate level is represented by the stability of the extremes tested.

Stability studies should be performed for dietary ingredients packaged in different container–closure systems (e.g., HDPE containers, aluminum canisters). In certain cases, stability data using one type of container–closure system may be used to support the stability of the product in a different type of container–closure system (e.g., HDPE versus PET container) with supporting scientific justification regarding the moisture, vapor, and light protection characteristics of the two types of container–closure systems.

Long-term and accelerated (and intermediate as necessary) stability studies should be undertaken according to a prescribed stability protocol. The resultant data must be properly evaluated. The degree of variability of stability data between or within individual batches affects the confidence in the data. The data may show such little degradation and variability that it is apparent the product will meet specifications throughout the proposed retest or expiry date. When the data on a quantitative attribute changes with time and shows significant degradation or significant variability, it is necessary to use formal statistical analysis to determine the retest or expiry date for the dietary ingredient. A stability report should be prepared for the dietary ingredient stating the proposed storage conditions and retest or expiry date of the dietary ingredient(s), along with the stability data and its evaluation.

## 7.9 Laboratory Testing Records

Laboratory control records should include complete data derived from all tests conducted to ensure compliance with established specifications and standards, including examinations and assays, as follows:

- A description of samples received for testing, including material name or source, batch number or other distinctive code, date sample was taken, and, when appropriate, the quantity and date the sample was received for testing
- A statement or reference to each test procedure used
- A statement of the weight or measure of sample used for each test as described by the test procedure
- Data on or cross-reference to the preparation and testing of reference standards, reagents, and standard solutions
- A complete record of all raw data generated during each test, in addition to graphs, charts, and spectra from laboratory instrumentation, properly identified to show the specific material and batch tested
- A record of all calculations performed in connection with the test, including, for example, units of measure, conversion factors, and equivalency factors
- A statement of the test results and how they compare with established acceptance criteria
- The signature of the person who performed each test and the date(s) the tests were performed
- The date and signature of a second person showing that the original records have been reviewed for accuracy, completeness, and compliance with established procedures

A certificate of analysis should be issued for each batch of dietary ingredients. The certificate of analysis should list the name and item code of the dietary ingredient, the batch number, the date of manufacture, the date tested and released, recommended retest date, analytical method reference for each attribute, and the expiry date. The certificate of analysis also should list each test performed, the specific identity of the test procedure, the acceptance limits or criteria, and the results with numerical units, as appropriate. The certificate of analysis should be dated and signed by authorized quality unit personnel. For certificates of analysis issued for external use, the name, address, and telephone number of the manufacturer should be listed.

## 7.10 Laboratory Operations and Controls Documentation

The following documentation must be made and kept for fulfilling the requirements of the laboratory controls quality system (see *1. General Provisions*).

### 7.10.1 WRITTEN PROCEDURES

Written procedures for laboratory operations must be established and followed for the following:

- The tests and examinations conducted to determine whether specifications are met
- Establishment, review, and approval of material specifications
- Preparation, review, and approval of written test procedures

https://pharmacopeia.com/

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M15255_02_01
@2024 USPC

- Validation and verification of test procedures for their intended use
- Selection, preparation, and handling of reagents and reference standards
- Establishment, review, and approval of sampling plans, including reduced sampling inspections
- Sampling, testing, approval, and rejection of materials, and recording and storage of laboratory data
- Investigation of deviations or OOS test results
- Establishment and implementation of a stability-testing program

### 7.10.2 RECORDS

Records must be made and kept for the following:

- Documentation that established laboratory test and examination procedures are followed
- Documentation that established laboratory methodology is followed, recorded at the time of performance by the person who conducts the testing and examination
- Documentation for laboratory tests and examinations that include the data and results of the testing and examination
- Any modification to an established test procedure
- OOS investigations and corresponding corrective actions
- Test procedure method validation or verification protocols and reports that support test procedure suitability for use
- The periodic calibration of laboratory instruments and controls
- Stability protocols and stability data and reports that support a product's retest or expiry date

## GLOSSARY

**Acceptance criteria:** Predetermined limits (e.g., number, numerical ranges, or other suitable measures) for acceptance of examination or test results.

**Acid foods or acidified foods:** Any foods that have an equilibrium at a pH of 4.6 or below.

**Adequate:** Item/area/system/knowledge that meets basic minimum requirements that are needed to accomplish intended purpose in keeping with good public health practice.

**Adulteration:** A food that contains any poisonous or deleterious substance as specified in §402(a)(1) and (a)(2) of the FD&C Act; that consists of any filthy, putrid, or decomposed substance, or an adulterant that is otherwise unfit for food as specified in 402(a)(3); that has been prepared, packed, or held under insanitary conditions as specified in §402(a)(4); whose its container is composed of any poisonous or deleterious substance that may render the contents injurious to health as specified in §402(a)(6); or that has been intentionally subjected to radiation as specified in §402(a)(7); for which the contents have been altered or that has concealed damage and or inferiority as specified in §402(b)(1-4); that contains a color additive that is unsafe as specified in §402(c); that is a dietary ingredient or contains a dietary ingredient that presents a significant or unreasonable risk of illness or injury as specified in §402(f)(1); or that is a dietary ingredient that has not been prepared, packed, or held under conditions that do not meet current good manufacturing practice regulations as specified in §402(g)(1); or that has not been transported in compliance with regulations as specified in §402(i).

**Adverse event:** Any undesirable experience associated with the use of a food or dietary ingredient in a person.

**Adverse event report:** A direct communication from an identifiable first-hand reporter of an adverse event that includes at least the following information: an identifiable reporter, an identifiable person(s) who experienced the adverse event(s), an identifiable food or dietary ingredient, and one or more adverse events.

**Affiliate:** Any facility that controls, is controlled by, or is under common control with another facility.

**Allergen:** A major food allergen as defined in section 201(qq) of the FD&C Act, and can be any of the following: 1) milk, egg, fish (e.g., bass, flounder, or cod), Crustacean shellfish (e.g., crab, lobster, or shrimp), tree nuts (e.g., almonds, pecans, or walnuts), wheat, peanuts, and soybeans; (2) a food ingredient that contains protein derived from a food specified in 1), except either any highly refined oil derived from a food specified in 1) and any ingredient derived from such highly refined oil, or a food ingredient that is exempt under paragraph (6) and (7) of section 403(w) of the FD&C Act.

**Allergen cross-contact:** The unintentional incorporation of a food allergen into a dietary ingredient.

**Article:** Substances (e.g., raw materials, other ingredients, in-process material, dietary ingredients), consumer products (e.g., foods or dietary ingredients), and materials (e.g., packaging containers and closures and labels).

**Audit:** A planned, systematic, objective, independent, and documented examination (through observation, investigation, records review, discussions with employees of the audited firm, and, as appropriate, sampling and laboratory analysis) to assess whether agreed upon requirements are being met, such as assessing a supplier's food safety processes and procedures.

**Batch:** A specific quantity of a dietary ingredient or other article that is intended to be uniform; that is intended to meet specifications for identity, purity, strength, and composition; and that is produced during a specified time period according to a single manufacturing record during the same cycle of manufacture.

**Batch (or lot) number:** Any distinctive group of letters, numbers, or symbols, or any combination of them, from which the complete history of the manufacturing, packaging, labeling, and/or holding of a batch or lot of dietary ingredients can be determined.

**Blanching:** Except for tree nuts and peanuts, a prepackaging heat treatment of foodstuffs for an adequate time and at an adequate temperature to partially or completely inactivate the naturally occurring enzymes and to effect other physical or biochemical changes in the food.

**Calibration:** The demonstration that a particular instrument or device produces results within specified limits by comparison with those produced by a reference or traceable standard over an appropriate range of measurements.

**Certificate of Analysis:** A document relating specifically to the results of testing a representative sample drawn from the batch of material. The certificate of analysis should list each test performed in accordance with compendial or manufacturer requirements, including reference to the test procedure, the acceptance limits, and the results obtained.

@2024 USPC

**Code of Federal Regulations (CFR):** The annual codification of the general and permanent rules and regulations published in the Federal Register by the executive departments and agencies of the US federal government. It is structured into 50 subject matter titles; Title 1 applies to general provisions, while Title 21 applies to food and drugs. Titles are broken down into parts, subparts, sections and paragraphs. For example, 21 CFR 11.10(k)(2) is read as title 21, part 11 (subpart B, not specified here), section 10, paragraph (k)(2). The CFR annual edition is published by the Office of the Federal Register, National Archives and Records Administration, and the Government Publishing Office. In addition to this annual edition, the CFR is published in an unofficial format online in electronic format (www.ecfr.gov), which is updated daily.

**Component:** Any substance intended for use in the manufacture of a dietary ingredient that appears in the finished batch of the dietary ingredient.

**Composition:** The specified mix of product and product-related substances (i.e., specified mix of food ingredients or excipients and dietary ingredients) in a dietary ingredient.

**Contact surface:** Any surface that contacts a raw material, other ingredient, in-process material, or dietary ingredient, and those surfaces for which drainage can occur either to or from the raw material, other ingredient, in-process material, or dietary ingredient, and which occurs during the normal course of operations. Examples of contact surfaces include containers, utensils, tables, contact surface of equipment, and packaging material.

**Contamination:** The undesired introduction of a biological (including allergenic), chemical (including radiological), or microbiological nature, or of foreign matter, into or onto a raw material, other ingredient, in-process material, or dietary ingredient during production, sampling, packaging, repackaging, storage or transport.

**Contract manufacturer:** A manufacturer performing some aspect of manufacturing on behalf of the original manufacturer.

**Corrective action (or correction):** An action that is developed and implemented to ensure that any identified root cause of a nonconformity does not reoccur. Also, an action to identify and correct a problem that occurred during the production of dietary ingredient but without other actions associated with a corrective action procedure (e.g., action to reduce the likelihood that the problem will reoccur, evaluation of all affected food for safety, and prevention of affected food from entering commerce).

**Critical:** A manufacturing process step, process condition, test requirement, or other relevant parameter or item that must be controlled within predetermined criteria to ensure the dietary ingredient meets its specification.

**Critical control point:** A point, step, or procedure in a food process at which control can be applied and is essential to prevent or eliminate a food safety hazard or reduce such hazard to an acceptable level.

**Design qualification (DQ):** The documented collection of activities that defined the functional and operational specifications and intended purpose of the equipment or instrument. DQ states what the user wants the equipment or instrument to do and shows that the selected equipment or instrument is suitable.

**Defect action level:** A level of a non-hazardous, naturally occurring, and unavoidable defect at which the FDA may regard a food product as "unadulterated" and subject to enforcement action under section 402(a)(3) of the FD&C Act.

**Deviation:** Departure from an approved instruction or procedure or from an established standard (i.e., a failure, or OOS result). Deviations can be planned or unplanned (i.e., a nonconformity).

**Dietary ingredient:** An ingredient intended for use or used in a dietary supplement that is a vitamin; a mineral; an herb or other botanical; an amino acid; a dietary substance to supplement the human diet by increasing the total dietary intake; a concentrate, metabolite, constituent, or extract; or a combination of any of the listed ingredients.

**Dietary supplement:** A product (other than tobacco) intended to supplement the diet that bears or contains one or more of the following dietary ingredients: a vitamin; a mineral; an herb or other botanical; an amino acid; a dietary substance to supplement the human diet by increasing the total daily intake; or a concentrate, metabolite, constituent, extract or combination of the aforementioned ingredients. It is intended for ingestion in a tablet, capsule, powder, softgel, gelcap, or liquid form; it is not represented for use as a conventional food or as a sole item of a meal or the diet; it is labeled as a dietary supplement. It does include an article approved as a new drug, certified antibiotic, or licensed biologic, and was marketed as a dietary supplement or food prior to such approval, certification, or license, unless the Secretary of Health and Human Services had issued a regulation finding that the article is unlawful when used as or in a dietary supplement under the conditions of use and dosages set forth in the labeling.

**Disposition decision:** A decision to approve or reject material, QC, and manufacturing related processes or documents, based on a scientifically valid reason. Disposition decisions can be made regarding the release of raw materials, in-process materials, dietary ingredients, packaging materials, labels, and returned dietary ingredients, based on a determination of whether or not established specifications are met, or made regarding reprocessing treatments and in-process adjustments, master production and control records, batch production and control records, repackaging or relabeling, calibrations of an instrument or control, modification or deviations from standard procedures, and whether or not a deviation or unanticipated occurrence during the production and in-process control system could lead to the adulteration of a dietary ingredient.

**Documentation:** Written material related to the requirements of the quality system, including paper and electronic records, that consist of raw data, reports, protocols, and procedures related to manufacturing controls and laboratory testing. Official documents are records that support procedure, product, or the manufacturer's quality systems (e.g., standard operating procedures, master batch records, material specifications, standard test procedures, protocols, reports). Source documents are records that contain original data or information (e.g., forms, notebooks, log books, instrument printouts).

**Equipment:** Devices used to manufacture, package, or hold dietary ingredients, or to maintain or clean the physical plant and devices.

**Environmental pathogen:** A pathogen capable of surviving and persisting within the manufacturing, processing, packing, or holding environment so that it could contaminate food and may result in foodborne illness if that food is consumed without treatment to significantly minimize the environmental pathogen. Examples of environmental pathogens include *Listeria* monocytogenes and *Salmonella* subspecies but do not include the spores of pathogenic spore-forming bacteria.

**Expiry (use by) date:** The date after which the dietary ingredient will no longer meet applicable specifications of identity, strength, quality, and purity when stored under labeled conditions.

Unofficial

https://pharmacopeia.cn/

**Facility:** A place, amenity, utility, or piece of equipment provided for a particular purpose. Also, a domestic facility or foreign facility that is required to register under section 415 of the FD&C Act, in accordance with the requirements of 21 CFR Part 1, Subpart H.

**Farm:** A primary production farm is an operation under one management in one general (but not necessarily contiguous) physical location devoted to the growing of crops, the harvesting of crops, the raising of animals (including seafood), or any combination of these activities. In addition to these activities, a primary production farm may pack or hold raw agricultural commodities, may pack or hold processed food, or may manufacture/process food under certain conditions defined in 21 CFR 1.227.

**Federal Food, Drug, and Cosmetic Act (FD&C Act):** The official compilation and codification of the federal statutes of the United States that gives authority to the FDA to oversee the safety of food, drugs, medical devices, and cosmetics (21 USC §§301–392).

**Food:** As defined in section 201(f) of the FD&C Act, 1) articles used for food, dietary supplements, or drink for man or other animals, 2) chewing gum, and 3) articles used for components of any such article. Food includes raw materials, other ingredient, and dietary ingredients.

**Harvesting:** Activities that are traditionally performed on farms for the purpose of removing raw agricultural commodities from the place they were grown or raised and preparing them for use as food. Harvesting applies to farms and farm-mixed-type facilities, and is limited to activities performed on raw agricultural commodities or on processed foods created by drying/dehydrating a raw agricultural commodity without additional manufacturing/processing on a farm. Harvesting does not include activities that transform a raw agricultural commodity into a processed food as defined in §201(gg) of the FD&C Act.

**Hazard:** Any biological (including microbiological hazards such as parasites, environmental pathogens, and other pathogens), chemical (including radiological hazards, substances such as pesticides and drug residues, natural toxins, decomposition, unapproved food or color additives, and food allergens), or physical agent (such as stones, glass, and metal fragments) that has the potential to cause illness or injury.

**Hazard requiring a preventive control:** A known or reasonably foreseeable hazard for which a person knowledgeable about the safe manufacturing, processing, packing, or holding of food would establish and manage one or more preventive controls to significantly minimize or prevent that hazard in food and raw materials and other ingredients. These controls are based on the outcome of a hazard analysis (which includes an assessment of the severity of the illness or injury if the hazard were to occur and the probability that the hazard will occur in the absence of preventive controls), and are managed (e.g., monitoring, corrections or corrective actions, verification, and records) as appropriate to the food, the facility, and the nature of the preventive control and its role in the facility's food safety system.

**Holding:** Storage of food, including incidental activities performed for that storage (e.g., activities performed for the safe or effective storage of food, such as fumigating food during storage, and drying/dehydrating raw agricultural commodities when the drying/dehydrating does not create a distinct commodity). Holding also includes activities performed as a practical necessity for the distribution of food (e.g., blending of the same raw agricultural commodity and breaking down pallets) but does not include activities that transform a raw agricultural commodity into a processed food as defined in §201(gg) of the FD&C Act. (A holding facility could include warehouses, cold storage facilities, storage silos, grain elevators, and liquid storage tanks.)

**Ingredient:** Any substance that is used in the manufacture of a food or dietary ingredient and that is intended to be present in the finished batch of the food or dietary ingredient.

**In-process control (or process control):** Checks performed during production in order to monitor and, if appropriate, to adjust the process and/or to ensure the dietary ingredient conforms to its specification.

**In-process material:** Any material that is fabricated, compounded, blended, ground, extracted, sifted, sterilized, derived by chemical reaction, or processed in any other way for use in the manufacture of a dietary ingredient.

**In-process tests:** Tests that may be performed during the manufacture of the dietary ingredient rather than as part of the formal battery of tests, which are conducted prior to release.

**Instrument (or instrumentation):** A sophisticated measuring device or tool used for analytical or scientific work.

**Installation qualification (IQ):** The documented collection of activities necessary to establish that an equipment or instrument is delivered as designed and specified and is properly installed in the selected environment, and that the environment is suitable for the instrument.

**Known or reasonably foreseeable hazard:** A biological, chemical (including radiological), or physical hazard that is known to be or has the potential to be associated with the facility or the food.

**Label:** A display of written, printed, or graphic matter on the immediate container of a dietary ingredient.

**Labeling:** All labels and other written, printed, or graphic matter on any dietary ingredient or any of its containers or wrappers, or accompanying such dietary ingredient at any time while the dietary ingredient is held for sale after shipment or delivery for shipment in interstate commerce. The term "accompanying" is interpreted liberally to mean more than physical association with the dietary ingredient. It extends to documentation such as posters, tags, pamphlets, circulars, booklets, brochures, and fillers.

**Lot:** A batch or a specific identified portion of a batch (identified by an establishment's specific code) that is intended to be uniform and that is intended to meet specifications for identity, purity, strength, and composition.

**Manufacture:** All operations of receipt of raw materials, production, packaging, labeling, QC testing, release, storage, and distribution of dietary ingredients and related controls.

**Material:** A general term used to denote raw materials, in-process materials, dietary ingredients, and packaging and labeling material.

**Microorganisms:** Yeast, molds, bacteria, viruses, and other microscopic organisms having public health or sanitary concern. These include undesirable species that may have public health significance, that may cause a raw material or dietary ingredient to decompose, that indicate that a raw material or dietary ingredient is contaminated with filth, or that otherwise may cause a raw material a dietary ingredient to be adulterated.

**Monitor:** A means to conduct a planned sequence of observations or measurements to assess whether control measures are operating as intended.

Draft

https://pharmacopeia.cn/

**Nonconformity:** An event that occurs when a specified requirement is not met or results from an undesirable situation or defect. This covers departure from a procedure, standard or requirement, or the absence of dependability. This typically arises from the inability to meet documented procedures, expectations, or specifications.

**Operational qualification (OQ):** The documented collection of activities necessary to demonstrate that an equipment or instrument will function according to its operational specification testing in the selected environment. OQ demonstrates fitness for the selected use and demonstrates user requirement specifications.

**Other ingredients:** Substances that are added to a dietary ingredient preparation that are not intended or expected to be a dietary ingredient. Other ingredients are substances other than the dietary ingredient(s) that have been appropriately evaluated for safety and are intentionally included in a preparation to do one or more of the following: aid in the manufacture of a dietary supplement; protect, support, or enhance stability, bioavailability, or consumer acceptability; assist in product identification; and/or enhance any other attribute of the overall safety or delivery of the dietary ingredient during storage or use. The term is sometimes used synonymously with the terms "inactive ingredients", "pharmaceutical excipients", and "food ingredients".

**Packing:** Placing food into a container other than packaging the food. Packing includes repacking and activities performed incidental to packing or repacking a food (e.g., activities performed for the safe or effective packing or repacking of that food, such as sorting, culling, grading, and weighing or conveying incidental to packing or repacking), but does not include activities that transform a raw agricultural commodity into a processed food.

**Packaging:** Placing food into a container that transforms a dietary ingredient into a processed food or dietary ingredient.

**Packaging material:** Container and/or closure for raw materials, other ingredients, in-process material, and dietary ingredients.

**Pathogen:** A microorganism of public health significance.

**Performance qualification (PQ):** The documented collection of activities necessary to demonstrate that an equipment or instrument consistently performs according to the specifications defined by the user and is appropriate for the intended use. PQ verifies the fitness for purpose of the equipment or instrument under actual conditions of use.

**Pest:** Any objectionable insect or other animal including but not limited to birds, rodents, flies, mites, and larvae.

**Physical plant:** All or any part of a building or facility used for or in connection with manufacturing, packaging, labeling, or holding of a dietary ingredient.

**Preparation:** Combining, admixing, or diluting one or more dietary ingredients with or without other ingredients. The term is sometimes used synonymously with the term "premix".

**Preventive action:** An action taken to eliminate the cause of potential nonconformities or other undesirable situations in order to prevent occurrence and continuously improve an existing system or process.

**Preventive controls:** Risk-based and reasonably appropriate procedures, practices, and processes that a person knowledgeable about the safe manufacturing, processing, packing, or holding of food would employ to significantly minimize or prevent the hazard identified under the hazard analysis. Preventative controls are consistent with the current scientific understanding of safe food manufacturing, processing, packing, or holding at the time of analysis.

**Preventive controls-qualified individual:** A qualified individual who has successfully completed training in the development and application of risk-based preventive controls at least equivalent to that received in a standardized curriculum recognized as adequate by the FDA or is otherwise qualified through job experience to develop and apply a food safety system.

**Procedure:** A documented description of the operations to be performed, the precautions to be taken, and measures to be applied directly or indirectly related to the manufacture of a dietary ingredient.

**Process evaluation:** A set of tests performed on a process intended to evaluate its capacity to consistently produce the results for which it is intended.

**Product complaint:** Any written, electronic, or oral communication that contains any allegation or expression of concern, for any reason, with the quality of a dietary ingredient that could be related to current manufacturing practice.

**Purity:** The identity and amount of a substance that is the intended substance, typically expressed in units of percentage and determined by using tests for assay or content.

**Qualification:** Action of proving and documenting that equipment or ancillary systems are properly, work correctly, and that actually lead to the expected results. Qualification is part of validation, but the individual qualification steps alone do not constitute process validation.

**Qualified auditor:** A qualified individual who has the technical expertise obtained through education, training, or experience (or a combination thereof) necessary to perform the auditing function and who may be a government employee, including a foreign government employee, or an audit agent of a certification body that is accredited in accordance with ISO 17020 or in accordance with the regulations in 21 CFR part 1, subpart M.

**Qualified individual:** A person who has the education (or combination thereof) necessary to manufacture, process, pack, or hold clean and safe food as appropriate to the individual's assigned duties. A qualified individual may be, but is not required to be, an employee of the establishment.

**Quality:** A standard meaning that the raw materials, in-process materials, packaging materials, labeling and dietary ingredients meet established specifications for identity, purity, strength, and composition, as well as limits on contaminants, and that the dietary ingredient has been manufactured, packaged, labeled, and held under conditions to prevent adulteration.

**Quality assurance (QA):** The sum total of the organized arrangements made with the goal of ensuring that all dietary ingredients are of the quality required for their intended use and that quality systems are maintained.

**Quality assurance personnel (or unit):** Any person, persons, or group within or outside of the firm who is designated by that firm to be responsible for the duties relating to QA.

**Quality control (QC):** A planned and systematic operation or procedure necessary to ensure the quality of the dietary ingredient by checking or testing that specifications are met, and taking all actions necessary to prevent the dietary ingredient from being adulterated.

**Quality control personnel (or unit):** Any person, persons or group, within or outside of the firm, who is designated by that firm to be responsible for the duties relating to QC operations.

Official

https://pharmacopeia.cn/

**Quality unit (or personnel):** An organizational unit independent of production, which fulfills both QA and QC responsibilities, which can be in the form of separate QA and QC units or a single individual or group, depending on the size and structure of the organization.

**Quarantine:** The status of materials isolated physically or by other effective means pending a decision on their subsequent disposition decision.

**Raw material:** A general term used to denote starting materials, reagents, and solvents intended for use in the production of in-process materials (or intermediates) or dietary ingredients.

**Records:** Documents stating results achieved or providing evidence of activities performed (e.g., training records, executed batch production and control records, executed batch packaging records, validation reports, laboratory test results forms, laboratory notebooks, equipment logbooks, memos, and emails).

**Reduced testing (or sampling):** A reduced level of testing (or sampling) for a particular specified parameter(s) based on one or more of the following: statistical analysis of an adequate quantity of historical test data, statistical confidence in the capability of the manufacturing process as determined by suitable verification, or ongoing monitoring of the process using recognized SPC techniques.

**Reference standard, primary:** A substance that has been shown by an extensive set of analytical tests to be authentic material that should be of high purity. This standard is obtained from an officially recognized source (i.e., USP Reference Standard).

**Reference standard, secondary:** A substance of established quality and purity, as shown by comparison to a primary reference standard, that is used as a reference standard for routine laboratory analysis.

**Remedial (short term) action:** Action taken to provide temporary control over a situation or condition until permanent corrective actions are implemented (e.g., issuance of a temporary procedure, segregation of material).

**Representative sample:** A sample that consists of an adequate number of units that are drawn based on rational criteria, such as random sampling, and that is intended to ensure that the sample accurately portrays the material being sampled.

**Reprocessing:** The method to introduce clean and uncontaminated raw materials and other ingredients or dietary ingredients back into the manufacturing process and to repeat a step or other appropriate physical manipulation step (e.g., milling, packaging) that is part of the established manufacturing process. Continuation of a manufacturing process step after an in-process control test has shown that the step is incomplete is considered to be part of the normal manufacturing process and not reprocessing.

**Reserve sample:** A representative sample of an article that is held for a designated period of time.

**Retest date:** The date when a material should be re-examined to ensure that it is still suitable for use.

**Reworking:** The method to subject in-process material or dietary ingredients that do not conform to standards or specifications and that have been removed from processing for reasons other than unsanitary conditions to one or more processing steps that are different from the established manufacturing process in order to obtain acceptable quality in-process material or dietary ingredients.

**Root cause:** Any cause that is acted upon by a solution such that the problem does not reoccur.

**Safe-moisture level:** A level of moisture low enough to prevent the growth of undesirable microorganisms in the finished dietary ingredient under the intended conditions of manufacturing, processing, packing, and holding. The safe-moisture level for a dietary ingredient is related to its water activity. Water activity will be considered safe for a dietary ingredient if adequate data are available that demonstrate that the dietary ingredient at or below water activity will not support the growth of undesirable microorganisms.

**Sanitize:** To adequately treat cleaned equipment, containers, utensils, or other cleaned contact surface by a process that is effective in destroying vegetative cells of microorganisms of public health significance (i.e., pathogens), and in substantially reducing numbers of other microorganisms, but without adversely affecting the product or its safety for the consumer.

**Serious adverse event:** An event that results in death, a life-threatening experience, inpatient hospitalization, a persistent or significant disability or incapacity, or a congenital anomaly or birth defect, or that requires a medical or surgical intervention based on a reasonable medical judgment to prevent one of those outcomes.

**Serious adverse event report:** A report that must be submitted to the FDA using the MedWatch form when a manufacturer, packer, or distributor of a dietary ingredient receives any report of a serious adverse event associated with the use of the dietary ingredient in the United States [see §761(a)(3) and (b)(1) of the FD&C Act (21 USC §§379aa-1(a)(3), (b)(1)].

**Signature (signed):** The record of the individual who performed a particular action or review. A signature can be initials, full handwritten signature, or authenticated and secure electronic signature.

**Significantly minimize:** A reduction to an acceptable level, including elimination.

**Specification:** A list of tests, references to test procedures, and appropriate acceptance criteria for the tests described. It establishes the set of criteria to which a material should conform to be considered acceptable for its intended use. "Conformance to specifications" means that the raw material, in-process material, and/or dietary ingredient will meet the listed acceptance criteria when tested according to the listed test procedures. Specifications are critical quality standards that are proposed, justified, and approved by the manufacturer. Material specifications include test specifications for identity, purity, strength, limits on contaminants, and/or performance that define a standard of quality for the material.

**Strength:** The concentration or amount of a dietary ingredient per unit serving of a dietary ingredient. Strength only applies to a dietary ingredient.

**Subsidiary:** Any company that is owned or controlled directly or indirectly by another company.

**Supplier:** The establishment that manufactures/processes the food and raises the animal or grows the food provided to a receiving facility without further manufacturing/processing by another establishment, except for further manufacturing/processing that consists solely of the addition of labeling or similar activity of a *de minimis* nature.

**Supply-chain-applied control:** A preventive control for a hazard in a raw material or other ingredient when the hazard in the raw material or other ingredient is controlled before its receipt.

**Utensil:** A simple tool or device serving a useful purpose.

**Utility system (utility):** A useful system and source of material such as water, steam, gases, compressed air, and heating, ventilation, and air conditioning.

**Validation:** A documented program that provides a high degree of assurance that a specific process, method, or system will consistently produce a result that meets per-determined acceptance criteria. Also a means in obtaining and evaluating scientific and technical evidence that a control measure, combination of control measures, or the FSP as a whole, when properly implemented, is capable of effectively controlling the identified hazards.

**Validation protocol:** A written plan stating how validation will be conducted and defining acceptance criteria. For example, the protocol for a manufacturing process identifies manufacturing equipment, critical process parameters/operating ranges, product characteristics, sampling, test data to be collected, number of process runs, and acceptable test results.

**Verification:** The application of methods, procedures, tests and other evaluations, in addition to monitoring, to determine whether a control measure or combination of control measures is or has been operating as intended and to establish the validity of the FSP.

**Water activity:** A measure of the free moisture in a substance or material and is the quotient of the water vapor pressure of the substance divided by the vapor pressure of pure water at the same temperature.

**Written procedures for receiving raw materials and other ingredients:** Written procedures that ensure raw materials and other ingredients are received only from suppliers approved by the receiving facility (or, when necessary and appropriate, on a temporary basis from unapproved suppliers whose raw materials or other ingredients are subjected to adequate verification activities before acceptance for use).

**Yield, actual:** The quantity of material or percentage of theoretical yield that is actually produced at any appropriate step of production or during packaging and labeling of a particular dietary ingredient.

**Yield, expected:** The quantity of material or the percentage of theoretical yield anticipated at any appropriate phase of production or during packaging and labeling of a particular dietary ingredient, based on previous laboratory, pilot scale, or manufacturing data.

**Yield, theoretical:** The quantity of material that would be produced at any appropriate step of production or during packaging and labeling of a particular dietary ingredient, based on the quantity of raw materials, other ingredients, packaging, and labeling to be used, in the absence of any loss or error in actual production or packaging and labeling.

## APPENDIX

### Reference Table: Sections of 21 CFR Used in This Chapter

| Section of ⟨2740⟩ | 21 CFR |
|---|---|
| 2. QUALITY MANAGEMENT | |
| 2.2 Organization and Personnel | §§117.4(a)(1) and (2), 111.105(a)–(b), 111.12(a)–(c), 111.12(b), 111.113(c), 117.180(a), 117.180(b)–(d)(1) and (2), 111.13(a), 117.4(b)(2)(d); 111.10(a)(1) and (2), 117.10(a), 111.10(b)(1)–(9), and 117.10(b)(1)–(9) |
| 2.3 Documentation and Records | §§111.605(a)–(c) and 111.610(a)–(b) |
| 2.5 Deviations and Material Reviews | §§111.103, 111.140(b)(1)(3)(i)–(viii), 111.87, 111.113(a)–(b)(1)–(2), 111.77(a), and 111.140(b)(2)(i)–(ii) |
| 2.7 Hazard Analysis and Risk-Based Preventive Controls (HARPC) | §§117.126(a)–(b)(1)–(7), 117.130 (a)–(c)(1)–(2), 117.135(a)–(c)(1)–(6), 117.405(a)(2)(b)–(c), 117.410(a)(1)–(4)(b)(1)–(4)(c)–(d)(1)(i)–(iii)(a–c)(iv)(e), 117.430(a)(f), 117.435(a),(b)(c)(1)–(2)(d), 117.415(a)–(c), 117.475(b)(c)(1)–(18), 111.105(b), 117.139(a)–(b), 117.150(a)(1)(2)(b), 117.155(a)–(b), 117.160(a)–(c), 117.165(a)–(b), 117.170(a)–(f), and 117.190(a)(2)–(6) |
| 2.9 Complaints | §§111.553, 111.570(b)(1)–(2),111.560(a)(1)–(2)(b)(c), 111.135, 117.410(a)(1)–(2), (b)(1)–(4) and (d), 117.420(a), 117.430(a), and 117.425; §111.105(b) |
| 2.12 Quality Management Documentation | §§111.14(b)(1), 111.103, 111.140(b)(1)–(2), 111.553, 111.570(b)(1)(2), 117.305(a)–(f), 117.310(a)7(b), 117.315(a)(1)(b)–(d), and 117.330(a)–(b) |
| 3. Physical Plant and Equipment | |
| 3.1 Grounds Maintenance | §§111.15(a)(1)–(5) and 117.20(a)(1)–(4) |
| 3.2 Physical Plant Design | §§111.20(a)(b), 117.20(b)(1), 111.20(b)(2),111.310, 111.20(c), 117.20(b)(4), 117.20(b)(4)(6)(d), and 111.20(b)(3)(i)–(iv)(5)(7)(d)–(f)(h) |
| 3.3 Physical Plant Sanitation and Facilities | §§111.15(b), 117.35(a)(b)(1)(i)–(iv)(2)(c)(d)(1)–(3)(e)-(f),117.37(a), 111.15(e)–(g)(j), 117.37(b)(1)–(5)(c)(f)(d)(e)(f), 117.80(c)(6), 111.15(g)(h)(i)(j)(k), and 117.20(b)(2) |
| 3.4 Equipment, Instruments, and Utensils | §§111.27(a), 117.40(a)(1)(c)(d),111.27(a)(2)(3)(6)(7)(i)–(v)(4)(5)(d)(2)-(7), 117.40(a)(2)(6)(b)(e)(f), 111.30(a)–(b),117.80(c)(1),117.40(g)–(f), 111.27(b)(c)(d)(1)(4), and 111.605(c) |
| 3.5 Physical Plant and Equipment Documentation | §§111.16, 111.23(b)(c), 111.25(a)-(c), and 111.35(b)(1)(i)(ii)(2)–(4)(6) |
| 4. Materials Management Operations and Controls | |
| 4.1 Establishing Material and In-Process Production Specifications | §§111.70(a)(b)(1)–(3), 117.80(b)(2)–(4), 111.70(c)(1)–(3)(d)(e)(f)(g), and 117.110(a) and (b) |
| 4.2 Determining Compliance with Specifications | §§111.73, 111.75(a)(1)(2)b(1)(2)(c)(1)(2)–(4)(e)f(1)(2)(g)(h)(1), 117.77(a)(b)(c), and 111.90(a)(1)–(2)(c) |

# ⟨2750⟩ MANUFACTURING PRACTICES FOR DIETARY SUPPLEMENTS

***Change to read:***

## ▲GENERAL PROVISIONS

The aim of this chapter is to establish requirements that address the specific regulatory obligations of the dietary supplement industry and the additional requirements necessary to achieve compliance with the *USP–NF* quality specifications. The chapter covers the process, facilities, and controls to be used in the manufacturing, packaging, labeling, holding, and distributing of dietary supplements consistent with the FDA current good manufacturing practices (cGMP) regulations in title 21, part 111 of the *Code of Federal Regulations* in order to help dietary supplement manufacturers ensure that dietary supplements are consistently produced and controlled to the quality standards appropriate to their intended use and as required by the product specification according to USP standards.

A manufacturing and in-process control system must be designed and implemented to cover all stages of manufacturing, packaging, labeling, holding, and distribution of the dietary supplement to ensure the quality of the dietary supplement and its proper packaging and labeling as specified in the master manufacturing and packaging control records.

An overall scheme of quality systems adopted in the chapter consists of the following:

1. *Quality management system*—This system assures overall compliance with cGMPs and internal procedures and specifications. This system includes the quality control unit and all of its review and approval duties (e.g., change control, reprocessing, batch release, annual record review, validation protocols, and reports, etc.). It includes all product defect evaluations and evaluation of returned and salvaged products. The quality management system must define the quality unit obligations and authorities to ensure that all material use and disposition decisions are independent of any conflict of interest.
2. *Physical plant and equipment system*—This system includes the measures and activities which provide an appropriate physical environment and resources used in the production of the finished products. It includes buildings and facilities along with maintenance; equipment qualifications, calibration, and preventative maintenance; utilities that are not intended to be incorporated into the product such as heating, ventilation, and air-conditioning (HVAC), compressed gases, steam and water systems. The water systems refer to both the “equipment system” and the “material system”.
3. *Materials management system*—This system includes measures and activities to control finished products; components, including water or gases that are incorporated into the product; and containers and closures. It includes validation of computerized inventory control processes, product storage, distribution controls, and records.
4. *Production operations and controls system*—This system includes measures and activities to control the manufacture of finished products, including batch compounding, dosage form production, in-process sampling and testing, and process validation.
5. *Packaging and labeling operations and controls system*—This system includes measures and activities that control the packaging and labeling of finished products. It includes written procedures, label examination and usage, label storage and issuance, packaging and labeling operations controls, and validation of these operations.
6. *Laboratory control system*—This system includes measures and activities related to laboratory procedures, testing, analytical methods development and validation or verification, and the stability program.

Warehouses or other storage facilities for a retailer as well as warehouses or other storage facilities that sell directly to individual consumers must comply with the requirements pertaining to holding dietary supplements. The requirements pertaining to holding dietary supplements do not apply to holding those dietary supplements at a retail establishment for the sole purpose of direct retail sale to individual consumers.

# 1. QUALITY MANAGEMENT

## 1.1 General Principles

Quality unit operations must be implemented in manufacturing, packaging, labeling, laboratory, and holding operations for the production of dietary supplements to ensure the quality of the supplements and their packaging and labeling is in accordance with the specifications.

Quality should be the responsibility of all persons involved in manufacturing, testing, packaging, labeling, and holding dietary supplements. An effective system for managing quality that involves the active participation of management and appropriate manufacturing personnel must be established, documented, and followed. Management oversight of quality should encompass the organizational structure, procedures, processes, resources, and activities necessary to ensure that the dietary supplement will meet its intended specifications for quality. All quality-related activities must be defined and documented.

There must be a quality unit(s) that is independent of production (and any other conflicts of interest) and that fulfills both quality assurance (QA) and quality control (QC) responsibilities. This can be in the form of separate QA and QC units or a single individual or group, depending on the size and structure of the organization.

All quality- and manufacturing-related activities must be recorded and reviewed contemporaneously, signed, and dated.

https://nhathuocngocanh.com/

## 1.2 Organization and Personnel

### 1.2.1 GENERAL

Written procedures must be established and followed for creating and maintaining job position descriptions and listing job responsibilities and required qualifications for education, training, and experience. There must be an organizational chart clearly delineating the structure of the organization and the relationships and relative ranks of its parts and job positions.

### 1.2.2 RESPONSIBILITIES OF THE QUALITY UNIT(S)

A quality unit involved in all quality related matters must be established, which must review all appropriate quality related documents. Quality unit personnel must ensure that manufacturing, packaging, labeling, and holding operations ensure the quality of the dietary supplement and that the dietary supplement is packaged and labeled in accordance with the specifications.

The primary responsibilities of the independent quality unit(s) should not be delegated, and these responsibilities shall be described in writing. The quality unit(s) shall have the primary responsibility and authority for the following:

- Approving the release or rejection of (i.e., making a disposition decision for) all dietary supplements for distribution or in-process materials for use outside the control of the manufacturer;
- Establishing a system to approve the release or rejection of components, in-process materials, packaging materials, and labeling materials;
- Reviewing and approving the release or rejection of products manufactured, packaged, labeled, or held under contract by another company;
- Reviewing and approving all specifications;
- Reviewing and approving all master production, packaging, and labeling instructions;
- Reviewing and approving all procedures impacting the quality of in-process materials and dietary supplements;
- Reviewing completed production records to ensure that no errors have occurred or, if errors have occurred, that they have been investigated and resolved;
- Ensuring that all deviations are properly documented and that critical deviations are investigated and resolved;
- Ensuring that internal audits (self-inspections) are performed;
- Ensuring that corrective and preventative actions as a result of investigations (deviations and complaints) and internal audits are implemented in a timely manner;
- Establishing a system to evaluate and approve suppliers of components, packaging materials, and labeling as well as suppliers of manufacturing and laboratory services (i.e., contract manufacturers and contract laboratories);
- Establishing a system to evaluate and approve changes that potentially impact the quality of dietary supplements;
- Reviewing and approving test method validation protocols and reports;
- Establishing a system to handle complaints and ensure that quality-related complaints are investigated and resolved;
- Establishing effective systems for maintaining and calibrating equipment and instruments;
- Ensuring that materials are properly tested and the results are reported;
- Ensuring that there is stability data to support the shelf-life or expiry date and labeled storage conditions of dietary supplements;
- Performing product quality reviews and trend analysis, as needed;
- Reviewing and approving cGMP training documentations and ensuring the maintenance of these records.

The quality control unit (i.e., quality control laboratory) must have the responsibility for approving or rejecting all laboratory processes procedures, specifications, controls, tests, examinations, and deviations (planned and unplanned) from or modifications to them, that may affect the identity, strength, quality, and purity of the dietary supplement. All responsibilities and procedures applicable to the quality control unit must be in writing.

The quality unit personnel must be identified and qualified to perform quality assurance and/or quality control operations. Any other responsibility that such personnel may have within the company must not interfere or conflict with the ability to make independent judgments about quality.

The designated quality control personnel who conducts a material review and makes the disposition decision must, at the time of performance, document the material review and disposition decision made.

### 1.2.3 RESPONSIBILITIES FOR PRODUCTION OPERATIONS

The responsibilities for production operations must be documented in writing and should include the following:

- Preparing, reviewing, approving, and distributing the instructions for the production of in-process materials and dietary supplements according to written procedures;
- Reviewing all production batch records and ensuring that they are completed and signed;
- Ensuring that production facilities are clean and sanitized, if needed;
- Ensuring that the premises and equipment are maintained and records kept;
- Ensuring that HVAC, dust collection, and other systems are appropriately designed to minimize the potential for cross-contamination;
- Ensuring that, when appropriate, physical and spatial separation are used in combination to minimize the potential for cross-contamination and to prevent mix-ups;
- Ensuring that manufacturing verification/validation protocols and reports are reviewed and approved, if available;
- Evaluating proposed changes in product, process, or equipment; and

- Ensuring that new and any modified facilities and equipment are qualified through an appropriate documented change control system.

### 1.2.4 PERSONNEL QUALIFICATIONS

Each person engaged in the manufacture of dietary supplements should have the proper education, training, and experience (or any combination thereof) needed to perform the assigned functions. Training should be in the particular operation(s) that the employee performs as they relate to the employee's functions.

Each person responsible for supervising the manufacture of dietary supplements must have the proper education, training, and experience (or any combination thereof) to perform assigned functions in such a manner as to provide assurance that the dietary supplement has the safety, identity, strength, quality, and purity that it is represented to possess.

An adequate number of qualified personnel to perform and supervise the manufacture of dietary supplements should be provided.

Personnel qualifications apply equally to contractors, consultants, and temporary employees. Records should be maintained stating the name, address, qualifications, and type of service provided by contractors and consultants.

### 1.2.5 PERSONNEL TRAINING

Training should be regularly conducted by qualified persons and should cover, at minimum, the particular operations that the employee performs and current good manufacturing practice (GMP) as it relates to the employee's functions. Training requirements should be specified, e.g., read and understand, instructional with trainer, on-the-job training. Training should be periodically assessed by reviewing and approving GMP training documentation and ensuring that these records are maintained. Appropriate documentation of training must be retained by the company, including date of training, the type of training, name of trainer if applicable, the person(s) trained, and any assessment results (e.g., test results).

### 1.2.6 PERSONNEL RESPONSIBILITIES

The company management must take all reasonable measures and precautions to ensure the following:

**1.2.6.1 Preventing microbial contamination:** Any person who, by medical examination, by the person's self acknowledgment, or supervisory observation, is shown to have, or appears to have an illness (including a fever, coughing, and sneezing), infection, open lesion, or any other abnormal source of microbial contamination that could result in microbial contamination of components, in-process material, dietary supplements, or contact surfaces must be excluded from working in any operations that may result in such contamination until the aforementioned conditions no longer exist, or unless conditions such as open lesions, boils, and infected wounds are adequately covered (e.g., by an impermeable cover). Personnel must be instructed to report such conditions to their supervisors.

**1.2.6.2 Hygienic practices:** All persons working in an operation during which adulteration of components, in-process material, dietary supplements, or contact surfaces could occur must use hygienic practices to the extent necessary to protect against such adulteration. These practices include the following:

- Wearing outer garments in a manner that protects against the contamination of components, in-process material, or dietary supplements, or any contact surface;
- Maintaining adequate personal cleanliness;
- Removing cosmetics from parts of the body that may contact components, in-process materials, dietary supplements, or contact surfaces;
- Washing hands thoroughly (and sanitizing if necessary to protect against allergen cross-contact and contamination with microorganisms) in an adequate hand-washing facility before starting work, and at any other time when the hands may have become soiled or contaminated;
- Removing all unsecured jewelry and other objects that might fall into components, in-process materials, dietary supplements, equipment, or packaging materials, and removing hand jewelry that cannot be adequately sanitized during periods in which components, in-process materials, or dietary supplements are manipulated by hand. If hand jewelry and cosmetics cannot be removed, they must be covered by material that is maintained in an intact, clean, and sanitary condition and that effectively protects against contamination of components, in-process materials, dietary supplements, or contact surfaces;
- Maintaining gloves used in handling components, in-process materials, or dietary supplements in an intact, clean, and sanitary condition. The gloves must be of impermeable material;
- Wearing face masks when working within the production and packaging areas;
- Wearing where appropriate, in an effective manner, hair nets, caps, beard covers, or other effective hair restraints;
- Storing clothing or other personal belongings in areas other than where components, in-process materials, dietary supplements, or any contact surface are exposed, where contact surfaces are washed, or where clean work uniforms and gowning are stored;
- Maintaining footwear protocol when working within the production and packaging areas;
- Not eating food, chewing gum, drinking beverages, or using tobacco products in GMP or critical areas where components, in-process materials, dietary supplements, or contact surfaces are exposed or where contact surfaces are washed; and
- Taking any other precautions necessary to protect against allergen cross-contact and contamination of components, in-process materials, dietary supplements, or contact surfaces with microorganisms, allergens, filth, foreign substances, or other extraneous materials, including perspiration, hair, cosmetics, tobacco, chemicals, and medicines applied to the skin. This may include restricting the movement of individuals working in unit operations with known allergens so that those individuals are not allowed to move into non-allergen production areas, and/or color coding of in-process allergen-containing materials to differentiate from non-allergen-containing materials.

## 1.3 Documentation and Records

### 1.3.1 GENERAL

Clear, complete, accurate records for all operations and procedures should be documented appropriately. [NOTE—see *Good Documentation Guidelines* ⟨1029⟩ for recommendations about appropriate documentation practices.]

All documents related to the manufacture of dietary supplements must be initiated, prepared, reviewed, approved, distributed, and archived according to written procedures. Such documents can be in paper or electronic form. If the firm chooses to maintain its documentation electronically, the resulting documents and related records must be 21 CFR Part 11 compliant.

When entries are made in records, these must be made legibly and indelibly in spaces provided for such entries, directly after performing the activities, and should identify the person making the entry, and the day, and time as needed, when the entry was made. All dates must include day, month, and year in a consistent format. Numerical results must have appropriate numerical units, and calculations must be made with appropriate rounding and significant figures. Corrections to entries must be dated and signed, leaving the original entry still legible. If the reason for the correction is not obvious (e.g., date transcription error), then a statement should be made to provide clarity on the correction.

### 1.3.2 CONTROL OF DOCUMENTATION

The issuance and revision, superseding and withdrawal of all documents must be controlled with maintenance of revision histories. A procedure should be established for retaining all appropriate documentation (e.g., procedures and records). There should be proper control over:

- Standard operating procedures (SOPs) and work instructions;
- Forms: content, revision, review; each form must be associated with one or more SOPs and correspondingly numbered/versioned/dated;
- Master manufacturing records;
- Laboratory testing method;
- Spreadsheets: spreadsheet for specific project—accuracy checked by reviewer, spreadsheet for routine use—validated, access/revision controlled;
- External documents: proprietary documents, guidance documents issued by outside agency;
- Uncontrolled documents;
- For reference only documents;
- Employee notes and memos.

A formal documentation filing system (physical or electronic) should be established, with appropriate security.

### 1.3.3 RECORDS RETENTION

The retention periods for these documents must be specified. Written records must be kept, at minimum, for one (1) year past the shelf life date of the dietary supplement associated with those records. Records must be kept as original records, as true copies (such as photocopies, microfilm, compact disk, or other accurate reproductions of the original records), or as electronic copies. All electronic records must comply with 21 CFR Part 11—*Electronic Records; Electronic Signatures*.

Serious adverse event reports must be kept, at minimum, for six (6) years from the date the report is received by the responsible party.

All records or copies of records required under this general chapter must be readily available during the retention period for inspection by the FDA when requested. If encryption or data reduction techniques are used, suitable equipment to retrieve the information must be made readily available to the FDA.

## 1.4 Change Control

A formal change control system must be established to evaluate all changes that may affect the production and quality of dietary supplements. Written procedures should provide for the identification, documentation, appropriate review, and approval of changes to components, packaging materials, labeling, material specifications, analytical procedures, facilities, utility systems, equipment, computer systems, production operations, and packaging and labeling operations.

Any proposals for GMP relevant changes should be drafted, reviewed, and approved by the appropriate approved units, and reviewed and approved by the quality unit(s).

The potential impact of the proposed change on the quality of the dietary supplement should be evaluated. A change classification system based on the nature and extent of the change (e.g., major, minor) and its impact on the process (e.g., critical, non-critical) should be established with clear definitions. This classification system should be used to determine the level of testing, validation, and documentation needed to justify changes to a system or process. When implementing approved changes, measures should be taken to ensure that all documents affected by the change are revised.

The potential for changes to affect established expiry dates (e.g., changes to product formulation) should be evaluated. If necessary, the dietary supplement produced by the change can be placed on an accelerated stability program and/or added to the stability monitoring program.

Manufactures should require their contract manufactures or packagers to notify them of changes from established production process controls that can affect the quality of the dietary supplement.

Official

https://pharmacopeia.cn/v29240/

## 1.5 Deviations and Material Reviews

### 1.5.1 DEVIATIONS

Written procedures must be established and followed for documenting all deviations, and for investigating critical deviations. Any deviation from established procedures and standards should be documented and explained. Critical deviations should be investigated, and the investigation and its conclusions should be documented. The investigation should extend to any and all batches of material that may have been associated with the specific failure or deviation. The quality unit must ensure that critical deviations are investigated and resolved. Corrective and preventative actions should be implemented and verified in a timely manner.

### 1.5.2 MATERIAL REVIEW

Written procedures must be established and followed for conducting material reviews and making disposition decisions, and for the quality unit to approve or reject any treatment or in-process adjustment of a component that is rejected, or reprocessing of a dietary supplement that is rejected.

Quality unit personnel must conduct all required material reviews and make all required disposition decisions. Quality unit personnel must conduct a material review and make a disposition decision if:

- A specification is not met for a component, in-process material, packaging, labeling, dietary supplement, a dietary supplement received for packaging and labeling, or finished packaged and labeled dietary supplement;
- A batch record that deviates from the master manufacturing record, including when any step is not completed, and any deviation from the instructions contained therein;
- There is any unanticipated occurrence during manufacturing operations that adulterates or may lead to adulteration and/or misbranding of the component, dietary supplement, or packaging, or could lead to the use of a label not specified in the master manufacturing record;
- Calibration of an instrument or control suggests a problem that may have resulted in a failure to ensure the quality of a batch or batches of a dietary supplement;
- A dietary supplement is returned.

When there is a deviation or unanticipated occurrence during the production and in-process control system that results in or could lead to adulteration of a component, dietary supplement, or packaging, or could lead to the use of a label not specified in the master manufacturing record, quality unit personnel must reject the material unless it approves a treatment, an in-process adjustment, or reprocessing to correct the deviation or unanticipated occurrence.

When an established specification is not met, quality unit personnel must reject the component, in-process material, dietary supplement, packaging, or labeling, unless quality unit personnel approve a treatment, an in-process adjustment, or reprocessing, that will ensure the quality of the finished dietary supplement and that the dietary supplement is packaged and labeled as required in the master manufacturing record.

The quality unit personnel and each qualified individual who provides information relevant to the material review and disposition decision and subsequent approval or rejection of the treatment, in-process adjustment, or reprocessing of the subject material must document performance of the review, by signing and dating in the deviation investigation and material review report at the time of performance.

Deviation investigation and material review reports must include:

- Description of the specific deviation or unanticipated occurrence;
- Description of the root cause investigation;
- Evaluation of whether or not the deviation or unanticipated occurrence has resulted in or could lead to a failure to ensure the quality of the dietary supplement or failure to package and label the dietary supplement as specified in the master manufacturing record;
- Identification of corrective action(s) and preventive action(s) taken with timelines;
- Description of any material reviews, and a scientifically valid reason for any treatment or in-process adjustment of a component or in-process material that is rejected, or any reprocessing of a dietary supplement that is rejected, so as to correct the applicable deviation or unanticipated occurrence, along with the quality unit personnel's approval signature and date, when performed;
- Conclusion(s), including the explanation of the final disposition decision (approval or rejection) made for the subject article; and
- Signatures of individual(s) designated to perform quality unit operations, who conducted the material review and made the disposition decision, and of each qualified individual who provides information relevant to that material review and disposition decision.

Documentation of any material review and disposition decision, or reference to the deviation investigation and material review report, must be included in the appropriate batch production record.

## 1.6 Corrective Actions and Preventative Actions (CAPA)

The CAPA operating plan is the essential instruction by which personnel plan to achieve correction of violative, unacceptable, and improper practices, and to prevent recurrence. CAPAs may arise from many sources, including deviations, customer complaints, investigations, internal audit findings, and external audit findings.

The quality unit must establish, monitor, and maintain a CAPA program. The CAPA program should include a tracking system for deviations, nonconformities, including out-of-specification laboratory results, and CAPAs. All persons must identify deviations

and nonconformities and notify management and/or the quality unit. Supervisors must determine root causes and develop and implement appropriate remedial action(s), corrective action(s), and/or preventive action(s). The quality unit must monitor CAPAs and manage the CAPA program to assist with adequate development, implementation, and closure of CAPAs.

## 1.7 Supplier Qualification

A written risk-based supplier qualification program, where appropriate, must be established and implemented for components for which the manufacturer has identified a hazard that requires a supply-chain-applied control.

When a supply-chain applied control is applied by an entity other than the manufacturer's supplier (e.g., a component manufacturer applies controls that are under different management than the distributor supplying the component to the manufacturer), the manufacturer must verify the supply-chain control, or obtain documentation of appropriate verification activity from another entity, review and assess the entity's applicable documentation, and document that review and assessment. For the purposes of this section, verification means the application of methods, procedures, tests, and other evaluations, in addition to monitoring, to determine whether a control measure or combination of control measures is or has been operating as intended and to establish the validity of the safety plan [as specified in 21 CFR §117.126(b)].

The supplier qualification program must include:

- Using approved suppliers, and documenting that approval before receiving components from those suppliers;
- Determining appropriate supplier verification activities, including determining the frequency of conducting the activity by considering 21 CFR §§117.410(a)(2), 117.410(d), and 117.425:
    - The hazard analysis of the component, including the nature of the hazard controlled before receipt of the component;
    - The entity or entities that will be applying controls for the hazards requiring a supply-chain-applied control;
    - Supplier performance, including:
        - The supplier's procedures, processes, and practices inherent to the hazards associated with the component;
        - Applicable food safety regulations and information relevant to the supplier's compliance with those regulations, including warning letters or import alert relating to the safety of the component and other regulatory compliance actions related to component safety (or, when applicable, relevant laws and regulations and information relevant to the supplier's compliance with those laws and regulations);
        - The supplier's food safety history relevant to the component that the manufacturer receives from the supplier, including available information about results from testing components for hazards, audit results relating to the safety of the component, and responsiveness of the supplier in correcting problems; and
        - Any other factors as appropriate and necessary, such as storage and transportation practices;
- Conducting one or more supplier qualification activities for components and approving each supplier before using the component:
    - Risked-based supplier qualification activities may include:
        - On-site audits;
        - Sampling and testing of components (certificate of analysis verification);
        - Review of supplier's relevant food safety records; and
        - Other appropriate supplier verification activities based on supplier performance and the risk associated with the component;
- Documenting supplier qualification activities.

The manufacturer's supplier qualification management may require internal cross-functional support from procurement, research and development, manufacturing operations, quality unit operations, and regulatory affairs. Due to limited internal resources, if a large number of components are used by the manufacturer, risk management principles need to be applied to qualify suppliers of components. Quality risk factors to consider include the complexity of the supply chain, component characteristics, and the level of the supplier's technical performance and regulatory compliance. The risk-based supplier qualification program must be written, implemented, and followed.

Supplier qualification activities must be documented. Formal reports should be generated for each component from each supplier summarizing initial qualification activities and analyses, and plans and schedule for continuous monitoring. An approved list of components and suppliers should be readily available to staff. A unique component item code should be assigned for each component from each supplier; however, the manufacturer may identify equivalencies between the same components from different suppliers as long as they meet the same critical specification for identity, strength, purity, composition, and limits on contaminants.

Quality unit personnel must review and approve the documentation setting forth the basis for the qualification of any supplier.

## 1.8 Contract Manufacturers and Contract Laboratories

All contract manufacturers and contract laboratories should comply with the requirements of this general chapter or equivalent regulatory oversight system requirements. Special consideration should be given to the prevention of cross-contamination and to maintaining traceability.

Contract manufacturers and contract laboratories should be evaluated by the contract giver to ensure GMP compliance of the specific operations occurring at the contract sites.

There should be a written and approved contract or quality agreement between the contract giver and the contract acceptor that defines in detail the cGMP responsibilities, including the quality measures, of each party. The contract should include provisions for the contract giver to audit, onsite and/or virtual, the contract acceptor's facilities for compliance with GMPs. Where subcontracting is allowed, the contract acceptor should not pass to a third party any of the work entrusted to it under the contract without the contract giver's prior evaluation and approval of the arrangements.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99987_02_01
@2024 USPC

Manufacturing and laboratory records should be kept at the site where the activity occurs and be readily available. Changes in the process, equipment, test methods, specifications, or other contractual requirements should not be made unless the contract giver has been informed and has approved the changes.

## 1.9 Complaints, Serious Adverse Event Reporting, and Recalls

### 1.9.1 COMPLAINTS

All quality related complaints, whether received orally or in writing, should be recorded and investigated according to written procedures.

Complaint records should include:

- Name and address of complainant;
- Name and phone number of person submitting the complaint;
- Name of dietary supplement, item code, and lot number;
- Nature of the complaint, including, if known, how the product was used;
- Date the complaint was received;
- Investigation undertaken and initial findings, including dates and identity of person(s) conducting the investigation;
- Action initially taken, including dates and identity of person(s) taking the action;
- Any follow up action taken;
- Response provided to the originator of the complaint, including date response was sent;
- Final findings and decision on product lot; and
- Quality unit personnel review and approval signature.

A qualified person must review and investigate all product complaints to determine whether the product complaint involves a possible failure of a dietary supplement to meet any of its specifications, or any other requirements of this general chapter, including those specifications and other requirements that, if not met, may result in risk of illness or injury.

Quality unit personnel must review and approve decisions about whether to investigate a product complaint and review and approve the findings and follow-up action of any investigation performed.

The review of the product complaint and any investigation performed must extend to all relevant batches and records.

Records of complaints should be retained in order to evaluate trends, product related frequencies, and severity with a view of taking additional, and if appropriate, immediate corrective action.

### 1.9.2 ADVERSE EVENT REPORTING

The manufacturer, packer, or distributor whose name appears on the label of a dietary supplement must maintain records related to dietary supplement adverse event reports that they receive, whether or not the adverse event is serious. The product labeling must include a continuously operating toll free telephone number for reporting adverse events involving the product. [NOTE—Products distributed with labels that do not contain the required telephone number or address are misbranded in the United States.]

All serious adverse event reports associated with the use of a dietary supplement must be submitted to the relevant regulatory agency, with a copy of the dietary supplement label, within 15 business days or within the time required by the regulatory authority after the report is received. [NOTE—In the United States, use MedWatch form FDA 3500A.]

If a retailer's name appears on the label as a distributor, the retailer may, by agreement, authorize the manufacturer or packer of the product to submit the required reports, as long as the retailer directs to the manufacturer or packer all adverse events associated with the product's use that are reported to it through the address or telephone number.

### 1.9.3 RETENTION OF ADVERSE EVENT REPORTING RECORDS

A responsible party must maintain records of any adverse event report it receives, whether serious or not, for 6 years from the date the report is received by the responsible party. Responsible parties must also give the authorized government officials timely access to the records. Responsible parties must maintain records containing the submission of serious-adverse-event reports, records containing submission of new medical information related to serious-adverse event reports, and records containing communications by the responsible party with anyone reporting a serious adverse event to the company. Responsible parties must maintain the records regardless of the source and regardless of any determination that the adverse event was caused by, or associated with, the product.

### 1.9.4 RECALLS

There should be a written procedure that defines the circumstances under which recall of a dietary supplement should be considered. The recall procedure should designate who should be involved in evaluating the information, how a recall should be initiated, who should be informed about the recall, and how the recalled dietary supplement should be treated. In the event of a serious or potentially life-threatening situation, local, national, and/or international regulatory authorities should be informed and regulations followed to ensure proper execution and disposition of the recall under international regulations.

Mock recalls should be performed annually.

Official

https://pharmacopeia.com/

## 1.10 Internal (Self-Inspection) Audits

In order to verify compliance with the requirements of this general chapter, regular internal audits should be performed according to an approved schedule. Audit findings and corrective actions should be documented and brought to the attention of responsible management. Acceptable corrective action should be completed in a timely and effective manner.

## 1.11 Product Quality Review

Regular quality reviews of dietary supplements should be conducted annually with the objective of verifying the consistency of the manufacturing process.

Such review should normally be conducted annually and should include a review of:

- Critical dietary supplement test results;
- All batches that failed to meet established specification(s);
- Critical deviations or nonconformities and related investigations;
- Adequacy of corrective actions;
- Changes to the manufacturing process and analytical procedures;
- Results of the stability monitoring program; and
- Quality-related returns, complaints, and recalls.

The results of this review should be evaluated and an assessment made of whether any additional corrective action or any revalidation should be undertaken. Reasons for such corrective actions should be documented. Acceptable corrective actions should be completed in a timely and effective manner.

## 1.12 Quality Management Documentation

The following documentation must be made and kept for fulfilling the requirements of the Quality Management System (quality system 1).

### 1.12.1 WRITTEN PROCEDURES

Written procedures must be established and followed for:

- Creating and maintaining job position descriptions, listing job responsibilities and required qualifications for education, training and experience;
- Implementing a training program;
- Implementing a documentation and records control management system;
- Implementing a change control program;
- Implementing a deviation management program;
- Conducting material reviews;
- Implementing a corrective action and preventive action management program;
- Implementing a supplier qualification program;
- Implementing contract (manufacturing and laboratory) services program;
- Implementing a complaints handling program;
- Handling recalls;
- Conducting internal audits; and
- Conducting product quality reviews.

### 1.12.2 RECORDS

Records must be made and kept for:

- Organizational chart and job position descriptions; curriculum vitae should be available for all key management individuals in operations and quality;
- Training, including the date of the training, the type of training, name of trainer if applicable, the person(s) trained, and any assessment results (e.g., test results);
- List of and copies of current standard operating procedures, master manufacturing records, and standard test methods;
- List of and reports of changes that affect the production and quality of dietary supplements;
- List of and reports of unanticipated occurrences and deviations from approved instructions or established standards;
- List of and copies of executed batch manufacturing records;
- List of and reports of material reviews;
- List of and reports of corrective actions and preventative actions taken;
- List of approved suppliers of components, packaging materials, and labeling, and corresponding supplier qualification evaluation reports;
- List of approved suppliers of manufacturing and laboratory services, and corresponding evaluation reports, and quality agreements;
- List of complaints and corresponding investigation reports;

- Product quality review reports.

# 2. PHYSICAL PLANT AND EQUIPMENT

## 2.1 Grounds Maintenance

The grounds around the physical plant must be kept in a condition that protects against the contamination of components, in-process material, dietary supplements, and contact surfaces. The methods for adequate ground maintenance include the following:

- Properly storing equipment, removing litter and waste, and cutting weeds or grass within the immediate vicinity of the physical plant so that it does not constitute an attractant, breeding place, or harborage for pests;
- Maintaining roads, yards, and parking lots so that they do not constitute a source of contamination in areas where components, in-process material, dietary supplements, or contact surfaces are exposed;
- Adequately draining areas that may contribute to the contamination of components, in-process materials, dietary supplements, or contact surfaces by seepage, filth, or any other extraneous materials, or by providing a breeding place for pests;
- Adequately operating systems for waste treatment and disposal so that they do not constitute a source of contamination in areas where components, in-process materials, dietary supplements, or contact surfaces are exposed;
- If the physical plant grounds are bordered by grounds not under the operator's control and not maintained in the aforementioned manner, care must be exercised in the plant by inspection, extermination, or other means to exclude pests, dirt, filth, or any other extraneous materials that may be a source of contamination.

## 2.2 Physical Plant Design

Any physical plant used in the manufacture of dietary supplements must be of suitable size, construction and design to facilitate maintenance, cleaning, and sanitizing operations. The physical plant must have adequate space for the orderly placement of equipment and holding of materials as is necessary for maintenance, cleaning, and sanitizing operations, and to prevent contamination and mix-up of materials. The flow of materials and personnel throughout the physical plant should be designed to prevent contamination and mix-up of materials.

### 2.2.1 SEPARATE AND DEFINED AREAS

The physical plant must have and the manufacturer must use separate, defined areas of adequate size or other control systems —such as computerized inventory controls or automated systems of separation, physical or spatial separation—to prevent contamination or allergen cross-contact and mix-up of components, in-process materials, dietary supplements, packaging materials, and labels, during the following operations:

- Receiving, identifying, sampling, holding, and withholding from use materials to be used in manufacturing;
- Separating materials to be used in manufacturing from materials awaiting material review and disposition (i.e., in quarantine);
- Performing production, packaging, labeling, and holding operations;
- Physically separating allergen-containing raw materials from non-allergen raw materials;
- Holding rejected materials before further disposition (e.g., return, reprocessing, or destruction);
- Performing and separating the manufacturing, packaging, labeling, and holding of different product types, including different types of dietary supplements, and other foods, cosmetics, and pharmaceutical products;
- Cleaning and sanitizing contact surfaces;
- Performing and separating chemical and microbiological laboratory analyses and holding of laboratory samples and supplies.

Laboratory areas/operations should normally be separated from production areas. Some laboratory areas, particularly those used for in-process controls, can be located in production areas, provided the operations of the production process do not adversely affect the accuracy of the laboratory measurements, and the laboratory and its operations do not adversely affect the production process.

Dedicated production areas, which can include facilities, air handling equipment and/or process equipment, should be considered when materials of an allergenic nature are involved, unless validated cleaning procedures are established and maintained.

### 2.2.2 DESIGN AND CONSTRUCTION

The physical plant must be designed and constructed in a manner that prevents contamination of materials and contact surfaces by having the following:

- Floors, walls, and ceilings that can be adequately cleaned and kept in good repair;
- Fixtures, ducts, and pipes that do not contaminate materials and contact surfaces by dripping or other leakage, or condensate;

Official

https://nhathuoclocanh.com/

- Adequate ventilation or environmental control equipment such as airflow systems, including filters, fans, and other air-blowing equipment that minimize odors and vapors (including steam and noxious fumes) in areas where they may cause allergen cross-contact or contamination of materials or contact surfaces, and that are located and operated in a manner that minimizes the potential for allergens, microorganisms, and particulate matter to contaminate materials or contact surfaces;
- Equipment that controls air pressure, temperature, and humidity, as needed to ensure the quality of the dietary supplement; particular attention should be given to areas where components, in-process materials, and dietary supplements are exposed to the environment;
- Aisles or working spaces between equipment and walls that are adequately unobstructed and of adequate width to permit staff to perform their duties and to protect against contamination of materials and contact surfaces with clothing or personal contact;
- Adequate lighting in all areas where material is examined, processed, or held, or where contact surfaces are cleaned; and in hand-washing areas, dressing and locker rooms, and bathrooms;
- Safety-type light bulbs, fixtures, skylights, or other glass or glass-like materials when suspended over exposed materials in any step of manufacture;
- Adequate screening or other protection against pests and insects, where necessary;
- Adequate protection of materials in bulk fermentation vessels by, for example, use of protective coverings; placement in areas where harborages for pests can be eliminated over and around the vessels; placement where staff can check regularly for pests, pest infestation, filth, biofilm, organic material, or any other extraneous materials; or by use of skimming equipment.

## 2.3 Physical Plant Sanitation and Facilities

The physical plant must be kept clean and sanitary, and maintained in repair sufficient enough to prevent materials and contact surfaces from becoming contaminated.

Written procedures should be established assigning responsibility for sanitation and describing the cleaning schedules, methods, equipment, and materials to be used in cleaning buildings and facilities.

Utilities that could affect dietary supplement quality (e.g., purified water, potable water, steam, gases, compressed air, heating, ventilation, and air conditioning) should be qualified and appropriately monitored and action should be taken when acceptance criteria are not met. Drawings for these utility systems should be made and available.

### 2.3.1 CLEANING COMPOUNDS, SANITIZING AGENTS, PESTICIDES, AND OTHER TOXIC MATERIALS

Cleaning compounds and sanitizing agents must be free from undesirable microorganisms and must be safe and adequate under the conditions of use. All toxic materials should be purchased with a safety data sheet and supplier's guarantee or certification. Toxic materials must not be used or held in the physical plant in which components, in-process materials, dietary supplements, and contact surfaces are manufactured or exposed, unless those materials are required to maintain clean and sanitary conditions, to conduct laboratory test procedures, to maintain or operate the physical plant or equipment, or to use in the physical plant's operations. Toxic materials must be identified and held in a manner that protects against contamination of components, in-process materials, dietary supplements, and contact surfaces. All relevant federal, state, and local government regulations for the use and holding of these toxic materials must be followed.

Any substances associated with the operation of equipment, such as lubricants, heating fluids, or coolants, should not contact in-process materials or dietary supplements so as to alter their quality beyond established specifications. Any deviations from this should be evaluated to ensure that there are no detrimental effects upon the suitability for use of the material. When possible, food grade lubricants and oils should be used. When the lubricant used is placed in direct contact with an in-process material (e.g., in the production of soft gelatin capsule film) a food grade is required.

### 2.3.2 PEST CONTROL

Animals or pests must not be allowed in any area of the physical plant. Effective measures must be taken to exclude pests from the physical plant and to protect against contamination of materials and contact surfaces on the premises by pests. The use of pesticides, such as insecticides, fumigants, fungicides, or rodenticides, is permitted only if precautions are taken to protect against the contamination of components, in-process materials, dietary supplements, and contact surfaces. Pesticides should be registered and used in accordance with the Federal Insecticide, Fungicide, and Rodenticide Act.

### 2.3.3 WATER SUPPLY

Potable water at a suitable temperature, and under pressure as needed, must be supplied in a plumbing system free of defects that protects against contamination or undesirable chemical reaction of components, in-process materials, dietary supplements, and contact surfaces. Potable water must meet, at minimum, all the requirements for drinking water promulgated in the U.S. Environmental Protection Agency's National Primary Drinking Water Regulations (40 CFR §141), and any applicable state and local drinking water requirements that are more stringent. For manufacturers outside the U.S., potable water meeting equivalent requirements may be acceptable with justification, for example, the drinking water regulations of the European Union (European Commission Directive 98/93/EC) or Japan Drinking Water Quality Standards. Water not meeting such requirements should not be permitted for use in the water purification system for *Purified Water*.

If water is to be used as a component of a dietary supplement, e.g., when such water contacts components, in-process materials, dietary supplements, or any contact surface, it should be assessed to ensure that the quality of such water does not negatively affect the quality of the dietary supplement over its designated shelf life. Where water used in the manufacturing

https://pharmacopeia.cn/v-cn/

process is treated by the manufacturer to achieve a defined quality, the treatment process should be qualified and monitored with appropriate acceptance and action level criteria.

Water from a private source should be used in a manner such that the water may become a component of the dietary supplement, comply with any state and local requirements, and not contaminate the dietary supplement. Satisfying this requirement may involve performing appropriate water treatment procedures, including filtration, sedimentation, and chlorination.

#### 2.3.4 PLUMBING

The plumbing in the physical plant must be of an adequate size and design and be adequately installed and maintained to:

- Carry sufficient amounts of water to the required locations throughout the physical plant;
- Properly convey sewage and liquid disposable waste from the physical plant;
- Avoid being a source of contamination to components, in-process materials, dietary supplements, or any contact surface, or creating an unsanitary condition;
- Provide adequate floor drainage in all areas where floors are subject to flooding-type cleaning or where normal operations release or discharge water or other liquid waste on the floor; and
- Not allow backflow from, or cross connection between piping systems that discharge waste water or sewage and piping systems that carry water used for manufacturing dietary supplements, for cleaning contact surfaces, or for use in bathrooms or hand-washing facilities.

Permanently installed pipework should be appropriately identified. This can be accomplished by identifying individual lines with content and directional flow arrows, documentation of computer control systems, or alternative means.

#### 2.3.5 SEWAGE AND TRASH DISPOSAL

Sewage, refuse, and other waste in and from buildings and the immediate surrounding area should be disposed of in a safe, timely, and sanitary manner. Sewage must be disposed of into an adequate sewage system. Trash and hazardous waste must be conveyed, stored, and disposed of in a manner to minimize the development of odors; minimize the potential for the trash to attract, harbor, or become a breeding place for pests; and protect against contamination of materials, contact surfaces, water supplies, and grounds surrounding the physical plant. Containers and/or pipes for waste material should be clearly identified.

#### 2.3.6 BATHROOMS AND HAND-WASHING FACILITIES

Adequate and readily accessible bathrooms and hand-washing facilities must be provided and kept clean, and must not be a potential source of contamination of materials and contact surfaces. The facilities must be designed to provide water at a suitable temperature, soap and sanitizing agents, air driers, or single-service towels [cGMP, 21 CFR §111.15(h)–(i)]. Adequate facilities for showering and/or changing clothes should be provided, when appropriate.

#### 2.3.7 ALLERGEN CROSS-CONTAMINATION REDUCTION CONTROL

Adequate precautions must be taken to reduce the potential for allergen cross-contact of components, in-process materials, dietary supplements, and contact surfaces by adequate food safety controls and operating practices or effective design of the physical plant, including the separation of operations in which allergen cross-contact is likely to occur, by one or more of the following means: location, time, partition, air flow systems, dust control systems, enclosed systems, or other effective means [cGMP, 21 CFR §117.20(b)(2)].

#### 2.3.8 SANITATION SUPERVISORS

One or more employees must be assigned to supervise overall sanitation, and must be qualified by education, training, and/or experience to develop and supervise sanitation procedures, using appropriate risk-based assessments and preventative controls.

### 2.4 Equipment, Instruments, and Utensils

Equipment, instruments, and utensils used in the manufacture of dietary supplements must be of appropriate design, construction, and workmanship, to enable them to be suitable for their intended use and suitably located to facilitate operations for their intended use and to be adequately cleaned and properly maintained.

Equipment and utensils include, but are not limited to, the following: equipment used to hold or convey; equipment used to measure (i.e., instruments); equipment using compressed air or gas; equipment used to carry out processes in closed pipes and vessels; and equipment used in automatic, mechanical, or electronic systems.

Major equipment and permanently installed processing lines used during the production, packaging, and labeling of dietary supplements should be appropriately identified. A set of current drawings and/or manuals should be maintained for equipment and critical installations (e.g., instrumentation and utility systems). Equipment should be identified as to its contents and its cleanliness status by appropriate means.

#### 2.4.1 DESIGN AND CONSTRUCTION

Equipment and utensils must be appropriate in design and construction to:

Official

@2024 USPC

- Prevent contamination of components, packaging materials, in-process materials, or finished product with lubricants, fuel, coolants, metal or glass fragments, filth or any other extraneous material, contaminated water, or any other contaminants;
- Be corrosion-resistant and made of nontoxic materials if the equipment or utensils contact components, in-process materials, or dietary supplements;
- Withstand the environment in which they are used in manufacturing, cleaning, and sanitizing;
- Must have seams that are smoothly bonded or maintained to minimize accumulation of dirt, filth, biofilm, organic material, particles of components, in-process materials, dietary supplements, or any other extraneous materials or contaminants;
- Constructed so that surfaces that contact components, in-process materials, or dietary supplements are not corrosive, reactive, additive, or absorptive so as to alter the quality of the product beyond the established requirements.

Automated, mechanical, or electronic equipment that is used to manufacture, package, label, or hold a dietary supplement must be designed or selected to ensure that the dietary supplement specifications are consistently met.

The suitability of the equipment must be determined by ensuring that the equipment is capable of operating satisfactorily within the operating limits required by the process.

### 2.4.2 INSTALLATION AND MAINTENANCE

Equipment and utensils must be installed and maintained to facilitate cleaning the equipment and utensils and adjacent spaces, and to protect components, in-process materials, and dietary supplements from being contaminated by any source.

Each freezer, refrigerator, and cold storage compartment used to hold components, in-process materials, or dietary supplements:

- Must be fitted with a calibrated indicating thermometer, temperature-measuring device, or temperature-recording device that shows, indicates, and records, or allows for recording by hand, the temperature accurately within the compartment. If recording by hand, monitoring must occur at a frequency established according to risk management principles.
- Must have an automated device for regulating temperature or an automated alarm system to indicate a significant temperature change in a manual operation.

Compressed air or other gases introduced mechanically into or onto components, in-process materials, dietary supplements, or contact surfaces, or that are used to clean any contact surface, must be treated in such a way (e.g., proper filtration) that the component, in-process material, dietary supplement, or contact surface is not contaminated.

Instruments or controls used in the manufacturing, packaging, labeling, or holding of a dietary supplement, and instrument controls used to measure, regulate, or record temperatures, pH, water activity, or other conditions, and to control or prevent the growth of microorganisms or other contamination must be accurate and precise, calibrated periodically, adequately maintained, and adequate in number for their designated uses.

### 2.4.3 OPERATION AND CALIBRATION

Control, weighing, measuring, monitoring, and test equipment, i.e., instruments and controls, which are critical for assuring the quality of dietary supplements, must be calibrated according to written procedures and an established schedule. Equipment and instruments used in the manufacture of dietary supplements must only be used within its qualified operating range. Equipment calibrations should be performed using compendial reference standards, or standards traceable to certified standards, if available.

Instruments and controls used in manufacturing or testing a component, in-process material, or dietary supplement must be calibrated against a reference standard before first use; at a frequency specified in writing by the manufacturer of the instrument or control, and at routine intervals or as otherwise necessary to ensure the accuracy and precision of the instrument and control.

Instruments or controls that cannot be adjusted to agree with the reference standard must be repaired or replaced.

Balances used to accurately weigh material should comply with *Balances* ⟨41⟩ and *Weighing on an Analytical Balance* ⟨1251⟩. This should include the determination and posting of the minimum accurate weight on all scales and balances used throughout the production and laboratory testing units.

Automated, mechanical, or electronic equipment that is used to manufacture, package, label, or hold a dietary supplement must be routinely calibrated, inspected, or checked to ensure proper performance. The quality unit must periodically approve these calibrations, inspections, or checks.

The appropriate controls for automated, mechanical, and electronic equipment (including software for a computer-controlled process) must be established and used to ensure that any changes to the manufacturing, packaging, labeling, holding, or other operations are approved by the quality unit and instituted only by authorized personnel.

The appropriate controls must be established and used to ensure that the equipment functions in accordance with its intended use. These controls must be approved by the quality control unit.

Deviations from approved standards of calibration on critical instruments should be investigated to determine if these could have had an impact on the quality of in-process materials or dietary supplements using this equipment since the last successful calibration.

Quality unit personnel must:

- Review and approve all processes for calibrating equipment and instruments;
- Periodically review all records for calibration of equipment, instruments, and controls;
- Periodically review all records for calibrations, inspections, and checks of automated, mechanical, or electronic equipment; and
- Review and approve controls to ensure that automated, mechanical, or electronic equipment functions in accordance with its intended use.

## 2.4.4 CLEANING AND MAINTENANCE

Equipment, utensils, and any other contact surfaces used to manufacture, package, label, or hold components, in-process materials, or dietary supplements must be maintained, cleaned, and sanitized, as necessary, to protect against allergen cross-contact and contamination of components, in-process materials, and dietary supplements. Equipment and utensils must be taken apart as necessary for thorough maintenance, cleaning, and sanitizing.

Schedules and procedures, including assignment of responsibility, should be established for the preventative maintenance of equipment.

Written procedures should be established for cleaning of equipment and its subsequent release for use in the manufacture of dietary supplements. Cleaning procedures should contain sufficient details to enable operators to clean each type of equipment in a reproducible and effective manner. These procedures should include:

- Assignment of responsibility for cleaning of equipment;
- Cleaning schedules, and sanitizing schedules as needed;
- Complete description of the methods and materials, including dilution of cleaning agents used to clean equipment;
- Instructions, as needed, for disassembling and reassembling each part of equipment to ensure proper cleaning;
- Instructions for the removal or obliteration of previous batch identification;
- Instructions for the protection of clean equipment from contamination prior to use, and the maximum time that may elapse between completion of cleaning and use in manufacturing;
- Inspection of equipment cleanliness immediately before use; and
- Establishing the maximum time that may elapse between the completion of manufacturing processing and equipment cleaning.

All contact surfaces must be cleaned and sanitized, as necessary, before use and after any interruption during which the contact surfaces may have become contaminated. In consecutive operations involving batches of different dietary supplements, the contact surfaces must be adequately cleaned, and sanitized as needed, to prevent cross-contamination; in consecutive operations involving different batches of the same dietary supplement, the contact surfaces must be inspected, and adequately cleaned and sanitized, as necessary to prevent buildup and carry-over of contaminants (e.g., objectionable levels of microorganism). Acceptance criteria for residues and the choice of cleaning procedures and cleaning agents should be defined and justified. The cleaning status of equipment should be stated on the equipment.

Surfaces that do not come into direct contact with components, in-process materials, or dietary supplements must be cleaned as frequently as necessary to protect against contaminating components, in-process materials, or dietary supplements.

Effective systems should be used to reduce the potential of non-contact surfaces from becoming sources of contamination, such as floor sticky pads between different production areas and a captive shoe policy and program.

Plastic pallets should be used in high risk areas where components, in-process materials, dietary supplements, and contact surfaces are exposed. At minimum, heat treated pallets must be used in areas where components, in-process materials, dietary supplements, and contact surfaces are exposed. An effective pallet cleaning, maintenance, inspection, and management program must be established, documented, and followed.

Contact surfaces used for manufacturing or holding low-moisture components, in-process materials, or dietary supplements must be in a clean, dry, sanitary condition before use. When the surfaces are wet-cleaned, they must be sanitized, when necessary, and thoroughly dried before subsequent use.

If wet processing is used during manufacturing, all contact surfaces must be cleaned and sanitized, as necessary, to protect against the introduction of microorganisms into components, in-process materials, or dietary supplements. When cleaning and sanitizing is necessary, all contact surfaces must be cleaned and sanitized before use and after any interruption during which the contact surface may have become contaminated. In a continuous production operation or in consecutive operations involving different batches of the same dietary supplement, the contact surfaces must be adequately cleaned and sanitized, as necessary.

Single-service articles (such as utensils intended for one-time use, paper cups, and paper towels) must be stored in appropriate containers; and handled, dispensed, used, and disposed of in a manner that protects against contamination of components, in-process materials, dietary supplements, or any contact surface.

Cleaning compounds and sanitizing agents must be adequate for their intended use and safe under their conditions of use.

The portable equipment and utensils that have contact surfaces must be cleaned, sanitized, and stored in a location and manner that protects them from contamination.

## 2.4.5 EQUIPMENT AND INSTRUMENT QUALIFICATION

Equipment and instruments must be demonstrated to be “fit for purpose.” There are many ways of demonstrating that equipment and instruments are “fit for purpose” and under control, and these can include qualification, calibration, and maintenance. Equipment or instrument qualification activities necessary to establish “fitness for purpose” may be grouped into four phases: design qualification (DQ), installation qualification (IQ), operational qualification (OQ), and performance qualification (PQ). In order to ensure “fitness for purpose”, an integrated approach, based upon a risk assessment, should be undertaken.

A variety of equipment and instruments, ranging from a simple apparatus to complex computerized systems, is used in the dietary supplement industry to manufacture, package, label, test, and hold dietary supplements. The risk assessment enables the classification of equipment and instruments to determine the extent of qualification and actions needed to demonstrate “fitness for purpose.” Generally, the more complex the equipment or instrument, or the higher the criticality of its operation, the greater the amount of work required to ensure “fitness for purpose.”

Requirements for the intended use should be appropriately defined to ensure that the particular needs and technical and operational requirements are met. Qualification activities are described in *Analytical Instrument Qualification* ⟨1058⟩.

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:37:45 AM(EST)
Printed by: USP NF
Do Not Distribute

When an equipment or instrument undergoes major repairs or modifications, this should be evaluated using change control. Relevant equipment qualification should be repeated to verify that the equipment continues to operate satisfactorily. If equipment is moved to another location, an assessment should be made of what, if any, qualification stage should be repeated.

### 2.4.6 Computerized Systems

Written procedures should be available for the operation and maintenance of computerized systems.

Appropriate installation qualification and operational qualification should demonstrate the suitability of the computer hardware and software to perform assigned tasks.

GMP related computerized systems must be validated. The depth and scope of validation depends on the diversity, complexity, and criticality of the computerized application. Commercially available software that has been validated may require an abbreviated level of testing. If an existing system was not validated at time of installation, a retrospective validation could be conducted if appropriate documentation is available.

Where critical data are being entered manually, there must be an additional check on the accuracy of the entry. This can be done by a second operator or by the system itself, e.g., barcode reader.

Changes to the computerized system must be made according to a change control procedure and should be formally authorized, documented, and tested. Records must be kept of all change, including modifications and enhancements made to hardware and software. These records should demonstrate that the system is maintained in a validated state.

If system breakdowns or failures would result in the permanent loss of records, a back-up system should be provided. A means of ensuring data protection should be established for all GMP related computerized systems. Data can be recorded by a second means in addition to the computer system.

All electronic records must comply with 21 CFR Part 11—*Electronic Records; Electronic Signatures*.

**2.4.6.1 Computer systems procedures and controls:** GMP related computerized systems used to create, modify, maintain, or transmit electronic records must employ procedures and controls designed to ensure the authenticity, integrity, and, when appropriate, the confidentiality of electronic records, and to ensure that the signer cannot readily repudiate the signed record as not genuine. Such procedures and controls must include, but are not limited to, the following:

- Validation of systems to ensure accuracy, reliability, consistent intended performance, and the ability to discern invalid or altered records;
- The ability to generate accurate and complete copies of records (including controls to prevent omissions in data, e.g., system turned off and data not captured) for inspection, review, and copying;
- Protection of records to enable their accurate and ready retrieval throughout the records retention period;
- Limiting system access to authorized individuals to prevent unauthorized access or changes to data;
- Use of secure, computer-generated, time-stamped audit trails to independently record the date and time of operator entries and actions that create, modify, or delete electronic records;
- Establishment of, and adherence to, written policies that hold individuals accountable and responsible for actions initiated under their electronic signatures in order to deter record and signature falsification;
- Use of appropriate controls over systems documentation including distribution of, access to, and use of documentation for system operation and maintenance; and revision and change control procedures to maintain an audit trail that documents time-sequenced development and modification of systems documentation.

**2.4.6.2 Electronic signatures:** Signed electronic records must contain information associated with the signing that clearly indicates all of the following: the printed name of the signer, the date and time when the signature was executed, and the task performed (such as review, approval, responsibility, or authorship) associated with the signature.

Each electronic signature must be unique to one individual and must not be reused by, or reassigned to, anyone else. Electronic must employ at least two distinct identification components such as an identification code and password. Persons who used electronic signatures must employ controls to ensure their security and integrity.

## 2.5 Physical Plant and Equipment Documentation

The following documentation must be made and kept for fulfilling the requirements of the Physical Plant and Equipment System (quality system 2).

### 2.5.1 Written Procedures

Written procedures must be established and followed for:

- Maintaining, cleaning, and sanitizing, as necessary, the physical plant and facilities;
- Pest control;
- Maintaining, cleaning, and sanitizing, as necessary, equipment, utensils, and any other contact surfaces that are used to manufacture, package, label, or hold components in-process materials, and dietary supplements;
- Use of cleaning compounds, sanitizing agents, pesticides, and other toxic materials;
- Pallet inspection;
- Equipment and instrument qualification;
- Calibrating instruments and controls used in manufacturing or testing a component, in-process material, or dietary supplement;
- Calibrating, inspecting, and checking automated, mechanical, and electronic equipment and instruments; and
- Operating and maintaining GMP related computerized systems.

Official

https://nhathuocngocanh.com/

#### 2.5.2 RECORDS

Records must be made and kept for:

- List of approved cleaning compounds, sanitizing agents, and corresponding safety data sheets;
- Drawings for utility systems, e.g., water, steam, gases, compressed air, heating, ventilation, and air conditioning;
- Physical plant and facility maintenance, cleaning and sanitizing schedules, and logs of the date of maintenance, cleaning, and sanitizing, as necessary, unless such documentation is kept with the batch record;
- Pest control;
- Demonstrating that water, when used in as a component of a dietary supplement, meets the relevant Compendial requirements;
- List of manufacturing equipment and instrumentation;
- Drawings and/or manuals for equipment and critical installations;
- Documentation, in individual equipment logs, of the date of use, maintenance, cleaning, and sanitizing of equipment, unless such documentation is kept with the batch record;
- Documentation of the controls used to ensure that equipment and instruments function in accordance with their intended use;
- Documentation of any calibration, each time the calibration is performed, for instruments and controls used in manufacturing or testing a component, in-process materials, or dietary supplement:
    - The documentation must identify the instrument or control calibrated and date of calibration, identify the reference standard used including the certification of accuracy of the reference standard and history of recertification of accuracy, identify the calibration method used including appropriate acceptance limits for accuracy and precision of instruments and controls when calibrating, provide the calibration reading(s) found, identify the recalibration method used and reading(s) found if accuracy and/or precision acceptance limits were not met, and initials of the person who performed the calibration or recalibration;
- Documentation of pallet inspection and disposition;
- Documentation of equipment and instrument qualification;
- Documentation of calibrations, inspections, and checks of automated, mechanical, and electronic equipment; and
- Backup file(s) of current and outdated software, as necessary, to retrieve records that are required to be kept, and of data entered into the computer system used to manufacture, package, label, and hold dietary supplements:
    - Backup file(s) (e.g., a hard copy of data entered, tapes, compact disks, flash drives) must be an exact and complete record of the date entered, and must be kept secure from alterations, inadvertent erasures, or loss.

## 3. MATERIALS MANAGEMENT OPERATIONS AND CONTROLS

The persons authorized to release components, packaging materials, labeling, and dietary supplements should be specified. No materials should be released or used before the satisfactory completion of evaluation by the quality unit(s) unless there are appropriate systems in place to allow for such use (e.g., release under quarantine, see distribution procedures).

### 3.1 Establishing Material and In-Process Production Specifications

Specifications must be established for any point, step, or stage in the manufacturing process where control is necessary to ensure the quality of the dietary supplement and that the dietary supplement is packaged and labeled as specified in the master manufacturing and packaging control record.

#### 3.1.1 COMPONENT SPECIFICATIONS

Specifications must be established for each component that is used in the manufacture of a dietary supplement to ensure that the specifications for the purity, strength, and composition of the dietary supplement, manufactured using the components, are met. The specification for the components should include specifications for:

- Identity;
- Purity;
- Content or assay;
- Limits on contaminants that may adulterate or may lead to adulteration of the finished batch of dietary supplements;
- Applicable specific tests (e.g., peroxide value, anisidine value for oil rancidity);
- Physical characteristics impacting manufacturing process (e.g., particle size, bulk density);
- Special claims should also be included in the specifications and be verified by the user of the material. Special claims include gluten-free, no soy, no dairy, etc.

Generally, dietary supplements are prepared from ingredients that meet *USP*, *NF*, or *Food Chemical Codex* standards. Where such standards do not exist, substances may be used in dietary supplements if they have been shown to be of acceptable food grade quality using other suitable procedures.

The purity of water used as a component of a dietary supplement should be appropriately defined to maintain the stability of the dietary supplement throughout its shelf life.

Official

https://pharmacopeia.com/

Printed by: USP NF
Do Not Distribute
Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Aug-2021
DOI Ref: 0pf8r
DocId: GUID-B1EB10D3-6473-4AC9-99B7-4AD444683A01_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99987_02_01
@2024 USPC

Ingredients may be added to dietary supplements provided that the ingredients comply with applicable regulatory requirements, and do not interfere with the assay and tests prescribed for determining compliance with the bulk or finished dietary supplement specification.

Adequate documentation must be provided for the basis for why the component specifications will help ensure that the specifications are met for the identity, purity, strength, and composition of the dietary supplements and for limits on those types of contamination that may adulterate or may lead to adulteration of the finished batch of the dietary supplement.

Each component received from a supplier that is liable to contamination with microorganisms, filth, insect infestation, allergens, aflatoxins, other natural toxins, pesticides, organic impurities, residual solvents, inorganic impurities, elemental contaminants, foreign substances, or other extraneous substances that may be a source of contamination that is objectionable in view of its intended use must be tested or examined against established specifications for such contamination. Applicable *USP* general chapters should be used, including the following:

*Residual Solvents* ⟨467⟩
*Articles of Botanical Origin* ⟨561⟩, *Test for Aflatoxins* and *Pesticide Residue Analysis*
*Microbial Enumeration Tests* ⟨2021⟩
*Absence of Specified Microorganisms* ⟨2022⟩
*Microbiological Attributes of Nonsterile Nutritional and Dietary Supplements* ⟨2023⟩
*Elemental Contaminants in Dietary Supplements* ⟨2232⟩

### 3.1.2 IN-PROCESS PRODUCTION SPECIFICATIONS

Specifications must be established for in-process production for any point, step, or stage in the master manufacturing record where control is necessary to help ensure that specifications are met for the identity, purity, strength, and composition of the dietary supplements and, as necessary, for limits on those types of contamination that may adulterate or may lead to adulteration of the finished batch of the dietary supplement.

Adequate documentation must be provided for the basis for why meeting the in-process specifications, in combination with meeting component specifications, will help ensure that the specifications are met for the identity, purity, strength, and composition of the dietary supplements and for limits on those types of contamination that may adulterate or may lead to adulteration of the finished batch of the dietary supplement. Quality unit personnel must review and approve this documentation.

### 3.1.3 LABELING AND PACKAGING MATERIAL SPECIFICATIONS

Specifications must be established for labeling (label specifications, see *Labeling* ⟨7⟩) and packaging materials that come in contact with dietary supplements (packaging specifications, see *Packaging and Storage Requirements* ⟨659⟩, *Containers—Glass* ⟨660⟩, *Plastic Packaging Systems and Their Materials of Construction* ⟨661⟩, *Plastic Materials of Construction* ⟨661.1⟩, *Plastic Packaging Systems for Pharmaceutical Use* ⟨661.2⟩, *Auxiliary Packaging Components* ⟨670⟩, and *Containers—Performance Testing* ⟨671⟩). Packaging that may come into contact with dietary supplements must be safe and suitable for its intended use and must not be reactive or absorptive or otherwise affect the safety or quality of the dietary supplement.

### 3.1.4 IN-PROCESS (BULK) DIETARY SUPPLEMENT SPECIFICATIONS

Specifications must be established for each dietary supplement that is manufactured. The specification for the dietary supplement should include specifications for:

- Identity;
- Purity;
- Strength or composition (i.e., content or assay);
- Limits on contaminants that may adulterate or may lead to adulteration of the finished batch of dietary supplements;
- Applicable specific characteristics (e.g., peroxide value, anisidine value for oil rancidity);
- Performance (i.e., disintegration and/or dissolution);
- Dosage forms quality tests (e.g., tablet friability, weight variation, or content uniformity).

Dietary supplements for which a monograph is provided in the *USP* should comply with the monograph standard and other applicable standards in that compendium.

**Defect action levels:** Some dietary supplements, even when produced under good manufacturing practices, contain naturally occurring unavoidable defects that at low levels present no health hazard. Defect action levels are set because it is economically impractical to grow, harvest, or process raw products that are totally free of non-hazardous, naturally, unavoidable defects. Products harmful to consumers are subject to regulatory action whether or not they exceed the defect action levels. The manufacturer, packer, and holder of a dietary supplement must, at all times, utilize quality unit operations that reduce natural or unavoidable defects to the lowest level currently feasible. The mixing of a dietary supplement containing defects at levels that render that dietary supplement adulterated with another lot of dietary supplement is not permitted and renders the final dietary supplement adulterated, regardless of the defect action level of the final dietary supplement.

### 3.1.5 RECEIVED IN-PROCESS (BULK) DIETARY SUPPLEMENT SPECIFICATIONS

Specifications must be established for an in-process (bulk) dietary supplement received from a supplier for packaging and labeling, and for distribution. The specification must provide sufficient assurance that the in-process (bulk) dietary supplement received is adequately identified, consistent with the purchase order, and the CoA meets agreed-upon specifications or supplier quality agreement.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99987_02_01
@2024 USPC

### 3.1.6 FINISHED DIETARY SUPPLEMENT SPECIFICATIONS

Specifications must be established for the packaging and labeling of the finished packaged and labeled dietary supplements that ensures that the correct packaging and labeling was used.

## 3.2 Determining Compliance with Specifications

[NOTE—*General Notices* should apply.]

### 3.2.1 GENERAL

Quality unit personnel must determine whether the specifications set for components, in-process materials, packaging materials, labeling, in-process (bulk) dietary supplements, received in-process (bulk) dietary supplements, and finished dietary supplements are met.

Quality control (laboratory control) unit personnel must conduct the necessary tests to determine whether the specifications for components, in-process materials, and dietary supplements comply with specifications. On the basis of adequate process verification, in-process controls, and statistical confidence, a reduced testing (or sampling) plan is an alternative to fully testing every batch of material, provided that:

- For components, at least one identification test or examination with sufficient specificity is conducted;
- For packaging material and labeling, at least one identification test is conducted;
- For dietary supplements, at least one measure representative of the overall quality is performed.

Tests that are used to determine whether material specifications are met must be appropriate for their intended use and must be validated methods according to *Validation of Compendial Procedures* ⟨1225⟩.

The quality control unit must conduct an out-of-specification investigation and corrective action plans must be established for use when an established specification is not met.

### 3.2.2 COMPONENTS

Before any component is used in manufacturing, at least one appropriate test or examination must be conducted to verify the identity of the component, and determine whether other applicable component specifications are established by doing the following:

- Conduct appropriate tests or examinations for all of the test specifications; or
- Rely on the certificate of analysis from the supplier of the component received, provided that:
    - The supplier is qualified by establishing the reliability of the supplier's certificate of analysis through confirmation of the results through independent tests, on-site audit, and other appropriate supplier qualification activities;
    - The certificate of analysis includes a description of the specific tests or examination methods used (i.e., specific reference to a test procedure that can be performed by an experienced scientist); acceptance criteria for the tests or examinations, and actual results of the tests or examinations;
    - Documentation is maintained of how the supplier was qualified;
    - The reliability of the supplier's certificate of analysis is periodically re-confirmed by conducting independent tests for the specifications that consistently confirm the values shown in the certificate of analysis;
    - Quality unit personnel have reviewed and approved the documentation setting forth the basis for qualification and re-qualification of the supplier.

### 3.2.3 IN-PROCESS PRODUCTION

In-process points, steps, or stages where control is necessary to ensure the quality of the finished batch of dietary supplements must be monitored to determine whether in-process specifications are met; and to detect any deviation or unanticipated occurrence that may result in the failure of the dietary supplement to meet specifications.

### 3.2.4 DIETARY SUPPLEMENTS

For a subset of dietary supplement batches (for in-process (bulk) dietary supplements and/or finished dietary supplements) that have been identified through a sound statistical sampling plan (i.e., reduced sampling), or for every batch of dietary supplements, the manufacturer must verify that the batch of dietary supplement meets product specifications for identity, purity, strength, and composition, and for limits on those types of contamination that may adulterate or that may lead to adulteration of the dietary supplement, applicable specific tests, performance, and manufacturing quality tests. To do so:

- One or more established specifications for identity, purity, strength, and composition, and the limits on those types of contamination that may adulterate or that may lead to adulteration of the dietary supplement, applicable specific tests, performance, and manufacturing quality tests, that if tested or examined on the batches of dietary supplement (i.e., reduced testing), would verify that the production process control system is producing a dietary supplement that meets all product specifications;
- Appropriate tests or examinations must be conducted to determine compliance with the applicable specifications;
- Adequate documentation must be provided on the basis for determining how compliance with the test specification(s) selected for reduced testing will ensure that the finished batch of dietary supplement will meet all product specifications for identity, purity, strength, and composition, and for the limits on those types of contamination that may adulterate or

Official

https://pharmacopeia.com/

that may lead to adulteration of the dietary supplement, applicable specific tests, performance, and manufacturing quality tests; and

- Quality unit personnel must review and approve all supporting documentation for reduced testing.

### 3.2.5 RECEIVED IN-PROCESS (BULK) DIETARY SUPPLEMENT

Before packaging or labeling a dietary supplement received for packaging or labeling as a dietary supplement, for distribution rather than for return to the supplier, the product must be visually examined, and documentation must be provided or obtained through testing and examination to determine whether the in-process (bulk) product specifications are met.

### 3.2.6 PACKAGING MATERIAL AND LABELING

Before packaging material is used, at minimum, a visual identification of the containers and closures must be conducted, and the supplier's invoice, guarantee, or certification must be reviewed to determine whether the packaging specifications are met.

Before labeling is used, at minimum, a visual identification of the labeling must be conducted, and the supplier's invoice, guarantee, or certification must be reviewed to determine whether the labeling specifications are met.

### 3.2.7 FINISHED DIETARY SUPPLEMENTS

At minimum, a visual examination of the packaging and labeling of the finished packaged and labeled dietary supplement must be conducted to determine whether the packaging used and the label applied were specified in the master packaging control record.

### 3.2.8 DISPOSITION DECISION FOR MATERIALS

For components, in-process materials, packaging materials, labeling, and dietary supplements that meet specifications, the quality unit may approve the material for use in manufacturing.

For components, in-process materials, packaging materials, labeling, and dietary supplements that do not meet specifications, the quality unit must reject the material for use in manufacturing, unless quality unit personnel approve a treatment, an in-process adjustment, or reprocessing that will ensure the quality of the finished dietary supplement, and that the dietary supplement is packaged and labeled as specified in the master packaging record.

For components that do not meet specification(s) for identity (i.e., identification), quality control personnel must reject the component and the component must not be used in manufacturing the dietary supplement.

For a dietary supplement received from a supplier for packaging and/or labeling as a dietary supplement and for distribution rather than for return to the supplier that does not meet specifications, quality control personnel must reject the product and the product may not be packaged or labeled for distribution as a dietary supplement.

The quality unit personnel must not approve and release for distribution any batch or reprocessed batch of dietary supplement:

- For which any component in the batch does not meet its identity specification;
- That does not meet all product specifications;
- That has not been manufactured, packaged, labeled, and held under conditions to prevent adulteration; and
- That was received from a supplier for packaging or labeling as a dietary supplement, and for distribution rather than return to the supplier, for which sufficient assurance is not provided to adequately identify the product and to determine that the product is consistent with its purchase order.

### 3.2.9 TREATMENTS, IN-PROCESS ADJUSTMENTS, AND REPROCESSING

A rejected dietary supplement must not be reprocessed, and a rejected component or any component, packaging material, or labeling must not undergo treatment or in-process adjustment to make it suitable for use in the manufacture of a dietary supplement, unless:

- Quality unit personnel conduct a material review and make a disposition decision that is based on a scientifically valid reason and approves the reprocessing, treatment, or in-process adjustment;
- The reprocessing, treatment, or in-process adjustment will ensure the quality of the finished dietary supplement and that the dietary supplement is packaged and labeled as specified in the master manufacturing record; and
- All components in the batch met its identity (i.e., identification) specification.

For a rejected dietary supplement received from a supplier for packaging and/or labeling as a dietary supplement and for distribution rather than for return to the supplier that does not meet specifications, quality control personnel must reject the product and the product may not be packaged or labeled for distribution as a dietary supplement.

Any batch of dietary supplement that is reprocessed, that contains components that have been treated, or to which in-process adjustments have been made to make them suitable for use in the manufacture of the dietary supplement must be approved by quality unit personnel before release for distribution.

The quality unit personnel must not approve and release for distribution any batch or reprocessed batch of dietary supplement:

- For which any component in the batch does not meet its identity specification;
- That does not meet all product specifications;
- That has not been manufactured, packaged, labeled, and held under conditions to prevent adulteration; and

Official

https://nhathuocngocanh.com/

- That was received from a supplier for packaging or labeling as a dietary supplement, and for distribution rather than return to the supplier, for which sufficient assurance is not provided to adequately identify the product and to determine that the product is consistent with its purchase order.

## 3.3 Receiving and Release of Materials

### 3.3.1 COMPONENTS, PACKAGING MATERIALS, AND LABELS

The person responsible for receiving components, packaging, or labels should perform a visual inspection of each truck and examine the containers in the shipment that is received for appropriate content label, container damage, or broken seals to determine whether the container condition may have resulted in contamination or deterioration of the components, packaging materials, or labels. The correct temperature of all refrigerated trailers should be verified prior to unloading. The person must visually examine the supplier's invoice, guarantee, or certification in a shipment that is received to ensure the components, packaging materials, or labels are consistent with the purchase order.

The components, packaging materials, and labels must be placed in quarantine, either physically separated from approved goods or within integrated storage locations strictly controlled through a physical or electronic inventory system, before they are used in the manufacture of a dietary supplement until:

- Representative samples are collected of each unique shipment of components, packaging materials, and labels received, and of each unique lot within each unique shipment of components, packaging materials, and labels;
- Quality unit personnel review and approve the results of any tests or examinations conducted on components, packaging materials, and labels; and
- Quality unit personnel approves the components, packaging materials, and labels for use in the manufacture of a dietary supplement, including approval of any treatment or in-process adjustments of components, packaging materials, and labels to make them suitable for use in the manufacture of a dietary supplement, and releases them from quarantine.

Each unique lot within each unique shipment of components, packaging materials, and labels that is received, and any lot of components that are produced, must be identified in a manner that allows a person to trace the lot to the supplier; the date received; the name of the component, packaging material, and label; the status of the component, packaging material, and label (e.g., quarantined, approved, or rejected); and to the dietary supplement that was manufactured and distributed. This unique identifier must be used whenever recording the disposition of each unique lot within each unique shipment of components, packaging material, and labels that was received, and any lot of components produced.

Components, packaging material, and labels must be held under conditions that will protect against contamination and deterioration, and avoid mix-ups.

### 3.3.2 PRODUCT RECEIVED FOR PACKAGING AND LABELING AS A DIETARY SUPPLEMENT

The person responsible for receiving product that is received for packaging or labeling as a dietary supplement, and for distribution rather than for return to the supplier, must visually examine each immediate container or grouping of immediate containers in a shipment that is received for appropriate content label, container damage, or broken seals to determine whether the container condition may have resulted in contamination or deterioration of the received product. The person must visually examine the supplier's invoice, guarantee, or certification in a shipment of received product to ensure the received product is consistent with the purchase order.

The received product must be placed in quarantine before it is used in the packaging and labeling of a dietary supplement until:

- Representative samples are collected of each unique shipment of received product, and of each unique lot within each unique shipment of received product;
- Quality unit personnel review and approve results of any tests or examinations conducted on the received product, and review and approve the documentation supplied with the received product to determine whether the received product meets specifications; and
- Quality unit personnel approves the received product for packaging and labeling as a dietary supplement, and releases the received product from quarantine.

Each unique lot within each unique shipment of received product must be identified in a manner that allows a person to trace the lot to the supplier; the date received; the name of the received product, packaging material, and label; the status of the received product (e.g., quarantined, approved, or rejected); and to the dietary supplement that was packaged and labeled and distributed. This unique identifier must be used whenever recording the disposition of each unique lot within each unique shipment of received product.

Received product must be held under conditions that will protect against contamination and deterioration, and avoid mix-ups.

## 3.4 Representative Samples and Reserve Samples

### 3.4.1 REPRESENTATIVE SAMPLES

Quality unit personnel must collect representative samples:

- Of each unique shipment, and of each unique lot within each unique shipment, of components, packaging material, and labels to be used in manufacturing to determine whether the materials meet established specifications;

Official

https://pharmacopeia.cn/
Printed on: Fri Jan 05 2024 06:37:45 AM(EST)
Printed by: USP NF
Do Not Distribute
Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Aug-2021
DOI Ref: 0pf8r
DocId: GUID-B1EB10D3-6473-4AC9-99B7-4AD444683A01_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99987_02_01
@2024 USPC

- Of in-process materials for each manufactured batch at points, steps, or stages in the manufacturing process as specified in the master manufacturing record where control is necessary to ensure identity, purity, strength, and composition of dietary supplements, to determine whether in-process materials meet specifications;
- Of each finished manufactured batch dietary supplement before releasing for distribution to verify that the finished batch of dietary supplement meets specifications;
- Of each unique shipment, and of each unique lot within each unique shipment, of product received for packaging or labeling as a dietary supplement and for distribution rather than for return to the supplier to determine whether the received product meets established specifications; and
- Of each lot of packaged and labeled dietary supplement to determine whether the packaging used and the label applied was specified in the master packaging control record.

Design of the sample room should be consistent with controls necessary to prevent cross-contamination.

Written procedures for sampling must be established and followed. The number of containers sampled, and the amount of material to be sampled from each container, should be based upon appropriate criteria such as component variability, statistical confidence levels, and degree of precision desired, the past quality history of the supplier, and the quantity of material needed for analysis and reserve, when required. Sampling procedures should include:

- Cleaning the containers of components selected for sampling prior to opening;
- Containers should be opened, sampled, and resealed in a manner designed to prevent contamination of their contents and contamination of other components, product containers, or closures; and
- Containers should be identified so that the following information can be determined: name of the material sampled, the lot number, the container from which the sample was taken, the date on which the sample was taken, and the name of the person who collected the sample.

Sampling of botanicals should be in compliance with the provisions in ⟨561⟩.

#### 3.4.2 RESERVE SAMPLES

Quality unit personnel must collect and hold reserve samples:

- Of each lot of packaged and labeled dietary supplements that is distributed, which must be held using the same container-closure system in which the packaged and labeled dietary supplement is distributed;
- Of each lot of dietary supplement that is being distributed to be packaged and labeled, which must be held using a container-closure system that provides essentially the same characteristics to protect against contamination or deterioration as the one in which it is distributed for packaging and labeling elsewhere.

Reserve samples of dietary supplements must be identified with the batch, lot, or control number. The reserve sample of each batch of dietary supplements must consist of at least twice the quantity necessary for all tests or examinations to determine whether or not the dietary supplement meets product specifications, and must be collected and retained for at least one (1) year past its shelf life (expiry) date.

### 3.5 Holding, Distribution, and Transportation

Written procedures must be established and followed for holding or warehousing and distributing operations.

#### 3.5.1 HOLDING

Components and dietary supplements must be held under appropriate conditions of temperature, humidity, and light so that the identity, purity, strength, and composition of the components and dietary supplements are not affected. Temperature and humidity of each warehouse must be monitored and should be mapped where appropriate during both the summer and winter to ensure that required storage conditions are controlled and documented. Packaging materials and labeling must be held under appropriate conditions so that the packaging materials and labeling are not adversely affected. Components, dietary supplements, packaging materials, and labeling must be held under conditions that do not lead to the mix-up or contamination of components, dietary supplements, packaging materials, and labeling.

In-process material must be identified and held under appropriate conditions that protect against mix-up and contamination. In-process material must be held under appropriate conditions of temperature, humidity, and light to protect against deterioration.

Components, in-process materials that contain food allergens must be clearly identified and held in a manner that prevents allergen cross-contact.

Spills of allergen-containing components must be cleaned promptly and assessed to determine the potential for cross-contamination to adjacent materials.

Reserve samples of dietary supplements must be held in a manner that protects against contamination and deterioration. Reserve samples of dietary supplements must be held under conditions consistent with the label conditions stated on the product labels, or if no storage conditions are recommended on the label [e.g., for in-process (bulk) dietary supplements], under ordinary storage conditions consistent with expected storage conditions for the finished product while on display at retail. Reserve samples of dietary supplements must be held using the same container-closure system in which packaged and labeled dietary supplements are distributed, or if distributing dietary supplements to be packaged and labeled, using a container-closure system that provides essentially the same characteristics to protect against contamination or deterioration as the one in which dietary supplements will be distributed.

Reserve samples must be retained for one (1) year past the shelf life (expiry) date of the dietary supplement for use in appropriate investigations.

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99987_02_01
@2024 USPC

### 3.5.2 REJECTED MATERIALS

Any component, packaging material, labels, and product received for packaging and labeling as a dietary supplement and for distribution rather than return to the supplier that is rejected and is unsuitable for use in manufacturing, packaging, and labeling operations, must be clearly identified, held, and controlled under a quarantine system for appropriate disposition. The quarantine system for rejected materials must include physical segregation and conspicuous labeling of the material in addition to electronic controls.

### 3.5.3 RETURNED DIETARY SUPPLEMENTS

Returned dietary supplements must be identified and quarantined until quality unit personnel conduct a material review and make a disposition decision.

Returned dietary supplements must be destroyed, or otherwise suitably disposed of, unless the outcome of a material review and disposition decision is that quality control personnel do the following:

- Approve the salvage of the returned dietary supplement for redistribution; or
- Approve the returned dietary supplement for reprocessing.

A returned dietary supplement may be salvaged only if quality control personnel conduct a material review and make a disposition decision to allow the salvage.

Any returned dietary supplements that are reprocessed must meet all in-process (bulk) dietary supplement specifications, and quality control personnel must approve or reject the release for distribution any returned dietary supplement that is reprocessed.

If the reason for a dietary supplement being returned implicates other batches, an investigation must be conducted of the manufacturing processes and each of those other batches to determine compliance with specifications.

### 3.5.4 DISTRIBUTION

Dietary supplements must be distributed under conditions that will protect the dietary supplement against contamination and deterioration. Distributing operations must be designed to facilitate recall of the dietary supplement, if necessary.

### 3.5.5 TRANSPORTATION OPERATIONS

All transportation operations must be conducted under such conditions and controls necessary to prevent dietary supplements from becoming spoiled or adulterated during transportation.

Vehicles and transportation equipment used in transportation operations must be:

- Designed and maintained, and equipped as necessary to provide adequate temperature control to prevent components and dietary supplements requiring temperature control (e.g., chewable gels, soft gelatin capsules) from becoming spoiled during transportation; and
- Stored in a manner that prevents it from harboring pests or becoming contaminated in any other manner that could result in components or dietary supplements for which it will be used becoming adulterated during transportation operations.

Responsibility for ensuring that transportation operations are carried out adequately must be assigned to competent supervisory personnel.

Shippers, receivers, loaders, and carriers engaged in transportation must conduct all transportation operations under such conditions and controls necessary to prevent components and dietary supplements from becoming unsafe during transportation. Such operations include taking effective measures:

- Such as segregation, isolation, or the use of packaging to protect components and dietary supplements from contamination from other articles in the same load;
- To ensure that components and dietary supplements that requires temperature control for safety and quality are transported under adequate temperature control; and
- Restricting the co-shipment of non-food items that might render the components or finished dietary supplements adulterated through cross-contamination.

Shippers must specify to the carrier and the loader all necessary sanitary specifications for the carrier's vehicle and transportation equipment including any specific design specifications (e.g. temperature control) and cleaning procedures.

Loaders must determine, considering as appropriate specifications provided by the shipper, that the vehicle or transportation equipment is in appropriate sanitary and operational condition for the transport of components and dietary supplements.

Receivers, upon receipt of components and dietary supplements, must take steps to adequately assess that the components and dietary supplements were not subjected to adverse conditions that may have caused them to become adulterated.

Carriers must ensure that vehicles and transportation equipment meet the shipper's specifications and are otherwise appropriate to prevent components and dietary supplements from becoming adulterated during transportation operations.

Measures to implement requirements and procedures may be accomplished by the shipper or the carrier or another party involved in transportation operations under a written agreement.

Records should be maintained regarding specifications, agreements, procedures, associated records related to transportation (maintenance, cleaning, previous cargoes, temperature control), and training.

## 3.6 Quality Unit Responsibilities for Materials Management Operations

Before components, packaging materials, and labeling are used in manufacturing, quality unit personnel must:

- Review all receiving records for components, packaging, and labeling;

Official

https://pharmacopeia.cn/

- Determine whether all components, packaging, and labeling conformed to established specifications;
- Conduct any required material review and make any required disposition decision;
- Approve or reject any treatment and in-process adjustments of components, in-process materials, packaging, or labeling to make them suitable for use in the manufacture of a dietary supplement; and
- Approve, and release from quarantine, all components, packaging, and labeling before they are used in manufacturing.

For returned dietary supplements, quality unit personnel must:

- Conduct any required material review and make any required disposition decision, including determining whether tests or examinations are necessary to determine compliance with established product specifications, and review the results of any tests or examinations that are conducted to determine compliance with established product specifications;
- Approve or reject any salvage and redistribution of any returned dietary supplements;
- Approve or reject any reprocessing of any returned dietary supplement; and
- Determine whether the reprocessed dietary supplement meets product specifications and either approve for release, or reject, any returned dietary supplement that is reprocessed.

## 3.7 Materials Management Operations and Controls Documentation

The following documentation must be made and kept for fulfilling the requirements of the Material Management Controls System (quality system 3).

### 3.7.1 WRITTEN PROCEDURES

Written procedures must be established and followed for materials management operations and controls, including:

- Preparing, reviewing, and approving material and in-process production specifications;
- Material receiving, sampling, testing, and making a disposition decision for materials to be used in manufacturing;
- Warehousing maintenance, cleaning, and inventory controls;
- Pallet inspection, cleaning, and maintenance;
- Implementing a supplier qualification program;
- Holding and distributing operations;
- Receiving and conducting material reviews and making disposition decisions for returned dietary supplements.

### 3.7.2 RECORDS

Records must be made and kept for:

- Specifications for components, in-process production, packaging materials, labeling, in-process (bulk) dietary supplements, received in-process (bulk) dietary supplements, and finished dietary supplements;
- List of approved suppliers of components, packaging materials and labeling, and corresponding supplier qualification evaluation reports for the purpose of relying on the supplier's certificate of analysis;
- Documentation for why meeting in-process specifications, in combination with meeting component specifications, helps to ensure the dietary supplement meets the specifications for identity, purity, strength, and composition, and for limits on those types of contamination that may adulterate or may lead to adulteration of the finished batch of the dietary supplement;
- Documentation that justifies why a reduced testing program is appropriate;
- Receiving records (including, certificates of analysis, supplier's invoice, and supplier's guarantee) for components, packaging, and labels, and for products received for packaging or labeling as a dietary supplement, and for distribution rather than for return to the supplier;
- Documentation by the person who performs the required operation, at the time of performance, that the required operation was performed, including:
  - The date that the components, packaging, labeling, or products received for packaging or labeling as a dietary supplement were received;
  - The initials of the person performing the required operation;
  - The results of any tests or examinations conducted on components, packaging, or labeling, and of any visual examination of product received for packaging or labeling as a dietary supplement; and
  - Any material review and disposition decision conducted on components, packaging material, labeling, or products received for packaging and labeling as a dietary supplement;
- Inventory control records documenting material history of use;
- Documentation, at the time of performance, demonstrating that quality control unit personnel determined whether the specifications set for materials to be used in manufacturing were met (i.e., performed the required tests and made a disposition decision for materials);
- Dietary supplement distribution;
- Documentation of any material review and disposition decisions on a returned dietary supplement;
- The results of any testing or examination of returned dietary supplements to determine compliance with product specifications; and

Official

https://nhathuocngocanh.com/

- Documentation of the reevaluation by quality unit personnel of any dietary supplement that is reprocessed and the determination by quality unit personnel of whether the reprocessed dietary supplement meets in-process (bulk) dietary supplement specifications.

# 4. PRODUCTION OPERATIONS AND CONTROLS

## 4.1 Master Manufacturing Records

Written master manufacturing records must be prepared and followed for each unique formulation of dietary supplements manufactured, and for each batch size, to ensure uniformity in the finished batch from batch to batch.

The master manufacturing record may include all manufacturing, packaging, and labeling directions and controls, or be separated into two records: one for manufacturing and another for packaging and labeling. In some cases, such as in soft gelatin product manufacturing, the gelatin manufacturing record may be separated from that of the fill material used to make a specific final product lot.

The master manufacturing record must:

- Identify in-process production specifications for the points, steps, or stages in the manufacturing process where control is necessary to ensure the quality of the dietary supplement and that the dietary supplement is packaged and labeled as specified in the master manufacturing record; and
- Establish controls and procedures to ensure that each batch of dietary supplement that is manufactured meets in-process specifications.

The batch production record must include:

- The name of the dietary supplement to be manufactured and the strength, concentration, weight, or measure of each dietary ingredient and excipient for each batch size;
- A complete list of components to be used;
- An accurate statement of the weight or measure of each component to be used;
- Any necessary weight or measure adjustment due to actual strength or purity of the dietary ingredients with labeled dietary supplements claims;
- The identity and weight or measure of each dietary ingredient that will be declared on the supplement facts label and the identity of each ingredient that will be declared on the ingredients list of the dietary supplement;
- A statement of any intentional overage amount of a dietary ingredient;
- A statement of theoretical yield of a manufactured dietary supplement expected at each point, step, or stage of the manufacturing process where control is needed to ensure the quality of the dietary supplement, and the expected yield at the end of manufacturing the dietary supplement, including the maximum and minimum percentages of theoretical yield beyond which a deviation investigation of a batch is necessary and material review is conducted and disposition is made; and a description of packaging and a representative label, or cross-reference to the physical location of the actual or representative label.

The master manufacturing record must also include written instructions, including the following:

- Specifications for each point, step, or stage in the manufacturing process where control is necessary to ensure the quality of the dietary supplement and that the dietary supplement is packaged and labeled as specified in the master manufacturing record;
- Procedures for sampling and cross-reference to procedures for tests and examinations;
- Specific actions necessary to perform and verify points, steps, or stages in the manufacturing process where control is necessary to ensure the quality of the dietary supplement and that the dietary supplement is packaged and labeled as specified in the master manufacturing record:
    - Such specific actions must include verifying the weight or measure of any component and verifying the addition of any component; and
    - For manual operations, such specific actions must include:
        - One person weighing or measuring a component and another person verifying the weight or measure; and
        - One person adding the component and another person verifying the addition;
- Special notations and precautions to be followed; and
- Corrective action plans for use when a specification is not met.

Detailed production instructions should also include:

- Sequences to be followed;
- Ranges of process parameters to be used;
- Time limits for completion of individual processing steps or the total process, where appropriate.

The dietary supplement must be formulated with the intent to provide 100% of the quantitative label amount of each dietary ingredient and may include overage inputs as necessary to ensure the product meets label claim at the end of shelf life. The contents of the declared dietary ingredients and/or their marker compounds must be consistent with the strengths stated on the label within the tolerances established as acceptance criteria set in the specifications and the local regulatory requirements.

## 4.2 Executed Batch Production Records

An executed batch production record must be prepared every time a batch of dietary supplements is manufactured, and it must include complete information relating to the production and control of each batch. The executed batch production record

Official

https://pharmacopeia.cn/
Printed on: Fri Jan 05 2024 06:37:45 AM(EST)
Printed by: USP NF
Do Not Distribute
Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Aug-2021
DOI Ref: 0pf8r
DocId: GUID-B1EB10D3-6473-4AC9-99B7-4AD444683A01_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99987_02_01
@2024 USPC

must accurately follow the appropriate master manufacturing record and each step in the production of the batch must be performed.

The executed batch production record must include:

- The batch, lot, or control number of the dietary supplement; of each lot of packaged and labeled dietary supplement from a finished batch of dietary supplement; and each lot of dietary supplement, from the finished batch of dietary supplement, that is distributed to another person for packaging or labeling;
- The identity of equipment and processing lines used in producing the batch;
- The date and time of the maintenance, cleaning, and sanitizing of the equipment and processing lines used in producing the batch, or a cross-reference to records, such as individual equipment logs, where this information is retained;
- The unique identifier that was assigned to each component, or, when applicable, to a product that was received from a supplier for packaging and labeling as a dietary supplement, packaging and label used;
- The identity and weight or measure of each component used;
- A statement of the actual yield and a statement of the percentage of theoretical yield at appropriate phases of processing;
- The actual results obtained during any monitoring operation;
- The results of any testing or examination performed during the batch production, or a cross-reference to such results;
- Documentation that the finished dietary supplement meets the in-process (bulk) dietary supplement and finished dietary supplement specifications.

The executed batch production record must also include documentation, at the time of performance, of the manufacture of the batch, including:

- The date on which each step of the master manufacturing record was performed;
- The initials of the person performing each step, including initials of the person responsible for:
  - Weighing or measuring each component used in the batch;
  - Verifying the weight or measure of each component used in the batch;
  - Adding the component to the batch; and
  - Verifying the addition of components to the batch;
- Documentation, at the time of performance, of packaging and labeling operations, including:
  - The unique identifier that was assigned to packaging and labels used, the quantity of the packaging and labels used, and, when label reconciliation is required, reconciliation of any discrepancies between issuance and use of labels;
  - An actual or representative label, or a cross-reference to the physical location of the actual or representative label specified in the master manufacturing (or packaging and labeling) record; and
  - The results of any tests or examinations conducted on packaged and labeled dietary supplements, including repackaged or relabeled dietary supplements, or a cross-reference to the physical location of such results;
- Documentation at the time of performance that quality unit personnel:
  - Reviewed the batch production record, including review of any monitoring operation required for determining compliance to material specifications, and review of the results of any tests and examinations, including tests and examinations conducted on components, in-process materials, finished batches of dietary supplements, and packaged and labeled dietary supplements;
  - Approved or rejected any reprocessing or repackaging;
  - Approved and released, or rejected, the batch for distribution, including any reprocessed batch;
  - Approved and released, or rejected, the packaged and labeled dietary supplement, including any repackaged or relabeled dietary supplement;
- Documentation at the time of performance or any required material review and disposition decision; and
- Documentation at the time of performance of any reprocessing.

## 4.3 Manufacturing Operations Production and Process Controls

Written procedures must be established and followed for manufacturing operations. Manufacturing processes must be designed and selected to ensure that dietary supplement specifications are consistently met.

All manufacturing operations must be conducted in accordance with adequate sanitation principles.

All necessary precautions must be taken during the manufacture of a dietary supplement to prevent contamination of components or dietary supplements. These precautions include:

- Performing manufacturing operations under conditions and controls that protect against the potential for growth of microorganisms; the potential for allergen cross-contact and contamination; and the potential for the adulteration of raw materials, in-process materials, and finished product;
- Washing and cleaning components that contain soil and other contaminants;
- Using water that, at a minimum, complies with the applicable federal, state, and local requirements and does not contaminate the dietary supplement when the water may become a component of the finished batch of dietary supplement;
- Performing chemical, microbiological, or other testing, as necessary to prevent the use of contaminated components;
- Sterilizing, pasteurizing, freezing, refrigerating, controlling hydrogen-ion concentration (pH), controlling humidity, controlling water activity ($a_w$), or using any other effective means to remove, destroy, or prevent the growth of microorganisms and prevent decomposition;
- Holding components and dietary supplements that can support the rapid growth of microorganisms of public health significance in a manner that prevents the components and dietary supplements from becoming adulterated;

DOI: https://doi.org/10.31003/USPNF_M99987_02_01

@2024 USPC

- Identifying and holding any components or dietary supplements, for which a material review and disposition decision is required, in a manner that protects components or dietary supplements that are not under a material review against contamination and mix-up with those that are under a material review;
- Performing mechanical manufacturing steps (such as cutting, sorting, inspecting, shredding, drying, grinding, blending, and sifting) by any effective means to protect the dietary supplements against contamination by, for example:
  - Cleaning and sanitizing contact surfaces;
  - Using temperature controls; and
  - Using time controls;
- Using effective measures to protect against the inclusion of metal or other foreign material in components or dietary supplements, by, for example, filters or strainers, traps, magnets, or electronic metal detectors;
- Segregating and identifying all containers for a specific batch of dietary supplements to identify their contents and, when necessary, the phase of manufacturing; and
- Identifying all processing lines and major equipment used during manufacturing to indicate their contents, including the name of the dietary supplement and the specific batch or lot number and, when necessary, the phase of manufacturing.

## 4.4 Quality Unit Responsibilities for Production

Quality unit personnel must:

- Review and approve all master manufacturing records (MMR) and all modifications to them;
- Review and approve all master packaging and labeling records (if separate from the MMR) and all modifications to them;
- Review and approve all batch production-related records;
- Review all monitoring required for determining compliance to material specifications;
- Conduct any material review and make any required disposition decisions;
- Approve or reject any treatments, in-process adjustments, and reprocessing;
- Determine whether all in-process production specifications are met;
- Determine whether each finished batch of dietary supplements conforms to its specifications; and
- Make a disposition decision (approving and releasing, or rejecting) each finished batch of dietary supplements, including any reprocessed finished batch of dietary supplements, for distribution.

## 4.5 Disposition Decision for Production

For supplements that meet specifications and that were manufactured, packaged, labeled, and held under conditions to ensure the quality of the dietary supplement, the quality unit may approve and release the batch of dietary supplements for distribution.

The quality unit personnel must not approve and release for distribution any batch or reprocessed batch of dietary supplement:

- For which any component in the batch does not meet its identity specification;
- That does not meet all product specifications;
- That has not been manufactured, packaged, labeled, and held under conditions to prevent adulteration; and
- That was received from a supplier for packaging or labeling as a dietary supplement, and for distribution rather than return to the supplier, for which sufficient assurance is not provided to adequately identify the product and to determine that the product is consistent with its purchase order.

## 4.6 Production Operations and Controls Documentation

The following documentation must be made and kept for fulfilling the requirements of the Production Operations and Controls System (quality system 4).

### 4.6.1 WRITTEN PROCEDURES

Written procedures for manufacturing operations must be established and followed for:

- Preparing and approving master manufacturing records and production instructions;
- Cleaning and inspecting manufacturing facilities;
- Conducting manufacturing production operations; and
- Quality unit responsibilities and operations.

### 4.6.2 RECORDS

Records must be made and kept for manufacturing operations, including:

- Master manufacturing records and executed batch production records;
- Equipment and production suite cleaning records; and
- Documentation of any material reviews and disposition decisions by the quality unit.

@2024 USPC

# 5. PACKAGING AND LABELING OPERATIONS AND CONTROLS

## 5.1 General

There must be written procedures designed to ensure that correct packaging materials and labels are used. Packaging and labeling operations must be designed to prevent mix-ups.

There should be written procedures describing the receipt, identification, quarantine, sampling, examination and/or testing and release, and handling of packaging and labeling materials.

Packaging and labeling material should conform to established specifications. Those that do not comply with such specifications should be rejected to prevent their use in operations for which they are unsuitable.

Records should be maintained for each shipment of labels and packaging materials showing receipt, examination or testing, and whether accepted or rejected.

## 5.2 Packaging Materials

### 5.2.1 GENERAL

Necessary actions must be taken to determine whether packaging for dietary supplements meets specifications so that the condition of the packaging will ensure the quality of the dietary supplements [cGMP, 21 CFR §111.410(a)]. Containers must provide adequate protection against deterioration or contamination of the dietary supplement that may occur during transportation and recommended storage.

Chapter ⟨659⟩ provides packaging definitions, auxiliary packaging information, and storage condition definitions relevant to the storage and distribution of dietary supplements, and should be consulted.

Containers must be clean and, where indicated by the nature of the product, sanitized to ensure that they are suitable for their intended use. These containers must not be reactive, additive, or absorptive so as to alter the quality of the dietary supplement beyond specified limits.

If containers (e.g., for components, in-process materials, or bulk material) are re-used, they should be cleaned in accordance with documented procedures and all previous labels should be removed or defaced.

### 5.2.2 TAMPER-RESISTANT PACKAGING

Dietary supplements for retail sale must be packaged in a tamper-resistant package. A tamper-resistant package is one having an indicator or barrier to entry which, if breached or missing, can reasonably be expected to provide visible evidence to consumers that tampering has occurred. To reduce the likelihood of substitution of a tamper-resistant feature after tampering, the indicator or barrier to entry must be distinctive by design or by the use of an identifying characteristic (e.g., a pattern, name, registered trademark, logo, or picture). The term “distinctive by design” means that the packaging cannot be duplicated with commonly available materials or through commonly available processes. A tamper-resistant package may involve a primary container–closure system, a secondary container or carton system, or any combination of systems intended to provide a visual indication of package integrity. The tamper-resistant feature should be designed to remain intact when handled in a reasonable manner during manufacture and distribution, or held at retail display.

## 5.3 Labeling

### 5.3.1 GENERAL

Labeling must comply with applicable federal and state labeling regulations or dietary supplements.

Quantitative label claims for the product must be truthful and accurately reflect the contents of the declared dietary ingredients and/or their marker compounds.

Reference to the *USP–NF* on the label or labeling must be appropriate and completely accurate in accordance with the *General Notices, 3.20 Indicating Conformance*. When the dietary supplement product monograph title appears on the label, the product must fully conform to the specified compendial standard.

Labeling must comply with applicable labeling regulations for dietary supplements, including, but not limited to, listing:

- The term “dietary supplement” or “supplement”;
- The quantity of each dietary ingredient and the correct reference daily intake, listed as percent daily value, as necessary;
- The common or usual name of each ingredient in descending order of predominance by weight, except that dietary ingredients listed in the nutrition label supplement facts need not be repeated in the ingredient list; incidental additives including water, present in a dietary supplement at insignificant levels are exempted from this requirement;
- With respect to a proprietary blend of ingredients, the total quantity of all ingredients in the blend is provided in order of predominance by weight and identified by the term “proprietary blend” or other appropriately descriptive term;
- Products making a claim of health benefit (including statements, symbols, or vignettes) do so in a manner that is consistent with the applicable regulatory requirements; health benefit claims include structure/function claims, health claims, and qualified health claims.

For botanicals, the common or usual name and/or the Latin binomial of the botanical species must be listed on the label. The American Herbal Product Association’s publication, *Herbs of Commerce*, current edition, should be consulted regarding the appropriate common or usual name of a botanical ingredient. Additionally, the proper Latin binomial name should be provided in parenthesis on the label, except that this name is not required when it is synonymous with the common or usual name for

Official

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:37:45 AM(EST)
Printed by: USP NF
Do Not Distribute

the botanical species. The label must include the plant part(s) used. The terms "whole", "root", "seed", "aerial", and "leaf" are all acceptable terminology.

Labels for dietary supplements containing iron or iron salts for use as an iron source must include the following required cautionary statement: "WARNING: Accidental overdose of iron-containing products is a leading cause of fatal poisoning in children under 6. Keep this product out of reach of children. In case of accidental overdose, call a doctor or poison control center immediately."

Dietary supplements that contain over 250 mg of elemental iron in a single package must comply with the Consumer Product Safety Commission's regulations for child resistant packaging.

Labeling for dietary supplements must comply with applicable allergen labeling requirements as promulgated in the Food Allergen Labeling and Consumer Protection Act (FALCPA).

The label must include a statement of the necessary storage requirements for the dietary supplement.

The label must accurately state the country of origin for any product of foreign origin imported into the United States.

The name and place (city, state, zip code) of business of the manufacturer, packer, or distributor must be located to the right of the principle display panel. When the name appearing on the label is not that of the actual manufacturer, the name should be qualified in a manner to accurately reflect this relationship (e.g., "Manufactured for ___", "Distributed by ___"). The label must include a domestic address or phone number through which an adverse event report for a dietary supplement may be received.

#### 5.3.2 SHELF LIFE (EXPIRY) DATE

Dietary supplement labeling must state a shelf life (expiry) date that is indicative of the date before which the dietary supplement is ensured to meet applicable specifications of identity, strength, quality, and purity when stored under labeled conditions. The shelf life (expiry) date must be supported by suitable stability data.

There must be a written procedure designed to ensure that the correct shelf life (expiry) date is printed on the finished dietary supplement labeling.

#### 5.3.3 TAMPER-RESISTANT LABELING

Each retail package of a dietary supplement covered by this section must bear a statement that is prominently placed so that consumers are alerted to the specific tamper-resistant feature of the package. The labeling statement should be so placed that it will be unaffected if the tamper-resistant feature of the packaging is breached or missing. If the tamper-resistant feature chosen to meet the requirement above is one that uses an identifying characteristic, that characteristic should be referred to in the labeling statement. For example, the labeling statement on a bottle with a shrink band could say "For your protection, this bottle has an imprinted seal around the neck."

### 5.4 Labeling Issuance and Control

Access to the label storage areas (i.e., label control room) must be limited to authorized personnel. Procedures for labeling issuance and control should be established to ensure that labels are stored in a manner that prevents mix-ups and provides proper identification used to reconcile the quantities of labels issued, used, and returned, and to evaluate discrepancies found between the number of containers labeled and the number of labels issued and used. Such discrepancies should be investigated, and the investigation should be approved by the quality unit(s).

All excess labels bearing batch numbers or other batch-related printing should be destroyed. Returned labels should be maintained. Obsolete and outdated labels, and incorrect labels should be destroyed to ensure that they are not used in any future packaging and labeling operations.

Printing devices used to print labels for packaging operations (e.g., for bulk packaging) should be controlled to ensure that all imprinting conforms to the print specified in the batch production record.

Labeling issuance must be designed to prevent mix-ups. Strict control must be exercised over issuance of labeling for use in finished dietary supplement labeling operations. Labels should be delivered to packaging lines in a secured container (e.g., locked box or cage).

Labeling materials issued for a batch should be carefully examined for proper identity and conformity to the labeling specifications in the batch packaging record. A printed label or copy of the printed label representative of those used must be included in the batch packaging record.

Procedures should be used to reconcile the quantities of labeling issued, used, and returned, and should require evaluation of discrepancies found. If discrepancies are found between the quantity of product finished and the quantity of labeling issued and are outside preset limits based on historical operating data, such discrepancies should be investigated.

If a 100-percent examination for correct labels has been performed by appropriate electronic or electromechanical equipment during or after completion of finishing operations, then label reconciliation is not required for cut or rolled labels.

Returned labeling should be maintained and sorted in a manner to prevent mix-ups and provide proper identification. All excess labeling bearing lot or control numbers should be destroyed and documented.

### 5.5 Packaging and Labeling Operations

Filling, assembling, packaging, labeling, and other related operations must be performed in a manner that ensures the quality of the dietary supplement, and that the dietary supplement is packaged and labeled as specified in the master packaging record. This must be done using any effective mean including the following:

- Cleaning and sanitizing all filling and packaging equipment, utensils, and dietary supplement packaging, as appropriate;
- Protecting manufactured dietary supplements from contamination, particularly airborne contamination;

Official

https://pharmacopeia.com/

- Using sanitary handling procedures;
- Establishing physical or spatial separation of packaging and labeling operations from operations on other components and dietary supplements to prevent mix-ups;
- Identifying, by any effective means, filled dietary supplement containers that are set aside and held in unlabeled conditions for future label operations, to prevent mix-ups;
- Assigning a batch, lot, or control number to each lot of packaged and labeled dietary supplement from a finished batch of dietary supplement; and each lot of dietary supplement, that you distribute to another person for packaging or labeling;
- Examining a representative sample of each batch of the packaged and labeled dietary supplement to determine whether the finished dietary supplement meets its specifications; and
- Suitably disposing of labels and packaging for dietary supplements that are obsolete or incorrect to ensure that they are not used in any future packaging and labeling operations.

There must be written procedures designed to ensure that correct packaging materials and labeling are used. Issuance and use of packaging and labels and reconciliation of any issuance and use discrepancies must be controlled. Before packaging and labeling operations begin, packaging and labeling for each batch of dietary supplements must be examined to determine whether the packaging and labeling conforms to the batch packaging control record. Packaging and labeling materials must be identified by item control number and lot number.

Packaging and labeling facilities must be inspected immediately before use to ensure that all materials not needed for the next packaging operation have been removed, and that packaging and labeling facilities have been properly cleaned. Results of the inspection and cleaning should be documented in the batch packaging control records, the packaging facility log, or other documentation system.

Packaged and labeled dietary supplements should be examined to ensure that containers and packages in the batch have the correct label. This examination should be part of the packaging operation. Results of these examinations must be recorded in the batch packaging control record.

A reserve sample of each batch of finished dietary supplements, consisting of at least twice the quantity necessary for finished dietary supplement specification tests and examinations, must be collected and retained for at least one (1) year past its shelf life (expiry) date.

In-process dietary supplements that are transported outside the manufacturer's control must be sealed in a manner such that, if the seal is breached or missing, the recipient will be alerted to the possibility that the contents may have been altered.

Any packaged and labeled dietary supplement that is rejected for distribution must be clearly identified, held, and controlled under a quarantine system for appropriate disposition.

The complete manufacturing history and control of the packaged and labeled dietary supplement through distribution must be traceable.

## 5.6 Repackaging and Relabeling

Dietary supplements may be repackaged or relabeled only after quality unit personnel have approved such repackaging or relabeling. A representative sample of each batch of repackaged or relabeled dietary supplements must be examined to determine whether the repackaged or relabeled dietary supplements meet all established specifications. Quality unit personnel must approve or reject each batch of repackaged or relabeled dietary supplements prior to its release for distribution.

*Good Repackaging Practices* ⟨1178⟩ should be consulted.

## 5.7 Quality Unit Responsibilities for Packaging and Labeling Operations

For packaging and labeling operations, quality unit personnel must:

- Review the results of any visual examination and documentation to ensure that specifications for product received from a supplier, for packaging and labeling as a return to the supplier, is met;
- Approve, and release from quarantine, all products received for packaging and labeling as a dietary supplement, and for distribution rather than for return to the supplier, before they are used for packaging and labeling;
- Review and approve all records for packaging and labeling operations;
- Determine whether the finished packaged and labeled dietary supplement conforms to established specifications;
- Conduct any required material review and make any required disposition decisions;
- Approve or reject any repackaging of a packaged dietary supplement;
- Approve or reject any relabeling of a packaged and labeled dietary supplement; and
- Approve for release, or reject, any packaged and labeled dietary supplement, including repackaged or relabeled dietary supplements, for distribution.

## 5.8 Packaging and Labeling Operations and Controls Documentation

The following documentation must be made and kept for fulfilling the requirements of the Packaging and Labeling Operations and Controls System (quality system 5).

### 5.8.1 WRITTEN PROCEDURES

Written procedures for packaging and labeling operations must be established and followed for:

- Receipt, identification, quarantine, sampling, examination and/or testing and release, and handling of packaging and labeling materials;

Official

https://pharmacopeia.cn/

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99987_02_01
@2024 USPC

- Preparation and approval of packaging material and labeling specifications;
- Preparation and approval and master batch packaging and labeling control records;
- Cleaning and inspecting packaging and labeling facilities;
- Filling, assembling, packaging, labeling, and other related operations; and
- Determination and issuance of finished dietary supplement shelf-life (expiry) date to batch packaging and labeling control records.

5.8.2 RECORDS

Records for packaging and labeling must be made and kept for:

- Packaging and labeling specifications;
- Packaging and labeling facility cleaning and inspection records;
- Executed batch packaging and labeling control records; and
- Executed batch repackaging and relabeling control records.

# 6. LABORATORY OPERATIONS AND CONTROLS

## 6.1 General

Written procedures must be established and followed for laboratory operations, including written procedures for the tests and examinations to be conducted to determine whether specifications are met.

Adequate laboratory facilities must be used for whatever testing or examinations are necessary to determine whether components, packaging materials, labeling, in-process materials, and dietary supplements meet specifications.

Laboratory control processes must be established and followed that are reviewed and approved by quality unit personnel, including the following:

- Criteria to be used for establishing appropriate specifications;
- Sampling plans for obtaining representative samples of:
  - Components, packing materials, and labels;
  - In-process materials;
  - Finished batches of dietary supplements;
  - Product that is received for packaging or labeling as a dietary supplement, and for distribution rather than for return to the supplier; and
  - Packaged and labeled dietary supplements;
- Use of criteria for selecting appropriate examination and testing methods;
- Use of criteria for selecting standard reference materials used in performing tests and examinations; and
- Use of test methods and examinations in accordance with established criteria.

Quality control personnel must verify that the laboratory examination and testing methodologies are appropriate for their intended use. Quality control personnel must identify and use appropriate scientifically validated methods for each established specification for which testing or examination is required to determine whether the specification is met.

Specifications, sampling plans, and test procedures, including changes or modifications to them, should be drafted by the appropriate quality control unit personnel and reviewed and approved by the appropriate quality assurance unit personnel. Specifications should be established in accordance with accepted standards and consistent with the manufacturing process.

There must be documented procedures describing sampling, testing, approval and rejection of materials, and recording and storage of laboratory data.

## 6.2 Reagents and Reference Standards

Reagents and standard solutions should be prepared and labeled following written procedures. “Use by” dates should be established and applied as appropriate for analytical reagents and standard solutions.

Primary reference standards should be obtained as appropriate for the manufacture of dietary supplements. The source of each primary reference standard must be documented. Records should be maintained of each primary reference standard’s storage and use in accordance with the supplier’s recommendations. Primary reference standards obtained from an officially recognized source, e.g., USP Reference Standards, may be used without testing if stored under conditions consistent with the supplier’s recommendations.

Where a primary reference standard is not available from an officially recognized source, an “in-house primary standard” must be established. Appropriate testing needs to be performed to establish fully the identity and purity of the “in-house primary reference standard”. Appropriate documentation of this testing should be maintained.

Secondary reference standards should be appropriately prepared, identified, tested, approved, and stored. The suitability of each batch of secondary reference standard should be determined prior to first use by comparing against a primary reference standard. Each batch of secondary reference standards should be periodically requalified in accordance with a written protocol.

## 6.3 Scientifically Validated Test Procedures

Tests and examinations that are used to determine whether material specifications are met must be scientifically validated methods, and appropriate for their intended use. Tests methods or procedures must meet proper standards of accuracy and reliability.

### 6.3.1 VALIDATION OF TEST PROCEDURES

If the test procedure is not in an official compendium, the procedure must be validated according to ⟨1225⟩. Method performance characteristics include specificity, linearity, range accuracy, precision, detection limit, and quantitation limit, and those of interest may vary depending on the type of test: identification, assay, impurities, or performance.

For microbial test procedures, the following *USP* general chapters should be consulted:

- *Biological Assay Validation* ⟨1033⟩
- *Validation of Alternative Microbiological Methods* ⟨1223⟩
- *Validation of Microbial Recovery from Pharmacopeial Articles* ⟨1227⟩

For performance test procedures, the following *USP* general chapter should be consulted:

- *The Dissolution Procedure: Development and Validation* ⟨1092⟩

### 6.3.2 VERIFICATION OF OFFICIAL TEST PROCEDURES

If the test procedure is in an official compendium, such as *USP–NF* or AOAC International *Official Methods of Analysis*, the procedure only needs to be verified for its suitability under actual conditions of use, according to *Verification of Compendial Procedures* ⟨1226⟩. Verification requirements should be based on an assessment of the complexity of both the procedure and the material to which the procedure is applied. Verification is not required for basic compendial procedures, such as loss on drying, residue on ignition, and simple instrumental determinations, such as pH measurements.

## 6.4 Test Procedures

Test procedures must have clear, complete descriptions, so as to provide an analyst with directions on how to reproducibly perform the given test. Test procedures should include the following information, as applicable:

- Purpose;
- Safety information, if applicable;
- Materials and equipment;
- Procedure, as applicable:
    - System suitability;
    - Preparation of solutions and reagents;
    - Preparation of standards and samples;
    - Instrumental parameters; and
    - Calculations and reporting;
- Review and approval with approval dates;
- Revision history.

The tests and examinations can include gross organoleptic analyses, macroscopic analyses, microscopic analyses, chemical (inorganic and organic) analyses, microbiological analyses, DNA-based analyses, and other scientifically valid methods.

Test procedures should be followed and documented at the time of performance, and any departure from established test procedures should be documented and explained.

All validated procedures must have backup data that is readily available for review and audit.

## 6.5 Transfer of Analytical Test Procedures

Testing materials for compliance to specifications is critical in establishing the quality of the dietary supplement. The transfer of analytical procedures (TAP), also referred to as method transfer, is the documented process that qualifies a laboratory (the receiving unit) to use an analytical test procedure that originated in another laboratory (the transferring unit), thus ensuring that the receiving unit has the procedural knowledge and ability to perform the transferred analytical procedure as intended. *USP* general chapter *Transfer of Analytical Procedures* ⟨1224⟩ summarizes the types of transfers that may occur and outlines the potential components of a transfer protocol, and should be consulted to qualify a laboratory (both internal and external to the manufacturer) to ensure it has the procedural knowledge and ability to perform the test procedure as intended.

## 6.6 Reduced Testing

### 6.6.1 GENERAL

Reduced testing or inspection provides a way of reducing the testing or inspection effort on received components, in-process material, and dietary supplements of high quality, in which all batches are expected to be of the similar quality.

Reduced testing for a particular specified parameter(s) should be based upon one or more of the following:

- Statistical analysis of an adequate quantity of historical test data;

Official

Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99987_02_01
@2024 USPC

- Statistical confidence in the capability of the manufacturing process as determined by suitable verification; and
- Ongoing monitoring of the process using recognized statistical process control (SPC) techniques.

Control procedures should be established to monitor the output of manufacturing processes that may cause variability for in-process material and dietary supplements, which may include, but are not limited to: clarity, completeness, or pH of solution; blend uniformity; friability; weight variation or content uniformity; and disintegration or dissolution time.

The following terms are useful when describing reduced testing:

- Lot-by-lot inspection means inspection of products submitted in a series of lots;
- Reduced sampling inspection means a sampling inspection procedure in which some lots in a series are accepted without full testing when the sampling results for a stated number of immediately preceding lots meet stated criteria;
- Inspection sampling frequency means probability that a lot is fully tested (e.g., every fifth lot);
- Disqualification means failure to qualify for reduced sampling inspection;
- Requalification means qualification for a resumption of reduced sampling inspection;
- Supplier qualification means assessment of the supplier's GMP competence so as to implement reduced sampling inspection;
- Product qualification means assessment of product (i.e., component, in-process material, or dietary supplement) quality to determine its suitability for reduced sampling inspection.

### 6.6.2 REDUCED TESTING REQUIREMENTS

Reduced sampling inspection may only be used when both the supplier's GMP quality systems and product (i.e., the component, in-process material, or dietary supplement) are qualified. See *1.7 Supplier Qualification* for guidance.

- Requirements for supplier qualification:
  - The supplier must have established, documented, and followed effective and applicable GMP quality systems for managing quality that involves the active participation of personnel;
  - An assessment of the supplier's GMP quality systems must be performed;
  - Ongoing assessment of the supplier's GMP quality systems should be performed on a specified frequency; and
  - The supplier must not have experienced changes in its GMP quality systems that adversely affect product quality.
- Requirements for product (i.e., component, in-process material or dietary supplement) qualification:
  - An assessment for product qualification should not be made prior to the assessment of the supplier's GMP quality systems;
  - The preceding three (3), at minimum, or more consecutive lots have been accepted, and results of resubmitted lots are not included.

The following are examples of typical reduced inspection and rotational testing that can be performed:

- Reduced testing, for example, a typical approach:
  - Conduct lot-by-lot full inspection on the first 3 lots;
  - If successful, conduct reduced sampling inspection on every fifth (5th) lot for a set period of time;
  - If successful, reduce sampling inspection to every tenth (10th) lot, until there is a failure;
  - Test a minimum of 1 lot every year; and
  - If a failure is encountered, disqualify the supplier and its product, and conduct a root cause investigation and return to full testing of the next 3 lots.
- Rotational testing, for example, a typical approach:
  - Establish testing levels, e.g., I, II, III, specifying what tests on the product specification are to be conducted on a given lot in sequence (i.e., I, II, III), such that all test on the product specification are tested at least once on every 3 lots;
  - A subset of tests should be selected for identification, potency, limit of contaminants, and performance;
  - Tests for key potential contaminants are conducted for every lot; and
  - Some critical tests are conducted for every lot.

### 6.6.3 RECEIVED COMPONENTS, IN-PROCESS MATERIALS, AND DIETARY SUPPLEMENTS

On the basis of adequate supplier qualification, process validation, in-process controls, and statistical confidence, a reduced testing plan is an alternative to fully testing every batch of components received from a supplier provided that at least one identity (i.e., identification) test is conducted. Such identification tests must include sufficient specificity to determine the identity of the component.

Each batch of components received from a supplier that is liable to be contaminated with microorganisms, filth, insect infestation, allergens, aflatoxins, other natural toxins, pesticides, organic impurities (e.g., residual solvents), and/or inorganic impurities (e.g., foreign substances, or other extraneous substances that may be a source of contamination that is objectionable in view of its intended use) must be tested or examined against established specifications for such contamination. In such cases, reduced testing of examination must not apply until risk is mitigated by the supplier.

### 6.6.4 IN-PROCESS MATERIALS AND DIETARY SUPPLEMENTS

On the basis of process validation, in-process controls, and statistical confidence, a reduced testing plan is an alternative to fully testing every batch of in-process material and dietary supplements provided that at least one representative measure (i.e., rotational testing) is performed.

## 6.7 Out-Of-Specification (OOS) Investigations

Written procedures must be established and followed for investigating critical deviations or the failure of a batch of material to meet specifications (i.e., out-of-specification investigations), and corrective action plans must be established for use when an established specification is not met. The investigation should extend to other batches that may have been associated with the specific failure or deviation. The procedure should require analysis of the data, assessment of whether a significant problem exists, allocation of the tasks for corrective actions, and conclusions. Any resampling and/or retesting after OOS test results should be performed according to a documented procedure. Regulatory guidance for investigating OOS test results should be consulted.

## 6.8 Stability Testing

A documented on-going testing program must be designed to monitor the stability characteristics of dietary supplements, and the results must be used to establish appropriate storage conditions and shelf life (expiry) dates for the dietary supplements. Test procedures used in stability testing must be validated. Stability samples should be stored in container-closure systems that simulate the packaging proposed to distribute the finished dietary supplement in the marketplace. Stability studies should include testing of those attributes of the dietary supplement that are susceptible to change during storage and that influence the quality of the dietary supplement.

Ideally the first three (3), but at minimum one (1), production batch(s) should be placed on the stability monitoring program to establish the product shelf life (expiry) date. Ideally, thereafter, at least one (1) batch per year of manufactured dietary supplement (unless none is produced that year) should be added to the stability monitoring program.

As appropriate, the stability storage conditions for temperature and relative humidity (RH) should be as follows:

- Long term = 25 ± 2° and 60 ± 5% RH;
- Intermediate = 30 ± 2° and 65 ± 5% RH;
- Accelerated = 40 ± 2° and 75 ± 5% RH.

Long term studies can also be performed under the labeled storage conditions, e.g., at room temperature (ambient conditions), or in a cool, dry place (8°–15° and NMT 40% RH). Alternative storage conditions should be considered for products marketed outside the United States in different climatic zones.

The frequency of testing should be sufficient to establish the stability profile of the dietary supplement. The following testing frequencies are recommended:

- Long term = 0, 3, 6, 9, 12, 18, and 24 months;
- Intermediate = 0, 3, 6, 9, and 12 months;
- Accelerated = 0, 1, 2, 3, and 6 months.

For long term studies, frequency of testing should be sufficient to establish the stability profile of the dietary supplement.

Accelerated stability studies are designed to increase the rate of chemical degradation or physical change and are intended to evaluate the effect of short-term excursions outside the labeled storage conditions such as might occur during shipping. Although accelerated stability studies may not adequately reflect the stability of the product under labeled (e.g., long term) conditions, results from accelerated stability can be used to estimate a preliminary shelf life (expiry) date for a dietary supplement that should eventually be supported with data from long term stability studies.

Preliminary shelf life (expiry) dates can be based on pilot scale batches if the pilot batch is at least one-tenth (1/10th) the size of the commercial batch size and the pilot batch employs a manufacturing process that simulates the process to be used on a commercial manufacturing scale. Bench scale batches should not be used for stability studies.

In certain cases, dietary supplements being closely related in composition may be grouped together using one representative dietary supplement formulation with which to obtain stability data to support the shelf life (expiry) date of all dietary supplement formulations within that group. Under such circumstances, sufficient scientific justification should be provided as to support grouping of the dietary supplements for stability purposes.

The design of the stability studies may also bracket dietary supplements such that only dietary supplements on the extremes of certain factors, e.g., strength, package size, are tested. This design assumes that the stability of any intermediate level is represented by the stability of the extremes tested.

Stability studies should be performed for dietary supplements packaged in different container–closure systems [e.g., high density polyethylene (HDPE) bottles, polyethylene terephthalate (PET) bottles, blister packs]. In certain cases, stability data using one type of container–closure system may be used to support stability of the product in a different type of container–closure system (e.g., HDPE versus PET bottles) with supporting scientific justification regarding the moisture, vapor, and light protection characteristics of the two types of container–closure systems.

Long term and accelerated (and intermediate) stability studies should be undertaken according to a prescribed stability protocol. The resultant data must be properly evaluated. The degree of variability of stability data between or within individual batches affects the confidence in the data. The data may show little degradation and little variability such that it is apparent from looking at the data that the product will meet specifications throughout the proposed shelf-life (expiry) date. When the data on a quantitative attribute changes with time and shows significant degradation or significant variability, it is necessary to use formal statistical analysis to determine the shelf life (expiry) date for the dietary supplement. A stability report should be prepared for the dietary supplement stating the proposed storage conditions and shelf life (expiry) date of the dietary supplement(s), along with the stability data and its evaluation.

## 6.9 Laboratory Testing Records

Laboratory control records should include complete data derived from all tests conducted to ensure compliance with established specifications and standards, including examinations and assays, as follows:

Official

https://pharmacopeia.cn/
Printed on: Fri Jan 05 2024 06:37:45 AM(EST)

Do Not Distribute
Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Aug-2021
DOI Ref: 0pf8r
DocId: GUID-B1EB10D3-6473-4AC9-99B7-4AD444683A01_2_en-US
Document Type: GENERAL CHAPTER
DOI: https://doi.org/10.31003/USPNF_M99987_02_01
@2024 USPC

- A description of samples received for testing, including material name or source, batch number or other distinctive code, date sample was taken, and, where appropriate, the quantity and date the sample was received for testing;
- A statement or reference to each test procedure used;
- A statement of the weight or measure of sample used for each test as described by the test procedure;
- Data on or cross-reference to the preparation and testing of reference standards, reagents, and standard solutions;
- A complete record of all raw data generated during each test, in addition to graphs, charts, and spectra from laboratory instrumentation, properly identified to show the specific material and batch tested;
- A record of all calculations performed in connection with the test, including, for example, units of measure, conversion factors, and equivalency factors;
- A statement of the test results and how they compare with established acceptance criteria;
- The signature of the person who performed each test and the date(s) the tests were performed; and
- The date and signature of a second person showing that the original records have been reviewed for accuracy, completeness, and compliance with established procedures.

A certificate of analysis (CoA) should be issued for each batch of dietary supplements. The certificate of analysis should list the name and item code of the dietary supplement, the batch number, the release date, and the expiry date. The CoA should list each test performed, the specific identity of the test procedure, the acceptance limits or criteria, and the results with numerical units, as appropriate. The CoA should be dated and signed by authorized quality unit personnel. For CoA issued for external use, the CoA should list the name, address, and telephone number of the manufacturer.

## 6.10 Quality Control Unit Responsibilities for Laboratory Operations and Controls

For laboratory operations, quality control unit personnel must:

- Review and approve all laboratory control processes associated with the production and process control system;
- Ensure that all tests and examinations required to determine compliance to specifications are conducted; and
- Review and approve the results of all tests and examinations required to determine compliance to specifications.

## 6.11 Laboratory Operations and Controls Documentation

The following documentation must be made and kept for fulfilling the requirements of the laboratory controls system (quality system 6).

### 6.11.1 WRITTEN PROCEDURES

Written procedure for laboratory operations must be established and followed for:

- The tests and examinations conducted to determine whether specifications are met;
- Establishing, reviewing, and approving material specifications;
- Preparation, review, and approval of written test procedures;
- Validating and verifying test procedures for their intended use;
- Selection, preparation, and handling of reagents and reference standards;
- Establishing, reviewing, and approving sampling plans, including reduced sampling inspections;
- Sampling, testing, approval, and rejection of materials, and recording and storage of laboratory data;
- Investigating critical deviations or out-of-specification test results; and
- Establishment and implementation of a stability testing program.

### 6.11.2 RECORDS

Records must be made and kept for:

- Documentation that established laboratory test and examination procedures are followed;
- The person who conducts the testing and examination must document, at the time of performance, that established laboratory methodology is followed;
- Documentation for laboratory tests and examinations must include the data and results of the testing and examination;
- Any modification to an established test procedure;
- Out-of-specification (OOS) investigations and corresponding corrective actions;
- Test procedure method validation or verification protocols and reports, supporting test procedure suitability for use;
- The periodic calibration of laboratory instruments and controls;
- Stability protocols and stability data and reports, supporting a product's shelf life (expiry) date.

# GLOSSARY

**Acceptance criteria:** Predetermined limits (e.g., number, numerical ranges, or other suitable measures) for acceptance of examination or test results.

**Adequate:** Item/area/system/knowledge that meets basic minimum requirements that are needed to accomplish intended purpose.

**Adulteration:** A food shall be deemed to be adulterated if it contains any poisonous or deleterious substance as specified in §402(a)(1)–(2) of the FFDCA: or if it consists of any filthy, putrid, or decomposed substance, or if it is otherwise unfit for food

Official

https://pharmacopeia.com/

as specified in §402(a)(3) of the FFDCA; or if it has been prepared, packed, or held under insanitary conditions as specified in §402(a)(4) of the FFDCA; or if its container is composed of any poisonous or deleterious substance which may render the contents injurious to health as specified in §402(a)(6) of the FFDCA; or if it has been intentionally subjected to radiation as specified in §402(a)(7) of the FFDCA; or if the contents have been altered, or if damage and or inferiority has been concealed as specified in §402(b)(1)–(4); or if it contains a color additive which is unsafe as specified in §402(c); or if it is a dietary supplement or contains a dietary ingredient that presents a significant or unreasonable risk of illness or injury as specified in §402(f)(1); or if it is a dietary supplement that has been prepared, packed, or held under conditions that do not meet current good manufacturing practice regulations as specified in §402(g)(1); or if it has not been transported in compliance with regulations as specified in §402(i).

**Adverse event:** Any undesirable experience associated with the use of a dietary supplement in a person.

**Adverse event report:** A direct communication from an identifiable first-hand reporter of an adverse event that includes at least the following information: an identifiable reporter, an identifiable person(s) who experienced the adverse event(s), an identifiable dietary supplement, and one or more adverse events.

**Allergen cross-contact:** The unintentional incorporation of a food allergen into a dietary supplement.

**Allergen:** A major food allergen as defined in §201(qq) of the FFDCA, means any of the following: (1) milk, egg, fish (e.g., bass, flounder, or cod), Crustacean shellfish (e.g., crab, lobster, or shrimp), tree nuts (e.g., almonds, pecans, or walnuts), wheat, peanuts, and soybeans; (2) a food ingredient that contains protein derived from a food specified in (1), except (A) any highly refined oil derived from a food specified in (1) and any ingredient derived from such highly refined oil, and (B) a food ingredient that is exempt under paragraphs (6) and (7) of §403(w) of the FFDCA.

**Article:** Includes substances (such as components, in-process material, dietary ingredients), products (such as dietary supplements), and materials (such as packaging containers and closures, and labels).

**Audit:** A planned, systematic, objective, independent, and documented examination (through observation, investigation, records review, discussions with employees of the audited firm, and, as appropriate, sampling and laboratory analysis) to assess whether agreed-upon requirements are being met.

**Batch:** A specific quantity of a dietary supplement or other article that is intended to be uniform; that is intended to meet specifications for identity, purity, strength, and composition; and that is produced during a specified time period according to a single manufacturing record during the same cycle of manufacture.

**Batch (or lot) number:** Any distinctive group of letters, numbers, or symbols, or any combination of them, from which the complete history of the manufacturing, packaging, labeling, and/or holding of a batch or lot of dietary supplements can be determined.

**Calibration:** The demonstration that a particular instrument or device produces results within specified limits by comparison with those produced by a reference or traceable standard over an appropriate range of measurements.

**Can:** Used to indicate a possibility or a capability.

**Certificate of analysis (CoA):** A document relating specifically to the results of testing a representative sample drawn from the batch of material. The CoA should list each test performed in accordance with compendial or manufacturer requirements, including reference to the test procedure, the acceptance limits, and the results obtained.

**Code of Federal Regulations:** The *Code of Federal Regulations* (CFR) annual edition is the codification of the general and permanent rules and regulations published in the Federal Register by the executive departments and agencies of the federal government of the United States. It is structured into 50 subject matter titles; title 1 applies to general provisions, and title 21 applies to food and drugs. Titles are broken down into parts, subparts, sections, and paragraphs. For example, 21 CFR §11.10(k)(2) would be read as title 21, part 11 (subpart B, not specified here), section 10, paragraph (k)(2). The CFR annual edition is published by the Office of the Federal Register, National Archives and Records Administration and the Government Publishing Office. In addition to this annual edition, the CFR is published in an unofficial format online in electronic format (eCFR), which is updated daily.

**Component:** Any substance intended for use in the manufacture of a dietary supplement, including those that may not appear in the finished batch of the dietary supplement.

**Composition:** The specified mix of product and product-related substances, i.e., specified mix of food ingredients or excipients and dietary ingredients in a dietary supplement.

**Contact surface:** Any surface that contacts a component, in-process material, or dietary supplement, and those surfaces from which drainage onto the component or dietary supplement, or onto the surfaces that contact the component or dietary supplement, occurs during the normal course of operations. Examples of contact surfaces include containers, utensils, tables, contact surface of equipment, and packaging.

**Contamination:** The undesired introduction of a chemical or microbiological nature, or of foreign matter, into or onto a component, in-process material, or dietary supplement during production, sampling, packaging, repackaging, storage, or transport.

**Contract manufacturer:** A manufacturer performing some aspect of manufacturing on behalf of the original manufacturer.

**Corrective action:** An action that is developed and implemented to ensure that any identified root cause of a nonconformity does not recur.

**Critical:** Describes a manufacturing process step, process condition, test requirement, or other relevant parameter or item that must be controlled within predetermined criteria to ensure the dietary supplement meets its specification.

**Design qualification (DQ):** DQ is the documented collection of activities that defined the functional and operational specifications and intended purpose of the equipment or instrument. DQ states what the user wants the equipment or instrument to do and shows that the selected equipment or instrument is suitable.

**Defect action level:** A level of a non-hazardous, naturally occurring, unavoidable defect at which FDA may regard a food product "unadulterated" and subject to enforcement action under §402(a)(3) of the FFDCA.

**Deviation:** Departure from an approved instruction or procedure, or from an established standard (i.e., a failure, or an out of specification result). Deviations can be planned, or unplanned (i.e., a nonconformity).

Official

https://pharmacopeia.com/

**Dietary ingredient:** An ingredient intended for use or used in a dietary supplement that is: a vitamin; a mineral; an herb or other botanical; an amino acid; a dietary substance for use by man to supplement the diet by increasing the total dietary intake, or a concentrate, metabolite, constituent, extract; or a combination of the aforementioned ingredients.

**Dietary supplement:** A product (other than tobacco) intended to supplement the diet that bears or contains one or more of the following dietary ingredients: a vitamin; a mineral; an herb or other botanical; an amino acid; a dietary substance for use by man to supplement the diet by increasing the total daily intake; or a concentrate, metabolite, constituent, extract or combination of the aforementioned ingredients; that is intended for ingestion in a tablet, capsule, powder, softgel, gelcap, or liquid form; that is not represented for use as a conventional food or as a sole item of a meal or the diet; and is labeled as a dietary supplement; and does include an article approved as a new drug, certified antibiotic, or licensed biologic, and was prior to such approval, certification, or license, marketed as a dietary supplement or food unless the Secretary of Health and Human Services has issued a regulation finding that the article, when used as or in a dietary supplement under the conditions of use and dosages set forth in the labeling for such dietary supplement is unlawful.

**Disposition decision:** A decision to approve or reject material, quality control, and manufacturing related processes or documents, based on a scientifically valid reason. Disposition decisions can be made regarding release of components, in-process materials, dietary supplements, packaging materials, labels, returned dietary supplements, based on a determination of whether or not established specifications are met; or regarding reprocessing treatments and in-process adjustments, master manufacturing records and batch production records, repackaging or relabeling, calibrations of an instrument or control, modification or deviations from standard procedures, and whether or not a deviation or unanticipated occurrence during the production and in-process control system could lead to adulteration of a dietary supplement.

**Documentation:** Written material related to the requirements of the quality system, including paper and electronic records, that consist of raw data, reports, protocols, and procedures related to manufacturing controls and laboratory testing. Official documents are records that support procedures, products, or the manufacturer's quality systems (e.g., standard operating procedures, master batch records, material specifications, standard test procedures, protocols, reports). Source documents are records that contain original data or information (e.g., forms, notebooks, logbooks, instrument printouts).

**Equipment:** Devices used to manufacture, package, or hold dietary supplements, or to maintain or clean the physical plant and devices.

**Facility:** A place, amenity, utility, or piece of equipment provided for a particular purpose.

**Federal Food, Drug, and Cosmetic Act:** Federal Food, Drug and Cosmetic Act (FFDCA or FD&C Act) [United States Code (USC) title 21, chapter 9] is the official compilation and codification of the federal statutes of the US that gives authority to the Food and Drug Administration (FDA) oversee the safety of food, drugs, medical devices and cosmetics in the US.

**Ingredient:** Any substance that is used in the manufacture of a dietary supplement and that is intended to be present in the finished batch of the dietary supplement.

**In-process control (or process control):** Checks performed during production in order to monitor and, if appropriate, to adjust the process and/or to ensure the dietary supplement conforms to its specification.

**In-process material:** Any material that is fabricated, compounded, blended, ground, extracted, sifted, sterilized, derived by chemical reaction, or processed in any other way for use in the manufacture of a dietary supplement.

**In-process test:** A test that may be performed during the manufacture of the dietary supplement, rather than as part of the formal battery of tests that are conducted prior to release.

**Instrument (or instrumentation):** A sophisticated measuring device or tool used for analytical or scientific work.

**Installation qualification (IQ):** The documented collection of activities necessary to establish that an equipment or instrument is delivered as designed and specified, is properly installed in the selected environment, and that the environment is suitable for the instrument.

**Label:** A display of written, printed, or graphic matter upon the immediate container of a dietary supplement.

**Labeling:** All labels and other written, printed, or graphic matter upon any dietary supplement or any of its containers, or wrappers, or accompanying such dietary supplement at any time while the dietary supplement is held for sale after shipment or delivery for shipment in interstate commerce. The term "accompanying" is interpreted liberally to mean more than physical association with the dietary supplement. It extends to posters, tags, pamphlets, circulars, booklets, brochures, fillers, etc.

**Lot:** A batch, or a specific identified portion of a batch, that is intended to be uniform and that is intended to meet specifications for identity, purity, strength, and composition.

**Manufacture:** All operations of receipt of components, production, packaging, labeling, quality control testing, release, storage, and distribution of dietary supplements and related controls.

**Material:** A general term used to denote components, in-process materials, dietary supplements, and packaging and labeling material.

**May:** Used to indicate a permission.

**Microorganism:** Any yeasts, molds, bacteria, viruses, or other microscopic organisms having public health or sanitary concern. This includes undesirable species that may have public health significance; that may cause a component or dietary supplement to decompose; that indicate that a component or dietary supplement is contaminated with filth; or that otherwise may cause a component a dietary supplement to be adulterated.

**Must:** Used to state a requirement.

**Nonconformity:** An event that occurs when a specified requirement is not met or results from an undesirable situation or defect. This covers departure from a procedure, standard or requirement, or the absence of dependability. This typically arises from the inability to meet documented procedures, expectations or specifications.

**Operational qualification (OQ):** OQ is the documented collection of activities necessary to demonstrate that an equipment or instrument will function according to its operational specification testing in the selected environment. OQ demonstrates fitness for the selected use and demonstrates user requirement specifications.

**Packaging material:** Container and/or closure for components, in-process material and dietary supplements.

**Performance qualification (PQ):** PQ is the documented collection of activities necessary to demonstrate that an equipment or instrument consistently performs according to the specifications defined by the user, and is appropriate for the intended use. PQ verifies the fitness for purpose of the equipment or instrument under actual conditions of use.

**Pest:** Any objectionable insect or other animal including, but not limited to, birds, rodents, flies, mites, and larvae.

**Physical plant:** All or any part of a building or facility used for or in connection with manufacturing, packaging, labeling, or holding of a dietary supplement.

**Preventive action:** An action taken to eliminate the cause of potential nonconformities or other undesirable situations in order to prevent occurrence, and continuously improve an existing system or process.

**Preventive controls qualified individual (PCQI):** A qualified individual who has successfully completed training in the development and application of risk-based preventive controls at least equivalent to that received under a standardized curriculum recognized as adequate by FDA or is otherwise qualified through job experience to develop and apply a food safety system.

**Procedure:** A documented description of the operations to be performed, the precautions to be taken, and measures to be applied directly or indirectly related to the manufacture of a dietary supplement.

**Process evaluation:** A set of tests performed on a process intended to evaluate its capacity to consistently produce the results that it is intended for.

**Product complaint:** Any communication that contains any allegation, written, electronic, or oral, expressing concern, for any reason, with the quality of a dietary supplement, that could be related to current manufacturing practice.

**Purity:** The identity and amount of a substance that is the intended substance, typically expressed in units of percentage, and determined using tests for assay or content.

**Qualification:** Action of proving and documenting that equipment or ancillary systems are properly, work correctly, and actually lead to the expected results. Qualification is part of validation, but the individual qualification steps alone do not constitute process validation.

**Quality:** Means that the components, in-process materials, packaging materials, labeling, and dietary supplements meet established specifications for identity, purity, strength and composition, and limits on contaminants, and that the dietary supplement has been manufactured, packaged, labeled, and held under conditions to prevent adulteration.

**Quality assurance:** The sum total of the organized arrangements made with the goal of ensuring that all dietary supplements are of the quality required for their intended use and that quality systems are maintained.

**Quality assurance personnel (or unit):** Any person, persons or group, within or outside of the firm who is designated by the firm to be responsible for the duties relating to quality assurance.

**Quality control:** A planned and systematic operation or procedure necessary to ensure the quality of the dietary supplement, by checking or testing that specifications are met.

**Quality control personnel (or unit):** Any person, persons or group, within or outside of the firm, who is designated by the firm to be responsible for the duties relating to quality control operations.

**Quality unit (or personnel):** An organizational unit independent of production, which fulfills both quality assurance and quality control responsibilities, which can be in the form of separate quality assurance and quality control units or a single individual or group, depending upon the size and structure of the organization.

**Quarantine:** The status of materials isolated physically or by other effective means pending a decision on their subsequent disposition decision.

**Records:** Records are documents stating results achieved or providing evidence of activities performed, e.g., training records, executed batch production records, executed batch packaging records, validation reports, laboratory test results forms, laboratory notebooks, equipment logbooks, memos, and emails.

**Reduced testing (**or **sampling):** A reduced level of testing (or sampling) for a particular specified parameter(s) based upon one or more of the following: statistical analysis of an adequate quantity of historical test data; statistical confidence in the capability of the manufacturing process as determined by suitable verification; or ongoing monitoring of the process using recognized statistical process control (SPC) techniques.

**Reference standard, primary:** A substance that has been shown by an extensive set of analytical tests to be authentic material that should be of high purity. This standard is obtained from an officially recognized source, i.e., USP RS.

**Reference standard, secondary:** A substance of established quality and purity, as shown by comparison to a primary reference standard, used as a reference standard for routine laboratory analysis.

**Remedial (short term) action:** Action taken to provide temporary control over a situation or condition until permanent corrective actions are implemented (e.g., issuance of a temporary procedure, segregation of material).

**Representative sample:** A sample that consists of an adequate number of units that are drawn based on rational criteria, such as random sampling, and that is intended to ensure that the sample accurately portrays the material being sampled.

**Reprocessing:** Introducing clean and uncontaminated components or dietary supplements, back into the manufacturing process and repeating a step or other appropriate physical manipulation step (e.g., milling, packaging) that are part of the established manufacturing process. Continuation of a manufacturing process step after an in-process control test has shown that the step is incomplete is considered to be part of the normal manufacturing process and not reprocessing.

**Responsible party:** The person who submits the registration under section 415(a) of the FD&C Act (21 USC 350(d)) for a food facility that is required to register under section 415(a), at which such article of food is manufactured, processed, packed, or held. Persons who are required to submit a facility registration under section 415 of the FD&C Act are the owner, operator, or agent in charge of a domestic or foreign facility engaged in manufacturing, processing, packing, or holding food for consumption in the United States. “Person” is defined in section 201(e) of the FD&C Act (21 USC 321(e)) as including individuals, partnerships, corporations, and associations.

**Reworking:** Subjecting in-process material or dietary supplements that do not conform to standards or specifications and that have been removed from processing for reasons other than unsanitary conditions, to one or more processing steps that are different from the established manufacturing process to obtain acceptable quality in-process material or dietary supplement.

**Reserve sample:** A representative sample of an article that is held for a designated period of time.

**Risk:** The combination of the probability of occurrence of harm and the severity of that harm.

**Risk assessment:** A systematic process of organizing information to support a risk decision to be made within a risk management process. It consists of the identification of hazards and the analysis and evaluation of risks associated with exposure to those hazards.

**Risk control:** Actions implementing risk management decisions to reduce risk and/or accept risks in order to reduce risk to an acceptable level.

**Risk management (quality):** A systematic process for the assessment, control, communication, and review of risks to the quality of the dietary supplement throughout the dietary supplement's shelf life. Risk management tools that might be used in quality risk management include facilitation methods (e.g., flowcharts, check sheets, process mapping, cause and effect diagrams); failure mode effects analysis (FMEA); failure mode, effects, and criticality analysis (FMECA); fault tree analysis (FTA); hazard analysis and critical control points (HACCP); and supporting statistical tools (e.g., control charts, histograms, pareto charts, process capability analysis, design of experiments).

**Root cause:** Any cause that is acted upon by a solution such that the problem does not recur.

**Sanitize:** To adequately treat cleaned equipment, containers, utensils, or other cleaned contact surface by a process that is effective in destroying vegetative cells of microorganisms of public health significance, and in substantially reducing numbers of other microorganisms, but without adversely affecting the product or its safety for the consumer.

**Serious adverse event:** An event that results in death, a life-threatening experience, inpatient hospitalization, a persistent or significant disability or incapacity, or a congenital anomaly or birth defect; or requires based on a reasonable medical judgment, a medical or surgical intervention to prevent an outcome previously described.

**Serious adverse event report:** A report that must be submitted to the FDA using the MedWatch form when a manufacturer, packer, or distributor of a dietary supplement receives any report of a serious adverse event associated with the use of the dietary supplement in the United States. (See §761(a)(3) and (b)(1) of the FD&C Act [21 USC §379aa–1(a)(3) and (b)(1)]).

**Shelf-life (use by** or **expiry) date:** The date before which the dietary supplement is ensured to meet applicable specifications of identity, strength, quality, and purity, when stored under labeled conditions.

**Should:** Used to indicate a recommendation.

**Signature (signed):** The record of the individual who performed a particular action or review. This record can be initials, full handwritten signature, or authenticated and secure electronic signature.

**Specification:** A list of tests, references to test procedures, and appropriate acceptance criteria for the tests described. It establishes the set of criteria to which a material should conform to be considered acceptable for its intended use. "Conformance to specifications" means that the component, in-process material, and/or dietary supplement, when tested according to the listed test procedures, will meet the listed acceptance criteria. Specifications are critical quality standards that are proposed, justified and approved by the manufacturer. Material specifications include test specifications for identity, purity, strength, limits on contaminants, and/or performance that define a standard of quality for the material.

**Strength:** The concentration or amount of a dietary ingredient per unit serving of a dietary supplement. Strength only applies to a dietary supplement.

**Utensil:** A simple tool or device serving a useful purpose.

**Utility system (utility):** A useful system and source of material such as water, steam, gases, compressed air, heating, ventilation, and air conditioning (HVAC).

**Validation:** A documented program that provides a high degree of assurance that a specific process, method, or system will consistently produce a result meeting predetermined acceptance criteria.

**Validation protocol:** A written plan stating how validation will be conducted and defining acceptance criteria. For example, the protocol for a manufacturing process identifies manufacturing equipment, critical process parameters/operating ranges, product characteristics, sampling, test data to be collected, number of validation runs, and acceptable test results.

**Water activity ($a_w$):** A measure of the free moisture in a component or dietary supplement and is the quotient of the water vapor pressure of the substance divided by the vapor pressure of pure water at the same temperature.

**Yield, actual:** The quantity of material or percentage of theoretical yield that is actually produced at any appropriate step of production, or packaging and labeling of a particular dietary supplement.

**Yield, expected:** The quantity of material or the percentage of theoretical yield anticipated at any appropriate phase of production, or packaging and labeling, based on previous laboratory, pilot scale, or manufacturing data.

**Yield, theoretical:** The quantity of material that would be produced at any appropriate step of manufacture or packaging and labeling of a particular dietary supplement, based on the quantity of components, packaging labeling to be used, in the absence of any loss or error in actual production.

# ALCOHOLOMETRIC TABLE

***Change to read:***

## ▲INTRODUCTION

Ethanol ($C_2H_5OH$) content of water mixtures is based on specific gravity (also known as relative density) and is calculated using the *Alcoholometric Table*. The information in the table is based on a method and specifications that were developed from regulations from the Bureau of Alcohol, Tobacco, Firearms and Explosives (ATF). The table is based on the measurement of alcohol at 15.56° (60° F) as standard temperature for alcohol determination. When alcohol and water are mixed together, the volume of the mixture is invariably less than the sum of the initial volumes, and the degree of contraction varies with the proportion of alcohol present. Therefore, the specific gravities of alcohol and water mixtures in all proportions and at various temperatures have been established experimentally.

Relevant values have been reproduced in the *Alcoholometric Table* to help stakeholders perform the *Specific Gravity* test in air at 25°, if a stable 15.56° is not achievable. The table includes the specific gravities and the corresponding percentages of alcohol by weight and by volume (v/v) for the aqueous alcoholic mixtures most commonly used in compendial applications. Comprehensive values can be found in other sources (*1*). The specific gravities are reduced to air values and represent the ratio of the weight of a given volume of spirit to the weight of the same volume of water at 15.56°, under the same atmospheric conditions.

Therefore, the objective is for the user to determine the specific gravity of a sample mixture of alcohol and water in air at 25°. Then, the user locates the specific gravity value in either column *1* or *5*, depending on whether the percentage of ethanol is required to be known v/v (columns *3* or *8*) or by weight (columns *4* or *7*). For example, a specific gravity value of 0.9480 in column *5* corresponds to a solution that contains 33% alcohol by weight or 39.59% alcohol v/v. Similarly, a specific gravity value of 0.8092 in column *1* corresponds to a solution that contains 95% alcohol ▲v/v▲ (ERR 1-Dec-2021) or 92.42% alcohol ▲by weight.▲ (ERR 1-Dec-2021) If the user is able to determine the specific gravity of a sample mixture of alcohol and water in air at 15.56°, then the specific gravity value in either column *2* or *6* can be used to find the respective percentage of ethanol v/v (columns *3* or *8*) or by weight (columns *4* or *7*). If the measured specific gravity falls between two values in the table, a simple linear interpolation or a spline fit can be applied to determine the percentage of ethanol.

This Alcoholometric Table is only valid for ethanol–water mixtures. It does not apply if other components are added. For example, this table is not applicable for hand sanitizer solutions.

The following table is based on data appearing in the *Bulletin of the Bureau of Standards*, a publication of the National Bureau of Standards (now the National Institute of Standards and Technology) (*2*).▲ (USP 1-Dec-2021)

# Articles of Incorporation

In May of 1900, the USP Board of Trustees was directed by the Convention to incorporate the USP organization under the laws of the District of Columbia. Because the District of Columbia required that the majority of officers subscribing to the Certificate of Incorporation be residents, the filing was slightly delayed in order to appoint appropriate representatives. Nevertheless, the articles of incorporation were prepared, appropriately signed, and finally filed on July 11th of that year. The original certificate reads as follows:

# Certification of Incorporation

Official

This is to certify that we, whose names are hereunto subscribed, citizens of the United States, of full age, and a majority citizens of the District of Columbia, do associate ourselves together pursuant to the provisions of sections 545–552 inclusive of the Revised Statutes of the United States relating to the District of Columbia and of the Act of Congress to amend the same, approved the twenty-third day of April 1884, under the corporate name of The United States Pharmacopoeial Convention.

This Association is organized for a period of nine hundred and ninety-nine years. The particular objects and business of this Association are the encouragement and promotion of the science and art of medicine and pharmacy by selecting by research and experiment and other proper methods and by naming such materials as may be properly used as medicines and drugs with formulas for their preparation; by establishing one uniform standard and guide for the use of those engaged in the practice of medicine and pharmacy in the United States whereby the identity, strength, and purity of all such medicines and drugs may be accurately determined, and for other like and similar purposes; and by printing and distributing at suitable intervals such formulas and the results of such and similar selections, names and determinations among the members of this Association, pharmacists, and physicians generally in the United States and others interested in pharmacy and medicine.

The management and control of the affairs, funds, and property of this Association for the first year of its existence shall be vested in a Board of Trustees consisting of the seven following persons:

Albert E. Ebert
Samuel A.D. Sheppard
William S. Thompson
Charles E. Dohme
George W. Sloan
Horatio C. Wood
Charles Rice

In testimony whereof we have hereunto set our hands and affixed our seals this seventh day of July, 1900.

Identification

- ⟨11⟩ *USP Reference Standards*
- ⟨89⟩ *Enzymes Used as Ancillary Materials in Pharmaceutical Manufacturing*
- ⟨89.1⟩ *Collagenase I*
- ⟨89.2⟩ *Collagenase II*
- ⟨121⟩ *Insulin Assays*
- ⟨121.1⟩ *Physicochemical Analytical Procedures for Insulins*
- ⟨123⟩ *Glucagon Bioidentity Tests*
- ⟨126⟩ *Somatropin Bioidentity Test*
- ⟨191⟩ *Identification Tests—General*
- ⟨197⟩ *Spectroscopic Identification Tests*
- ⟨621⟩ *Chromatography*
- ⟨736⟩ *Mass Spectrometry*
- ⟨761⟩ *Nuclear Magnetic Resonance Spectroscopy*
- ⟨821⟩ *Radioactivity*
- ⟨852⟩ *Atomic Absorption Spectroscopy*
- ⟨853⟩ *Fluorescence Spectroscopy*
- ⟨854⟩ *Mid-Infrared Spectroscopy*
- ⟨857⟩ *Ultraviolet-Visible Spectroscopy*
- ⟨1025⟩ *Pancreatin*
- ⟨1030⟩ *Biological Assay Chapters—Overview and Glossary*
- ⟨1032⟩ *Design and Development of Biological Assays*
- ⟨1033⟩ *Biological Assay Validation*
- ⟨1034⟩ *Analysis of Biological Assays*
- ⟨1052⟩ *Biotechnology Derived Articles—Amino Acid Analysis*
- ⟨1053⟩ *Capillary Electrophoresis*
- ⟨1054⟩ *Biotechnology Derived Articles—Isoelectric Focusing*
- ⟨1055⟩ *Biotechnology Derived Articles—Peptide Mapping*
- ⟨1056⟩ *Biotechnology Derived Articles—Polyacrylamide Gel Electrophoresis*
- ⟨1057⟩ *Biotechnology Derived Articles—Total Protein Assay*
- ⟨1102⟩ *Immunological Test Methods—General Considerations*
- ⟨1103⟩ *Immunological Test Methods—Enzyme-Linked Immunosorbent Assay (ELISA)*
- ⟨1104⟩ *Immunological Test Methods—Immunoblot Analysis*
- ⟨1736⟩ *Applications of Mass Spectrometry*
- ⟨1761⟩ *Applications of Nuclear Magnetic Resonance Spectroscopy*
- ⟨1776⟩ *Image Analysis of Pharmaceutical Systems*
- ⟨1852⟩ *Atomic Absorption Spectroscopy—Theory and Practice*
- ⟨1853⟩ *Fluorescence Spectroscopy—Theory and Practice*
- ⟨1854⟩ *Mid-Infrared Spectroscopy—Theory and Practice*
- ⟨1856⟩ *Near-Infrared Spectroscopy—Theory and Practice*
- ⟨1857⟩ *Ultraviolet-Visible Spectroscopy—Theory and Practice*

Characterization

- ⟨89⟩ *Enzymes Used as Ancillary Materials in Pharmaceutical Manufacturing*
- ⟨89.1⟩ *Collagenase I*
- ⟨89.2⟩ *Collagenase II*
- ⟨111⟩ *Design and Analysis of Biological Assays*
- ⟨121.1⟩ *Physicochemical Analytical Procedures for Insulins*
- ⟨124⟩ *Erythropoietin Bioassays*
- ⟨129⟩ *Analytical Procedures for Recombinant Therapeutic Monoclonal Antibodies*
- ⟨208⟩ *Anti-factor Xa and Anti-factor IIa Assays for Unfractionated and Low Molecular Weight Heparins*
- ⟨209⟩ *Low Molecular Weight Heparin Molecular Weight Determinations*
- ⟨212⟩ *Oligosaccharide Analysis*
- ⟨432⟩ *Determination of Zeta Potential by Electrophoretic Light Scattering*
- ⟨507⟩ *Protein Determination Procedures*
- ⟨509⟩ *Residual DNA Testing*
- ⟨621⟩ *Chromatography*

# Chapter Guide: Biotechnology-Derived Drug Substances

To return to the Chapter Charts main list, *click here*.

Description

- ⟨7⟩ *Labeling*
- ⟨631⟩ *Color and Achromicity*
- ⟨695⟩ *Crystallinity*
- ⟨1025⟩ *Pancreatin*
- ⟨1041⟩ *Biologics*
- ⟨1121⟩ *Nomenclature*

Identification

- ⟨11⟩ *USP Reference Standards*
- ⟨121⟩ *Insulin Assays*
- ⟨121.1⟩ *Physicochemical Analytical Procedures for Insulins*
- ⟨126⟩ *Somatropin Bioidentity Test*
- ⟨191⟩ *Identification Tests—General*
- ⟨197⟩ *Spectroscopic Identification Tests*
- ⟨209⟩ *Low Molecular Weight Heparin Molecular Weight Determinations*
- ⟨621⟩ *Chromatography*
- ⟨736⟩ *Mass Spectrometry*
- ⟨761⟩ *Nuclear Magnetic Resonance Spectroscopy*
- ⟨852⟩ *Atomic Absorption Spectroscopy*
- ⟨853⟩ *Fluorescence Spectroscopy*
- ⟨854⟩ *Mid-Infrared Spectroscopy*
- ⟨856⟩ *Near-Infrared Spectroscopy*
- ⟨857⟩ *Ultraviolet-Visible Spectroscopy*
- ⟨858⟩ *Raman Spectroscopy*
- ⟨1025⟩ *Pancreatin*
- ⟨1030⟩ *Biological Assay Chapters—Overview and Glossary*
- ⟨1032⟩ *Design and Development of Biological Assays*
- ⟨1033⟩ *Biological Assay Validation*
- ⟨1034⟩ *Analysis of Biological Assays*
- ⟨1052⟩ *Biotechnology-Derived Articles—Amino Acid Analysis*
- ⟨1053⟩ *Capillary Electrophoresis*
- ⟨1054⟩ *Biotechnology-Derived Articles—Isoelectric Focusing*
- ⟨1055⟩ *Biotechnology-Derived Articles—Peptide Mapping*
- ⟨1056⟩ *Biotechnology-Derived Articles—Polyacrylamide Gel Electrophoresis*
- ⟨1057⟩ *Biotechnology-Derived Articles—Total Protein Assay*
- ⟨1102⟩ *Immunological Test Methods—General Considerations*
- ⟨1103⟩ *Immunological Test Methods—Enzyme-Linked Immunosorbent Assay (ELISA)*

# DESCRIPTION AND RELATIVE SOLUBILITY

## Description and Relative Solubility of USP and NF Articles

The "description" and "solubility" statements pertaining to an article (formerly included in the individual monograph) are general in nature. The information is provided for those who use, prepare, and dispense drugs, solely to indicate descriptive and solubility properties of an article complying with monograph standards. The properties are not in themselves standards or tests for purity even though they may indirectly assist in the preliminary evaluation of the integrity of an article.

## Taste and Odor

Organoleptic characteristics are indicated in many instances because they may be useful and descriptive properties of substances. However, they are not meant to be applied as tests for identifying materials.

The inclusion of odor or taste among other descriptive properties may aid in identifying the causative agent following accidental exposure to or contact with a substance. This information is provided as a warning or to make an individual aware of sensations that may be encountered. The use of odor or taste as a test for identification or content is strongly discouraged.

The characteristic odor of a volatile substance becomes apparent immediately on opening a container of it. The odor may be agreeable (e.g., Peppermint Oil), unpleasant (e.g., Sulfur Dioxide), or potentially hazardous on prolonged exposure (e.g., Coal Tar). Moreover, an unexpected odor may be encountered if the characteristics of a substance are not known or if a container is incorrectly labeled. Consequently, containers of such substances should be opened cautiously, preferably in a well-ventilated fume hood. A characteristic taste or sensation produced in the oral cavity likewise is apparent if traces of residue materials on fingers are inadvertently brought into contact with the tongue or adjacent mucosal tissues.

## Solubility

Only where a special, quantitative solubility test is given in the individual monograph, and is designated by a test heading, is it a test for purity.

The approximate solubilities of Pharmacopeial and National Formulary substances are indicated by the descriptive terms in the accompanying table. The term "miscible" as used in this Pharmacopeia pertains to a substance that yields a homogeneous mixture when mixed in any proportion with the designated solvent.

| Descriptive Term | Parts of Solvent Required for 1 Part of Solute |
|---|---|
| Very soluble | Less than 1 |
| Freely soluble | From 1 to 10 |
| Soluble | From 10 to 30 |
| Sparingly soluble | From 30 to 100 |
| Slightly soluble | From 100 to 1000 |
| Very slightly soluble | From 1000 to 10,000 |
| Practically insoluble, or Insoluble | 10,000 and over |

Soluble Pharmacopeial and National Formulary articles, when brought into solution, may show traces of physical impurities, such as minute fragments of filter paper, fibers, and other particulate matter, unless limited or excluded by definite tests or other specifications in the individual monographs.

**Abacavir Sulfate:** White to off-white powder. Soluble in water, in ethyl acetate, in absolute alcohol, and in methanol.

**Abiraterone Acetate:** White to off-white powder. Freely soluble in methylene chloride, in tetrahydrofuran, and in toluene; soluble in methanol, in ethanol, in ethyl acetate, in isobutyl methyl ketone, in *N,N*-dimethylformamide, and in acetone; sparingly soluble in acetonitrile and in dimethyl sulfoxide; slightly soluble in hexane; very slightly soluble in 0.1 N hydrochloric acid; practically insoluble in aqueous media over a wide range of pH values.

**Acacia:** Is practically odorless and produces a mucilaginous sensation on the tongue. Insoluble in alcohol. Optical rotation varies depending on the source of Acacia. For example, specific rotation values, calculated on the anhydrous basis and determined on a 1.0% (w/v) solution, usually are between −25° and −35° for *Acacia senegal* and between +35° and +60° for *Acacia seyal*. *NF category:* Emulsifying agent; suspending and/or viscosity-increasing agent; wet binder.

**Acamprosate Calcium:** A white or almost-white powder. Freely soluble in water; practically insoluble in alcohol and in methylene chloride.

**Acebutolol Hydrochloride:** White or almost white, crystalline powder. Soluble in alcohol and in water; very slightly soluble in acetone and in methylene chloride; practically insoluble in ether. Melts at about 141° to 144°.

**Acesulfame Potassium:** A white, crystalline powder or colorless crystals. Soluble in water; very slightly soluble in acetone and in alcohol. *NF category:* Sweetening agent.

**Acetaminophen:** White, odorless, crystalline powder, having a slightly bitter taste. Freely soluble in alcohol; soluble in boiling water and in 1 N sodium hydroxide.

**Acetazolamide:** White to faintly yellowish-white, crystalline, odorless powder. Sparingly soluble in practically boiling water; slightly soluble in alcohol; very slightly soluble in water.

**Acetic Acid:** Clear, colorless liquid, having a strong, characteristic odor, and a sharply acid taste. Specific gravity is about 1.045. Miscible with water, with alcohol, and with glycerin. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Glacial Acetic Acid:** Clear, colorless liquid, having a pungent, characteristic odor and, when well diluted with water, an acid taste. Boils at about 118°. Specific gravity is about 1.05. Miscible with water, with alcohol, and with glycerin. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Acetohydroxamic Acid:** White, slightly hygroscopic, crystalline powder. Melts, after drying at about 80° for 2 to 4 hours, at about 88°. Freely soluble in water and in alcohol; very slightly soluble in chloroform.

**Acetone:** Transparent, colorless, mobile, volatile liquid, having a characteristic odor. A solution (1 in 2) is neutral to litmus. Miscible with water, with alcohol, with ether, with chloroform, and with most volatile oils. *NF category:* Solvent.

**Acetylcholine Chloride:** White or off-white crystals or crystalline powder. Very soluble in water; freely soluble in alcohol; insoluble in ether. Is decomposed by hot water and by alkalies.

**Acetylcysteine:** White, crystalline powder, having a slight acetic odor. Freely soluble in water and in alcohol; practically insoluble in chloroform and in ether.

**Acetyltributyl Citrate:** Clear, practically colorless, oily liquid. Freely soluble in alcohol, in isopropyl alcohol, in acetone, and in toluene; insoluble in water. *NF category:* Plasticizer.

**Acetyltriethyl Citrate:** Clear, practically colorless, oily liquid. Freely soluble in alcohol, in isopropyl alcohol, in acetone, and in toluene; insoluble in water. *NF category:* Plasticizer.

**Acitretin:** Yellow or greenish, crystalline powder. Sparingly soluble in tetrahydrofuran; slightly soluble in acetone and in alcohol; very slightly soluble in cyclohexane; practically insoluble in water.

**Acyclovir:** White to off-white, crystalline powder. Melts at temperatures higher than 250°, with decomposition. Soluble in diluted hydrochloric acid; slightly soluble in water; insoluble in alcohol.

**Adapalene:** White or almost white powder. Soluble in tetrahydrofuran; sparingly soluble in ethanol; practically insoluble in water.

**Ademetionine Disulfate Tosylate:** White powder. Freely soluble in water.

**Adenine:** White crystals or crystalline powder. Is odorless and tasteless. Sparingly soluble in boiling water; slightly soluble in alcohol; very slightly soluble in water; practically insoluble in ether and in chloroform.

**Adenosine:** White, odorless, crystalline powder. Slightly soluble in water; practically insoluble in alcohol. Melts at about 235°.

**Adipic Acid:** A white, crystalline powder. Freely soluble in alcohol and in methanol; soluble in boiling water and in acetone; slightly soluble in water. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent); flavors and fragrance.

**Agar:** Odorless or has a slight odor, and produces a mucilaginous sensation on the tongue. Soluble in boiling water; insoluble in cold water. *NF category:* Suspending and/or viscosity-increasing agent; emulsifying agent; suppository base; wet binder.

**Alamic Acid:** *NF category:* Suspending and/or viscosity-increasing agent.

**Alanine:** White, odorless crystals or crystalline powder, having a slightly sweet taste. Freely soluble in water; slightly soluble in 80% alcohol; insoluble in ether.

**Albendazole:** White to faintly yellowish powder. Freely soluble in anhydrous formic acid; very slightly soluble in ether and in methylene chloride; practically insoluble in alcohol and in water.

**Albumin Human:** Practically odorless, moderately viscous, clear, brownish fluid.

**rAlbumin Human:** Clear, slightly viscous, and colorless to yellow amber in color. *NF category:* Vehicle (sterile).

**Albuterol:** White, crystalline powder. Soluble in alcohol; sparingly soluble in water. Melts at about 156°.

**Albuterol Sulfate:** White or practically white powder. Freely soluble in water; slightly soluble in alcohol, in chloroform, and in ether.

**Alcohol:** Clear, colorless, mobile, volatile liquid. Has a characteristic odor and produces a burning sensation on the tongue. Is readily volatilized even at low temperatures, and boils at about 78°. Is flammable. Miscible with water and with practically all organic solvents. *NF category:* Solvent; antimicrobial preservative.

**Dehydrated Alcohol:** Clear, colorless, mobile, volatile liquid. Has a characteristic odor and produces a burning sensation on the tongue. Is readily volatilized even at low temperatures, and boils at about 78°. Is flammable. Miscible with water and with practically all organic solvents.

**Diluted Alcohol:** Clear, colorless, mobile liquid, having a characteristic odor and producing a burning sensation on the tongue. *NF category:* Solvent.

**Rubbing Alcohol:** Transparent, colorless, or colored as desired, mobile, volatile liquid. Has an extremely bitter taste and, in the absence of added odorous constituents, a characteristic odor. Is flammable.

**Alendronate Sodium:** White, free-flowing powder. Soluble in water; very slightly soluble in dimethyl sulfoxide, in methyl alcohol, and in propylene glycol; practically insoluble in acetone, in acetonitrile, in alcohol, in chloroform, and in isopropyl alcohol.

**Alfadex:** White or almost white, amorphous or crystalline powder. Freely soluble in water and in propylene glycol; practically insoluble in ethanol and in methylene chloride. *NF category:* Chelating and/or complexing agent.

**Alfentanil Hydrochloride:** White to almost white powder. Freely soluble in methanol, in alcohol, and in chloroform; soluble in water; sparingly soluble in acetone. Melting point range, crystals from acetone: 136°–143° (anhydrous) and reported as crystals from aqueous hydrochloric acid: 116°–126° (monohydrate).

**Alfentanil Injection:** Clear, colorless solution.

**Alfuzosin Hydrochloride:** White to almost white powder, slightly hygroscopic. Freely soluble in water; sparingly soluble in alcohol; practically insoluble in methylene chloride.

**Alginic Acid:** White to yellowish white, fibrous powder. Is odorless, or practically odorless, and is tasteless. Soluble in alkaline solutions; insoluble in water and in organic solvents. *NF category:* Suspending and/or viscosity-increasing agent; wet binder; disintegrant; film-forming agent; release-modifying agent.

**Alkyl (C12-15) Benzoate:** Clear, practically colorless, oily liquid. Soluble in acetone, in alcohol, in isopropyl alcohol, in ethyl acetate, in isopropyl myristate, in isopropyl palmitate, in lanolin, in mineral oil, in vegetable oils, and in volatile silicones; insoluble in water, in glycerin, and in propylene glycol. *NF category:* Vehicle (oleaginous); emollient.

**Allantoin:** White, crystalline powder. Slightly soluble in water; very slightly soluble in alcohol. Melts at about 225°, with decomposition.

**Allopurinol:** Fluffy white to off-white powder, having only a slight odor. Soluble in solutions of potassium and sodium hydroxides; very slightly soluble in water and in alcohol; practically insoluble in chloroform and in ether.

**Allyl Isothiocyanate:** Colorless to pale yellow, very refractive, liquid. Pungent irritating odor, acrid taste. [**Caution**—*Lachrymator.*] Miscible with alcohol, with carbon disulfide, and with ether. Slightly soluble in water.

**Almond Oil:** Clear, pale straw-colored or colorless, oily liquid, having a bland taste. Remains clear at –10°, and does not congeal until cooled to almost –20°. Slightly soluble in alcohol. Miscible with ether, with chloroform, with benzene, and with solvent hexane. *NF category:* Flavors and fragrance; vehicle (oleaginous); emollient; solvent.

**Almotriptan Malate:** White to slightly yellow, crystalline powder. Soluble in water; slightly soluble in methanol and in *N*,*N*-dimethylformamide; very slightly soluble in acetone, in acetonitrile, in ethanol, in ethyl acetate, in propanol, in tetrahydrofuran, and in toluene; practically insoluble in chloroform and in methylene chloride.

**Aloe:** Has a characteristic, somewhat sour and disagreeable, odor.

**Alosetron Hydrochloride:** White to beige solid. Very soluble in water and in 0.1 M hydrochloric acid; freely soluble in pH 6 phosphate buffer; soluble in pH 8 phosphate buffer; sparingly soluble in methanol.

**Alprazolam:** A white to off-white, crystalline powder. Melts at about 225°. Freely soluble in chloroform; soluble in alcohol; sparingly soluble in acetone; slightly soluble in ethyl acetate; insoluble in water.

**Alprostadil:** A white to off-white, crystalline powder. Melts at about 110°. Freely soluble in alcohol; soluble in water and

Official

https://pharmacopeia.cn/

in acetone; slightly soluble in ethyl acetate; very slightly soluble in chloroform and in ether.

**Altretamine:** White, crystalline powder. Soluble in chloroform; insoluble in water.

**Ammonium Alum:** Large, colorless crystals, crystalline fragments, or white powder. Is odorless, and has a sweetish, strongly astringent taste. Its solutions are acid to litmus. Very soluble in boiling water; freely soluble in water and in glycerin; insoluble in alcohol.

**Potassium Alum:** Large, colorless crystals, crystalline fragments, or white powder. Is odorless, and has a sweetish, strongly astringent taste. Its solutions are acid to litmus. Very soluble in boiling water; freely soluble in water and in glycerin; insoluble in alcohol.

**Aluminum Acetate Topical Solution:** Clear, colorless liquid having a faint odor of acetic acid, and a sweetish, astringent taste. Specific gravity is about 1.02.

**Aluminum Chloride:** White, or yellowish-white, deliquescent, crystalline powder. Is practically odorless, and has a sweet, very astringent taste. Its solutions are acid to litmus. Very soluble in water; freely soluble in alcohol; soluble in glycerin.

**Aluminum Hydroxide Gel:** White, viscous suspension, from which small amounts of clear liquid may separate on standing.

**Dried Aluminum Hydroxide Gel:** White, odorless, tasteless, amorphous powder. Soluble in dilute mineral acids and in solutions of fixed alkali hydroxides; insoluble in water and in alcohol.

**Aluminum Monostearate:** Fine, white to yellowish-white, bulky powder, having a faint, characteristic odor. Insoluble in water, in alcohol, and in ether. *NF category:* Suspending and/or viscosity-increasing agent; emollient.

**Aluminum Oxide:** Occurs as a white or almost white, amorphous powder. It is very slightly soluble in dilute mineral acids and in solutions of alkali hydroxides. It is practically insoluble in water. *NF category:* Coloring agent.

**Aluminum Phosphate Gel:** White, viscous suspension from which small amounts of water separate on standing.

**Aluminum Subacetate Topical Solution:** Clear, colorless or faintly yellow liquid, having an odor of acetic acid and an acid reaction to litmus. Gradually becomes turbid on standing, through separation of a more basic salt.

**Aluminum Sulfate:** White, crystalline powder, shining plates, or crystalline fragments. Is stable in air. Is odorless, and has a sweet taste, becoming mildly astringent. Freely soluble in water; insoluble in alcohol.

**Amantadine Hydrochloride:** White or practically white, crystalline powder, having a bitter taste. Freely soluble in water; soluble in alcohol and in chloroform.

**Amifostine:** White, crystalline powder. Freely soluble in water.

**Amikacin:** White, crystalline powder. Sparingly soluble in water.

**Amikacin Sulfate:** White, crystalline powder. Freely soluble in water.

**Amiloride Hydrochloride:** Yellow to greenish-yellow, odorless or practically odorless powder. Freely soluble in dimethyl sulfoxide; sparingly soluble in methanol; slightly soluble in water; insoluble in ether, in ethyl acetate, in acetone, and in chloroform.

**Amino Methacrylate Copolymer:** Colorless to yellowish granules or white powder. Soluble in acetone, in isopropyl alcohol, and in diluted acids; practically insoluble in water. The solutions are clear to slightly cloudy. *NF category*: Coating agent; polymer membrane; wet binder; diluent; film-forming agent.

**Aminobenzoate Potassium:** White, crystalline powder. The pH of a 1 in 100 solution in water is about 7. Very soluble in water; soluble in alcohol; practically insoluble in ether.

**Aminobenzoic Acid:** White or slightly yellow, odorless crystals or crystalline powder. Discolors on exposure to air or light. Freely soluble in alcohol and in solutions of alkali hydroxides and carbonates; sparingly soluble in ether; slightly soluble in water and in chloroform. *NF category:* Free radical scavenger.

**Aminocaproic Acid:** Fine, white, crystalline powder. Is odorless, or practically odorless. Its solutions are neutral to litmus. Melts at about 205°. Freely soluble in water, in acids, and in alkalies; slightly soluble in methanol and in alcohol; practically insoluble in chloroform and in ether.

**Aminohippuric Acid:** White, crystalline powder. Discolors on exposure to light. Melts at about 195°, with decomposition. Freely soluble in alkaline solutions, with some decomposition, and in diluted hydrochloric acid; sparingly soluble in water and in alcohol; very slightly soluble in benzene, in carbon tetrachloride, in chloroform, and in ether.

**Aminolevulinic Acid Hydrochloride:** White to off-white, odorless, crystalline solid. Very soluble in water; slightly soluble in methanol and in ethanol; practically insoluble in chloroform, in hexane, and in mineral oil.

**Aminophylline:** White or slightly yellowish granules or powder, having a slight ammoniacal odor and a bitter taste. Upon exposure to air, it gradually loses methamphetamine and absorbs carbon dioxide with the liberation of free theophylline. Its solutions are alkaline to litmus. One g dissolves in 25 mL of water to give a clear solution; 1 g dissolved in 5 mL of water crystallizes upon standing, but redissolves when a small amount of ethylenediamine is added. Insoluble in alcohol and in ether.

**Aminophylline Tablets:** May have a faint ammoniacal odor.

**Aminosalicylic Acid:** White or practically white, bulky powder, that darkens on exposure to light and air. Is odorless, or has a slight acetous odor. Soluble in alcohol; slightly soluble in water and in ether; practically insoluble in benzene.

**Amiodarone Hydrochloride:** White or almost white, fine, crystalline powder. Freely soluble in methylene chloride; soluble in methanol; sparingly soluble in alcohol; very slightly soluble in water.

**Amitriptyline Hydrochloride:** White or practically white, odorless or practically odorless, crystalline powder or small crystals. Freely soluble in water, in alcohol, in chloroform, and in methanol; insoluble in ether.

**Amlodipine Besylate:** A white or almost white powder. Freely soluble in methanol; sparingly soluble in alcohol; slightly soluble in 2-propanol and in water.

**Strong Ammonia Solution:** Clear, colorless liquid, having an exceedingly pungent, characteristic odor. Specific gravity is about 0.90. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Aromatic Ammonia Spirit:** Practically colorless liquid when recently prepared, but gradually acquiring a yellow color on standing. Has the taste of ammonia, has an aromatic and pungent odor, and is affected by light. Specific gravity is about 0.90.

**Ammonio Methacrylate Copolymer:** Colorless, clear to white-opaque granules or a white powder, both with a faint amine-like odor. Soluble to freely soluble in methanol, in alcohol, and in isopropyl alcohol, each of which contains small amounts of water; soluble to freely soluble in acetone, in ethyl acetate, and in methylene chloride. The solutions are clear to slightly cloudy. Insoluble in petroleum ether and in water. *NF category:* Coating agent; wet binder; polymer membrane; diluent; film-forming agent.

**Ammonio Methacrylate Copolymer Dispersion:** Milky-white liquids of low viscosity with a faint characteristic odor. Miscible with water in any proportion, the milky-white appearance being retained. A clear or slightly cloudy solution is obtained on mixing one part with five parts of acetone, alcohol, or isopropyl alcohol. When mixed with methanol in a ratio of 1:5, Ammonio Methacrylate Copolymer Dispersion Type A dissolves completely, and Ammonio Methacrylate Copolymer Dispersion Type B dissolves only partially. *NF category:* Coating agent; polymer membrane; wet binder; diluent; film-forming agent.

**Ammonium Carbonate:** White powder, or hard, white or translucent masses, having a strong odor of ammonia, without empyreuma, and a sharp, ammoniacal taste. Its solutions are alkaline to litmus. On exposure to air, it loses ammonia and carbon dioxide, becoming opaque, and is finally converted into friable porous lumps or a white powder of ammonium bicarbonate. Freely soluble in water, but is decomposed by hot water. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Ammonium Chloride:** Colorless crystals or white, fine or coarse, crystalline powder. Has a cool, saline taste, and is somewhat hygroscopic. Freely soluble in water and in glycerin, and even more so in boiling water; sparingly soluble in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Ammonium Glycyrrhizate:** White or yellowish-white, hygroscopic powder. It is slightly soluble in water; very slightly soluble in anhydrous ethanol; practically insoluble in acetone. It dissolves in dilute solutions of acids and of alkali hydroxides. *NF category:* Flavors and fragrance; wetting and/or solubilizing agent.

**Ammonium Molybdate:** Colorless or slightly greenish or yellowish crystals. Soluble in water; practically insoluble in alcohol.

**Ammonium Phosphate:** Colorless or white granules or powder, having a saline taste. Freely soluble in water; practically insoluble in acetone and in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Ammonium Sulfate:** Colorless or white crystals or granules that decompose at temperatures above 280°. One g is soluble in about 1.5 mL of water. It is insoluble in alcohol. The pH of a 0.1 M solution is between 4.5 and 6.0.

**Amobarbital Sodium:** White, friable, granular powder. Is odorless, has a bitter taste, and is hygroscopic. Its solutions decompose on standing, heat accelerating the decomposition. Very soluble in water; soluble in alcohol; practically insoluble in ether and in chloroform.

**Amodiaquine:** Very pale yellow to light tan-yellow, odorless powder. Sparingly soluble in 1.0 N hydrochloric acid; slightly soluble in alcohol; practically insoluble in water.

**Amodiaquine Hydrochloride:** Yellow, crystalline powder. Is odorless and has a bitter taste. Soluble in water; sparingly soluble in alcohol; very slightly soluble in benzene, in chloroform, and in ether.

**Amoxapine:** White to yellowish crystalline powder. Freely soluble in chloroform; soluble in tetrahydrofuran; sparingly soluble in methanol and in toluene; slightly soluble in acetone; practically insoluble in water.

**Amoxicillin:** White, practically odorless, crystalline powder. Slightly soluble in water and in methanol; insoluble in benzene, in carbon tetrachloride, and in chloroform.

**Amphetamine Sulfate:** White, odorless, crystalline powder, having a slightly bitter taste. Its solutions are acid to litmus, having a pH of 5 to 6. Freely soluble in water; slightly soluble in alcohol; practically insoluble in ether.

**Amphotericin B:** Yellow to orange powder; odorless or practically so. Soluble in dimethylformamide, in dimethyl sulfoxide, and in propylene glycol; slightly soluble in methanol; insoluble in water, in anhydrous alcohol, in ether, in benzene, and in toluene.

**Amphotericin B for Injection:** It yields a colloidal dispersion in water.

**Ampicillin:** White, practically odorless, crystalline powder. Slightly soluble in water and in methanol; insoluble in benzene, in carbon tetrachloride, and in chloroform.

**Ampicillin Sodium:** White to off-white, odorless or practically odorless, crystalline powder. Is hygroscopic. Very soluble in water and in isotonic sodium chloride and dextrose solutions.

**Amprolium** ($C_{14}H_{19}ClN_4 \cdot HCl$)**:** White to light yellow powder. Freely soluble in water, in methanol, in alcohol, and in dimethylformamide; sparingly soluble in dehydrated alcohol; practically insoluble in isopropyl alcohol, in butyl alcohol, and in acetone.

**Amyl Nitrite:** Clear, yellowish liquid, having a peculiar, ethereal, fruity odor. Is volatile even at low temperatures, and is flammable. Boils at about 96°. Practically insoluble in water. Miscible with alcohol and with ether.

**Amylene Hydrate:** Clear, colorless liquid, having a camphoraceous odor. Its solutions are neutral to litmus. Freely soluble in water. Miscible with alcohol, with chloroform, with ether, and with glycerin. *NF category:* Solvent.

**Anagrelide Hydrochloride:** Off-white to pale pinkish powder. Sparingly soluble in dimethylsulfoxide and in dimethylformamide; very slightly soluble in water.

**Anastrozole:** White to off-white crystalline powder. Very soluble in acetonitrile; freely soluble in methanol, in acetone, in alcohol, and in tetrahydrofuran.

**Anethole:** Colorless or faintly yellow liquid at or above 23°. Has a sweet taste and the aromatic odor of anise. Is affected by light. Freely soluble in alcohol; very slightly soluble in water. Readily miscible with ether and with chloroform. *NF category:* Flavors and fragrance.

**Anise Oil:** Clear, colorless to light yellow in the liquid state having a powerful and characteristic licorice-like scent. Congeals between 15° and 19°. Miscible with alcohol. *NF category:* Flavors and fragrance.

**Antazoline Phosphate:** White to off-white, crystalline powder, having a bitter taste. Soluble in water; sparingly soluble in methanol; practically insoluble in benzene and in ether.

**Anthralin:** Yellowish-brown, crystalline powder. Is odorless and tasteless. Soluble in chloroform, in acetone, in benzene, and in solutions of alkali hydroxides; slightly soluble in alcohol, in ether, and in glacial acetic acid; insoluble in water.

**Anticoagulant Citrate Dextrose Solution:** Clear, colorless, odorless liquid. Is dextrorotatory.

**Anticoagulant Citrate Phosphate Dextrose Solution:** Clear, colorless to slightly yellow, odorless liquid. Is dextrorotatory.

**Anticoagulant Sodium Citrate Solution:** Clear and colorless liquid.

**Antimony Potassium Tartrate:** Colorless, odorless, transparent crystals, or white powder. The crystals effloresce upon exposure to air and do not readily rehydrate even on exposure to high humidity. Its solutions are acid to litmus. Freely soluble in boiling water; soluble in water and in glycerin; insoluble in alcohol.

**Antipyrine:** Colorless crystals, or white, crystalline powder. Is odorless and has a slightly bitter taste. Its solutions are neutral to litmus. Very soluble in water; freely soluble in alcohol and in chloroform; sparingly soluble in ether.

**Apomorphine Hydrochloride:** Minute, white or grayish-white, glistening crystals or white powder. Is odorless. It gradually acquires a green color on exposure to light and air. Its solutions are neutral to litmus. Soluble in water at 80°;

sparingly soluble in water and in alcohol; very slightly soluble in chloroform and in ether.

**Apraclonidine Hydrochloride:** White to off-white, odorless to practically odorless powder. Soluble in methanol; sparingly soluble in water and in alcohol; insoluble in chloroform, in ethyl acetate, and in hexanes.

**Aprepitant:** White to off-white powder. Sparingly soluble in alcohol; slightly soluble in acetonitrile; practically insoluble in water.

**Arginine:** White, practically odorless crystals. Freely soluble in water; sparingly soluble in alcohol; insoluble in ether.

**Arginine Hydrochloride:** White crystals or crystalline powder, practically odorless. Freely soluble in water.

**Aripiprazole:** A white to off-white, crystalline powder. Freely soluble in dichloromethane; sparingly soluble in toluene; insoluble in methanol and in water.

**Aromatic Elixir:** *NF category:* Vehicle (flavored and/or sweetened).

**Articaine Hydrochloride:** White or almost white, crystalline powder. Freely soluble in water and in alcohol.

**Ascorbic Acid:** White or slightly yellow crystals or powder. On exposure to light it gradually darkens. In the dry state, is reasonably stable in air, but in solution rapidly oxidizes. Melts at about 190°. Freely soluble in water; sparingly soluble in alcohol; insoluble in chloroform, in ether, and in benzene. *NF category:* Antioxidant.

**Ascorbyl Palmitate:** White to yellowish white powder, having a characteristic odor. Soluble in alcohol; very slightly soluble in water and in vegetable oils. *NF category:* Antioxidant.

**Asparagine:** White crystals or a crystalline powder. Soluble in water; practically insoluble in alcohol and in ether. Its solutions are acid to litmus. It melts at about 234°.

**Aspartame:** White, odorless, crystalline powder, having a sweet taste. Sparingly soluble in water; slightly soluble in alcohol. Melts at about 246°. The pH of an 8 in 1000 solution is about 5. *NF category:* Sweetening agent.

**Aspartame Acesulfame:** White, odorless, crystalline powder. Slightly soluble in water and in ethanol. *NF category:* Sweetening agent.

**Aspartic Acid:** White or almost white, crystalline powder, or colorless crystals. Soluble in dilute solutions of alkali hydroxides and in dilute mineral acids; slightly soluble in water; practically insoluble in alcohol and in ether.

**Aspirin:** White crystals, commonly tabular or needle-like, or white, crystalline powder. Is odorless or has a faint odor. Is stable in dry air; in moist air it gradually hydrolyzes to salicylic and acetic acids. Freely soluble in alcohol; soluble in chloroform and in ether; sparingly soluble in absolute ether; slightly soluble in water.

**Atazanavir Sulfate:** White to pale-yellow, crystalline powder. Soluble in methanol and in ethyl alcohol; slightly soluble in water; practically insoluble in heptane.

**Atenolol:** White or practically white, odorless powder. Melting point 146°–148° (crystals from ethyl acetate). Freely soluble in methanol; sparingly soluble in alcohol; slightly soluble in water and in isopropanol.

**Atomoxetine Hydrochloride:** White to practically white solid. Sparingly soluble in water.

**Atorvastatin Calcium:** White to off-white powder. Soluble to freely soluble in methanol; slightly soluble in alcohol; insoluble to very slightly soluble in distilled water, in pH 7.4 phosphate buffer, and in acetonitrile; insoluble in aqueous solutions of pH 4 and below.

**Atovaquone:** Yellow powder. Freely soluble in *N*-methyl-2-pyrrolidone and in tetrahydrofuran; soluble in chloroform; sparingly soluble in acetone, in di- *n*-butyl adipate, in dimethyl sulfoxide, and in polyethylene glycol 400; slightly soluble in alcohol, in 1,3-butanediol, in ethyl acetate, in glycerin, in octanol, and in polyethylene glycol 200; very slightly soluble in 0.1 N sodium hydroxide; insoluble in water.

**Atracurium Besylate:** White to yellowish white powder, slightly hygroscopic. Very soluble in acetonitrile, in alcohol, and in methylene chloride; soluble in water.

**Atropine:** White crystals, usually needle-like, or white, crystalline powder. Its saturated solution is alkaline to phenolphthalein TS. Is optically inactive, but usually contains some levorotatory hyoscyamine. Freely soluble in alcohol and in chloroform; soluble in glycerin and in ether; slightly soluble in water; sparingly soluble in water at 80°.

**Atropine Sulfate:** Colorless crystals, or white, crystalline powder. Odorless; effloresces in dry air; is slowly affected by light. Very soluble in water; freely soluble in alcohol and even more so in boiling alcohol; freely soluble in glycerin.

**Activated Attapulgite:** Cream-colored, micronized, nonswelling powder, free from gritty particles. The high heat treatment used in its preparation causes it to yield only moderately viscous aqueous suspensions, its dispersion consisting mainly of particle groups. Insoluble in water. *NF category:* Suspending and/or viscosity-increasing agent.

**Colloidal Activated Attapulgite:** Cream-colored, micronized, nonswelling powder, free from gritty particles. Yields viscous aqueous suspensions, as a result of dispersion into its constituent ultimate particles. Insoluble in water. *NF category:* Suspending and/or viscosity-increasing agent.

**Aurothioglucose:** Yellow, odorless or practically odorless powder. Is stable in air. An aqueous solution is unstable on long standing. The pH of its 1 in 100 solution is about 6.3. Freely soluble in water; practically insoluble in acetone, in alcohol, in chloroform, and in ether.

**Azathioprine:** Pale yellow, odorless powder. Soluble in dilute solutions of alkali hydroxides; sparingly soluble in dilute mineral acids; very slightly soluble in alcohol and in chloroform; insoluble in water.

**Azathioprine Sodium for Injection:** Bright yellow, hygroscopic, amorphous mass or cake.

**Azelastine Hydrochloride:** White or almost white, crystalline powder. Soluble in ethanol and in methylene chloride; sparingly soluble in water.

**Azithromycin:** White or almost white powder. Freely soluble in anhydrous ethanol and in methylene chloride; practically insoluble in water.

**Aztreonam:** White, odorless, crystalline powder. Soluble in dimethylformamide and in dimethyl sulfoxide; slightly soluble in methanol; very slightly soluble in dehydrated alcohol; practically insoluble in ethyl acetate, in chloroform, and in toluene.

**Bacampicillin Hydrochloride:** White or practically white powder. Is hygroscopic. Freely soluble in alcohol and in chloroform; soluble in methylene chloride and in water; very slightly soluble in ether.

**Bacitracin:** White to pale buff powder, odorless or having a slight odor. Is hygroscopic. Its solutions deteriorate rapidly at room temperature. Is precipitated from its solutions and is inactivated by salts of many of the heavy metals. Freely soluble in water; soluble in alcohol, in methanol, and in glacial acetic acid, the solution in the organic solvents usually showing some insoluble residue; insoluble in acetone, in chloroform, and in ether.

**Bacitracin Zinc:** White to pale tan powder, odorless or having a slight odor. Is hygroscopic. Sparingly soluble in water.

**Baclofen:** White to off-white, crystalline powder. Is odorless or practically so. Slightly soluble in water; very slightly soluble in methanol; insoluble in chloroform.

**Balsalazide Disodium:** Orange to yellow powder. Freely soluble in water and in isotonic saline; sparingly soluble in

methanol and in alcohol; practically insoluble in all other organic solvents.

**Adhesive Bandage:** The compress of Adhesive Bandage is substantially free from loose threads or ravelings. The adhesive strip may be perforated, and the back may be coated with a water-repellent film.

**Gauze Bandage:** One continuous piece, tightly rolled, in various widths and lengths and substantially free from loose threads and ravelings.

**Barium Sulfate:** Fine, white, odorless, tasteless, bulky powder, free from grittiness. Practically insoluble in water, in organic solvents, and in solutions of acids and of alkalies.

**Barium Sulfate for Suspension:** White or colored, bulky or granular powder.

**Beclomethasone Dipropionate:** White to cream white, odorless powder. Very soluble in chloroform; freely soluble in acetone and in alcohol; very slightly soluble in water.

**Behenoyl Polyoxylglycerides:** Waxy solid or fine powder. Soluble in methylene chloride; insoluble in alcohol; dispersible in water. *NF category:* Lubricant; emulsifying agent; wetting and/or solubilizing agent.

**Belladonna Leaf:** When moistened, its odor is slight, somewhat tobacco-like. Its taste is somewhat bitter and acrid.

**Benazepril Hydrochloride:** White to off-white, crystalline powder. Soluble in water, in methanol, and in alcohol.

**Bendamustine Hydrochloride:** White or almost-white powder. Freely soluble in methanol; slightly soluble in isopropyl alcohol, in acetonitrile, and in tetrahydrofuran.

**Bendroflumethiazide:** White to cream-colored, finely divided, crystalline powder. Is odorless, or has a slight odor. Melts at about 220°. Freely soluble in alcohol and in acetone; practically insoluble in water.

**Benoxinate Hydrochloride:** White, or slightly off-white, crystals or crystalline powder. Is odorless, or has a slight characteristic odor, has a salty taste, and exhibits local anesthetic properties when placed upon the tongue. Its solutions are neutral to litmus, and it melts at about 158°. Very soluble in water; freely soluble in chloroform and in alcohol; insoluble in ether.

**Bentonite:** Very fine, odorless, pale buff or cream-colored to grayish powder, free from grit. Has a slightly earthy taste. Is hygroscopic. Insoluble in water, but swells to approximately twelve times its volume when added to water; insoluble in, and does not swell in, organic solvents. *NF category:* Suspending and/or viscosity-increasing agent.

**Purified Bentonite:** Odorless, tasteless, fine (micronized) powder or small flakes that are creamy when viewed on their flat surfaces and tan to brown when viewed on their edges. Insoluble in water and in alcohol. Swells when added to water or glycerin. *NF category:* Suspending and/or viscosity-increasing agent.

**Bentonite Magma:** *NF category:* Suspending and/or viscosity-increasing agent.

**Benzaldehyde:** Colorless, strongly refractive liquid. Is affected by light. Slightly soluble in water. Miscible with alcohol, with ether, and with fixed and volatile oils. The specific gravity is 1.041–1.046 at 25° (see *Specific Gravity* ⟨841⟩), and the refractive index is 1.544–1.546 at 20° (see *Refractive Index* ⟨831⟩). *NF category:* Flavors and fragrance.

**Benzaldehyde Elixir, Compound:** *NF category:* Flavored and/or sweetened vehicle.

**Benzalkonium Chloride:** White or yellowish-white, thick gel or gelatinous pieces. Usually has a mild, aromatic odor. Its aqueous solution has a bitter taste, foams strongly when shaken, and usually is slightly alkaline. Very soluble in water and in alcohol. Anhydrous form freely soluble in benzene, and slightly soluble in ether. *NF category:* Antimicrobial preservative; wetting and/or solubilizing agent; emulsifying agent.

**Benzalkonium Chloride Solution:** Clear liquid; colorless or slightly yellow unless a color has been added. Has an aromatic odor and a bitter taste. *NF category:* Antimicrobial preservative.

**Benzethonium Chloride:** White crystals, having a mild odor. Its solution (1 in 100) is slightly alkaline to litmus. Soluble in water, in alcohol, and in chloroform; slightly soluble in ether. *NF category:* Antimicrobial preservative; wetting and/or solubilizing agent.

**Benzethonium Chloride Solution:** Odorless, clear liquid, slightly alkaline to litmus.

**Benzethonium Chloride Tincture:** Clear liquid, having the characteristic odor of acetone and of alcohol.

**Benzocaine:** Small, white crystals or white, crystalline powder. Is odorless, is stable in air, and exhibits local anesthetic properties when placed upon the tongue. Freely soluble in alcohol, in chloroform, and in ether; sparingly soluble in almond oil and in olive oil; very slightly soluble in water. Dissolves in dilute acids.

**Benzoic Acid:** White crystals, scales, or needles. Has a slight odor, usually suggesting benzaldehyde or benzoin. Somewhat volatile at moderately warm temperatures. Freely volatile in steam. Freely soluble in alcohol, in chloroform, and in ether; slightly soluble in water. *NF category:* Antimicrobial preservative.

**Benzoin:** Sumatra Benzoin has an aromatic and balsamic odor. When heated it does not emit a pinaceous odor. When Sumatra Benzoin is digested with boiling water, the odor suggests cinnamates or storax. Its taste is aromatic and slightly acrid. Siam Benzoin has an agreeable, balsamic, vanilla-like odor. Its taste is aromatic and slightly acrid.

**Benzonatate:** Clear, pale yellow, viscous liquid, having a faint, characteristic odor. Has a bitter taste, and exhibits local anesthetic properties when placed upon the tongue. Miscible with water in all proportions. Freely soluble in chloroform, in alcohol, and in benzene.

**Hydrous Benzoyl Peroxide:** White, granular powder, having a characteristic odor. Soluble in acetone, in chloroform, and in ether; sparingly soluble in water and in alcohol.

**Benzoyl Peroxide Gel:** A soft, white gel, having a characteristic odor.

**Benzoyl Peroxide Lotion:** White, viscous, creamy lotion, having a characteristic odor.

**Benzphetamine Hydrochloride:** White to off-white, crystalline powder. Freely soluble in alcohol and soluble in chloroform.

**Benztropine Mesylate:** White, slightly hygroscopic, crystalline powder. Very soluble in water; freely soluble in alcohol; very slightly soluble in ether.

**Benzyl Alcohol:** Clear, colorless, oily liquid. Boils at about 206°, without decomposition. Is neutral to litmus. Freely soluble in 50% alcohol; sparingly soluble in water. Miscible with alcohol, with ether, and with chloroform. The specific gravity is between 1.042 and 1.047. *NF category:* Antimicrobial preservative; solvent.

**Benzyl Benzoate:** Clear, colorless, oily liquid having a slight aromatic odor and producing a sharp, burning sensation on the tongue. Practically insoluble in water and in glycerin. Miscible with alcohol, with ether, and with chloroform. *NF category:* Solvent; emulsifying agent; plasticizer.

**Beta Carotene:** Red or reddish-brown to violet-brown crystals or crystalline powder. Soluble in carbon disulfide, in benzene, and in chloroform; sparingly soluble in ether, in solvent hexane, and in vegetable oils; practically insoluble in methanol and in alcohol; insoluble in water, in acids, and in alkalies.

**Betadex:** White, practically odorless, fine crystalline powder having a slightly sweet taste. Sparingly soluble in

water. *NF category:* Sequestering agent; chelating and/or complexing agent.

**Betadex Sulfobutyl Ether Sodium:** White to off-white, amorphous powder. Freely soluble in water; sparingly soluble in methanol; practically insoluble in ethanol, in *n*-hexane, in 1-butanol, in acetonitrile, in 2-propanol, and in ethyl acetate. *NF category:* Chelating and/or complexing agent; sequestering agent; wetting and/or solubilizing agent.

**Betahistine Hydrochloride:** White to almost yellow, crystalline powder. Very hygroscopic. Melts between 151° and 154°. Very soluble in water; freely soluble in alcohol; practically insoluble in isopropyl alcohol.

**Betaine Hydrochloride:** White, crystalline powder. Soluble in water and in alcohol; practically insoluble in chloroform and in ether.

**Betamethasone:** White to practically white, odorless, crystalline powder. Melts at about 240°, with some decomposition. Sparingly soluble in acetone, in alcohol, in dioxane, and in methanol; very slightly soluble in chloroform and in ether; insoluble in water.

**Betamethasone Acetate:** White to creamy white, odorless powder. Sinters and resolidifies at about 165°, and remelts at about 200° or 220°, with decomposition (see *Melting Range or Temperature* ⟨741⟩). Freely soluble in acetone; soluble in alcohol and in chloroform; practically insoluble in water.

**Betamethasone Dipropionate:** White to cream-white, odorless powder. Freely soluble in acetone and in chloroform; sparingly soluble in alcohol; insoluble in water.

**Betamethasone Sodium Phosphate:** White to practically white, odorless powder. Is hygroscopic. Freely soluble in water and in methanol; practically insoluble in acetone and in chloroform.

**Betamethasone Valerate:** White to practically white, odorless powder. Melts at about 190°, with decomposition. Freely soluble in acetone and in chloroform; soluble in alcohol; slightly soluble in benzene and in ether; practically insoluble in water.

**Betaxolol Hydrochloride:** White, crystalline powder. Freely soluble in water, in alcohol, in chloroform, and in methanol.

**Bethanechol Chloride:** Colorless or white crystals or white, crystalline powder, usually having a slight, amine-like odor. Is hygroscopic. Exhibits polymorphism, and of two crystalline forms observed, one melts at about 211° and the other melts at about 219°. Freely soluble in water and in alcohol; insoluble in chloroform and in ether.

**Bicalutamide:** Fine, white to off-white powder. Freely soluble in tetrahydrofuran and in acetone; soluble in acetonitrile; sparingly soluble in methanol; slightly soluble in alcohol.

**Biotin:** Practically white, crystalline powder. Very slightly soluble in water and in alcohol; insoluble in other common organic solvents.

**Bisacodyl:** White to off-white, crystalline powder, in which the number of particles having a longest diameter smaller than 50 µm predominate. Soluble in chloroform and in benzene; sparingly soluble in alcohol and in methanol; slightly soluble in ether; practically insoluble in water.

**Milk of Bismuth:** Thick, white, opaque suspension that separates on standing. Is odorless and practically tasteless. Miscible with water and with alcohol.

**Bismuth Citrate:** White, amorphous or crystalline powder. Stable in air. Melts at about 300°, with decomposition. Soluble in ammonia TS and in solutions of alkali citrates; insoluble in water and in alcohol.

**Bismuth Subcarbonate:** White or almost white powder. Practically insoluble in water, in alcohol, and in ether. Dissolves in dilute acids with effervescence.

**Bismuth Subgallate:** Amorphous, bright yellow powder. Is odorless and tasteless. Is stable in air, but is affected by light. Dissolves readily with decomposition in warm, moderately dilute hydrochloric, nitric, or sulfuric acid; readily dissolved by solutions of alkali hydroxides, forming a clear, yellow liquid that rapidly assumes a deep red color. Practically insoluble in water, in alcohol, in chloroform, and in ether; insoluble in very dilute mineral acids.

**Bismuth Subnitrate:** White, slightly hygroscopic powder. Practically insoluble in water and in alcohol; readily dissolved by hydrochloric acid or by nitric acid.

**Bismuth Subsalicylate:** Fine to off-white, microcrystalline, odorless, tasteless powder. Practically insoluble in water, in alcohol, and in ether. Reacts with alkalies and mineral acids.

**Bisoprolol Fumarate:** White, crystalline powder. Very soluble in water and in methanol; freely soluble in chloroform, in glacial acetic acid, and in alcohol; slightly soluble in acetone and in ethyl acetate.

**Bleomycin Sulfate:** Cream-colored, amorphous powder. Very soluble in water.

**Boric Acid:** Colorless, odorless scales of a somewhat pearly luster, or crystals, or white powder that is slightly unctuous to the touch. Is stable in air. Freely soluble in glycerin, in boiling water, and in boiling alcohol; soluble in water and in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent); antimicrobial preservative.

**Bretylium Tosylate:** White, crystalline powder. Is hygroscopic. Freely soluble in water, in methanol, and in alcohol; practically insoluble in ether, in ethyl acetate, and in hexane.

**Brimonidine Tartrate:** White, or slightly yellowish, or slightly brownish powder. Soluble in water; practically insoluble in anhydrous ethanol and in toluene.

**Brinzolamide:** White or almost white powder. Slightly soluble in alcohol and in methanol; insoluble in water.

**Bromocriptine Mesylate:** White or slightly colored, fine crystalline powder, odorless or having a weak, characteristic odor.

**Bromodiphenhydramine Hydrochloride:** White to pale buff, crystalline powder, having no more than a faint odor. Freely soluble in water and in alcohol; soluble in isopropyl alcohol; insoluble in ether and in solvent hexane.

**Brompheniramine Maleate:** White, odorless, crystalline powder. Freely soluble in water; soluble in alcohol and in chloroform; slightly soluble in ether and in benzene.

**Budesonide:** White to off-white, odorless, crystalline powder. Freely soluble in chloroform; sparingly soluble in alcohol; practically insoluble in water and in heptane.

**Bumetanide:** Practically white powder. Soluble in alkaline solutions; slightly soluble in water.

**Bupivacaine Hydrochloride:** White, odorless, crystalline powder. Melts at about 248°, with decomposition. Freely soluble in water and in alcohol; slightly soluble in chloroform and in acetone.

**Bupivacaine Hydrochloride Injection:** Clear, colorless solution.

**Bupivacaine Hydrochloride and Epinephrine Injection:** Clear, colorless solution.

**Bupropion Hydrochloride:** White powder. Soluble in water, in 0.1 N hydrochloric acid, and in alcohol.

**Buspirone Hydrochloride:** White crystalline powder. Very soluble in water; freely soluble in methanol and in methylene chloride; sparingly soluble in ethanol and in acetonitrile; very slightly soluble in ethyl acetate; practically insoluble in hexanes.

**Busulfan:** White, crystalline powder. Sparingly soluble in acetone; slightly soluble in alcohol; very slightly soluble in water.

**Butabarbital Sodium:** White powder, having a bitter taste. Freely soluble in water and in alcohol; practically insoluble in absolute ether.

**Butalbital:** White, crystalline, odorless powder, having a slightly bitter taste. Is stable in air. Its saturated solution is acid to litmus. Freely soluble in alcohol, in ether, and in chloroform; soluble in boiling water, and in solutions of fixed alkalies and alkali carbonates; slightly soluble in cold water.

**Butamben:** White, crystalline powder. Is odorless and tasteless. Soluble in dilute acids, in alcohol, in chloroform, in ether, and in fixed oils; very slightly soluble in water. Is slowly hydrolyzed when boiled with water.

**Butane:** Colorless, flammable gas (boiling temperature is about –0.5°). One volume of water dissolves 0.15 volume, and 1 volume of alcohol dissolves 18 volumes at 17° and 770 mm; 1 volume of ether or chloroform at 17° dissolves 25 or 30 volumes, respectively. Vapor pressure at 21° is about 1620 mm of mercury (17 psig). *NF category:* Propellant.

**Butoconazole Nitrate:** White to off-white, crystalline powder. Melts at about 160°. Sparingly soluble in methanol; slightly soluble in acetonitrile, in acetone, in dichloromethane, and in tetrahydrofuran; very slightly soluble in ethyl acetate; practically insoluble in water.

**Butorphanol Tartrate:** White powder. Its solutions are slightly acidic. Melts between 217° and 219°, with decomposition. Soluble in dilute acids; sparingly soluble in water; slightly soluble in methanol; insoluble in alcohol, in chloroform, in ethyl acetate, in ethyl ether, and in hexane.

**Butyl Alcohol:** Clear, colorless, mobile liquid, having a characteristic, penetrating vinous odor. Soluble in water. Miscible with alcohol, with ether, and with many other organic solvents. *NF category:* Solvent.

**Butylene Glycol:** Clear, colorless, hygroscopic, viscous liquid. It is miscible with water, with acetone, and with ether in all proportions; immiscible with fixed oils. It dissolves most essential oils and synthetic flavoring substances. *NF category*: Solvent; wetting and/or solubilizing agent.

**Butyl Palmitostearate:** Colorless or pale yellowish waxy solid at temperatures below 17°–24° or colorless or pale yellowish liquid at temperatures of 17°–24° or above. Soluble in acetone, in alcohol, in ether, in mineral oils, and in vegetable oils; practically insoluble in water and in propylene glycol. *NF category:* Emulsifying and/or solubilizing agent; flavors and fragrance; plasticizer.

**Butyl Stearate:** Colorless or pale yellowish waxy solid at temperatures below 19°–24° or colorless or pale yellowish liquid at temperatures of 19°–24° or above. Soluble in acetone, in alcohol, in ether, in mineral oils, and in vegetable oils; practically insoluble in water and in propylene glycol. *NF category:* Emulsifying and/or solubilizing agent; flavors and fragrance; plasticizer.

**Butylated Hydroxyanisole:** White or slightly yellow, waxy solid, having a faint, characteristic odor. Freely soluble in alcohol, in propylene glycol, in chloroform, and in ether; insoluble in water. *NF category:* Antioxidant.

**Butylated Hydroxytoluene:** White, crystalline solid, having a faint, characteristic odor. Freely soluble in alcohol, in chloroform, and in ether; insoluble in water and in propylene glycol. *NF category:* Antioxidant.

**Butylparaben:** Small, colorless crystals or white powder. Freely soluble in acetone, in alcohol, in ether, and in propylene glycol; very slightly soluble in water and in glycerin. *NF category:* Antimicrobial preservative.

**Cabergoline:** White or almost white, crystalline or amorphous powder. Freely soluble in alcohol (96%); slightly soluble in 0.1 M hydrochloric acid; very slightly soluble in hexane; practically insoluble in water.

**Caffeine:** White powder or white, glistening needles, usually matted together. Is odorless and has a bitter taste. Its solutions are neutral to litmus. The hydrate is efflorescent in air. Freely soluble in chloroform; sparingly soluble in water and in alcohol; slightly soluble in ether.

**Calamine:** Pink, odorless, practically tasteless, fine powder. Soluble in mineral acids; insoluble in water.

**Calcipotriene:** White or almost white crystalline powder. Freely soluble in alcohol; slightly soluble in methylene chloride; practically insoluble in water.

**Calcitriol:** White or almost white crystals. Freely soluble in alcohol; soluble in ether and in fatty oils; practically insoluble in water. It is sensitive to air, heat, and light.

**Calcium Acetate:** White, odorless or almost odorless, hygroscopic, crystalline powder. When heated to above 160°, it decomposes to calcium carbonate and acetone. Freely soluble in water; slightly soluble in methanol; practically insoluble in acetone, in dehydrated alcohol, and in benzene. *NF category:* Antimicrobial preservative; sequestering agent.

**Calcium Ascorbate:** White to slightly yellow, practically odorless powder. Freely soluble in water (approximately 50 g per 100 mL); slightly soluble in alcohol; insoluble in ether.

**Calcium Carbonate:** Fine, white, odorless, tasteless, microcrystalline powder. Is stable in air. Practically insoluble in water. Its solubility in water is increased by the presence of any ammonium salt or of carbon dioxide. The presence of any alkali hydroxide reduces its solubility. Insoluble in alcohol. Dissolves with effervescence in 1 N acetic acid, in 3 N hydrochloric acid, and in 2 N nitric acid. *NF category:* Diluent; pH modifier (acidifying agent/alkalizing agent/buffering agent); coating agent; wet binder.

**Calcium Chloride:** White, hard, odorless fragments or granules. Is deliquescent. Very soluble in boiling water; freely soluble in water, in alcohol, and in boiling alcohol. *NF category:* Desiccant; antimicrobial preservative.

**Calcium Citrate:** White, odorless, crystalline powder. Freely soluble in diluted 3 N hydrochloric acid and in diluted 2 N nitric acid; slightly soluble in water; insoluble in alcohol.

**Calcium Gluceptate:** White to faintly yellow, amorphous powder. Is stable in air, but the hydrous forms may lose part of their water of hydration on standing. Freely soluble in water; insoluble in alcohol and in many other organic solvents.

**Calcium Gluconate:** White, crystalline, odorless, tasteless granules or powder. Is stable in air. Its solutions are neutral to litmus. Freely soluble in boiling water; sparingly (and slowly) soluble in water; insoluble in alcohol.

**Calcium Hydroxide:** White powder. Has an alkaline, slightly bitter taste. Soluble in glycerin and in syrup; slightly soluble in water; very slightly soluble in boiling water; insoluble in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Calcium Hydroxide Solution:** Clear, colorless liquid having an alkaline taste. Is alkaline to litmus.

**Calcium Lactate:** White, practically odorless granules or powder. The pentahydrate is somewhat efflorescent and at 120° becomes anhydrous. The pentahydrate is soluble in water; it is practically insoluble in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent); antimicrobial preservative; wet binder.

**Calcium Levulinate:** White, crystalline or amorphous, powder, having a faint odor suggestive of burnt sugar. Has a bitter, salty taste. Freely soluble in water; slightly soluble in alcohol; insoluble in ether and in chloroform.

**Calcium Pantothenate:** Slightly hygroscopic, white powder. Is odorless and has a bitter taste. Freely soluble in water; soluble in glycerin; practically insoluble in alcohol, in chloroform, and in ether.

**Racemic Calcium Pantothenate:** White, slightly hygroscopic powder, having a faint, characteristic odor, and a bitter taste. Is stable in air. Its solutions are neutral or alkaline to litmus. Is optically inactive. Freely soluble in water; soluble

in glycerin; practically insoluble in alcohol, in chloroform, and in ether.

**Dibasic Calcium Phosphate:** White, odorless, tasteless powder. Is stable in air. Soluble in 3 N hydrochloric acid and in 2 N nitric acid; practically insoluble in water; insoluble in alcohol. *NF category:* Diluent.

**Tribasic Calcium Phosphate:** White, odorless, tasteless powder. Is stable in air. Freely soluble in 3 N hydrochloric acid and in 2 N nitric acid; practically insoluble in water; insoluble in alcohol. *NF category:* Diluent; pH modifier (acidifying agent/alkalizing agent/buffering solution); glidant and/or anticaking agent.

**Calcium Polycarbophil:** White to creamy white powder. Insoluble in water, in dilute acids, in dilute alkalies, and in common organic solvents.

**Calcium Propionate:** Occurs as a white crystalline solid. One g dissolves in about 3 mL of water. *NF category:* Antimicrobial preservative.

**Calcium Saccharate:** White, odorless, tasteless, crystalline powder. Soluble in dilute mineral acids and in solutions of calcium gluconate; slightly soluble in boiling water; very slightly soluble in alcohol, and in cold water; practically insoluble in ether and in chloroform.

**Calcium Silicate:** White to off-white, free-flowing powder that remains so after absorbing relatively large amounts of water or other liquids. Insoluble in water. Forms a gel with mineral acids. *NF category:* Glidant and/or anticaking agent.

**Calcium Stearate:** Fine, white to yellowish-white, bulky powder having a slight, characteristic odor. Is unctuous, and is free from grittiness. Insoluble in water, in alcohol, and in ether. *NF category:* Lubricant.

**Calcium Sulfate:** Fine, white to slightly yellow-white, odorless powder. Soluble in 3 N hydrochloric acid; slightly soluble in water. *NF category:* Desiccant; diluent.

**Calcium Undecylenate:** Fine, white powder, having a characteristic odor and no grit. Slightly soluble in hot alcohol; practically insoluble in water, in ether, in chloroform, in acetone, and in cold alcohol.

**Camphor:** Colorless or white crystals, granules, or crystalline masses; or colorless to white, translucent, tough masses. Has a penetrating, characteristic odor and a pungent, aromatic taste. Specific gravity is about 0.99. Slowly volatilizes at ordinary temperatures. Slightly soluble in water; very soluble in alcohol, in chloroform, and in ether; freely soluble in carbon disulfide, in solvent hexane, and in fixed and volatile oils.

***Change to read:***

**Candelilla Wax:** A hard, yellowish-brown-opaque to translucent wax. Its specific gravity is about 0.983. Soluble in chloroform and in toluene; insoluble in water. ▲*NF category:* Coating agent; colloid stabilizing agent; emollient; emulsifying agent; film-forming agent; ointment base; stiffening agent; vehicle.▲ (NF 1-Dec-2023)

**Candesartan Cilexetil:** White to off-white powder. Sparingly soluble in methanol; practically insoluble in water.

**Canola Oil:** Clear, pale yellow, slightly viscous liquid. Practically insoluble in water and in alcohol. Miscible with light petroleum (bp: 40° to 60°). *NF category:* Solvent; emollient; vehicle (oleaginous).

**Capecitabine:** White to off-white crystalline powder. Freely soluble in methanol; soluble in acetonitrile and in alcohol; sparingly soluble in water.

**Capreomycin Sulfate:** White to practically white, amorphous powder. Freely soluble in water; practically insoluble in most organic solvents.

**Caprylic Acid:** Clear, colorless or slightly yellowish, oily liquid. Very soluble in acetone and in alcohol; very slightly soluble in water. It dissolves in dilute solutions of alkali hydroxides. *NF category:* Emulsifying agent.

**Caprylocaproyl Polyoxylglycerides:** Pale yellow, oily liquids. Dispersible in hot water; freely soluble in methylene chloride. *NF category:* Ointment base; solvent; wetting and/or solubilizing agent; emulsifying agent.

**Capsaicin:** Off-white powder. Melts at about 65°. Soluble in alcohol, in benzene, in chloroform; slightly soluble in carbon disulfide; practically insoluble in cold water.

**Capsicum Oleoresin:** Dark red, oily liquid. Soluble in alcohol, in acetone, in ether, in chloroform, and in volatile oils; soluble with opalescence in fixed oils.

**Captopril:** White to off-white, crystalline powder, which may have a characteristic, sulfide-like odor. Melts in the range of 104° to 110°. Freely soluble in water, in methanol, in alcohol, and in chloroform.

**Caramel:** Thick, dark brown liquid having the characteristic odor of burnt sugar, and a pleasant, bitter taste. One part dissolved in 1000 parts of water yields a clear solution having a distinct yellowish-orange color. The color of this solution is not changed and no precipitate is formed after exposure to sunlight for 6 hours. When spread in a thin layer on a glass plate, it appears homogeneous, reddish-brown, and transparent. Miscible with water. Soluble in dilute alcohol up to 55% (v/v). Immiscible with ether, with chloroform, with acetone, with benzene, and with solvent hexane. *NF category:* Coloring agent.

**Carbachol:** White powder. Freely soluble in water; sparingly soluble in alcohol; practically insoluble in chloroform and in ether.

**Carbamazepine:** White to off-white powder. It exhibits polymorphism. Soluble to very slightly soluble in alcohol and in acetone; practically insoluble in water.

**Carbamide Peroxide Topical Solution:** Clear, colorless, viscous liquid, having a characteristic odor and taste.

**Carbidopa:** White to creamy white, odorless or practically odorless, powder. Freely soluble in 3 N hydrochloric acid; slightly soluble in water, and in methanol; practically insoluble in alcohol, in acetone, in chloroform, and in ether.

**Carbinoxamine Maleate:** White, odorless, crystalline powder. Very soluble in water; freely soluble in alcohol and in chloroform; very slightly soluble in ether.

**Carbol-Fuchsin Topical Solution:** Dark purple liquid, which appears purplish red when spread in a thin film.

**Carbomer 910:** White, fluffy powder, having a slight, characteristic odor. Is hygroscopic. The pH of a 1 in 100 dispersion is about 3. When neutralized with alkali hydroxides or with amines, it dissolves in water, in alcohol, and in glycerin. *NF category:* Suspending and/or viscosity-increasing agent.

**Carbomer 934:** See *Carbomer 910.*

**Carbomer 934P:** See *Carbomer 910.*

**Carbomer 940:** See *Carbomer 910.*

**Carbomer 941:** See *Carbomer 910.*

**Carbomer 1342:** See *Carbomer 910.*

**Carbomer Copolymer:** White, hygroscopic powder. It swells in water when a dispersion of it is neutralized with sodium hydroxide to a pH within the range of 7.3 to 7.8. *NF category:* Emulsifying agent; suspending and/or viscosity-increasing agent; wet binder; polymers for ophthalmic use; release-modifying agent.

**Carbomer Homopolymer:** White, fluffy hygroscopic powder, having a slight, characteristic odor. The pH of a 1 in 100 dispersion in water is about 3. When neutralized with alkali hydroxides or with amines, it swells giving the appearance of dissolving in water; when neutralized with lower amines and alkanolamines, it swells giving the appearance of dissolving in methanol or glycerin; when neutralized with ethoxylated long-chain ($C_{14}$–$C_{18}$) amines, it swells giving the appearance of dissolving in ethanol. *NF*

*category:* Wet binder; suspending and/or viscosity-increasing agent; emulsifying agent; polymers for ophthalmic use; release-modifying agent.

**Carbomer Interpolymer:** White, hygroscopic powder. It swells in water when a dispersion of it is neutralized with sodium hydroxide to a pH within the range of 5.5 to 9. *NF category:* Emulsifying agent; suspending and/or viscosity increasing agent; wet binder; polymers for ophthalmic use; release-modifying agent.

**Carbon Dioxide:** Odorless, colorless gas. Its solutions are acid to litmus. One L at 0° and at a pressure of 760 mm of mercury weighs 1.977 g. One volume dissolves in about 1 volume of water. *NF category:* Air displacement; propellant.

**Carboprost Tromethamine:** White to off-white powder. Soluble in water.

**Carboxymethylcellulose Calcium:** White to yellowish-white powder. Is hygroscopic. Practically insoluble in alcohol, in acetone, in ether, in chloroform, and in benzene. It swells with water to form a suspension; the pH of the suspension, obtained by shaking 1 g with 100 mL of water, is between 4.5 and 6.0. *NF category:* Suspending and/or viscosity-increasing agent; coating agent; emulsifying agent; film-forming agent; disintegrant.

**Carboxymethylcellulose Sodium:** White to cream-colored powder or granules. The powder is hygroscopic. Is easily dispersed in water to form colloidal solutions. Insoluble in alcohol, in ether, and in most other organic solvents. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; wet binder; film-forming agent; release-modifying agent; disintegrant.

**Carboxymethylcellulose Sodium 12:** Colorless or white to off-white powder or granules. Is odorless. Water solubility depends on degree of substitution (easily dispersed in water at all temperatures, forming a clear, colloidal solution). Insoluble in acetone, in alcohol, in ether, and in toluene. *NF category:* Suspending and/or viscosity-increasing agent.

**Enzymatically-Hydrolyzed Carboxymethylcellulose Sodium:** White or slightly yellowish or grayish, odorless, slightly hygroscopic granular or fibrous powder. Soluble in water; insoluble in alcohol. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; film-forming agent.

**Low-Substituted Carboxymethylcellulose Sodium:** A white or almost white powder or short fibers. Practically insoluble in acetone, in alcohol, and in toluene. It swells in water to form a gel.

**Carisoprodol:** White, crystalline powder, having a mild, characteristic odor and a bitter taste. Freely soluble in alcohol, in chloroform, and in acetone; very slightly soluble in water.

**Carmellose:** White powder. Practically insoluble in ethanol (99.5%). Swells with water to form a suspension. Becomes viscous in sodium hydroxide TS. Is hygroscopic. *NF category:* Suspending and/or viscosity-increasing agent; polymers for ophthalmic use.

**Carmustine:** Light yellow powder. Freely soluble in ether.

**Carprofen:** White crystalline powder. Freely soluble in ether, in acetone, in ethyl acetate, and in sodium hydroxide TS or sodium carbonate TS; practically insoluble in water.

**Carrageenan:** Yellowish or tan to white, coarse to fine powder. Is practically odorless and has a mucilaginous taste. Soluble in water at a temperature of about 80°, forming a viscous, clear or slightly opalescent solution that flows readily. Disperses in water more readily if first moistened with alcohol, with glycerin, or with a saturated solution of sucrose in water. *NF category:* Suspending and/or viscosity-increasing agent; release-modifying agent.

**Carvedilol:** White or nearly white, crystalline powder. Slightly soluble in alcohol; practically insoluble in water and in dilute acids.

**Casanthranol:** Light tan to brown, amorphous, hygroscopic powder. Freely soluble in water, with some residue; partially soluble in methanol and in hot isopropyl alcohol; practically insoluble in acetone.

**Cascara Sagrada:** Has a distinct odor and a bitter and slightly acrid taste.

**Castor Oil:** Pale yellowish or almost colorless, transparent, viscid liquid. Has a faint, mild odor; is free from foreign and rancid odor; and has a bland, characteristic taste. Soluble in alcohol. Miscible with dehydrated alcohol, with glacial acetic acid, with chloroform, and with ether. *NF category:* Plasticizer; emollient; solvent; vehicle.

**Hydrogenated Castor Oil:** White, crystalline wax. Insoluble in water and in most common organic solvents. *NF category:* Stiffening agent; lubricant.

**Cefaclor:** White to off-white, crystalline powder. Slightly soluble in water; practically insoluble in methanol, in chloroform, and in benzene.

**Cefadroxil:** White to off-white, crystalline powder. Slightly soluble in water; practically insoluble in alcohol, in chloroform, and in ether.

**Cefazolin:** White to slightly off-white, odorless, crystalline powder. Melts at about 198° to 200°, with decomposition. Soluble in dimethylformamide and in pyridine; sparingly soluble in acetone; slightly soluble in alcohol, in methanol, and in water; very slightly soluble in ethyl acetate, in isopropyl alcohol, and in methyl isobutyl ketone; practically insoluble in benzene, in chloroform, in ether, and in methylene chloride.

**Cefazolin Sodium:** White to off-white, practically odorless, crystalline powder, or white to off-white solid. Freely soluble in water, in saline TS, and in dextrose solutions; very slightly soluble in alcohol; practically insoluble in chloroform and in ether.

**Cefdinir:** White to light-yellow crystalline powder. Sparingly soluble in 0.1 M phosphate buffer (pH 7) solution; practically insoluble in water, in alcohol, and in diethyl ether.

**Cefepime Hydrochloride:** White to off-white, crystalline, nonhygroscopic solid. Freely soluble in water.

**Cefepime for Injection:** White to pale yellow powder. Freely soluble in water.

**Cefixime:** White to light yellow, crystalline powder. Soluble in methanol and in propylene glycol; slightly soluble in alcohol, in acetone, and in glycerin; very slightly soluble in 70% sorbitol and in octanol; practically insoluble in ether, in ethyl acetate, in hexane, and in water.

**Cefmetazole Sodium:** White solid. Very soluble in water and in methanol; soluble in acetone; practically insoluble in chloroform.

**Cefoperazone Sodium:** White to pale buff crystalline powder. Freely soluble in water; soluble in methanol; slightly soluble in dehydrated alcohol; insoluble in acetone, in ethyl acetate, and in ether.

**Cefotaxime Sodium:** Off-white to pale yellow crystalline powder. Freely soluble in water; practically insoluble in organic solvents.

**Cefoxitin Sodium:** White to off-white, granules or powder, having a slight characteristic odor. Is somewhat hygroscopic. Very soluble in water; soluble in methanol; sparingly soluble in dimethylformamide; slightly soluble in acetone; insoluble in ether and in chloroform.

**Cefpodoxime Proxetil:** White to light brownish-white powder. Odorless or having a faint odor, and has a bitter taste. Freely soluble in dehydrated alcohol; soluble in acetonitrile and in methanol; slightly soluble in ether; very slightly soluble in water.

**Ceftazidime:** White to cream-colored, crystalline powder. Soluble in alkali and in dimethyl sulfoxide; slightly soluble in dimethylformamide, in methanol, and in water; insoluble in

acetone, in alcohol, in chloroform, in dioxane, in ether, in ethyl acetate, and in toluene.

**Ceftiofur Hydrochloride:** White to beige powder. Sparingly soluble in dimethylformamide and in ethanol; slightly soluble in 0.1 N hydrochloric acid; very slightly soluble in tetrahydrofuran; practically insoluble in ethyl acetate.

**Ceftiofur Sodium:** White to beige powder. Freely soluble in propylene glycol; soluble in water; slightly soluble in tetrahydrofuran, in dehydrated alcohol, and in acetone; insoluble in methylene chloride.

**Ceftizoxime Sodium:** White to pale yellow crystalline powder. Freely soluble in water.

**Ceftriaxone Sodium:** White to yellowish-orange crystalline powder. Freely soluble in water; sparingly soluble in methanol; very slightly soluble in alcohol.

**Cefuroxime Axetil:** White to almost white powder. The amorphous form is freely soluble in acetone; soluble in chloroform, in ethyl acetate, and in methanol; slightly soluble in dehydrated alcohol; insoluble in ether and in water. The crystalline form is freely soluble in acetone; sparingly soluble in chloroform, in ethyl acetate, and in methanol; slightly soluble in dehydrated alcohol; insoluble in ether and in water.

**Cefuroxime Sodium:** White or faintly yellow powder. Freely soluble in water; soluble in methanol; very slightly soluble in alcohol, in ether, in ethyl acetate, and in chloroform.

**Celecoxib:** White or almost white, crystalline or amorphous powder. Soluble to freely soluble in ethanol; soluble in methylene chloride; practically insoluble in water.

**Cellaburate:** Fine white or almost white powder or granules. Available in a range of viscosities, acetyl and butyl contents. Slightly hygroscopic; soluble in acetone, in methylene chloride, in pyridine, and in dimethyl sulfoxide; practically insoluble in water and in alcohol. *NF category:* Coating agent; polymer membrane; film-forming agent; release-modifying agent; diluent.

**Cellacefate:** Free-flowing, white powder. May have a slight odor of acetic acid. Soluble in acetone and in dioxane; insoluble in water and in alcohol. *NF category:* Coating agent; film-forming agent.

**Cellulose Acetate:** Fine, white powder or free-flowing pellets. Available in a range of viscosities and acetyl contents. High viscosity, which reflects high molecular weight, decreases solubility slightly. High acetyl content cellulose acetates generally have more limited solubility in commonly used organic solvents than low acetyl content cellulose acetates, but are more soluble in methylene chloride. All acetyl content cellulose acetates are soluble in dioxane and in dimethylformamide; insoluble in alcohol and in water. *NF category:* Coating agent; polymer membrane; film-forming agent; diluent.

**Microcrystalline Cellulose:** Fine, white or almost white powder. It consists of free-flowing, nonfibrous particles. Practically insoluble in sodium hydroxide solution (1 in 20); insoluble in water, in dilute acids, and in most organic solvents. *NF category:* Diluent; disintegrant; wet binder; suspending and/or viscosity-increasing agent.

**Silicified Microcrystalline Cellulose:** White or almost white, very fine to moderately fine powder. It is a free-flowing material that may be compacted into self-binding tablets that disintegrate rapidly in water. Slightly soluble in sodium hydroxide solution (1 in 20); practically insoluble in water, in acetone, in ethanol, in toluene, and in diluted acid. *NF category:* Diluent; disintegrant; wet binder.

**Microcrystalline Cellulose and Carboxymethylcellulose Sodium:** Tasteless, odorless, white to off-white, coarse to fine powder. Swells in water, producing, when dispersed, a white, opaque dispersion or gel. Insoluble in organic solvents and in dilute acids. *NF category:* Suspending and/or viscosity-increasing agent.

**Oxidized Cellulose:** In the form of gauze or lint. Is slightly off-white in color, is acidic to the taste, and has a slight, charred odor. Soluble in dilute alkalies; insoluble in water and in acids.

**Oxidized Regenerated Cellulose:** A knit fabric, usually in the form of sterile strips. Slightly off-white, having a slight odor. Soluble in dilute alkalies; insoluble in water and in dilute acids.

**Powdered Cellulose:** White or almost white powder. Exhibits degrees of fineness ranging from a free-flowing dense powder to a coarse, fluffy, nonflowing material. Slightly soluble in sodium hydroxide solution (1 in 20); insoluble in water, in dilute acids, and in nearly all organic solvents. *NF category:* Filtering aid; sorbent; diluent; disintegrant; glidant and/or anticaking agent; suspending and/or viscosity-increasing agent.

**Cephalexin:** White to off-white, crystalline powder. Slightly soluble in water; practically insoluble in alcohol, in chloroform, and in ether.

**Cephalexin Hydrochloride:** White to off-white, crystalline powder. Soluble to the extent of 10 mg per mL in water, in acetone, in acetonitrile, in alcohol, in dimethylformamide, and in methanol; practically insoluble in chloroform, in ether, in ethyl acetate, and in isopropyl alcohol.

**Cephalothin Sodium:** White to off-white, practically odorless, crystalline powder. Freely soluble in water, in saline TS, and in dextrose solutions; insoluble in most organic solvents.

**Cephapirin Benzathine:** White, crystalline powder. Soluble in 0.1 N hydrochloric acid; practically insoluble in water, in ether, and in toluene; insoluble in alcohol.

**Cephapirin Sodium:** White to off-white, crystalline powder, odorless or having a slight odor. Very soluble in water; insoluble in most organic solvents.

**Cephradine:** White to off-white, crystalline powder. Sparingly soluble in water; very slightly soluble in alcohol and in chloroform; practically insoluble in ether.

**Cetirizine Hydrochloride:** White to almost white powder. Freely soluble in water; practically insoluble in acetone and in methylene chloride.

**Cetostearyl Alcohol:** Unctuous, white flakes or granules, having a faint, characteristic odor, and a bland, mild taste. Soluble in alcohol and in ether; insoluble in water. *NF category:* Stiffening agent; emollient; emulsifying agent; suspending and/or viscosity-increasing agent.

**Cetrimonium Bromide:** A white to creamy white, voluminous, free-flowing powder, with a characteristic faint odor and bitter, soapy taste. Freely soluble in water and in alcohol; practically insoluble in ether. *NF category:* Antimicrobial preservative.

**Cetyl Alcohol:** Unctuous, white flakes, granules, cubes, or castings. Has a faint characteristic odor and a bland, mild taste. Usually melts in the range between 45° and 50°. Soluble in alcohol and in ether, the solubility increasing with an increase in temperature; insoluble in water. *NF category:* Stiffening agent; coating agent; emulsifying agent.

**Cetyl Esters Wax:** White to off-white, somewhat translucent flakes, having a crystalline structure and a pearly luster when caked. Has a faint odor and a bland, mild taste, free from rancidity, and has a specific gravity of about 0.83 at 50°. Soluble in boiling alcohol, in ether, in chloroform, and in fixed and volatile oils; slightly soluble in cold solvent hexane; practically insoluble in cold alcohol; insoluble in water. *NF category:* Stiffening agent; emollient.

**Cetyl Palmitate:** White crystals or flakes. Freely soluble in alcohol and in ether; practically insoluble in water. *NF category:* Stiffening agent.

**Cetylpyridinium Chloride:** White to almost-white powder, having a slight, characteristic odor. Very soluble in

https://nhathuoclocanh.com/

water, in alcohol, and in chloroform; slightly soluble in benzene and in ether. *NF category:* Antimicrobial preservative; wetting and/or solubilizing agent; emulsifying agent.

**Cetylpyridinium Chloride Topical Solution:** Clear liquid. Is colorless unless a color has been added; has an aromatic odor and a bitter taste.

***Add the following:***

▲**Cevimeline Hydrochloride:** White to off-white, crystalline powder. Very soluble in water; freely soluble in alcohol and in chloroform; practically insoluble in ether.▲ (USP 1-Dec-2023)

**Activated Charcoal:** Fine, black, odorless, tasteless powder, free from gritty matter. *NF category:* Sorbent.

**Chitosan:** White or almost white powder or granules. Soluble in aqueous solutions of glycolic acid, of formic acid, of acetic acid, of hydrochloric acid, and of lactic acid; practically insoluble in organic solvents and in water. *NF category:* Coating agent; film-forming agent; suspending and/or viscosity-increasing agent; vehicle (solid carrier).

**Chloral Hydrate:** Colorless, transparent, or white crystals having an aromatic, penetrating, and slightly acrid odor, and a slightly bitter, caustic taste. Melts at about 55°, and slowly volatilizes when exposed to air. Very soluble in water and in olive oil; freely soluble in alcohol, in chloroform, and in ether.

**Chlorambucil:** Off-white, slightly granular powder. Freely soluble in acetone; soluble in dilute alkali; very slightly soluble in water.

**Chloramphenicol:** Fine, white to grayish-white or yellowish-white, needle-like crystals or elongated plates. Its solutions are practically neutral to litmus. Is reasonably stable in neutral or moderately acid solutions. Its alcohol solution is dextrorotatory and its ethyl acetate solution is levorotatory. Freely soluble in alcohol, in propylene glycol, in acetone, and in ethyl acetate; slightly soluble in water.

**Chloramphenicol Palmitate:** Fine, white, unctuous, crystalline powder, having a faint odor and a bland, mild taste. Freely soluble in acetone and in chloroform; soluble in ether; sparingly soluble in alcohol; very slightly soluble in solvent hexane; insoluble in water.

**Chloramphenicol Sodium Succinate:** Light yellow powder. Freely soluble in water and in alcohol.

**Chlordiazepoxide:** Yellow, practically odorless, crystalline powder. Is sensitive to sunlight. Melts at about 240°. Sparingly soluble in chloroform and in alcohol; insoluble in water.

**Chlordiazepoxide Hydrochloride:** White or practically white, odorless, crystalline powder. Is affected by sunlight. Soluble in water; sparingly soluble in alcohol; insoluble in solvent hexane.

**Chlorhexidine Acetate:** A white or almost white, microcrystalline powder. Soluble in alcohol; sparingly soluble in water; slightly soluble in glycerol and in propylene glycol.

**Chlorhexidine Gluconate Solution:** Almost colorless or pale yellow, clear liquid. Miscible with glacial acetic acid and with water; miscible with three times its volume of acetone and with five times its volume of dehydrated alcohol; further addition of acetone or dehydrated alcohol yields a white turbidity.

**Chlorhexidine Hydrochloride:** White or almost white, crystalline powder. Sparingly soluble in propylene glycol and in water; very slightly soluble in alcohol.

**Chlorobutanol:** Colorless to white crystals, having a characteristic, somewhat camphoraceous, odor and taste. Anhydrous form melts at about 95°, and hydrous form melts at about 76°. Freely soluble in alcohol, in ether, in chloroform, and in volatile oils; soluble in glycerin; slightly soluble in water. *NF category:* Antimicrobial preservative; plasticizer.

**Chlorocresol:** Colorless or practically colorless crystals or crystalline powder, having a characteristic, nontarry odor. Is volatile in steam. Very soluble in alcohol; soluble in ether, in terpenes, in fixed oils, and in solutions of alkali hydroxides; slightly soluble in water and more soluble in hot water. *NF category:* Antimicrobial preservative.

**Chloroprocaine Hydrochloride:** White, crystalline powder. Is odorless, and is stable in air. Its solutions are acid to litmus. Exhibits local anesthetic properties when placed upon the tongue. Soluble in water; slightly soluble in alcohol; very slightly soluble in chloroform; practically insoluble in ether.

**Chloroquine:** White or slightly yellow, crystalline powder. Is odorless, and has a bitter taste. Soluble in dilute acids, in chloroform, and in ether; very slightly soluble in water.

**Chloroquine Phosphate:** White, crystalline powder. Is odorless, has a bitter taste, and is discolored slowly on exposure to light. Its solutions have a pH of about 4.5. Exists in two polymorphic forms, one melting between 193° and 195° and the other between 210° and 215° (see *Melting Range or Temperature* ⟨741⟩); mixture of the forms melts between 193° and 215°. Freely soluble in water; practically insoluble in alcohol, in chloroform, and in ether.

**Chlorothiazide:** White or practically white, crystalline, odorless powder. Melts at about 340°, with decomposition. Freely soluble in dimethylformamide and in dimethyl sulfoxide; slightly soluble in methanol and in pyridine; practically insoluble in ether, in benzene, and in chloroform; very slightly soluble in water.

**Chloroxylenol:** White crystals or crystalline powder, having a characteristic odor. Is volatile in steam. Freely soluble in alcohol, in ether, in terpenes, in fixed oils, and in solutions of alkali hydroxides; very slightly soluble in water. *NF category:* Antimicrobial preservative.

**Chlorpheniramine Maleate:** White, odorless, crystalline powder. Its solutions have a pH between 4 and 5. Freely soluble in water; soluble in alcohol and in chloroform; slightly soluble in ether and in benzene.

**Chlorpromazine:** White, crystalline solid, having an amine-like odor. Darkens on prolonged exposure to light. Melts at about 60°. Freely soluble in alcohol, in benzene, in chloroform, in ether, and in dilute mineral acids; practically insoluble in water and in dilute alkali hydroxides.

**Chlorpromazine Hydrochloride:** White or slightly creamy white, odorless, crystalline powder. Darkens on prolonged exposure to light. Very soluble in water; freely soluble in alcohol and in chloroform; insoluble in ether and in benzene.

**Chlorpropamide:** White, crystalline powder, having a slight odor. Soluble in alcohol; sparingly soluble in chloroform; practically insoluble in water.

**Chlortetracycline Hydrochloride:** Yellow, crystalline powder. Is odorless, and has a bitter taste. Is stable in air, but is slowly affected by light. Soluble in solutions of alkali hydroxides and carbonates; sparingly soluble in water; slightly soluble in alcohol; practically insoluble in acetone, in chloroform, in dioxane, and in ether.

**Chlorthalidone:** White to yellowish-white, crystalline powder. Melts at a temperature above 215°, with decomposition. Soluble in methanol; slightly soluble in alcohol; practically insoluble in water, in ether, and in chloroform.

**Chlorzoxazone:** White or practically white, practically odorless, crystalline powder. Soluble in solutions of alkali hydroxides and ammonia; sparingly soluble in alcohol, in isopropyl alcohol, and in methanol; slightly soluble in water.

**Cholecalciferol:** White, odorless crystals. Is affected by air and by light. Melts at about 85°. Soluble in alcohol, in chloroform, and in fatty oils; insoluble in water.

Official

https://pharmacopeia.cn/v29240/

**Cholesterol:** White or faintly yellow, practically odorless, pearly leaflets, needles, powder, or granules. Acquires a yellow to pale tan color on prolonged exposure to light. Soluble in acetone, in chloroform, in dioxane, in ether, in ethyl acetate, in solvent hexane, and in vegetable oils; sparingly soluble in dehydrated alcohol; slightly (and slowly) soluble in alcohol; insoluble in water. *NF category:* Emulsifying agent; emollient.

**Cholestyramine Resin:** White to buff-colored, hygroscopic, fine powder. Is odorless or has not more than a slight amine-like odor. Insoluble in water, in alcohol, in chloroform, and in ether.

**Choline Bitartrate:** White, hygroscopic, crystalline powder. Clear, colorless liquid in solution. Melts between 148° and 153°. Is odorless, or may have a faint trimethylamine odor. Freely soluble in water; slightly soluble in alcohol; insoluble in ether and in chloroform.

**Choline Chloride:** Colorless or white crystals or crystalline powder, usually having a slight odor of trimethylamine. Clear and colorless in solution. Hygroscopic. Soluble in alcohol and in water.

**Sodium Chromate Cr 51 Injection:** Clear, slightly yellow solution.

**Chromic Chloride:** Dark green, odorless, slightly deliquescent crystals. Soluble in water and in alcohol; slightly soluble in acetone; practically insoluble in ether.

**Chymotrypsin:** White to yellowish-white, crystalline or amorphous, odorless, powder. An amount equivalent to 100,000 USP Units is soluble in 10 mL of water and in 10 mL of saline TS.

**Ciclopirox:** White to slightly yellowish-white, crystalline powder. Freely soluble in ethanol and in methylene chloride; soluble in ether; slightly soluble in water.

**Ciclopirox Olamine:** White to slightly yellowish-white, crystalline powder. Very soluble in alcohol and in methylene chloride; slightly soluble in water; practically insoluble in cyclohexane.

**Cidofovir:** White to off-white, crystalline powder. Soluble in 0.1 M sodium hydroxide; sparingly soluble in water; practically insoluble in methanol and in ethanol.

**Cilastatin Sodium:** White to tan-colored powder. Soluble in water and in methanol.

**Cilostazol:** White to off-white crystals. Freely soluble in chloroform; slightly soluble in methanol and in alcohol; practically insoluble in water.

**Cimetidine:** White to off-white, crystalline powder; odorless, or having a slight mercaptan odor. Freely soluble in methanol; soluble in alcohol and in polyethylene glycol 400; sparingly soluble in isopropyl alcohol; slightly soluble in water and in chloroform; practically insoluble in ether.

**Ciprofloxacin Hydrochloride:** Faintly yellowish to light yellow crystals. Sparingly soluble in water; slightly soluble in acetic acid and in methanol; very slightly soluble in dehydrated alcohol; practically insoluble in acetone, in acetonitrile, in ethyl acetate, in hexane, and in methylene chloride.

**Cisapride:** White or almost white powder. Freely soluble in dimethylformamide; soluble in methylene chloride; sparingly soluble in methanol; practically insoluble in water.

**Cisatracurium Besylate:** White to pale yellow hygroscopic powder. Very soluble in acetonitrile; freely soluble in chloroform and in methylene chloride; soluble in water; slightly soluble in methanol.

**Citalopram Hydrobromide:** White to almost white, crystalline powder. Soluble in alcohol; sparingly soluble in water and in dehydrated alcohol.

**Anhydrous Citric Acid:** Colorless, translucent crystals, or white, granular to fine, crystalline powder. Melts at about 153°, with decomposition. Very soluble in water; freely soluble in alcohol; very slightly soluble in ether. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Citric Acid Monohydrate:** Colorless, translucent crystals, or white, granular to fine, crystalline powder. Efflorescent in dry air. Very soluble in water; freely soluble in alcohol; very slightly soluble in ether. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent); antioxidant; chelating and/or complexing agent.

**Clarithromycin:** White to off-white, crystalline powder. Soluble in acetone; slightly soluble in dehydrated alcohol, in methanol, and in acetonitrile, and in phosphate buffer at pH values of 2 to 5; practically insoluble in water.

**Clavulanate Potassium:** White to off-white powder. Is moisture-sensitive. Freely soluble in water, but stability in aqueous solution is not good, optimum stability at a pH of 6.0 to 6.3; soluble in methanol, with decomposition.

**Clemastine Fumarate:** White to off-white, odorless powder. Its solutions are acid to litmus. Slightly soluble in methanol; very slightly soluble in water, and in chloroform.

**Clenbuterol Hydrochloride:** White or almost white, crystalline powder. Soluble in water and in alcohol; slightly soluble in acetone. It melts with decomposition at 173°.

**Clidinium Bromide:** White to nearly white, practically odorless, crystalline powder. Is optically inactive. Melts at about 242°. Soluble in water and in alcohol; slightly soluble in benzene and in ether.

**Clindamycin Hydrochloride:** White or practically white, crystalline powder. Is odorless or has a faint mercaptan-like odor. Is stable in the presence of air and light. Its solutions are acidic and are dextrorotatory. Freely soluble in water, in dimethylformamide, and in methanol; soluble in alcohol; practically insoluble in acetone.

**Clindamycin Palmitate Hydrochloride:** White to off-white amorphous powder, having a characteristic odor. Very soluble in ethyl acetate and in dimethylformamide; freely soluble in water, in benzene, in ether, in chloroform, and in alcohol.

**Clindamycin Phosphate:** White to off-white, hygroscopic, crystalline powder. Is odorless or practically odorless, and has a bitter taste. Freely soluble in water; slightly soluble in dehydrated alcohol; very slightly soluble in acetone; practically insoluble in chloroform, in benzene, and in ether.

**Clioquinol:** Voluminous, spongy, yellowish-white to brownish-yellow powder, having a slight, characteristic odor. Darkens on exposure to light. Melts at about 180°, with decomposition. Soluble in hot ethyl acetate and in hot glacial acetic acid; practically insoluble in water and in alcohol.

***Add the following:***

▲**Clobazam:** White or almost white, crystalline powder. Freely soluble in methylene chloride; sparingly soluble in ethanol; slightly soluble in water.▲ (USP 1-Dec-2023)

**Clobetasol Propionate:** White to cream, crystalline powder. Soluble in acetone, in dimethyl sulfoxide, in chloroform, in methanol, and in dioxane; sparingly soluble in ethanol; slightly soluble in benzene and in diethyl ether; practically insoluble in water.

**Clocortolone Pivalate:** White to yellowish-white, odorless powder. Melts at about 230°, with decomposition. Freely soluble in chloroform and in dioxane; soluble in acetone; sparingly soluble in alcohol; slightly soluble in benzene and in ether.

**Clofazimine:** Dark red crystals. Melts at about 217°, with decomposition. Soluble in chloroform and in benzene; sparingly soluble in alcohol, in acetone, and in ethyl acetate; practically insoluble in water.

**Clomiphene Citrate:** White to pale yellow, essentially odorless powder. Freely soluble in methanol; sparingly soluble

in alcohol; slightly soluble in water and in chloroform; insoluble in ether.

**Clomipramine Hydrochloride:** White to faintly yellow, crystalline powder. Freely soluble in water and in methylene chloride; soluble in alcohol; practically insoluble in ethyl ether and in hexane.

**Clonazepam:** Light yellow powder, having a faint odor. Sparingly soluble in acetone and in chloroform; slightly soluble in alcohol and in ether; insoluble in water.

**Clonidine:** White to almost white, crystalline powder. Melting point is about 130°. Freely soluble in methanol and in alcohol.

**Clopidogrel Bisulfate:** White to off-white powder. Freely soluble at pH 1; practically insoluble at neutral pH.

**Cloprostenol Sodium:** White or almost white, amorphous powder. Is hygroscopic. Freely soluble in water, in alcohol, and in methanol; practically insoluble in acetone.

**Clorazepate Dipotassium:** Light yellow, crystalline powder. Darkens on exposure to light. Soluble in water but, upon standing, may precipitate from the solution; slightly soluble in alcohol and in isopropyl alcohol; practically insoluble in acetone, in benzene, in chloroform, in ether, and in methylene chloride.

**Clorsulon:** White to off-white powder. Freely soluble in acetonitrile and in methanol; slightly soluble in water; very slightly soluble in methylene chloride.

**Clotrimazole:** White to pale yellow, crystalline powder. Melts at about 142°, with decomposition. Freely soluble in methanol, in chloroform, and in alcohol; freely soluble to soluble in acetone; practically insoluble in water.

**Cloxacillin Benzathine:** White or almost white, almost odorless, crystals or crystalline powder. Soluble in chloroform and in methanol; sparingly soluble in acetone; slightly soluble in water, in alcohol, and in isopropyl alcohol.

**Cloxacillin Sodium:** White, odorless, crystalline powder. Freely soluble in water; soluble in alcohol; slightly soluble in chloroform.

**Clozapine:** Yellow, crystalline powder. Soluble in chloroform, in acetone, and in alcohol; sparingly soluble in acetonitrile; insoluble in water.

**Coal Tar:** Nearly black, viscous liquid, heavier than water, having a characteristic, naphthalene-like odor, and producing a sharp, burning sensation on the tongue. Slightly soluble in water, to which it imparts its characteristic odor and taste and a faintly alkaline reaction; partially soluble in acetone, in alcohol, in carbon disulfide, in chloroform, in ether, in methanol, and in solvent hexane; soluble in benzene and nitrobenzene.

**Cocaine:** Colorless to white crystals or white, crystalline powder. Is levorotatory in 3 N hydrochloric acid solution. Its saturated solution is alkaline to litmus. Very soluble in warm alcohol; freely soluble in alcohol, in chloroform, and in ether; soluble in olive oil; sparingly soluble in mineral oil; slightly soluble in water.

**Cocaine Hydrochloride:** Colorless crystals or white, crystalline powder. Very soluble in water; freely soluble in alcohol; soluble in chloroform and in glycerin; insoluble in ether.

**Cocoa Butter:** Yellowish-white solid, having a faint, agreeable odor, and a bland, chocolate-like taste if the cocoa butter is obtained by pressing. If obtained by extraction, the taste is bland. Is usually brittle at temperatures below 25°. Freely soluble in ether and in chloroform; soluble in boiling dehydrated alcohol; slightly soluble in alcohol. *NF category:* Suppository base.

**Coconut Oil:** Clear, white to light yellow-tan, viscous liquid. Freely soluble in methylene chloride and in light petroleum (bp: 65° to 70°); very slightly soluble in alcohol; practically insoluble in water. *NF category:* Coating agent; emulsifying agent; emollient; ointment base.

**Hydrogenated Coconut Oil:** White to yellowish, fatty solid to semi-solid. Freely soluble in ether; very slightly soluble in alcohol; practically insoluble in water. *NF category:* Coating agent; lubricant; wet binder.

**Cod Liver Oil:** Thin, oily liquid, having a characteristic, slightly fishy but not rancid odor, and a fishy taste. Freely soluble in ether, in chloroform, in carbon disulfide, and in ethyl acetate; slightly soluble in alcohol.

**Codeine:** Colorless or white crystals or white, crystalline powder. It effloresces slowly in dry air, and is affected by light. In acid or alcohol solutions it is levorotatory. Its saturated solution is alkaline to litmus. Very soluble in chloroform; freely soluble in alcohol; sparingly soluble in ether; slightly soluble in water. When heated in an amount of water insufficient for complete solution, it melts to oily drops that crystallize on cooling.

**Codeine Phosphate:** Fine, white, needle-shaped crystals, or white, crystalline powder. Is odorless. Is affected by light. Its solutions are acid to litmus. Very soluble in hot water; freely soluble in water; slightly soluble in alcohol but more so in boiling alcohol.

**Codeine Sulfate:** White crystals, usually needle-like, or white, crystalline powder. Is affected by light. Freely soluble in water at 80°; soluble in water; very slightly soluble in alcohol; insoluble in chloroform and in ether.

**Colchicine:** Pale yellow to pale greenish-yellow, amorphous scales, or powder or crystalline powder. Is odorless or nearly so, and darkens on exposure to light. Freely soluble in alcohol and in chloroform; soluble in water; slightly soluble in ether.

**Colestipol Hydrochloride:** Yellow to orange beads. Swells but does not dissolve in water or dilute aqueous solutions of acid or alkali. Insoluble in the common organic solvents.

**Colistimethate Sodium:** White to slightly yellow, odorless, fine powder. Freely soluble in water; soluble in methanol; insoluble in acetone and in ether.

**Colistin Sulfate:** White to slightly yellow, odorless, fine powder. Freely soluble in water; slightly soluble in methanol; insoluble in acetone and in ether.

**Collodion:** Clear, or slightly opalescent, viscous liquid. Is colorless, or slightly yellowish, and has the odor of ether.

**Flexible Collodion:** Clear, or slightly opalescent, viscous liquid. Is colorless or slightly yellow, and has the odor of ether. The strong odor of camphor becomes noticeable as the ether evaporates.

**Copovidone:** White to yellowish-white powder or flakes. Is hygroscopic. Freely soluble in water, in alcohol, and in methylene chloride; practically insoluble in ether. *NF category:* Wet binder; coating agent; film-forming agent.

**Corn Oil:** Clear, light yellow, oily liquid, having a faint, characteristic odor and taste. Slightly soluble in alcohol. Miscible with ether, with chloroform, with benzene, and with solvent hexane. *Specific Gravity* ⟨841⟩: Between 0.914 and 0.921. *NF category:* Solvent; vehicle (oleaginous).

**Corn Syrup:** Clear, white to light yellow, viscous liquid. Is miscible in all proportions with water. *NF category:* Suspending and/or viscosity-increasing agent; sweetening agent; diluent; wet binder; tonicity agent.

**Corn Syrup Solids:** Sweet, white to light yellow powder or granules. Soluble in water. *NF category:* Coating agent; vehicle (flavored and/or sweetened and solid carrier); humectant; suspending and/or viscosity-increasing agent; sweetening agent; diluent; wet binder; tonicity agent.

**Corticotropin Injection:** Colorless or light straw-colored liquid.

**Corticotropin for Injection:** White or practically white, soluble, amorphous solid having the characteristic appearance of substances prepared by freeze-drying.

**Repository Corticotropin Injection:** Colorless or light straw-colored liquid, which may be quite viscid at room temperature. Is odorless or has an odor of an antimicrobial agent.

**Cortisone Acetate:** White or practically white, odorless, crystalline powder. Is stable in air. Melts at about 240°, with some decomposition (see *Melting Range or Temperature* ⟨741⟩). Freely soluble in chloroform; soluble in dioxane; sparingly soluble in acetone; slightly soluble in alcohol; insoluble in water.

**Purified Cotton:** White, soft, fine filament-like hairs appearing under the microscope as hollow, flattened, and twisted bands, striate and slightly thickened at the edges. Is practically odorless and practically tasteless. Soluble in ammoniated cupric oxide TS; insoluble in ordinary solvents.

**Cottonseed Oil:** Pale yellow, oily liquid. Is odorless or nearly so, and has a bland taste. At temperatures below 10° particles of solid fat may separate from the Oil, and at about 0° to –5° the Oil becomes a solid or nearly so. *Specific Gravity* ⟨841⟩: Between 0.915 and 0.921. Slightly soluble in alcohol. Miscible with ether, with chloroform, with solvent hexane, and with carbon disulfide. *NF category:* Solvent; vehicle (oleaginous).

**Hydrogenated Cottonseed Oil:** A white mass or powder that melts to a clear, pale yellow liquid when heated. Freely soluble in methylene chloride and in toluene; very slightly soluble in alcohol; practically insoluble in water.

**Creatinine:** White crystals or crystalline powder; odorless. Soluble in water; slightly soluble in alcohol; practically insoluble in acetone, in ether, and in chloroform. *NF category:* Bulking agent.

**Cresol:** Colorless, or yellowish to brownish-yellow, or pinkish, highly refractive liquid, becoming darker with age and on exposure to light. Has a phenol-like, sometimes empyreumatic odor. A saturated solution of it is neutral or only slightly acid to litmus. Sparingly soluble in water, usually forming a cloudy solution; dissolves in solutions of fixed alkali hydroxides. Miscible with alcohol, with ether, and with glycerin. *NF category:* Antimicrobial preservative.

**Cromolyn Sodium:** White, odorless, crystalline powder. Is tasteless at first, with a slightly bitter aftertaste. Is hygroscopic. Soluble in water; insoluble in alcohol and in chloroform.

**Cromolyn Sodium for Inhalation:** White to creamy white, odorless, hygroscopic, and very finely divided powder.

**Croscarmellose Sodium:** White, free-flowing powder. Partially soluble in water; insoluble in alcohol, in ether, and in other organic solvents. *NF category:* Disintegrant.

**Crospovidone:** White to creamy-white, hygroscopic powder, having a faint odor. Insoluble in water and in ordinary organic solvents. *NF category:* Disintegrant.

**Crotamiton:** Colorless to slightly yellowish oil, having a faint amine-like odor. Soluble in alcohol and in methanol.

**Cupric Chloride:** Bluish green, deliquescent crystals. Freely soluble in water; soluble in alcohol; slightly soluble in ether.

**Cupric Sulfate** ($CuSO_4 \cdot 5H_2O$)**:** Deep blue, triclinic crystals or blue, crystalline granules or powder. It effloresces slowly in dry air. Its solutions are acid to litmus. Very soluble in boiling water; freely soluble in water and in glycerin; slightly soluble in alcohol.

**Cupric Sulfate (anhydrous):** A white or grayish-white powder. Soluble in water; insoluble in alcohol.

**Cyanocobalamin:** Dark red crystals or amorphous or crystalline red powder. In the anhydrous form, it is very hygroscopic and when exposed to air it may absorb about 12% of water. Soluble in alcohol; sparingly soluble in water; insoluble in acetone, in chloroform, and in ether.

**Cyclizine Hydrochloride:** White, crystalline powder or small, colorless crystals. Is odorless or nearly so, and has a bitter taste. Melts indistinctly at about 285°, with decomposition. Sparingly soluble in chloroform; slightly soluble in water and in alcohol; insoluble in ether.

**Cyclobenzaprine Hydrochloride:** White to off-white, odorless, crystalline powder. Freely soluble in water, in alcohol, and in methanol; sparingly soluble in isopropanol; slightly soluble in chloroform and in methylene chloride; insoluble in hydrocarbons.

**Cyclopentolate Hydrochloride:** White, crystalline powder, which upon standing develops a characteristic odor. Its solutions are acid to litmus. Melts at about 138°, the melt appearing opaque. Very soluble in water; freely soluble in alcohol; insoluble in ether.

**Cyclophosphamide:** White, crystalline powder. Liquefies upon loss of its water of crystallization. Soluble in water and in alcohol.

**Cycloserine:** White to pale yellow, crystalline powder. Is odorless or has a faint odor. Is hygroscopic and deteriorates upon absorbing water. Its solutions are dextrorotatory. Freely soluble in water.

**Cyclosporine:** White to almost white powder. Soluble in acetone, in alcohol, in methanol, in ether, in chloroform, and in methylene chloride; slightly soluble in saturated hydrocarbons; practically insoluble in water.

**Cyproheptadine Hydrochloride:** White to slightly yellow, odorless or practically odorless, crystalline powder. Freely soluble in methanol; soluble in chloroform; sparingly soluble in alcohol; slightly soluble in water; practically insoluble in ether.

**Cysteine Hydrochloride:** White crystals or crystalline powder. Soluble in water, in alcohol, and in acetone.

**Cytarabine:** Odorless, white to off-white, crystalline powder. Freely soluble in water; slightly soluble in alcohol and in chloroform.

**Dactinomycin:** Bright red, crystalline powder. Is somewhat hygroscopic and is affected by light and by heat. Freely soluble in alcohol; soluble in water at 10° and slightly soluble in water at 37°; very slightly soluble in ether.

**Dalfampridine:** White powder. Soluble in water, in methanol, in acetone, in tetrahydrofuran, in isopropanol, in acetonitrile, in *N*,*N*-dimethylformamide, in dimethylsulfoxide, and in alcohol.

**Danazol:** White to pale yellow, crystalline powder. Melts at about 225°, with some decomposition. Freely soluble in chloroform; soluble in acetone; sparingly soluble in alcohol and in benzene; slightly soluble in ether; practically insoluble or insoluble in water and in hexane.

**Dantrolene Sodium:** Fine orange to orange-brown powder. Sparingly soluble in dimethylformamide and in glycerine; sparingly soluble to practically insoluble in acetone.

**Dapagliflozin Propanediol:** White to off-white powder which may contain lumps. Freely soluble in methanol, in tetrahydrofuran, in ethanol, and in acetone; soluble in acetonitrile; slightly soluble in water.

**Dapsone:** White or creamy white, crystalline powder. Is odorless and has a slightly bitter taste. Soluble in acetone and in dilute mineral acids; sparingly soluble in alcohol; very slightly soluble in water.

**Daunorubicin Hydrochloride:** Orange-red, crystalline, hygroscopic powder. Freely soluble in water and in methanol; slightly soluble in alcohol; very slightly soluble in chloroform; practically insoluble in acetone.

**Deferoxamine Mesylate:** White to off-white powder. Freely soluble in water; slightly soluble in methanol.

**Dehydroacetic Acid:** White or nearly white, crystalline powder. Soluble in aqueous solutions of alkalies; very slightly soluble in water. One g of sample dissolves in about 35 mL of alcohol and in 5 mL of acetone. *NF category:* Antimicrobial preservative.

**Dehydrocholic Acid:** White, fluffy, odorless powder, having a bitter taste. Soluble in glacial acetic acid and in solutions of alkali hydroxides and carbonates; sparingly soluble in chloroform (the solutions in alcohol and in chloroform usually are slightly turbid); slightly soluble in alcohol and in ether; practically insoluble in water.

**Demecarium Bromide:** White or slightly yellow, slightly hygroscopic, crystalline powder. Freely soluble in water and in alcohol; soluble in ether; sparingly soluble in acetone.

**Demeclocycline:** Yellow, crystalline, odorless powder, having a bitter taste. Soluble in alcohol; sparingly soluble in water. Dissolves readily in 3 N hydrochloric acid and in alkaline solutions.

**Demeclocycline Hydrochloride:** Yellow, crystalline, odorless powder, having a bitter taste. Sparingly soluble in water and in solutions of alkali hydroxides and carbonates; slightly soluble in alcohol; practically insoluble in acetone and in chloroform.

**Denatonium Benzoate:** Very soluble in chloroform and in methanol; freely soluble in water and in alcohol; very slightly soluble in ether. *NF category:* Alcohol denaturant; flavors and fragrance.

**Desipramine Hydrochloride:** White to off-white, crystalline powder. Melts at about 213°. Freely soluble in methanol and in chloroform; soluble in water and in alcohol; insoluble in ether.

**Desloratadine:** White to light pink-colored powder. Very soluble in ethanol and in propylene glycol; soluble in dichloromethane; slightly soluble in water.

**Desmopressin Acetate:** White, fluffy powder. Soluble in water, in alcohol, and in acetic acid.

**Desogestrel:** White or almost-white, crystalline powder. Very soluble in methanol; freely soluble in anhydrous ethanol and in methylene chloride; practically insoluble in water.

**Desonide:** White powder or crystal. Soluble in chloroform; sparingly soluble in ethanol and in acetone; practically insoluble in water.

**Desoximetasone:** White to practically white, odorless, crystalline powder. Freely soluble in alcohol, in acetone, and in chloroform; insoluble in water.

**Deoxycholic Acid:** Occurs as a white, crystalline powder. Freely soluble in alcohol; soluble in acetone and in solutions of alkali hydroxides and carbonates; slightly soluble in chloroform and in ether; practically insoluble in water. *NF category:* Emulsifying agent.

**Desvenlafaxine:** White to off-white, crystalline powder. Sparingly soluble in dimethyl sulfoxide.

**Desvenlafaxine Fumarate:** White to off-white powder. Soluble in methanol; slightly soluble in water.

**Desvenlafaxine Succinate:** White to creamish, crystalline powder. Sparingly soluble in dimethyl sulfoxide, in methanol, and in water.

**Dexamethasone:** White to practically white, odorless, crystalline powder. Is stable in air. Melts at about 250°, with some decomposition. Sparingly soluble in acetone, in alcohol, in dioxane, and in methanol; slightly soluble in chloroform; very slightly soluble in ether; practically insoluble in water.

**Dexamethasone Acetate:** Clear, white to off-white, odorless powder. Freely soluble in methanol, in acetone, and in dioxane; practically insoluble in water.

**Dexamethasone Sodium Phosphate:** White or slightly yellow, crystalline powder. Is odorless or has a slight odor of alcohol, and is exceedingly hygroscopic. Freely soluble in water; slightly soluble in alcohol; very slightly soluble in dioxane; insoluble in chloroform and in ether.

**Dexbrompheniramine Maleate:** White, odorless, crystalline powder. Exists in two polymorphic forms, one melting between 106° and 107° and the other between 112° and 113°. Mixtures of the forms may melt between 105° and 113°. The pH of a solution (1 in 100) is about 5. Freely soluble in water; soluble in alcohol and in chloroform.

**Dexchlorpheniramine Maleate:** White, odorless, crystalline powder. Freely soluble in water; soluble in alcohol and in chloroform; slightly soluble in benzene and in ether.

**Dexmedetomidine Hydrochloride:** White or almost white powder. Freely soluble in water, and has a pKa of 7.1.

**Dexpanthenol:** Clear, viscous, somewhat hygroscopic liquid, having a slight, characteristic odor. Some crystallization may occur on standing. Freely soluble in water, in alcohol, in methanol, and in propylene glycol; soluble in chloroform and in ether; slightly soluble in glycerin.

**Dextran 1:** A white to off-white powder. Is hygroscopic. Very soluble in water; sparingly soluble in alcohol.

**Dextrates:** Free-flowing, porous, white, odorless, spherical granules consisting of aggregates of microcrystals, having a sweet taste and producing a cooling sensation in the mouth. May be compressed directly into self-binding tablets. Freely soluble in water (heating increases its solubility in water); soluble in dilute acids and alkalies and in basic organic solvents such as pyridine; insoluble in the common organic solvents. *NF category:* Sweetening agent; diluent; wet binder.

**Dextrin:** Free-flowing, white, yellow, or brown powder. Its solubility in water varies; it is usually very soluble, but often contains an insoluble portion. *NF category:* Suspending and/or viscosity-increasing agent; diluent; wet binder; film-forming agent; stiffening agent.

**Dextroamphetamine Sulfate:** White, odorless, crystalline powder. Soluble in water; slightly soluble in alcohol; insoluble in ether.

**Dextromethorphan:** Practically white to slightly yellow, odorless, crystalline powder. Eleven mg of Dextromethorphan is equivalent to 15 mg of dextromethorphan hydrobromide monohydrate. Freely soluble in chloroform; practically insoluble in water.

**Dextromethorphan Hydrobromide:** Practically white crystals or crystalline powder, having a faint odor. Melts at about 126°, with decomposition. Freely soluble in alcohol and in chloroform; sparingly soluble in water; insoluble in ether.

**Dextrose:** Colorless crystals or white, crystalline or granular powder. Is odorless, and has a sweet taste. Very soluble in boiling water; freely soluble in water; soluble in boiling alcohol; slightly soluble in alcohol. *NF category:* Sweetening agent; tonicity agent; vehicle (flavored and/or sweetened); diluent.

**Dextrose Excipient:** Colorless crystals or white, crystalline or granular powder. Is odorless and sweet-tasting. Very soluble in boiling water; freely soluble in water; sparingly soluble in boiling alcohol; slightly soluble in alcohol. *NF category:* Sweetening agent; diluent.

**Diacetylated Monoglycerides:** Clear liquid. Very soluble in 80% (w/w) aqueous alcohol, in vegetable oils, and in mineral oils; sparingly soluble in 70% alcohol. *NF category:* Plasticizer.

**Diatrizoate Meglumine:** White, odorless powder. Freely soluble in water.

**Diatrizoate Meglumine Injection:** Clear, colorless to pale yellow, slightly viscous liquid.

**Diatrizoate Meglumine and Diatrizoate Sodium Injection:** Clear, colorless to pale yellow, slightly viscous liquid. May crystallize at room temperature or below.

**Diatrizoate Sodium:** White, odorless powder. Soluble in water; slightly soluble in alcohol; practically insoluble in acetone and in ether.

**Diatrizoate Sodium Injection:** Clear, colorless to pale yellow, slightly viscous liquid.

**Diatrizoate Sodium Solution:** Clear, pale yellow to light brown liquid.

**Diatrizoic Acid:** White, odorless powder. Soluble in dimethylformamide and in alkali hydroxide solutions; very slightly soluble in water and in alcohol.

**Diazepam:** Off-white to yellow, practically odorless, crystalline powder. Freely soluble in chloroform; soluble in alcohol; practically insoluble in water.

**Diazoxide:** White or cream-white crystals or crystalline powder. Very soluble in strong alkaline solutions; freely soluble in dimethylformamide; sparingly soluble to practically insoluble in water and in most organic solvents.

**Dibucaine:** White to off-white powder, having a slight, characteristic odor. Darkens on exposure to light. Soluble in 1 N hydrochloric acid and in ether; slightly soluble in water.

**Dibucaine Hydrochloride:** Colorless or white to off-white crystals or white to off-white, crystalline powder. Is odorless, is somewhat hygroscopic, and darkens on exposure to light. Its solutions have a pH of about 5.5. Freely soluble in water, in alcohol, in acetone, and in chloroform.

**Dibutyl Phthalate:** A clear, oily liquid, colorless or very slightly yellow. Practically insoluble in water. Miscible with alcohol and with ether. *NF category:* Film-forming agent; solvent.

**Dibutyl Sebacate:** Colorless, oily liquid of very mild odor. Soluble in alcohol, in isopropyl alcohol, and in mineral oil; very slightly soluble in propylene glycol; practically insoluble in water and in glycerin. *NF category:* Plasticizer.

**Dichlorphenamide:** White or practically white, crystalline compound. Soluble in dilute solutions of alkali hydroxides and carbonates; very slightly soluble in water.

**Diclazuril:** White to yellow powder. Sparingly soluble in dimethylformamide; practically insoluble in water, in alcohol, and in methylene chloride.

**Diclofenac Potassium:** White to off-white or slightly yellowish crystalline powder, slightly hygroscopic. Freely soluble in methanol; soluble in alcohol; sparingly soluble in water; slightly soluble in acetone.

**Diclofenac Sodium:** White to off-white, hygroscopic, crystalline powder. Melts at about 284°. Freely soluble in methanol; soluble in ethanol; sparingly soluble in water; practically insoluble in chloroform and in ether.

**Dicloxacillin Sodium:** White to off-white, crystalline powder. Freely soluble in water.

**Dicyclomine Hydrochloride:** Fine, white, crystalline powder. Is practically odorless and has a very bitter taste. Freely soluble in alcohol and in chloroform; soluble in water; very slightly soluble in ether.

**Dicyclomine Hydrochloride Injection:** Colorless solution, which may have the odor of a preservative.

**Didanosine:** White to off-white, crystalline powder. Very soluble in dimethyl sulfoxide; practically insoluble or insoluble in acetone and in methanol.

**Diethanolamine:** White or clear, colorless crystals, deliquescing in moist air; or colorless liquid. Miscible with water, with alcohol, with acetone, with chloroform, and with glycerin. Slightly soluble to insoluble in benzene, in ether, and in petroleum ether. *NF category:* Emulsifying agent; pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Diethylcarbamazine Citrate:** White, crystalline powder. Melts at about 136°, with decomposition. Is odorless or has a slight odor; is slightly hygroscopic. Very soluble in water; sparingly soluble in alcohol; practically insoluble in acetone, in chloroform, and in ether.

**Diethylene Glycol Monoethyl Ether:** Clear, colorless liquid. Is hygroscopic. Miscible with water, with acetone, and with alcohol; partially miscible with vegetable oils; immiscible with mineral oils. Specific gravity about 0.991. *NF category:* Ointment base; solvent; emulsifying agent.

**Diethylene Glycol Stearates:** White or almost white, waxy solid. Soluble in acetone and in hot alcohol; practically insoluble in water. *NF category:* Emulsifying agent.

**Diethyl Phthalate:** Colorless, practically odorless, oily liquid. Insoluble in water. Miscible with alcohol, with ether, and with other usual organic solvents. *NF category:* Plasticizer; film-forming agent; solvent.

**Diethyl Sebacate:** A colorless to slightly yellow liquid. Miscible with alcohol, with ether, with other organic solvents, and with most fixed oils; insoluble or practically insoluble in water. *NF category*: Flavors and fragrance.

**Diethylpropion Hydrochloride:** White to off-white, fine crystalline powder. Is odorless, or has a slight characteristic odor. It melts at about 175°, with decomposition. Freely soluble in water, in chloroform, and in alcohol; practically insoluble in ether.

**Diethylstilbestrol:** White, odorless, crystalline powder. Soluble in alcohol, in chloroform, in ether, in fatty oils, and in dilute alkali hydroxides; practically insoluble in water.

**Diethyltoluamide:** Colorless liquid, having a faint, pleasant odor. Boils at about 111° under a pressure of 1 mm of mercury. Practically insoluble in water and in glycerin. Miscible with alcohol, with isopropyl alcohol, with ether, with chloroform, and with carbon disulfide.

**Diflorasone Diacetate:** White to pale yellow, crystalline powder. Soluble in methanol and in acetone; sparingly soluble in ethyl acetate; slightly soluble in toluene; very slightly soluble in ether; insoluble in water.

**Diflunisal:** White to off-white, practically odorless powder. Freely soluble in alcohol and in methanol; soluble in acetone and in ethyl acetate; slightly soluble in chloroform, in carbon tetrachloride, and in methylene chloride; insoluble in hexane and in water.

**Digitoxin:** White or pale buff, odorless, microcrystalline powder. Sparingly soluble in chloroform; slightly soluble in alcohol; very slightly soluble in ether; practically insoluble in water.

**Digoxin:** Clear to white, odorless crystals or white, odorless crystalline powder. Freely soluble in pyridine; slightly soluble in diluted alcohol and in chloroform; practically insoluble in water and in ether.

**Dihydroergotamine Mesylate:** White to slightly yellowish powder, or off-white to faintly red powder, having a faint odor. Soluble in alcohol; slightly soluble in water and in chloroform.

**Dihydrostreptomycin Sulfate:** White or almost white, amorphous or crystalline powder. Amorphous form is hygroscopic. Freely soluble in water; practically insoluble in acetone, in chloroform, and in methanol.

**Dihydroxyacetone:** White to off-white crystalline powder. The monomeric form is freely soluble in water, in alcohol, and in ether. The dimeric form is freely soluble in water; soluble in alcohol; and sparingly soluble in ether.

**Dihydroxyaluminum Aminoacetate:** White, odorless powder having a faintly sweet taste. Soluble in dilute mineral acids and in solutions of fixed alkalies; insoluble in water and in organic solvents.

**Dihydroxyaluminum Aminoacetate Magma:** White, viscous suspension, from which small amounts of water may separate on standing.

**Dihydroxyaluminum Sodium Carbonate:** Fine, white, odorless powder. Soluble in dilute mineral acids with the evolution of carbon dioxide; practically insoluble in water and in organic solvents.

Official

**Diloxanide Furoate:** White or almost white, crystalline powder. Freely soluble in chloroform; slightly soluble in alcohol and in ether; very slightly soluble in water.

**Diltiazem Hydrochloride:** White, odorless, crystalline powder or small crystals. Freely soluble in chloroform, in formic acid, in methanol, and in water; sparingly soluble in dehydrated alcohol; insoluble in ether. Melts at about 210°, with decomposition.

**Dimenhydrinate:** White, crystalline, odorless powder. Freely soluble in alcohol and in chloroform; sparingly soluble in ether; slightly soluble in water.

**Dimercaprol:** Colorless or practically colorless liquid, having a disagreeable, mercaptan-like odor. Soluble in water, in alcohol, in benzyl benzoate, and in methanol.

**Dimercaprol Injection:** Yellow, viscous solution having a pungent, disagreeable odor. Specific gravity is about 0.978.

**Dimethicone:** A clear, colorless, and odorless liquid. Soluble in chlorinated hydrocarbons, in benzene, in toluene, in xylene, in *n*-hexane, in petroleum spirits, in ether, and in amyl acetate; very slightly soluble in isopropyl alcohol; insoluble in water, in methanol, in alcohol, and in acetone. *NF category:* Antifoaming agent; water-repelling agent; adhesive; emollient.

***Add the following:***

▲**Dimethyl Fumarate:** White to off-white, crystalline powder. Soluble in methanol; slightly soluble in water.▲ (USP 1-Dec-2023)

**Dimethyl Sulfoxide:** Clear, colorless, odorless, hygroscopic liquid. Melts at about 18.4°. Boils at about 189°. Soluble in water; practically insoluble in acetone, in alcohol, in benzene, in chloroform, and in ether. *NF category:* Solvent.

**Dinoprostone:** White to off-white, crystalline powder. Freely soluble in acetone, in alcohol, in ether, in ethyl acetate, in isopropyl alcohol, in methanol, and in methylene chloride; soluble in toluene and in diisopropyl ether; practically insoluble in hexanes.

**Dinoprost Tromethamine:** White to off-white, crystalline powder. Very soluble in water; freely soluble in dimethylformamide; soluble in methanol; slightly soluble in chloroform.

**Dioxybenzone:** Yellow powder. Freely soluble in alcohol and in toluene; practically insoluble in water.

**Diphenhydramine Hydrochloride:** White, odorless, crystalline powder. Slowly darkens on exposure to light. Its solutions are practically neutral to litmus. Freely soluble in water, in alcohol, and in chloroform; sparingly soluble in acetone; very slightly soluble in benzene and in ether.

**Diphenoxylate Hydrochloride:** White, odorless, crystalline powder. Its saturated solution has a pH of about 3.3. Freely soluble in chloroform; soluble in methanol; sparingly soluble in alcohol and in acetone; slightly soluble in water and in isopropanol; practically insoluble in ether and in solvent hexane.

**Dipivefrin Hydrochloride:** White, crystalline powder or small crystals, having a faint odor. Very soluble in water.

**Dipyridamole:** Intensely yellow, crystalline powder or needles. Very soluble in methanol, in alcohol, and in chloroform; slightly soluble in water; very slightly soluble in acetone and in ethyl acetate.

**Disopyramide Phosphate:** White or practically white, odorless powder. Melts at about 205°, with decomposition. Freely soluble in water; slightly soluble in alcohol; practically insoluble in chloroform and in ether.

**Disulfiram:** White to off-white, odorless, crystalline powder. Soluble in acetone, in alcohol, in carbon disulfide, and in chloroform; very slightly soluble in water.

**Divalproex Sodium:** White to off-white powder. Very soluble in chloroform; freely soluble in methanol and in ethyl ether; soluble in acetone; practically insoluble in acetonitrile.

**Dobutamine Hydrochloride:** White to practically white, crystalline powder. Soluble in pyridine; sparingly soluble in water, in alcohol, and in methanol.

**Docetaxel:** White or almost white, crystalline powder. Freely soluble in acetone; soluble in methanol; practically insoluble in water.

**Docusate Calcium:** White, amorphous solid, having the characteristic odor of octyl alcohol. It is free of the odor of other solvents. Very soluble in alcohol, in polyethylene glycol 400, and in corn oil; very slightly soluble in water.

**Docusate Potassium:** White, amorphous solid, having a characteristic odor suggestive of octyl alcohol. Very soluble in solvent hexane; soluble in alcohol and in glycerin; sparingly soluble in water.

**Docusate Sodium:** White, wax-like, plastic solid, having a characteristic odor suggestive of octyl alcohol, but no odor of other solvents. Very soluble in solvent hexane; freely soluble in alcohol and in glycerin; sparingly soluble in water. *NF category:* Wetting and/or solubilizing agent.

**Dofetilide:** White to off-white powder. Soluble in 0.1 N sodium hydroxide, in acetone, and in 0.1 N hydrochloric acid; very slightly soluble in water and in isopropyl alcohol.

**Dolasetron Mesylate:** White to off-white powder. Freely soluble in water and in propylene glycol; slightly soluble in alcohol and in saline TS.

**Donepezil Hydrochloride:** White to cream-colored, crystalline powder. Some polymorphic forms are very hygroscopic. Freely soluble in chloroform; soluble in water and in glacial acetic acid; slightly soluble in alcohol and in acetonitrile; practically insoluble in ethyl acetate and in *n*-hexane.

**Dopamine Hydrochloride:** White to off-white, crystalline powder. May have a slight odor of hydrochloric acid. Melts at about 240°, with decomposition. Freely soluble in water and in aqueous solutions of alkali hydroxides; soluble in methanol; insoluble in ether and in chloroform.

**Dorzolamide Hydrochloride:** White to off-white, crystalline powder. Soluble in water.

**Doxapram Hydrochloride:** White to off-white, odorless, crystalline powder. Melts at about 220°. Soluble in water and in chloroform; sparingly soluble in alcohol; practically insoluble in ether.

**Doxazosin Mesylate:** White to tan-colored powder. Freely soluble in formic acid; very slightly soluble in methanol and in water.

**Doxepin Hydrochloride:** White or almost white, crystalline powder. Freely soluble in water, in alcohol, and in methylene chloride.

**Doxercalciferol:** White to off-white powder or crystalline solid. Soluble in *N*,*N*-dimethylformamide; sparingly soluble in methanol; slightly soluble in acetonitrile; practically insoluble in water.

**Doxorubicin Hydrochloride:** Red-orange, hygroscopic, crystalline or amorphous powder. Soluble in water, in isotonic sodium chloride solution, and in methanol; practically insoluble in chloroform, in ether, and in other organic solvents.

**Doxycycline:** Yellow, crystalline powder. Freely soluble in dilute acid and in alkali hydroxide solutions; very slightly soluble in alcohol and in water; practically insoluble in chloroform and in ether.

**Doxycycline Hyclate:** Yellow, crystalline powder. Soluble in water and in solutions of alkali hydroxides and carbonates; slightly soluble in alcohol; practically insoluble in chloroform and in ether.

**Doxylamine Succinate:** White or creamy white powder, having a characteristic odor. Very soluble in water; freely

soluble in chloroform and in alcohol; very slightly soluble in ether.

**Dronabinol:** Light yellow resinous oil that is sticky at room temperature and hardens upon refrigeration. Insoluble in water.

**Dronedarone Hydrochloride:** A white to off-white, fine powder. Freely soluble in methylene chloride and in methanol; practically insoluble in water.

**Droperidol:** White to light tan, amorphous or microcrystalline powder. Freely soluble in chloroform; slightly soluble in alcohol and in ether; practically insoluble in water. Melts at about 145°.

**Drospirenone:** White to off-white powder. Freely soluble in methylene chloride; soluble in acetone and in methanol; sparingly soluble in ethyl acetate and in alcohol; practically insoluble in hexane and in water.

**Duloxetine Hydrochloride:** White to brownish-white solid. Freely soluble in methanol; sparingly soluble in water; practically insoluble in hexane.

**Dutasteride:** White to pale-yellow powder. Soluble in ethanol and methanol; slightly soluble in polyethylene glycol 400; and insoluble in water.

**Dyclonine Hydrochloride:** White crystals or white crystalline powder, which may have a slight odor. Exhibits local anesthetic properties when placed upon the tongue. Soluble in water, in acetone, in alcohol, and in chloroform.

**Dydrogesterone:** White to pale yellow, crystalline powder. Sparingly soluble in alcohol; practically insoluble in water.

**Dyphylline:** White, odorless, extremely bitter, amorphous or crystalline solid. Freely soluble in water; sparingly soluble in alcohol and in chloroform; practically insoluble in ether.

**Ecamsule Solution:** Clear yellow liquid.

**Echothiophate Iodide:** White, crystalline, hygroscopic solid having a slight mercaptan-like odor. Its solutions have a pH of about 4. Freely soluble in water and in methanol; soluble in dehydrated alcohol; practically insoluble in other organic solvents.

**Echothiophate Iodide for Ophthalmic Solution:** White, amorphous powder.

**Econazole Nitrate:** White or practically white, crystalline powder, having not more than a slight odor. Soluble in methanol; sparingly soluble in chloroform; slightly soluble in alcohol; very slightly soluble in water and in ether.

**Edetate Calcium Disodium:** White, crystalline granules or white, crystalline powder. Is odorless, is slightly hygroscopic, and has a faint, saline taste. Is stable in air. Freely soluble in water. *NF category:* Chelating and/or complexing agent.

**Edetate Disodium:** White, crystalline powder. Soluble in water. *NF category:* Chelating and/or complexing agent; transfer ligand.

**Edetic Acid:** White, crystalline powder. Melts above 220°, with decomposition. Soluble in solutions of alkali hydroxides; very slightly soluble in water. *NF category:* Chelating and/or complexing agent.

**Edrophonium Chloride:** White, odorless, crystalline powder. Its solution (1 in 10) is practically colorless. Very soluble in water; freely soluble in alcohol; insoluble in chloroform and in ether.

**Efavirenz:** White to slightly pink crystalline powder. Soluble in methanol; practically insoluble in water.

**Emedastine Fumarate:** White to faintly yellow, crystalline powder. Soluble in water.

**Emtricitabine:** White to almost white crystalline powder. Freely soluble in methanol and in water; practically insoluble in dichloromethane.

**Enalapril Maleate:** Off-white, crystalline powder. Melts at about 144°. Freely soluble in methanol and in dimethylformamide; soluble in alcohol; sparingly soluble in water; slightly soluble in semipolar organic solvents; practically insoluble in nonpolar organic solvents.

**Enalaprilat:** White to nearly white, hygroscopic, crystalline powder. Sparingly soluble in methanol and in dimethylformamide; slightly soluble in water and in isopropyl alcohol; very slightly soluble in acetone, in alcohol, and in hexane; practically insoluble in acetonitrile and in chloroform.

**Enflurane:** Clear, colorless, stable, volatile liquid, having a mild, sweet odor. Is nonflammable. Slightly soluble in water. Miscible with organic solvents, with fats, and with oils.

**Enrofloxacin:** Pale yellow to light yellow crystalline powder. Very slightly soluble in water at pH 7.

**Entacapone:** Greenish yellow to yellow powder. Sparingly soluble in acetone and in methanol; slightly soluble in ethanol, chloroform, isopropanol, and ether; very slightly soluble in toluene; practically insoluble in water.

**Entecavir:** White to off-white powder. Practically insoluble to slightly soluble in water; practically insoluble in anhydrous ethanol and in heptane.

**Ephedrine:** Unctuous, practically colorless solid or white crystals or granules. Gradually decomposes on exposure to light. Melts between 33° and 40°, the variability in the melting point being the result of differences in the moisture content, anhydrous Ephedrine having a lower melting point than the hemihydrate of Ephedrine. Its solutions are alkaline to litmus. Soluble in water, in alcohol, in chloroform, and in ether; sparingly and slowly soluble in mineral oil, the solution becoming turbid if the Ephedrine contains more than about 1% of water.

**Ephedrine Hydrochloride:** Fine, white, odorless crystals or powder. Is affected by light. Freely soluble in water; soluble in alcohol; insoluble in ether.

**Ephedrine Sulfate:** Fine, white, odorless crystals or powder. Darkens on exposure to light. Freely soluble in water; sparingly soluble in alcohol.

**Ephedrine Sulfate Nasal Solution:** Clear, colorless solution. Is neutral or slightly acid to litmus.

**Epinephrine:** White to practically white, odorless, microcrystalline powder or granules, gradually darkening on exposure to light and air. With acids, it forms salts that are readily soluble in water, and the base may be recovered by the addition of ammonia water or alkali carbonates. Its solutions are alkaline to litmus. Very slightly soluble in water and in alcohol; insoluble in ether, in chloroform, and in fixed and volatile oils.

**Epinephrine Injection:** Practically colorless, slightly acid liquid. Gradually turns dark on exposure to light and air.

**Epinephrine Inhalation Solution:** Practically colorless, slightly acid liquid. Gradually turns dark on exposure to light and air.

**Epinephrine Nasal Solution:** Nearly colorless, slightly acid liquid. Gradually turns dark on exposure to light and air.

**Epinephrine Ophthalmic Solution:** Colorless to faint yellow solution. Gradually turns dark on exposure to light and air.

**Epinephrine Bitartrate:** White, or grayish-white or light brownish-gray, odorless, crystalline powder. Slowly darkens on exposure to air and light. Its solutions are acid to litmus, having a pH of about 3.5. Freely soluble in water; slightly soluble in alcohol; practically insoluble in chloroform and in ether.

**Epinephrine Bitartrate for Ophthalmic Solution:** White to off-white solid.

**Epirubicin Hydrochloride:** Orange-red powder. Soluble in water and in methanol; slightly soluble in anhydrous ethanol; practically insoluble in acetone.

**Eprinomectin:** White to off-white powder. Insoluble in cold water.

**Ergocalciferol:** White, odorless crystals. Is affected by air and by light. Soluble in alcohol, in chloroform, in ether, and in fatty oils; insoluble in water.

**Ergocalciferol Oral Solution:** Clear liquid having the characteristics of the solvent used in preparing the Solution.

**Ergoloid Mesylates:** White to off-white, microcrystalline or amorphous, practically odorless powder. Soluble in methanol and in alcohol; sparingly soluble in acetone; slightly soluble in water.

**Ergonovine Maleate:** White to grayish-white or faintly yellow, odorless, microcrystalline powder. Darkens with age and on exposure to light. Sparingly soluble in water; slightly soluble in alcohol; insoluble in ether and in chloroform.

**Ergotamine Tartrate:** Colorless crystals or white to yellowish-white, crystalline powder. Is odorless. Melts at about 180°, with decomposition. One g dissolves in about 3200 mL of water; in the presence of a slight excess of tartaric acid 1 g dissolves in about 500 mL of water. Slightly soluble in alcohol.

**Erythorbic Acid:** White or slightly yellow crystals or powder. It gradually darkens when exposed to light. In the dry state, it is reasonably stable in air, but in solution, it rapidly deteriorates in the presence of air. It melts between 164° and 171° with decomposition. One g is soluble in about 2.5 mL of water and in about 20 mL of alcohol. Slightly soluble in glycerin. *NF category:* Antimicrobial preservative; antioxidant.

**Erythritol:** White or almost white, crystalline powder or free-flowing granules. It is stable to heat and is nonhygroscopic. Freely soluble in water; very slightly soluble in alcohol. *NF category:* Humectant; sweetening agent; diluent.

**Erythromycin:** White or slightly yellow, crystalline powder. Is odorless or practically odorless. Soluble in alcohol, in chloroform, and in ether; slightly soluble in water.

**Erythromycin Ethylsuccinate:** White or slightly yellow crystalline powder. Is odorless or practically odorless, and is practically tasteless. Freely soluble in alcohol, in chloroform, and in polyethylene glycol 400; very slightly soluble in water.

**Erythromycin Lactobionate for Injection:** White or slightly yellow crystals or powder, having a faint odor. Its solution (1 in 20) is neutral or slightly alkaline. Freely soluble in water, in alcohol, and in methanol; slightly soluble in acetone and in chloroform; practically insoluble in ether.

**Erythromycin Stearate:** White or slightly yellow crystals or powder. Is odorless or may have a slight, earthy odor, and has a slightly bitter taste. Soluble in alcohol, in chloroform, in methanol, and in ether; practically insoluble in water.

**Esmolol Hydrochloride:** White to off-white crystalline powder. Very soluble in water; freely soluble in alcohol.

**Escitalopram Oxalate:** Fine, white to slightly yellow powder. Freely soluble in methanol and in dimethyl sulfoxide; sparingly soluble in water and in alcohol; very slightly soluble in ethyl acetate and in isopropyl alcohol; insoluble in heptane.

**Esomeprazole Magnesium:** White to slightly colored powder. Soluble in methanol; slightly soluble in water; practically insoluble in heptane.

**Esomeprazole Strontium:** White to almost-white, crystalline powder. Soluble in water.

**Estazolam:** White to pale yellowish-white crystal. Soluble in methanol and in acetic anhydride; sparingly soluble in ethanol; practically insoluble in water and in ether.

**Estradiol:** White or creamy white, small crystals or crystalline powder. Is odorless, and is stable in air. Is hygroscopic. Soluble in alcohol, in acetone, in dioxane, and in solutions of fixed alkali hydroxides; slightly soluble in chloroform; sparingly soluble in vegetable oils; practically insoluble in water.

**Estradiol Benzoate:** White to off-white, crystalline powder. Soluble in alcohol and in acetone; slightly soluble in diethyl ether; insoluble in water.

**Estradiol Cypionate:** White to practically white, crystalline powder. Is odorless or has a slight odor. Soluble in alcohol, in acetone, in chloroform, and in dioxane; sparingly soluble in vegetable oils; insoluble in water.

**Estradiol Valerate:** White, crystalline powder. Is usually odorless but may have a faint, fatty odor. Soluble in castor oil, in methanol, in benzyl benzoate, and in dioxane; sparingly soluble in sesame oil and in peanut oil; practically insoluble in water.

**Estriol:** White to practically white, odorless, crystalline powder. Melts at about 280°. Soluble in acetone, in chloroform, in dioxane, in ether, and in vegetable oils; sparingly soluble in alcohol; insoluble in water.

**Conjugated Estrogens:** Conjugated Estrogens obtained from natural sources is a buff-colored, amorphous powder, odorless or having a slight, characteristic odor. The synthetic form is a white to light buff, crystalline or amorphous powder, odorless or having a slight odor.

**Esterified Estrogens:** White or buff-colored, amorphous powder, odorless or having a slight, characteristic odor.

**Estrone:** Small, white crystals or white to creamy white, crystalline powder. Is odorless, and is stable in air. Melts at about 260°. Soluble in alcohol, in acetone, in dioxane, and in vegetable oils; slightly soluble in solutions of fixed alkali hydroxides; practically insoluble in water.

**Estropipate:** White to yellowish-white, fine, crystalline powder. Is odorless, or may have a slight odor. Melts at about 190° to a light brown, viscous liquid, which solidifies on further heating and finally melts at about 245°, with decomposition. Soluble in warm water; very slightly soluble in water, in alcohol, in chloroform, and in ether.

**Eszopiclone:** White or light-yellow crystalline solid. Freely soluble in methylene chloride; soluble in pH 3.2 phosphate buffer and in dilute mineral acids; slightly soluble in alcohol; very slightly soluble in water.

**Ethacrynic Acid:** White or practically white, odorless or practically odorless, crystalline powder. Freely soluble in alcohol, in chloroform, and in ether; very slightly soluble in water.

**Ethambutol Hydrochloride:** White, crystalline powder. Freely soluble in water; soluble in alcohol and in methanol; slightly soluble in ether and in chloroform.

**Ethchlorvynol:** Colorless to yellow, slightly viscous liquid, having a characteristic pungent odor. Darkens on exposure to light and air. Immiscible with water; miscible with most organic solvents.

**Ether:** Colorless, mobile, volatile liquid, having a characteristic sweet, pungent odor. Is slowly oxidized by the action of air and light, with the formation of peroxides. It boils at about 35°. Soluble in water and in hydrochloric acid. Miscible with alcohol, with benzene, with chloroform, with solvent hexane, with methylene chloride, and with fixed and volatile oils.

**Ethinyl Estradiol:** White to creamy white, odorless, crystalline powder. Soluble in alcohol, in chloroform, in ether, in vegetable oils, and in solutions of fixed alkali hydroxides; insoluble in water.

**Ethiodized Oil Injection:** Straw-colored to amber-colored, oily liquid. It may possess an alliaceous odor. Soluble in acetone, in chloroform, in ether, and in solvent hexane; insoluble in water.

**Ethionamide:** Bright yellow powder, having a faint to moderate sulfide-like odor. Soluble in methanol; sparingly soluble in alcohol and in propylene glycol; slightly soluble in water, in chloroform, and in ether.

**Ethopabate:** White to pinkish-white, odorless or practically odorless powder. Soluble in acetonitrile, in acetone, in dehydrated alcohol, and in methanol; sparingly soluble in isopropyl alcohol, in dioxane, in ethyl acetate, and in

methylene chloride; slightly soluble in ether; very slightly soluble in water.

**Ethosuximide:** White to off-white, crystalline powder or waxy solid, having a characteristic odor. Freely soluble in water and in chloroform; very soluble in alcohol and in ether; very slightly soluble in solvent hexane.

**Ethotoin:** White, crystalline powder. Freely soluble in dehydrated alcohol and in chloroform; soluble in ether; insoluble in water.

**Ethyl Acetate:** Transparent, colorless liquid, having a fragrant, refreshing, slightly acetous odor, and a peculiar, acetous, burning taste. Soluble in water. Miscible with alcohol, with ether, with fixed oils, and with volatile oils. *NF category:* Flavors and fragrance; solvent.

**Ethyl Acrylate and Methyl Methacrylate Copolymer Dispersion:** Milky-white liquid of low viscosity with a faint, characteristic odor. It is miscible with water in any proportion; the milky-white appearance is retained. A clear or slightly opalescent, viscous solution is obtained on mixing one part with five parts of acetone, alcohol, or isopropyl alcohol; the polymer substance first precipitates, but then dissolves in the excess organic solvent. When mixed with 1 N sodium hydroxide in a ratio of 1:2, the dispersion does not dissolve; the milky-white appearance is retained. *NF category:* Coating agent; polymer membrane; wet binder; film-forming agent; diluent.

**Ethyl Maltol:** White, crystalline powder having a cotton-candy odor and a sweet, fruit-like flavor in dilute solution. One g dissolves in about 55 mL of water, 10 mL of alcohol, 17 mL of propylene glycol, and 5 mL of chloroform. It melts at about 90°. *NF category:* Vehicle (flavored and/or sweetened); flavors and fragrance.

**Ethyl Oleate:** Mobile, practically colorless liquid, having an agreeable taste. Insoluble in water. Miscible with vegetable oils, with mineral oil, with alcohol, and with most organic solvents. *NF category:* Vehicle (oleaginous); solvent.

**Ethyl Vanillin:** Fine, white or slightly yellowish crystals. Its taste and odor are similar to the taste and odor of vanillin. Is affected by light. Its solutions are acid to litmus. Freely soluble in alcohol, in chloroform, in ether, and in solutions of alkali hydroxides; sparingly soluble in water at 50°. *NF category:* Flavors and fragrance.

**Ethylcellulose:** Free-flowing, white to light tan powder. It forms films that have a refractive index of about 1.47. Its aqueous suspensions are neutral to litmus. Ethylcellulose containing less than 46.5% of ethoxy groups is freely soluble in tetrahydrofuran, in methyl acetate, in chloroform, and in mixtures of aromatic hydrocarbons with alcohol; Ethylcellulose containing not less than 46.5% of ethoxy groups is freely soluble in alcohol, in methanol, in toluene, in chloroform, and in ethyl acetate; insoluble in water, in glycerin, and in propylene glycol. *NF category:* Coating agent; wet binder; flavors and fragrance; film-forming agent; polymer membrane; release-modifying agent; suspending and/or viscosity-increasing agent.

**Ethylcellulose Dispersion Type B:** Off-white and slightly viscous liquid. Soluble in alcohol, in methyl alcohol, in tetrahydrofuran, and in ethyl acetate; insoluble in water and in chloroform. *NF category:* Coating agent; film-forming agent; polymer membrane; release-modifying agent.

**Ethylenediamine:** Clear, colorless or only slightly yellow liquid, having an ammonia-like odor and a strong alkaline reaction. Miscible with water and with alcohol.

**Ethylene Glycol Stearates:** White or almost white, waxy solid. Soluble in acetone and in hot alcohol; practically insoluble in water. *NF category:* Emulsifying agent; emollient.

**Ethylene Glycol and Vinyl Alcohol Graft Copolymer:** White or slightly yellowish powder. Very soluble in water; practically insoluble in anhydrous alcohol, and in acetone. It dissolves in dilute acids and dilute solutions of alkali hydroxides. *NF category:* Coating agent; wet binder; film-forming agent.

**Ethylparaben:** Small, colorless crystals or white powder. Freely soluble in acetone, in alcohol, in ether, and in propylene glycol; slightly soluble in water and in glycerin. *NF category:* Antimicrobial preservative.

**Ethylparaben Sodium:** White or almost-white, hygroscopic, crystalline powder. Freely soluble in water; soluble in anhydrous alcohol; practically insoluble in methylene chloride. *NF category:* Antimicrobial preservative.

**Ethynodiol Diacetate:** White, odorless, crystalline powder. Is stable in air. Very soluble in chloroform; freely soluble in ether; soluble in alcohol; sparingly soluble in fixed oils; insoluble in water.

**Etidronate Disodium:** White powder, which may contain lumps. Freely soluble in water; practically insoluble in alcohol.

**Etomidate:** White or almost white powder. Freely soluble in alcohol and in methylene chloride; very slightly soluble in water.

**Etoposide:** Fine, white to off-white, crystalline powder. Sparingly soluble in methanol; slightly soluble in alcohol, in chloroform, in ethyl acetate, and in methylene chloride; very slightly soluble in water.

**Etoposide Phosphate:** White powder. Freely soluble in water; soluble in dimethylsulfoxide.

**Eucalyptus Oil:** Colorless or pale yellow liquid. One mL of eucalyptus oil dissolves in 5 mL of 70% alcohol. Insoluble in cold water. *NF category*: Flavors and perfumes.

**Eugenol:** Colorless or pale yellow liquid, having a strongly aromatic odor of clove and a pungent, spicy taste. Upon exposure to air, it darkens and thickens. Is optically inactive. Slightly soluble in water. Miscible with alcohol, with chloroform, with ether, and with fixed oils.

**Exemestane:** White to slightly yellow, crystalline powder. Freely soluble in *N*,*N*-dimethylformamide; soluble in methanol; insoluble in water.

**Ezetimibe:** White powder. Freely soluble in alcohol; soluble in acetonitrile; insoluble in aqueous solvents and nonpolar solvents like hexane.

**Famciclovir:** A white to pale yellow solid. Freely soluble in methanol and in acetone; sparingly soluble in ethanol and in isopropyl alcohol.

**Famotidine:** White to pale yellowish-white, crystalline powder. Is sensitive to light. Freely soluble in dimethylformamide and in glacial acetic acid; slightly soluble in methanol; very slightly soluble in water; practically insoluble in acetone, in alcohol, in chloroform, in ether, and in ethyl acetate.

**Hard Fat:** White mass; almost odorless and free from rancid odor; greasy to the touch. On warming, melts to give a colorless or slightly yellowish liquid. When the molten material is shaken with an equal quantity of hot water, a white emulsion is formed. Freely soluble in ether; slightly soluble in alcohol; practically insoluble in water. *NF category:* Stiffening agent; suppository base.

**Felbamate:** White to off-white powder. Freely soluble in dimethyl sulfoxide; sparingly soluble in methanol; slightly soluble in acetonitrile; very slightly soluble in water.

**Felodipine:** Light yellow to yellow, crystalline powder. Freely soluble in acetone and in methanol; very slightly soluble in heptane; insoluble in water.

**Fenbendazole:** White to off-white powder. Sparingly soluble in dimethylformamide; very slightly soluble in methanol; practically insoluble in water.

**Fenofibrate:** White or almost white, crystalline powder. Very soluble in methylene chloride; slightly soluble in alcohol; practically insoluble in water.

Official

https://pharmacopeia.cn/

**Fenoldopam Mesylate:** White to off-white powder. Soluble in water.

**Fenoprofen Calcium:** White, crystalline powder. Slightly soluble in *n*-hexanol, in methanol, and in water; practically insoluble in chloroform.

**Fentanyl Citrate:** White, crystalline powder or white, glistening crystals. Melts at about 150°, with decomposition. Soluble in methanol; sparingly soluble in water; slightly soluble in chloroform.

**Ferric Oxide:** Powder exhibiting two basic colors (red and yellow), or other shades produced on blending the basic colors. Insoluble in water and in organic solvents; dissolves in hydrochloric acid upon warming, a small amount of insoluble residue usually remaining. *NF category:* Coloring agent.

**Ferric Subsulfate Solution:** Reddish-brown liquid, odorless or nearly so. Acid to litmus, and is affected by light. Specific gravity is about 1.548.

**Ferric Sulfate:** Grayish-white or yellowish powder or fawn-colored pearls. Hygroscopic. Slightly soluble in water and in ethanol (96%); practically insoluble in acetone and in ethyl acetate. Hydrolyzes slowly in aqueous solution.

**Ferrosoferric Oxide:** Black powder. Dissolves in hydrochloric acid upon warming, a small amount of insoluble residue usually remaining; insoluble in water and in organic solvents. *NF category:* Coloring agent.

**Ferrous Fumarate:** Reddish-orange to red-brown, odorless powder. May contain soft lumps that produce a yellow streak when crushed. Slightly soluble in water; very slightly soluble in alcohol. Its solubility in dilute hydrochloric acid is limited by the separation of fumaric acid.

**Ferrous Gluconate:** Yellowish-gray or pale greenish-yellow, fine powder or granules, having a slight odor resembling that of burned sugar. Its solution (1 in 20) is acid to litmus. Soluble in water, with slight heating; practically insoluble in alcohol.

**Ferrous Sulfate:** Pale, bluish-green crystals or granules. Is odorless and is efflorescent in dry air. Oxidizes readily in moist air to form brownish yellow basic ferric sulfate. Its solution (1 in 10) is acid to litmus, having a pH of about 3.7. Very soluble in boiling water; freely soluble in water; insoluble in alcohol.

**Dried Ferrous Sulfate:** Grayish-white to buff-colored powder, consisting primarily of $FeSO_4 \cdot H_2O$ with varying amounts of $FeSO_4 \cdot 4H_2O$. Slowly soluble in water; insoluble in alcohol.

**Fexofenadine Hydrochloride:** White to off-white powder. Freely soluble in methanol; very slightly to slightly soluble in water; very slightly soluble in acetone.

**Finasteride:** White to off-white, crystalline solid. Melts at about 257°. Freely soluble in chloroform and in alcohol; very slightly soluble in water.

**Fingolimod Hydrochloride:** White to practically white powder. Freely soluble in water and in alcohol. Soluble in propylene glycol.

**Fish Oil Containing Omega-3 Acids:** Pale yellow liquid. Very soluble in acetone and in heptane; slightly soluble in anhydrous alcohol; practically insoluble in water.

**Flavoxate Hydrochloride:** White or almost white, crystalline powder. Slightly soluble in alcohol, in water, and in methylene chloride.

**Flecainide Acetate:** White to slightly off-white, crystalline powder. Freely soluble in alcohol; soluble in water. $pK_a$ is 9.3.

**Fluconazole:** White or almost white, crystalline powder. Freely soluble in methanol; soluble in alcohol and in acetone; sparingly soluble in isopropanol and in chloroform; slightly soluble in water; very slightly soluble in toluene.

**Flucytosine:** White to off-white, crystalline powder. Is odorless or has a slight odor. Sparingly soluble in water; slightly soluble in alcohol; practically insoluble in chloroform and in ether.

**Fludarabine Phosphate:** White to off-white, crystalline, hygroscopic powder. Freely soluble in dimethylformamide; slightly soluble in water and in 0.1 M hydrochloric acid; practically insoluble in ethanol.

**Fludrocortisone Acetate:** White to pale yellow crystals or crystalline powder. Is odorless or practically odorless. Is hygroscopic. Sparingly soluble in alcohol and in chloroform; slightly soluble in ether; insoluble in water.

**Flumazenil:** White to off-white powder. Slightly soluble in acidic aqueous solutions; practically insoluble in water.

**Flunisolide:** White to creamy-white, crystalline powder. Melts at about 245°, with decomposition. Soluble in acetone; sparingly soluble in chloroform; slightly soluble in methanol; practically insoluble in water.

**Flunixin Meglumine:** White to off-white crystalline powder. Soluble in water, in alcohol, and in methanol; practically insoluble in ethyl acetate.

**Fluocinolone Acetonide:** White or practically white, odorless, crystalline powder. Is stable in air. Melts at about 270°, with decomposition. Soluble in methanol; slightly soluble in ether and in chloroform; insoluble in water.

**Fluocinonide:** White to cream-colored, crystalline powder, having not more than a slight odor. Sparingly soluble in acetone and in chloroform; slightly soluble in alcohol, in methanol, and in dioxane; very slightly soluble in ether; practically insoluble in water.

**Fluorescein:** Yellowish-red to red, odorless powder. Soluble in dilute alkali hydroxides; insoluble in water.

**Fluorescein Sodium:** Orange-red, hygroscopic, odorless powder. Freely soluble in water; sparingly soluble in alcohol.

**Fluorescein Sodium Ophthalmic Strip:** Each Strip is a dry, white piece of paper, one end of which is rounded and is uniformly orange-red in color because of the fluorescein sodium impregnated in the paper.

**Fluorometholone:** White to yellowish-white, odorless, crystalline powder. Melts at about 280°, with some decomposition. Slightly soluble in alcohol; very slightly soluble in chloroform; practically insoluble in water and in ether.

**Fluorouracil:** White to practically white, practically odorless, crystalline powder. Decomposes at about 282°. Sparingly soluble in water; slightly soluble in alcohol; practically insoluble in chloroform and in ether.

**Fluoxetine Hydrochloride:** White to off-white crystalline powder. Freely soluble in alcohol and in methanol; sparingly soluble in water and in dichloromethane; practically insoluble in ether.

**Fluoxymesterone:** White or practically white, odorless, crystalline powder. Melts at about 240°, with some decomposition. Sparingly soluble in alcohol; slightly soluble in chloroform; practically insoluble in water.

**Fluphenazine Decanoate:** Pale yellow to yellow-orange, viscous liquid or yellow solid. Slowly crystallizes at room temperature. Melts at about 30°–32°. Very soluble in chloroform, in ether, in cyclohexane, in dehydrated alcohol, and in methylene chloride; freely soluble in methanol; insoluble in water.

**Fluphenazine Enanthate:** Pale yellow to yellow-orange, clear to slightly turbid, viscous liquid, having a characteristic odor. Is unstable in strong light, but stable to air at room temperature. Freely soluble in alcohol, in chloroform, and in ether; insoluble in water.

**Fluphenazine Hydrochloride:** White or nearly white, odorless, crystalline powder. Melts, within a range of 5°, at a temperature above 225°. Freely soluble in water; slightly soluble in alcohol, in chloroform, and in methylene chloride; practically insoluble in benzene and in ether.

**Flurandrenolide:** White to off-white, fluffy, crystalline powder. Is odorless. Freely soluble in chloroform; soluble in

methanol; sparingly soluble in alcohol; practically insoluble in water and in ether.

**Flurazepam Hydrochloride:** Off-white to yellow, crystalline powder. Is odorless, or has a slight odor, and its solutions are acid to litmus. Melts at about 212°, with decomposition. Freely soluble in water and in alcohol; slightly soluble in isopropyl alcohol and in chloroform.

**Flurbiprofen:** White, crystalline powder. Freely soluble in acetone, in dehydrated alcohol, in ether, and in methanol; soluble in acetonitrile; practically insoluble in water. Optically inactive (1 in 50 solution in dehydrated alcohol).

**Flutamide:** Pale yellow, crystalline powder. Freely soluble in acetone, in ethyl acetate, and in methanol; soluble in chloroform and in ether; practically insoluble in mineral oil, in petroleum ether, and in water.

**Fluticasone Propionate (micronized):** Fine, white powder.

**Fluvastatin Sodium:** White to pale yellow, brownish-pale yellow, or reddish-pale yellow, hygroscopic powder. Soluble in alcohol, in methanol, and in water.

**Fluvoxamine Maleate:** White to off-white, crystalline powder. Freely soluble in alcohol and in chloroform; sparingly soluble in water; and practically insoluble in diethyl ether.

**Folic Acid:** Yellow, yellow-brownish, or yellowish-orange, odorless, crystalline powder. It readily dissolves in dilute solutions of alkali hydroxides and carbonates. Soluble in hot, 3 N hydrochloric acid, in hot, 2 N sulfuric acid, in hydrochloric acid, and in sulfuric acid, yielding very pale yellow solutions; very slightly soluble in water; insoluble in alcohol, in acetone, in chloroform, and in ether.

**Folic Acid Injection:** Clear, yellow to orange-yellow, alkaline liquid.

**Formaldehyde Solution:** Clear, colorless or practically colorless liquid, having a pungent odor. The vapor from it irritates the mucous membrane of the throat and nose. On long standing, especially in the cold, it may become cloudy because of the separation of paraformaldehyde. This cloudiness disappears when the solution is warmed. Miscible with water and with alcohol.

**Formoterol Fumarate Dihydrate:** White or almost white or slightly yellow powder. Freely soluble in dimethyl sulfoxide and in acetic acid; soluble in methanol; slightly soluble in water and in 2-propanol; practically insoluble in acetonitrile and in diethyl ether.

**Fosamprenavir Calcium:** White to cream-colored solid. Soluble in water, in ethanol, in dimethyl sulfoxide (DMSO), and in dimethyl formamide.

**Foscarnet Sodium:** White to almost white, crystalline powder. Soluble in water; practically insoluble in alcohol.

**Fosphenytoin Sodium:** White to pale yellow solid. Freely soluble in water.

**Fructose:** Colorless crystals or as a white, crystalline powder. Is odorless, and has a sweet taste. Freely soluble in water; soluble in alcohol and in methanol. *NF category:* Sweetening agent; diluent; flavors and fragrance.

**Basic Fuchsin:** Dark green powder or greenish glistening crystalline fragments, having a bronze-like luster and not more than a faint odor. Soluble in water, in alcohol, and in amyl alcohol; insoluble in ether.

**Fulvestrant:** White powder. Freely soluble in alcohol.

**Fumaric Acid:** White, odorless granules or crystalline powder. Soluble in alcohol; slightly soluble in water and in ether; very slightly soluble in chloroform. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent); flavors and fragrance; antioxidant.

**Furazolidone:** Yellow, odorless, crystalline powder. Is tasteless at first, then a bitter aftertaste develops. Practically insoluble in water, in alcohol, and in carbon tetrachloride.

**Furosemide:** White to slightly yellow, odorless, crystalline powder. Freely soluble in acetone, in dimethylformamide, and in solutions of alkali hydroxides; soluble in methanol; sparingly soluble in alcohol; slightly soluble in ether; very slightly soluble in chloroform; practically insoluble in water.

**Furosemide Injection:** Clear, colorless solution.

**Gabapentin:** White to off-white, crystalline solid. Freely soluble in water and in alkaline and acidic solutions.

**Gadobutrol:** White or almost-white powder. Anhydrous form may be hygroscopic. Freely soluble in water; practically insoluble in absolute alcohol and in heptane.

**Gadodiamide:** White, odorless powder. Freely soluble in water and in methanol; soluble in ethyl alcohol; slightly soluble in acetone and in chloroform.

**Gadoteridol:** White to off-white, crystalline, odorless powder. Freely soluble in water and in methyl alcohol; soluble in isopropyl alcohol. Melts at about 300°.

**Galactose:** A white, crystalline or finely granulated powder. Soluble in water; very slightly soluble in alcohol. *NF category:* Sweetening agent; chelating and/or complexing agent.

**Galantamine Hydrobromide:** White to almost white powder. Soluble in 0.1 N sodium hydroxide; sparingly soluble in water; very slightly soluble in alcohol; insoluble in *n*-propanol.

**Gamma Cyclodextrin:** White or almost white, amorphous or crystalline powder. Freely soluble in water and in propylene glycol; very slightly soluble in alcohol. *NF category:* Sequestering agent; chelating and/or complexing agent.

**Ganciclovir:** White to off-white, crystalline powder.

**Ganciclovir for Injection:** White to off-white powder. Soluble in water.

**Petrolatum Gauze:** The petrolatum recovered by draining in the *Assay* is a white or faintly yellowish, unctuous mass, transparent in thin layers even after cooling to 0°.

**Gelatin:** Sheets, flakes, or shreds, or coarse to fine powder. Is faintly yellow or amber in color, the color varying in depth according to the particle size. Has a slight, characteristic bouillon-like odor in solution. Is stable in air when dry, but is subject to microbic decomposition when moist or in solution. Gelatin has any suitable strength that is designated by Bloom Gelometer number. Type A Gelatin exhibits an isoelectric point between pH 7 and pH 9, and Type B Gelatin exhibits an isoelectric point between pH 4.7 and pH 5.2. Soluble in hot water, in 6 N acetic acid, and in a hot mixture of glycerin and water; insoluble in cold water, but swells and softens when immersed in it, gradually absorbing from 5 to 10 times its own weight of water, in alcohol, in chloroform, in ether, and in fixed and volatile oils. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; wet binder; capsule shell; colloid stabilizing agent; film-forming agent.

**Absorbable Gelatin Film:** Light amber, transparent, pliable film which becomes rubbery when moistened. Insoluble in water.

**Absorbable Gelatin Sponge:** Light, nearly white, nonelastic, tough, porous, hydrophilic solid. Insoluble in water.

**Gellan Gum:** Off-white powder. Soluble in hot or in cold deionized water. *NF category:* Suspending and/or viscosity-increasing agent.

**Gemcitabine Hydrochloride:** White to off-white solid. Soluble in water; slightly soluble in methanol; practically insoluble in alcohol and in polar organic solvents.

**Gemfibrozil:** White, waxy, crystalline solid. Soluble in alcohol, in methanol, and in chloroform; practically insoluble in water.

**Gemifloxacin Mesylate:** A white to light brown solid. Freely soluble at neutral pH.

**Gentamicin Sulfate:** White to buff powder. Freely soluble in water; insoluble in alcohol, in acetone, in chloroform, in ether, and in benzene.

**Gentamicin Injection:** Clear, slightly yellow solution, having a faint odor.

**Gentian Violet:** Dark green powder or greenish, glistening pieces having a metallic luster, and having not more than a faint odor. Soluble in alcohol, in glycerin, and in chloroform; sparingly soluble in water; insoluble in ether.

**Gentian Violet Cream:** Dark purple, water-washable cream.

**Gentian Violet Topical Solution:** Purple liquid, having a slight odor of alcohol. A dilution (1 in 100), viewed downward through 1 cm of depth, is deep purple in color.

**Powdered Asian Ginseng Extract:** Pale yellow-brown, hygroscopic, powdery or easily pulverizable mass. Soluble in water, forming a slightly cloudy solution.

**Glaze, Pharmaceutical:** Denatured alcohol solution. *NF category:* Coating agent; film-forming agent.

**Glimepiride:** White to almost white powder. Soluble in dimethylformamide; sparingly soluble in methylene chloride; slightly soluble in methanol; practically insoluble in water.

**Glipizide:** White to off-white powder. Freely soluble in dimethylformamide; soluble in 0.1 N sodium hydroxide; slightly soluble in methylene chloride.

**Glucagon:** Fine, white or faintly colored, crystalline powder. Is practically odorless and tasteless. Soluble in dilute alkali and acid solutions; insoluble in most organic solvents.

**Glucagon for Injection:** White, odorless powder.

**Gluconolactone:** Fine, white, practically odorless, crystalline powder. Melts at about 153°, with decomposition. Freely soluble in water; sparingly soluble in alcohol; insoluble in ether.

**Liquid Glucose:** Colorless or yellowish, thick, syrupy liquid. Odorless or nearly odorless, and has a sweet taste. Sparingly soluble in alcohol. Miscible with water. *NF category:* Wet binder; coating agent; sweetening agent.

**L-Glutamic Acid Hydrochloride:** A white, crystalline powder. 1 g dissolves in about 3 mL of water. It is almost insoluble in alcohol and in ether. Its solutions are acid to litmus. *NF category*: Flavors and fragrance.

**Glutamine:** White crystals or crystalline powder. Soluble in water; practically insoluble in alcohol and in ether.

**Glutaral Concentrate:** Clear, colorless or faintly yellow liquid, having a characteristic, irritating odor.

**Glycerin:** Clear, colorless, syrupy liquid, having a sweet taste. Has not more than a slight characteristic odor, which is neither harsh nor disagreeable. Is hygroscopic. Its solutions are neutral to litmus. Insoluble in chloroform, in ether, and in fixed and volatile oils. Miscible with water and with alcohol. *NF category:* Humectant; plasticizer; solvent; tonicity agent; antimicrobial preservative; emollient; sweetening agent.

**Glyceryl Dibehenate:** Fine powder, having a faint odor. Melts at about 70°. Soluble in chloroform; practically insoluble in water and in alcohol. *NF category*: Lubricant; coating agent; suspending and/or viscosity-increasing agent; wet binder.

**Glyceryl Distearate:** Hard, waxy mass or powder or white or almost white flakes. Soluble in methylene chloride and in tetrahydrofuran; slightly soluble in hot alcohol; insoluble in water. *NF category:* Emulsifying agent.

**Glyceryl Mono and Dicaprylate:** Colorless or slightly yellow, oily liquid or semisolid. Very soluble in alcohol; freely soluble in methylene chloride; practically insoluble in water. *NF category:* Lubricant; emulsifying agent.

**Glyceryl Mono and Dicaprylocaprate:** Colorless or slightly yellow, oily liquid or semisolid. Very soluble in alcohol; freely soluble in methylene chloride; practically insoluble in water. *NF category:* Lubricant; emulsifying agent.

**Glyceryl Monocaprylate:** Colorless or slightly yellow, oily liquid or semisolid. Very soluble in alcohol; freely soluble in methylene chloride; practically insoluble in water. *NF category*: Lubricant; emulsifying agent.

**Glyceryl Monocaprylocaprate:** Colorless or slightly yellow, oily liquid or semisolid. Very soluble in alcohol; freely soluble in methylene chloride; practically insoluble in water. *NF category*: Lubricant; emulsifying agent.

**Glyceryl Monolinoleate:** Amber, oily liquids that may be partially solidified at room temperature. Freely soluble in methylene chloride; soluble in tetrahydrofuran; practically insoluble in water. *NF category:* Emulsifying agent.

**Glyceryl Monooleate:** Amber, oily liquids that may be partially solidified at room temperature. Freely soluble in methylene chloride; soluble in tetrahydrofuran; practically insoluble in water. *NF category:* Emulsifying agent; emollient; release-modifying agent.

**Glyceryl Monostearate:** White to yellowish wax-like solid; or white to yellowish wax-like beads, flakes, or powder. Slight, agreeable, fatty odor and taste. Is affected by light. Dissolves in hot organic solvents such as alcohol, minerals or fixed oils, benzene, ether, and acetone. Insoluble in water, but it may be dispersed in hot water with the aid of a small amount of soap or other suitable surface-active agent. *NF category:* Emulsifying agent; emollient; release-modifying agent; lubricant.

**Glyceryl Tricaprylate:** Clear, colorless to pale-yellow liquid. Very soluble in alcohol; freely soluble in methylene chloride; practically insoluble in water. *NF category*: Lubricant; emulsifying agent; vehicle (solid carrier).

**Glyceryl Tristearate:** White, solid, microcrystalline powder. Soluble in hot alcohol, in acetone, and in chloroform; very slightly soluble in cold alcohol, in ether, and in petroleum ether; insoluble in water. *NF category:* Lubricant; emulsifying agent.

**Glycine:** White, odorless, crystalline powder, having a sweetish taste. Its solutions are acid to litmus. Freely soluble in water; very slightly soluble in alcohol and in ether. *NF category:* Bulking agent; disintegrant; wetting and/or solubilizing agent; pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Glycopyrrolate:** White, odorless, crystalline powder. Soluble in water and in alcohol; practically insoluble in chloroform and in ether.

**Gonadorelin Acetate:** White to slightly yellowish powder. Soluble in water; sparingly soluble in methanol.

**Chorionic Gonadotropin:** White or practically white, amorphous powder. Freely soluble in water.

**Chorionic Gonadotropin for Injection:** White or practically white, amorphous solid having the characteristic appearance of substances prepared by freeze-drying.

**Gramicidin:** White or practically white, odorless, crystalline powder. Soluble in alcohol; insoluble in water.

**Granisetron:** Off-white to pale-yellow powder. Soluble to freely soluble in methanol and in methylene chloride.

**Granisetron Hydrochloride:** White or almost white powder. Freely soluble in water; sparingly soluble in methylene chloride; slightly soluble in methanol.

**Green Soap:** Soft, unctuous, yellowish-white to brownish or greenish yellow, transparent to translucent mass. Has a slight, characteristic odor, often suggesting the oil from which it was prepared. Its solution (1 in 20) is alkaline to bromothymol blue TS.

**Griseofulvin:** White to creamy white, odorless powder, in which particles of the order of 4 µm in diameter predominate. Soluble in acetone, in dimethylformamide, and in chloroform; sparingly soluble in alcohol; very slightly soluble in water.

**Guaifenesin:** White to slightly gray, crystalline powder. May have a slight characteristic odor. Soluble in water, in

alcohol, in chloroform, and in propylene glycol; sparingly soluble in glycerin.

**Guanabenz Acetate:** White or almost white powder having not more than a slight odor. Soluble in alcohol and in propylene glycol; sparingly soluble in water and in 0.1 N hydrochloric acid.

**Guanethidine Monosulfate:** White to off-white, crystalline powder. Very soluble in water; sparingly soluble in alcohol; practically insoluble in chloroform.

***Add the following:***

▲**Guanfacine Hydrochloride:** White to off-white, crystalline powder. Sparingly soluble in water, in methanol, and in ethanol; slightly soluble in acetone.▲ (USP 1-Dec-2023)

**Guanidine Hydrochloride:** White crystalline powder. Freely soluble in water and in alcohol. *NF category*: Chaotropic agent; wetting and/or solubilizing agent.

**Guar Gum:** White to yellowish-white, practically odorless powder. Dispersible in hot or cold water, forming a colloidal solution. *NF category:* Suspending and/or viscosity-increasing agent; wet binder; polymers for ophthalmic use; release-modifying agent; disintegrant.

**Gutta Percha:** Lumps or blocks of variable size; externally brown or grayish-brown to grayish-white in color; internally reddish yellow or reddish gray and having a laminated or fibrous appearance. Is flexible but only slightly elastic. Has a slight, characteristic odor and a slight taste. Soluble in chloroform; partly soluble in benzene, in carbon disulfide, and in turpentine oil; insoluble in water.

**Halazone:** White, crystalline powder, having a characteristic chlorine-like odor. Is affected by light. Melts at about 194°, with decomposition. Soluble in glacial acetic acid; very slightly soluble in water and in chloroform. Dissolves in solutions of alkali hydroxides and carbonates with the formation of a salt.

**Halazone Tablets for Solution:** Soluble in water.

**Halcinonide:** White to off-white, odorless, crystalline powder. Soluble in acetone and in chloroform; slightly soluble in alcohol and in ethyl ether; insoluble in water and in hexanes.

**Halobetasol Propionate:** White to off-white powder. Freely soluble in dichloromethane and in acetone; practically insoluble in water.

**Haloperidol:** White to faintly yellowish, amorphous or microcrystalline powder. Its saturated solution is neutral to litmus. Soluble in chloroform; sparingly soluble in alcohol; slightly soluble in ether; practically insoluble in water.

**Haloperidol Decanoate:** A white or almost white powder. Very soluble in alcohol, in methanol, and in methylene chloride; practically insoluble in water.

**Halothane:** Colorless, mobile, nonflammable, heavy liquid, having a characteristic odor resembling that of chloroform. Its taste is sweet and produces a burning sensation. Slightly soluble in water. Miscible with alcohol, with chloroform, with ether, and with fixed oils.

**Helium:** Colorless, odorless, tasteless gas, which is not combustible and does not support combustion. Very slightly soluble in water. At 0° and at a pressure of 760 mm of mercury, 1000 mL of the gas weighs about 180 mg.

**Heparin Sodium:** White or pale-colored, amorphous powder. Is odorless or practically so, and is hygroscopic. Soluble in water.

**Hexachlorophene:** White to light tan, crystalline powder. Is odorless or has only a slight, phenolic odor. Freely soluble in acetone, in alcohol, and in ether; soluble in chloroform and in dilute solutions of fixed alkali hydroxides; insoluble in water.

**Hexachlorophene Liquid Soap:** Clear, amber-colored liquid, having a slight, characteristic odor. Its solution (1 in 20) is clear and has an alkaline reaction.

**Hexylene Glycol:** Clear, colorless, viscous liquid. Absorbs moisture when exposed to moist air. Miscible with water and with many organic solvents, including alcohol, ether, chloroform, acetone, and hexanes. *NF category:* Humectant; solvent.

**Histamine Phosphate:** Colorless, odorless, long prismatic crystals. Is stable in air but is affected by light. Its solutions are acid to litmus. Freely soluble in water.

**Histidine:** White, odorless crystals, having a slightly bitter taste. Soluble in water; very slightly soluble in alcohol; insoluble in ether.

**Homatropine Hydrobromide:** White crystals, or white, crystalline powder. Slowly darkens on exposure to light. Freely soluble in water; sparingly soluble in alcohol; slightly soluble in chloroform; insoluble in ether. Melts between 214° and 217°, with slight decomposition.

**Homatropine Methylbromide:** White, odorless powder. Slowly darkens on exposure to light. Melts at about 190°. Very soluble in water; freely soluble in alcohol and in acetone containing about 20% of water; practically insoluble in ether and in acetone.

**Hydralazine Hydrochloride:** White to off-white, odorless, crystalline powder. Melts at about 275°, with decomposition. Soluble in water; slightly soluble in alcohol; very slightly soluble in ether.

**Hydrochloric Acid:** Colorless, fuming liquid having a pungent odor. It ceases to fume when it is diluted with 2 volumes of water. Specific gravity is about 1.18. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Diluted Hydrochloric Acid:** Colorless, odorless liquid. Specific gravity is about 1.05. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Hydrochlorothiazide:** White, or practically white, practically odorless, crystalline powder. Freely soluble in sodium hydroxide solution, in *n*-butylamine, and in dimethylformamide; very slightly soluble in water; sparingly soluble in methanol; insoluble in ether, in chloroform, and in dilute mineral acids.

**Hydrocodone Bitartrate:** Fine, white crystals or a crystalline powder. Is affected by light. Soluble in water; slightly soluble in alcohol; insoluble in ether and in chloroform.

**Hydrocortisone:** White to practically white, odorless, crystalline powder. Melts at about 215°, with decomposition. Sparingly soluble in acetone and in alcohol; slightly soluble in chloroform; very slightly soluble in water and in ether.

**Hydrocortisone Acetate:** White to practically white, odorless, crystalline powder. Melts at about 220°, with decomposition. Slightly soluble in alcohol and in chloroform; insoluble in water.

**Hydrocortisone Butyrate:** White to practically white, practically odorless, crystalline powder. Freely soluble in chloroform; soluble in methanol, in alcohol, and in acetone; slightly soluble in ether; practically insoluble in water.

**Hydrocortisone Sodium Phosphate:** White to light yellow, odorless or practically odorless, powder. Is exceedingly hygroscopic. Freely soluble in water; slightly soluble in alcohol; practically insoluble in chloroform, in dioxane, and in ether.

**Hydrocortisone Sodium Succinate:** White or nearly white, odorless, hygroscopic, amorphous solid. Very soluble in water and in alcohol; very slightly soluble in acetone; insoluble in chloroform.

**Hydroflumethiazide:** White to cream-colored, finely divided, odorless, crystalline powder. Freely soluble in acetone; soluble in alcohol; very slightly soluble in water.

**Hydrogen Peroxide Concentrate:** Clear, colorless liquid. Is acid to litmus. Slowly decomposes, and is affected by light.

**Hydrogen Peroxide Solution:** Clear, colorless liquid, odorless, or having an odor resembling that of ozone. Is acid

Official

https://pharmacopeia.cn/

to litmus and to the taste and produces a froth in the mouth. Rapidly decomposes when in contact with many oxidizing as well as reducing substances. When rapidly heated, it may decompose suddenly. Is affected by light. Specific gravity is about 1.01.

**Hydromorphone Hydrochloride:** Fine, white or practically white, odorless, crystalline powder. Is affected by light. Freely soluble in water; sparingly soluble in alcohol; practically insoluble in ether.

**Hydroquinone:** Fine white needles. Darkens upon exposure to light and air. Freely soluble in water, in alcohol, and in ether.

**Hydroxocobalamin:** Dark red crystals or red crystalline powder. Is odorless, or has not more than a slight acetone odor. The anhydrous form is very hygroscopic. Sparingly soluble in water, in alcohol, and in methanol; practically insoluble in acetone, in ether, in chloroform, and in benzene.

**Hydroxyamphetamine Hydrobromide:** White, crystalline powder. Its solutions are slightly acid to litmus, having a pH of about 5. Freely soluble in water and in alcohol; slightly soluble in chloroform; practically insoluble in ether.

**Hydroxychloroquine Sulfate:** White or practically white, crystalline powder. Is odorless, and has a bitter taste. Its solutions have a pH of about 4.5. Exists in two forms, the usual form melting at about 240° and the other form melting at about 198°. Freely soluble in water; practically insoluble in alcohol, in chloroform, and in ether.

**Hydroxyethyl Cellulose:** White to light tan, practically odorless and tasteless, hygroscopic powder. Soluble in hot water and in cold water, giving a colloidal solution; practically insoluble in alcohol and in most organic solvents. *NF category:* Suspending and/or viscosity-increasing agent; coating agent; film-forming agent; polymers for ophthalmic use; wet binder.

**Hydroxyprogesterone Caproate:** White or creamy white, crystalline powder. Is odorless or has a slight odor. Soluble in ether; slightly soluble in benzene; insoluble in water.

**Hydroxypropyl Betadex:** White or almost white, amorphous or crystalline powder. Freely soluble in water and in propylene glycol. *NF category:* Sequestering agent; chelating and/or complexing agent; release-modifying agent.

**Hydroxypropyl Cellulose:** White to cream-colored, practically odorless and tasteless, granular solid or powder. Is hygroscopic after drying. Soluble in cold water, in alcohol, in chloroform, and in propylene glycol, giving a colloidal solution; insoluble in hot water. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; emulsifying agent; film-forming agent; release-modifying agent; wet binder.

**Low-Substituted Hydroxypropyl Cellulose:** White to yellowish-white, practically odorless and tasteless, fibrous or granular powder. Is hygroscopic. Practically insoluble in alcohol and in ether. Dissolves in a solution of sodium hydroxide (1 in 10), and produces a viscous solution. Swells in water, in sodium carbonate TS, and in 2 N hydrochloric acid. The pH of the suspension, obtained by shaking 1.0 g with 100 mL of water, is between 5.0 and 7.5. *NF category:* Disintegrant; wet binder.

**Hydroxyurea:** White to off-white powder. Is somewhat hygroscopic, decomposing in the presence of moisture. Melts at a temperature exceeding 133°, with decomposition. Freely soluble in water and in hot alcohol.

**Hydroxyzine Hydrochloride:** White, odorless powder. Melts at about 200°, with decomposition. Very soluble in water; soluble in chloroform; slightly soluble in acetone; practically insoluble in ether.

**Hydroxyzine Pamoate:** Light yellow, practically odorless powder. Freely soluble in dimethylformamide; practically insoluble in water and in methanol.

**Hymetellose:** A white, yellowish-white or grayish-white powder or granules. Hygroscopic after drying. Dissolves in cold water, giving a colloidal solution. Insoluble in hot water, in acetone, in alcohol, in ether, and in toluene.

**Hyoscyamine:** White, crystalline powder. Is affected by light. Its solutions are alkaline to litmus. Freely soluble in alcohol, in chloroform, and in dilute acids; sparingly soluble in ether; slightly soluble in water and in benzene.

**Hyoscyamine Hydrobromide:** White, odorless crystals or crystalline powder. The pH of a solution (1 in 20) is about 5.4. Is affected by light. Freely soluble in water, in alcohol, and in chloroform; very slightly soluble in ether.

**Hyoscyamine Sulfate:** White or almost white, crystalline powder or colorless needles. Is deliquescent and is affected by light. The pH of a solution (1 in 100) is about 5.3. Very soluble in water; freely soluble in alcohol; practically insoluble in ether. Melts at a temperature not less than 200°.

**Hypophosphorous Acid:** Colorless or slightly yellow, odorless liquid. Specific gravity is about 1.13. *NF category:* Antioxidant.

**Hypromellose:** White to slightly off-white, fibrous or granular powder. Swells in water and produces a clear to opalescent, viscous, colloidal mixture. Insoluble in dehydrated alcohol, in ether, and in chloroform. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; wet binder; polymers for ophthalmic use; capsule shell; emulsifying agent; film-forming agent; release-modifying agent.

**Hypromellose 2208:** White to slightly off-white, fibrous or granular powder. Swells in water and produces a clear to opalescent, viscous, colloidal mixture. Insoluble in dehydrated alcohol, in ether, and in chloroform. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; tablet binder.

**Hypromellose 2906:** White to slightly off-white, fibrous or granular powder. Swells in water and produces a clear to opalescent, viscous, colloidal mixture. Insoluble in dehydrated alcohol, in ether, and in chloroform. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; tablet binder.

**Hypromellose 2910:** White to slightly off-white, fibrous or granular powder. Swells in water and produces a clear to opalescent, viscous, colloidal mixture. Insoluble in dehydrated alcohol, in ether, and in chloroform. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; tablet binder.

**Hypromellose Acetate Succinate:** White to yellowish-white powder or pills. Odorless, or has a faint, acetic acid-like odor, and tasteless. Practically insoluble in water, in dehydrated alcohol, in xylene, and in hexane. On the addition of a mixture of dehydrated alcohol and dichloromethane (1:1) or acetone, a clear or turbid viscous liquid is produced. Dissolves in 1 N sodium hydroxide. Slightly hygroscopic. *NF category:* Coating agent; wet binder; film-forming agent.

**Hypromellose Phthalate:** White powder or granules. Is odorless and tasteless. Practically insoluble in water, in dehydrated alcohol, and in hexane. Produces a viscous solution in a mixture of methanol and dichloromethane (1:1), or in a mixture of dehydrated alcohol and acetone (1:1). Dissolves in 1 N sodium hydroxide. *NF category:* Coating agent; film-forming agent.

**Ibandronate Sodium:** White to off-white powder. Freely soluble in water; practically insoluble in methanol and in organic solvents.

**Ibuprofen:** White to off-white, crystalline powder, having a slight, characteristic odor. Very soluble in alcohol, in methanol, in acetone, and in chloroform; slightly soluble in ethyl acetate; practically insoluble in water.

**Ibutilide Fumarate:** White to off-white powder. Freely soluble in water; sparingly soluble in methanol.

**Ichthammol:** Reddish-brown to brownish-black, viscous fluid, having a strong, characteristic, empyreumatic odor. Miscible with water, with glycerin, and with fixed oils and fats. Partially soluble in alcohol and in ether.

**Idarubicin Hydrochloride:** Red-orange to red-brown powder. Soluble in methanol; slightly soluble in water; insoluble in acetone and in ethyl ether.

**Idoxuridine:** White, crystalline, practically odorless powder. Slightly soluble in water and in alcohol; practically insoluble in chloroform and in ether.

**Ifosfamide:** White, crystalline powder. Melts at about 40°. Very soluble in alcohol, in ethyl acetate, in isopropyl alcohol, in methanol, and in methylene chloride; freely soluble in water; very slightly soluble in hexanes.

**Imidurea:** White, odorless, tasteless powder. Soluble in water and in glycerin; sparingly soluble in propylene glycol; insoluble in most organic solvents. *NF category:* Antimicrobial preservative.

**Imipenem:** White to tan-colored crystalline powder. Slightly soluble in water and in methanol.

**Imipramine Hydrochloride:** White to pale yellow powder. Freely soluble in water and in alcohol; insoluble in ether and in benzene.

**Imipramine Pamoate:** Fine, yellow powder. Soluble in acetone, in chloroform, in carbon tetrachloride, in ethanol, and in ether; insoluble in water.

**Imiquimod:** White or almost white, powder or crystalline powder. Very slightly soluble in methanol; practically insoluble in water and in acetone.

**Inamrinone:** Pale yellow to tan powder. It is odorless or has a faint odor. Slightly soluble in methanol; practically insoluble or insoluble in chloroform and in water.

**Indapamide:** White to off-white, crystalline powder. Melts between 167° and 170°. Soluble in methanol, in alcohol, in acetonitrile, in glacial acetic acid, and in ethyl acetate; very slightly soluble in ether and in chloroform; practically insoluble in water.

**Indigotindisulfonate Sodium:** Dusky, purplish-blue powder, or blue granules having a coppery luster. Is affected by light. Its solutions have a blue or bluish purple color. Slightly soluble in water and in alcohol; practically insoluble in most other organic solvents.

**Indinavir Sulfate:** White or almost white, hygroscopic powder. Freely soluble in water; soluble in methanol; practically insoluble in heptane.

**Indocyanine Green:** Olive-brown, dark green, blue-green, dark blue, or black powder. Is odorless or has a slight odor. Its solutions are deep emerald-green in color. The pH of a solution (1 in 200) is about 6. Its aqueous solutions are stable for about 8 hours. Soluble in water and in methanol; practically insoluble in most other organic solvents.

**Indomethacin:** Pale yellow to yellow-tan, crystalline powder, having not more than a slight odor. Is sensitive to light. Melts at about 162°. Exhibits polymorphism. Sparingly soluble in alcohol, in chloroform, and in ether; practically insoluble in water.

**Inositol:** White or almost white, crystalline powder. Very soluble in water; practically insoluble in alcohol absolute and in ether. *NF category:* Humectant.

**Insulin:** White or practically white crystals. Soluble in solutions of dilute acids and alkalies.

**Insulin Injection:** The Injection containing, in each mL, not more than 100 USP Units is a clear, colorless or almost colorless liquid; the Injection containing, in each mL, 500 Units may be straw-colored. Contains between 0.1% and 0.25% (w/v) of either phenol or cresol. Contains between 1.4% and 1.8% (w/v) of glycerin.

**Insulin Lispro:** White or practically white crystals. Soluble in solutions of dilute acids and alkalies.

**Isophane Insulin Suspension:** White suspension of rod-shaped crystals, free from large aggregates of crystals following moderate agitation. Contains either (1) between 1.4% and 1.8% (w/v) of glycerin, between 0.15% and 0.17% (w/v) of metacresol, and between 0.06% and 0.07% (w/v) of phenol; or (2) between 1.4% and 1.8% (w/v) of glycerin and between 0.20% and 0.25% (w/v) of phenol. Contains between 0.15% and 0.25% (w/v) of dibasic sodium phosphate. When examined microscopically, the insoluble matter in the Suspension is crystalline, and contains not more than traces of amorphous material.

**Insulin Zinc Suspension:** Practically colorless suspension of a mixture of characteristic crystals predominantly between 10 and 40 µm in maximum dimension and many particles that have no uniform shape and do not exceed 2 µm in maximum dimension. Contains between 0.15% and 0.17% (w/v) of sodium acetate, between 0.65% and 0.75% (w/v) of sodium chloride, and between 0.09% and 0.11% (w/v) of methylparaben.

**Extended Insulin Zinc Suspension:** Practically colorless suspension of a mixture of characteristic crystals the maximum dimension of which is predominantly between 10 and 40 µm. Contains between 0.15% and 0.17% (w/v) of sodium acetate, between 0.65% and 0.75% (w/v) of sodium chloride, and between 0.09% and 0.11% (w/v) of methylparaben.

**Prompt Insulin Zinc Suspension:** Practically colorless suspension of particles that have no uniform shape and the maximum dimension of which does not exceed 2 µm. Contains between 0.15% and 0.17% (w/v) of sodium acetate, between 0.65% and 0.75% (w/v) of sodium chloride, and between 0.09% and 0.11% (w/v) of methylparaben.

**Inulin:** White, friable, chalk-like, amorphous, odorless, tasteless powder. Soluble in hot water; slightly soluble in cold water and in organic solvents. *NF category:* Sweetening agent; wet binder.

**Invert Sugar:** Colorless to pale yellow liquid. Miscible with water, with glycerin, and with glycols. *NF category*: Sweetening agent; diluent; wet binder.

**Iodine:** Heavy, grayish-black plates or granules, having a metallic luster and a characteristic odor. Freely soluble in carbon disulfide, in chloroform, in carbon tetrachloride, and in ether; soluble in alcohol and in solutions of iodides; sparingly soluble in glycerin; very slightly soluble in water.

**Iodine Topical Solution:** Transparent, reddish-brown liquid, having the odor of iodine.

**Strong Iodine Solution:** Transparent liquid having a deep brown color and having the odor of iodine.

**Iodine Tincture:** Transparent liquid having a reddish-brown color and the odor of iodine and of alcohol.

**Sodium Iodide I 123 Capsules:** Capsules may contain a small amount of solid or solids, or may appear empty.

**Sodium Iodide I 123 Solution:** Clear, colorless solution. Upon standing, both the Solution and the glass container may darken as a result of the effects of the radiation.

**Iodinated I 125 Albumin Injection:** Clear, colorless to slightly yellow solution. Upon standing, both the Albumin and the glass container may darken as a result of the effects of the radiation.

**Iodinated I 131 Albumin Injection:** Clear, colorless to slightly yellow solution. Upon standing, both the Albumin and the glass container may darken as a result of the effects of the radiation.

**Sodium Iodide I 131 Capsules:** May contain a small amount of solid or solids, or may appear empty.

**Sodium Iodide I 131 Solution:** Clear, colorless solution. Upon standing, both the Solution and the glass container may darken as a result of the effects of the radiation.

**Iodipamide:** White, practically odorless, crystalline powder. Slightly soluble in alcohol; very slightly soluble in water, in chloroform, and in ether.

**Iodipamide Meglumine Injection:** Clear, colorless to pale yellow, slightly viscous liquid.

**Iodixanol:** White to off-white, amorphous, odorless, hygroscopic powder. Freely soluble in water.

**Iodoform:** Lustrous greenish yellow powder, or lustrous crystals. It is slightly volatile even at ordinary temperatures, and distills slowly with steam. Freely soluble in ether and in chloroform; soluble in boiling alcohol; sparingly soluble in alcohol, in glycerin, and in olive oil; practically insoluble in water. Melts to a brown liquid at about 115°, and decomposes at a higher temperature, emitting vapors of iodine.

**Iodoquinol:** Light yellowish to tan, microcrystalline powder not readily wetted by water. Is odorless or has a faint odor; is stable in air. Melts with decomposition. Sparingly soluble in alcohol and in ether; practically insoluble in water.

**Iohexol:** White to off-white, hygroscopic, odorless powder. Very soluble in water and in methanol; practically insoluble or insoluble in ether and in chloroform.

**Iohexol Injection:** Clear, colorless to pale yellow liquid.

**Iopamidol:** Practically odorless, white to off-white powder. Very soluble in water; sparingly soluble in methanol; practically insoluble in alcohol and in chloroform.

**Iopromide:** White to slightly yellow powder. Freely soluble in water and in dimethyl sulfoxide; practically insoluble in alcohol, in acetone, and in ether.

**Iothalamate Meglumine Injection:** Clear, colorless to pale yellow, slightly viscous liquid.

**Iothalamate Meglumine and Iothalamate Sodium Injection:** Clear, colorless to pale yellow, slightly viscous liquid.

**Iothalamic Acid:** White, odorless powder. Soluble in solutions of alkali hydroxides; slightly soluble in water and in alcohol.

**Ioxilan:** White to off-white, practically odorless powder. Soluble in water and in methanol.

**Ioxilan Injection:** Clear, colorless to pale yellow liquid.

**Powdered Ipecac:** Pale brown, weak yellow, or light olive-gray powder.

**Ipratropium Bromide:** White to off-white, crystalline powder. Freely soluble in methanol; soluble in water; slightly soluble in alcohol.

**Irbesartan:** White to off-white, crystalline powder. Slightly soluble in alcohol and in methylene chloride; practically insoluble in water.

**Irinotecan Hydrochloride:** Pale yellow to yellow crystalline powder. Slightly soluble in water and in organic solvents.

**Iron Dextran Injection:** Dark brown, slightly viscous liquid.

**Isobutane:** Colorless, flammable gas (boiling temperature is about –11°). Vapor pressure at 21° is about 2950 mm of mercury (31 psig). *NF category:* Propellant.

**Isobutyl Alcohol:** Clear, colorless, mobile liquid. Soluble in water. Miscible with alcohol, with ether, and with many other organic solvents. *NF category*: Flavors and fragrance; solvent.

**Isoflurane:** Clear, colorless, volatile liquid, having a slight odor. Boils at about 49°. Insoluble in water. Miscible with common organic solvents and with fats and oils.

**Isoleucine:** White, practically odorless crystals, having a slightly bitter taste. Soluble in water; slightly soluble in hot alcohol; insoluble in ether.

**Isometheptene Mucate:** White, crystalline powder. Freely soluble in water; soluble in alcohol; practically insoluble in chloroform and in ether.

**Isoniazid:** Colorless or white crystals or white, crystalline powder. Is odorless and is slowly affected by exposure to air and light. Freely soluble in water; sparingly soluble in alcohol; slightly soluble in chloroform; very slightly soluble in ether.

**Isoniazid Injection:** Clear, colorless to faintly greenish-yellow liquid. Gradually darkens on exposure to air and light. Tends to crystallize at low temperatures.

**Isopropamide Iodide:** White to pale yellow, crystalline powder, having a bitter taste. Freely soluble in chloroform and in alcohol; sparingly soluble in water; very slightly soluble in benzene and in ether.

**Isopropyl Alcohol:** Transparent, colorless, mobile, volatile liquid, having a characteristic odor and a slightly bitter taste. Is flammable. Miscible with water, with alcohol, with ether, and with chloroform. *NF category:* Solvent.

**Azeotropic Isopropyl Alcohol:** Transparent, colorless, mobile, volatile liquid, having a characteristic odor and a slightly bitter taste. Is flammable. Miscible with water, with alcohol, with ether, and with chloroform.

**Isopropyl Isostearate:** Clear, colorless to pale-yellow liquid. Miscible with alcohol and with fatty oils. Insoluble in water. *NF category*: Emollient; emulsifying agent.

**Isopropyl Myristate:** Clear, practically colorless, oily liquid. Is practically odorless, and congeals at about 5°. Freely soluble in 90% alcohol; insoluble in water, in glycerin, and in propylene glycol. Miscible with most organic solvents and with fixed oils. *NF category:* Vehicle (oleaginous); emollient; solvent.

**Isopropyl Palmitate:** Colorless, mobile liquid having a very slight odor. Soluble in acetone, in castor oil, in chloroform, in cottonseed oil, in ethyl acetate, in alcohol, and in mineral oil; insoluble in water, in glycerin, and in propylene glycol. *NF category:* Vehicle (oleaginous); emollient; solvent.

**Isoproterenol Hydrochloride:** White to practically white, odorless, crystalline powder, having a slightly bitter taste. Gradually darkens on exposure to air and light. Its solutions become pink to brownish pink on standing exposed to air, doing so almost immediately when rendered alkaline. Its solution (1 in 100) has a pH of about 5. Freely soluble in water; sparingly soluble in alcohol and less soluble in dehydrated alcohol; insoluble in chloroform and in ether.

**Isoproterenol Hydrochloride Injection:** Colorless or practically colorless liquid, gradually turning dark on exposure to air and light.

**Isosorbide Concentrate:** Colorless to slightly yellow liquid. Soluble in water and in alcohol.

**Diluted Isosorbide Dinitrate:** Ivory-white, odorless powder. [NOTE—Undiluted isosorbide dinitrate occurs as white, crystalline rosettes.] Undiluted isosorbide dinitrate is very soluble in acetone; freely soluble in chloroform; sparingly soluble in alcohol; very slightly soluble in water.

**Isostearyl Isostearate:** Colorless to slightly yellow, oily liquid. *Specific Gravity* ⟨841⟩ : 0.840–0.880 at 20°. Soluble in methylene chloride and in mineral oil; insoluble in water and in alcohol. *NF category*: Emollient; emulsifying agent.

**Isotretinoin:** Yellow crystals. Soluble in chloroform; sparingly soluble in alcohol, in isopropyl alcohol, and in polyethylene glycol 400; practically insoluble in water.

**Isoxsuprine Hydrochloride:** White, odorless, crystalline powder, having a bitter taste. Melts at about 200°, with decomposition. Sparingly soluble in alcohol; slightly soluble in water.

**Isradipine:** Yellow, fine crystalline powder.

**Itraconazole:** A white or almost white powder. Freely soluble in methylene chloride; sparingly soluble in tetrahydrofuran; very slightly soluble in alcohol; practically insoluble in water.

**Ivermectin:** White to yellowish-white, crystalline powder. Slightly hygroscopic. Freely soluble in methanol and in methylene chloride; soluble in acetone and in acetonitrile; practically insoluble in hexane and in water.

Official

https://pharmacopeia.com/

**Ixabepilone:** White or almost white powder. Slightly soluble in acetonitrile.

**Juniper Tar:** Dark brown, clear, thick liquid, having a tarry odor and a faintly aromatic, bitter taste. Sparingly soluble in solvent hexane; very slightly soluble in water. One volume dissolves in 9 volumes of alcohol. Dissolves in 3 volumes of ether, leaving only a slight, flocculent residue. Miscible with amyl alcohol, with chloroform, and with glacial acetic acid.

**Kanamycin Sulfate:** White, odorless, crystalline powder. Freely soluble in water; insoluble in acetone, in ethyl acetate, and in benzene.

**Kaolin:** Soft, white or yellowish-white powder or lumps. Has an earthy or clay-like taste and, when moistened with water, assumes a darker color and develops a marked clay-like odor. Insoluble in water, in cold dilute acids, and in solutions of alkali hydroxides. *NF category:* Diluent; suspending and/or viscosity-increasing agent.

**Ketamine Hydrochloride:** White, crystalline powder, having a slight, characteristic odor. Freely soluble in water and in methanol; soluble in alcohol; sparingly soluble in chloroform.

**Ketorolac Tromethamine:** White to off-white, crystalline powder. Melts between 165° and 170°, with decomposition. Freely soluble in water and in methanol; slightly soluble in alcohol, in dehydrated alcohol, and in tetrahydrofuran; practically insoluble in acetone, in dichloromethane, in toluene, in ethyl acetate, in dioxane, in hexane, in butyl alcohol, and in acetonitrile.

**Labetalol Hydrochloride:** White to off-white powder. Melts at about 180°, with decomposition. Soluble in water and in alcohol; insoluble in ether and in chloroform.

**Lacosamide:** White to light yellow powder. Freely soluble in methanol; soluble in anhydrous ethanol; sparingly soluble in water; slightly soluble in acetonitrile; and practically insoluble in heptane.

**Alpha-Lactalbumin:** Free-flowing, slightly hygroscopic light cream-colored powder. Freely soluble in water; soluble in wide pH ranges; insoluble in methanol, in alcohol, in ether, and in acetone. *NF category:* Bulking agent; coating agent; emulsifying agent; stiffening agent; suspending and/or viscosity-increasing agent; diluent; wet binder; vehicle (solid carrier); pH modifier (acidifying agent/alkalizing agent/buffering agent); chelating and/or complexing agent.

**Lactic Acid:** Colorless or yellowish, practically odorless, syrupy liquid. Is hygroscopic. When it is concentrated by boiling, lactic acid lactate is formed. Specific gravity is about 1.20. Insoluble in chloroform. Miscible with water, with alcohol, and with ether. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Lactitol:** A white or light brown, odorless crystal. Has a mild, sweet taste, and no aftertaste. *NF category:* Flavors and fragrance; diluent; sweetening agent.

**Lactobionic Acid:** White or almost white, crystalline powder with a melting point of about 125° with decomposition. Freely soluble in water; slightly soluble in glacial acetic acid, in anhydrous ethanol, and in methanol. *NF category:* Antioxidant.

**Anhydrous Lactose:** White or almost white powder. Freely soluble in water; practically insoluble in alcohol. *NF category:* Diluent; carrier.

**Lactose Monohydrate:** White, free-flowing powder. Freely but slowly soluble in water; practically insoluble in alcohol. *NF category:* Diluent; carrier; wet binder.

**Lactulose Concentrate:** Colorless to amber syrupy liquid, which may exhibit some precipitation and darkening upon standing. Miscible with water.

**Lamivudine:** White to off-white solid. Soluble in water. Melts at about 176°.

**Lamotrigine:** White to pale cream-colored powder. Slightly soluble in 0.1 N hydrochloric acid, in acetone, and in methanol; very slightly soluble in water.

**Lanolin:** Yellow, tenacious, unctuous mass, having a slight, characteristic odor. Freely soluble in ether and in chloroform; soluble in hot alcohol; sparingly soluble in cold alcohol; insoluble in water, but mixes without separation with about twice its weight of water. *NF category:* Emulsifying agent; ointment base.

**Hydrogenated Lanolin:** White or pale yellow, unctuous substance. Soluble in boiling dehydrated alcohol and in light petroleum; insoluble in water. *NF category*: Emulsifying agent; emollient; humectant; ointment base.

**Lanolin Alcohols:** Hard, waxy, amber solid, having a characteristic odor. Freely soluble in chloroform, in ether, and in petroleum ether; slightly soluble in alcohol; insoluble in water. *NF category:* Emulsifying agent; ointment base.

**Lansoprazole:** White to brownish-white powder. Freely soluble in dimethylformamide; practically insoluble in water. Melts at about 166°, with decomposition.

**Latanoprost:** Colorless to slightly yellow oil. Very soluble in acetonitrile; freely soluble in acetone, in ethanol, in ethyl acetate, in isopropanol, in methanol, and in octanol; practically insoluble in water.

**Lauric Acid:** White or faintly yellow, somewhat glossy, crystalline solid or powder. Very soluble in alcohol, in ether, and in methanol; soluble in acetone; practically insoluble in water. *NF category*: Antifoaming agent; emulsifying agent; lubricant.

**Lauroyl Polyoxylglycerides:** Pale yellow semi-solids. Freely soluble in methylene chloride. Dispersible in hot water. *NF category*: Ointment base; solvent; emulsifying agent; wetting and/or solubilizing agent.

**Lecithin:** The consistency of both natural grades and refined grades of lecithin may vary from plastic to fluid, depending upon free fatty acid and oil content, and upon the presence or absence of other diluents. Its color varies from light yellow to brown, depending on the source, on crop variations, and on whether it is bleached or unbleached. It is odorless or has a characteristic, slight nut-like odor and a bland taste. Practically insoluble in water, but it readily hydrates to form emulsions. The oil-free phosphatides are soluble in fatty acids, but are practically insoluble in fixed oils. When all phosphatide fractions are present, lecithin is sparingly soluble in alcohol and practically insoluble in acetone. *NF category:* Emulsifying agent; emollient.

**Leflunomide:** White to almost white powder. Freely soluble in methanol, in alcohol, in 2-propanol, in ethyl acetate, in acetone, and in acetonitrile; practically insoluble in water.

**Letrozole:** White to yellowish, crystalline powder. Freely soluble in dichloromethane; slightly soluble in alcohol; practically insoluble in water.

**Leucine:** White, practically odorless, tasteless crystals. Sparingly soluble in water; insoluble in ether. *NF category:* Flavors and fragrance.

**Leucovorin Calcium:** Yellowish-white or yellow powder. Slightly soluble to freely soluble in water; practically insoluble in alcohol.

**Leucovorin Calcium Injection:** Clear, yellowish solution.

**Levamisole Hydrochloride:** White or almost white, crystalline powder. Freely soluble in water; soluble in alcohol; slightly soluble in methylene chloride; practically insoluble in ether.

**Levetiracetam:** White to almost white powder. Very soluble in water; soluble in acetonitrile; practically insoluble in hexane.

**Levmetamfetamine:** Clear, practically colorless liquid.

Official

https://nhathuoc.org.vn/

**Levobunolol Hydrochloride:** White crystalline, odorless powder. Soluble in water and in methanol; slightly soluble in alcohol and in chloroform.

**Levocarnitine:** White crystals or crystalline powder. Hygroscopic. Freely soluble in water, and in hot alcohol; practically insoluble in acetone, in ether, and in benzene.

**Levocetirizine Dihydrochloride:** White to almost white powder. Freely soluble in water and in methanol.

**Levodopa:** White to off-white, odorless, crystalline powder. In the presence of moisture, is rapidly oxidized by atmospheric oxygen and darkens. Freely soluble in 3 N hydrochloric acid; slightly soluble in water; insoluble in alcohol.

**Levofloxacin:** Light yellowish-white to yellow-white crystals or crystalline powder. Soluble in dimethylsulfoxide and in acetic acid; sparingly soluble in water, in acetone, and in methanol; practically insoluble in glycerin and in *n*-octanol.

**Levonordefrin:** White to buff-colored, odorless, crystalline solid. Melts at about 210°. Freely soluble in aqueous solutions of mineral acids; slightly soluble in acetone, in chloroform, in alcohol, and in ether; practically insoluble in water.

**Levonorgestrel:** White or practically white, odorless powder. Soluble in chloroform; slightly soluble in alcohol; practically insoluble in water.

**Levorphanol Tartrate:** Practically white, odorless, crystalline powder. Sparingly soluble in water; slightly soluble in alcohol; insoluble in chloroform and in ether. Melts, in a sealed tube, at about 110°, with decomposition.

**Levothyroxine Sodium:** Light yellow to buff-colored, odorless, tasteless, hygroscopic powder. Is stable in dry air but may assume a slight pink color upon exposure to light. The pH of a saturated solution is about 8.9. Soluble in solutions of alkali hydroxides and in hot solutions of alkali carbonates; slightly soluble in alcohol; very slightly soluble in water; insoluble in acetone, in chloroform, and in ether.

**Lidocaine:** White or slightly yellow, crystalline powder. Has a characteristic odor and is stable in air. Very soluble in alcohol and in chloroform; freely soluble in benzene and in ether; practically insoluble in water. Dissolves in oils.

**Lidocaine Hydrochloride:** White, odorless, crystalline powder, having a slightly bitter taste. Very soluble in water and in alcohol; soluble in chloroform; insoluble in ether.

**Lincomycin Hydrochloride:** White or practically white, crystalline powder. Is odorless or has a faint odor. Is stable in the presence of air and light. Its solutions are acid and dextrorotatory. Freely soluble in water; soluble in dimethylformamide; very slightly soluble in acetone.

**Lincomycin Hydrochloride Soluble Powder:** White to off-white, or light tan free-flowing, fine powder.

**Lindane:** White, crystalline powder, having a slight, musty odor. Freely soluble in chloroform; soluble in dehydrated alcohol; sparingly soluble in ether; slightly soluble in ethylene glycol; practically insoluble in water.

**Linezolid:** White to off-white or cream-colored, crystalline powder. Sparingly soluble in acetone, in ethanol, and in methanol; very slightly soluble in water.

**Linoleoyl Polyoxylglycerides:** Amber, oily liquids. May develop deposit after prolonged storage periods at 20°. Freely soluble in methylene chloride; practically insoluble but dispersible in water. *NF category:* Ointment base; solvent; emulsifying agent; wetting and/or solubilizing agent.

**Liothyronine Sodium:** Light tan, odorless, crystalline powder. Slightly soluble in alcohol; very slightly soluble in water; practically insoluble in most other organic solvents.

**Lisinopril:** White, crystalline powder. Melts at about 160°, with decomposition. Soluble in water; sparingly soluble in methanol; practically insoluble in alcohol, in acetone, in acetonitrile, and in chloroform.

**Lithium Carbonate:** White, granular, odorless powder. Sparingly soluble in water; very slightly soluble in alcohol. Dissolves, with effervescence, in dilute mineral acids.

**Lithium Citrate:** White, odorless, deliquescent powder or granules, having a cooling, faintly alkaline taste. Freely soluble in water; slightly soluble in alcohol.

**Lomustine:** Yellow crystalline powder. Freely soluble in acetone, and in methylene chloride; soluble in ethanol; practically insoluble in water.

**Loperamide Hydrochloride:** White to slightly yellow powder. Melts at about 225°, with some decomposition. Freely soluble in methanol and in chloroform; slightly soluble in water and in dilute acids; very slightly soluble in isopropyl alcohol.

**Lopinavir:** White powder. Freely soluble in methanol and alcohol; soluble in isopropanol; practically insoluble in water.

**Loratadine:** White to off-white powder. Freely soluble in acetone, in chloroform, in methanol, and in toluene; insoluble in water.

**Lorazepam:** White or practically white, practically odorless powder. Sparingly soluble in alcohol; slightly soluble in chloroform; insoluble in water.

**Losartan Potassium:** White to off-white powder. Freely soluble in water; sparingly soluble in isopropyl alcohol; slightly soluble in acetonitrile.

**Lovastatin:** White to off-white, crystalline powder. Freely soluble in chloroform; soluble in acetone, in acetonitrile, and in methanol; sparingly soluble in alcohol; practically insoluble in hexane; insoluble in water.

**Loxapine Succinate:** White to yellowish, crystalline powder. Is odorless.

**Lufenuron:** White or pale yellow powder. Freely soluble in acetonitrile; soluble in dehydrated alcohol; practically insoluble in water.

**Lumefantrine:** Yellow crystalline powder. Freely soluble in *N,N*-dimethylformamide, in chloroform, and in ethyl acetate; soluble in dichloromethane; slightly soluble in ethanol and in methanol; practically insoluble in water.

**Lutein:** Red, crystalline powder. Soluble in ethanol, in ethyl acetate, and in methylene chloride; partially soluble in hexane.

**Lysine Acetate:** White, odorless crystals or crystalline powder, having an acid taste. Freely soluble in water.

**Lysine Hydrochloride:** White, odorless powder. Freely soluble in water. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Mafenide Acetate:** White to pale yellow, crystalline powder. Freely soluble in water.

**Magaldrate:** White, odorless, crystalline powder. Soluble in dilute solutions of mineral acids; insoluble in water and in alcohol.

**Milk of Magnesia:** White, opaque, more or less viscous suspension from which varying proportions of water usually separate on standing. pH is about 10.

**Magnesium Aluminometasilicate:** White powder or granules with an amorphous structure. Very slightly soluble in acids; practically insoluble or insoluble in water, in alcohol, and in alkalies.

**Magnesium Aluminosilicate:** White powder or granules with an amorphous structure. Very slightly soluble in acids; practically insoluble or insoluble in water, in alcohol, and in alkalies.

**Magnesium Aluminum Silicate:** Odorless, tasteless, fine (micronized) powder, small cream to tan granules, or small flakes that are creamy when viewed on their flat surfaces and tan to brown when viewed on their edges. Insoluble in water and in alcohol. Swells when added to water or glycerin. *NF category:* Suspending and/or viscosity-increasing agent; disintegrant.

**Magnesium Carbonate:** Light, white, friable masses or bulky, white powder. Is odorless, and is stable in air. Practically insoluble in water to which, however, it imparts a slightly alkaline reaction; insoluble in alcohol, but is dissolved by dilute acids with effervescence. *NF category:* Diluent.

**Magnesium Chloride:** Colorless, odorless, deliquescent flakes or crystals, which lose water when heated to 100° and lose hydrochloric acid when heated to 110°. Very soluble in water; freely soluble in alcohol.

**Magnesium Citrate Oral Solution:** Colorless to slightly yellow, clear, effervescent liquid, having a sweet, acidulous taste and a lemon flavor.

**Magnesium Gluconate:** Colorless crystals or white powder or granules. Is odorless and tasteless. Freely soluble in water; very slightly soluble in alcohol; insoluble in ether.

**Magnesium Hydroxide:** Bulky, white powder. Soluble in dilute acids; practically insoluble in water and in alcohol.

**Magnesium Oxide:** Very bulky, white powder or relatively dense, white powder or granulated powder. Soluble in dilute acids; practically insoluble in water; insoluble in alcohol. *NF category:* Emulsifying agent; glidant and/or anticaking agent; diluent.

**Magnesium Phosphate:** White, odorless, tasteless powder. Soluble in diluted mineral acids; practically insoluble in water.

**Magnesium Salicylate:** White, odorless, efflorescent, crystalline powder. Freely soluble in methanol; soluble in alcohol and in water; slightly soluble in ether.

**Magnesium Silicate:** Fine, white, odorless, tasteless powder, free from grittiness. Insoluble in water and in alcohol. Is readily decomposed by mineral acids. *NF category:* Glidant and/or anticaking agent.

**Magnesium Stearate:** Very fine, light, white powder, slippery to touch. Insoluble in water, in alcohol, and in ether. *NF category:* Lubricant.

**Magnesium Sulfate:** Small, colorless crystals, usually needle-like, with a cooling, saline, bitter taste. It effloresces in warm, dry air. Very soluble in boiling water; freely soluble in water; freely (and slowly) soluble in glycerin; sparingly soluble in alcohol.

**Magnesium Trisilicate:** Fine, white, odorless, tasteless powder, free from grittiness. Insoluble in water and in alcohol. Is readily decomposed by mineral acids. *NF category:* Glidant and/or anticaking agent.

**Malathion:** Clear, colorless, or slightly yellowish liquid, having a characteristic odor. Congeals at about 2.9°. Slightly soluble in water. Miscible with alcohols, with esters, with ketones, with ethers, with aromatic and alkylated aromatic hydrocarbons, and with vegetable oils.

**Maleic Acid:** White, crystalline powder. Freely soluble in water and in alcohol; sparingly soluble in ether. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Malic Acid:** White or practically white, crystalline powder or granules, having a strongly acid taste. Melts at about 130°. Very soluble in water; freely soluble in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent); flavors and fragrance; antioxidant, chelating and/or complexing agent.

**Maltitol:** White, crystalline powder. Very soluble in water; practically insoluble in ethanol. *NF category:* Humectant; sweetening agent; diluent; coating agent.

**Maltodextrin:** White, hygroscopic powder or granules. Freely soluble or readily dispersible in water; slightly soluble to insoluble in anhydrous alcohol. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; diluent; wet binder.

**Maltol:** A white, crystalline powder having a characteristic caramel-butterscotch odor, suggestive of a fruity-strawberry aroma in dilute solution. One g dissolves in about 82 mL of water, in 21 mL of alcohol, in 80 mL of glycerin, and in 28 mL of propylene glycol. *NF category:* Flavors and fragrance.

**Maltose:** Maltose occurs in either the anhydrous state or as a monohydrate. It is a white, crystalline powder, odorless, and has a sweet taste. Very slightly soluble in ethanol; freely soluble in water; slightly soluble in methanol; practically insoluble in ether. *NF category:* Sweetening agent; diluent; disintegrant; wet binder.

**Mandelic Acid:** White to light yellow powder or crystalline solid. Soluble in alcohol, in isopropyl alcohol; sparingly soluble in water. *NF category*: Antimicrobial preservative.

**Manganese Chloride:** Large, irregular, pink, odorless, translucent crystals. Soluble in water and in alcohol; insoluble in ether.

**Manganese Sulfate:** Pale red, slightly efflorescent crystals, or purple, odorless powder. Soluble in water; insoluble in alcohol.

**Mannitol:** White, crystalline powder or free-flowing granules. Is odorless and has a sweet taste. Freely soluble in water; soluble in alkaline solutions; slightly soluble in pyridine; very slightly soluble in alcohol; practically insoluble in ether. *NF category:* Sweetening agent; tonicity agent; bulking agent; diluent; plasticizer.

**Maprotiline Hydrochloride:** Fine, white to off-white, crystalline powder. Is practically odorless. Freely soluble in methanol and in chloroform; slightly soluble in water; practically insoluble in isooctane.

**Mebendazole:** White to slightly yellow powder. Is almost odorless. Melts at about 290°. Freely soluble in formic acid; practically insoluble in water, in dilute solutions of mineral acids, in alcohol, in ether, and in chloroform.

**Mechlorethamine Hydrochloride:** White, crystalline powder. Is hygroscopic.

**Meclizine Hydrochloride:** White or slightly yellowish, crystalline powder. Has a slight odor and is tasteless. Slightly soluble in dilute acids and in alcohol; practically insoluble in water and in ether; freely soluble in chloroform, in pyridine, and in acid-alcohol-water mixtures.

**Meclofenamate Sodium:** A white to creamy white, odorless to almost odorless, crystalline powder. Freely soluble in water, the solution sometimes being somewhat turbid due to partial hydrolysis and absorption of carbon dioxide; soluble in methanol; slightly soluble in chloroform; practically insoluble in ether. The solution is clear above pH 11.5.

**Medroxyprogesterone Acetate:** White to off-white, odorless, crystalline powder. Melts at about 205°. Is stable in air. Freely soluble in chloroform; soluble in acetone and in dioxane; sparingly soluble in alcohol and in methanol; slightly soluble in ether; insoluble in water.

**Mefenamic Acid:** White to off-white, crystalline powder. Melts at about 230°, with decomposition. Soluble in solutions of alkali hydroxides; sparingly soluble in chloroform; slightly soluble in alcohol and in methanol; practically insoluble in water.

**Mefloquine Hydrochloride:** White or slightly yellow, crystalline powder. It exhibits polymorphism. Freely soluble in methanol; soluble in alcohol; very slightly soluble in water.

**Megestrol Acetate:** White to creamy white, tasteless and essentially odorless, crystalline powder. Very soluble in chloroform; soluble in acetone; sparingly soluble in alcohol; slightly soluble in ether and in fixed oils; insoluble in water. Is unstable under aqueous conditions at pH 7 or above.

**Meglumine:** White to faintly yellowish-white, odorless crystals or powder. Freely soluble in water; sparingly soluble in alcohol.

**Melengestrol Acetate:** White to light yellow, crystalline powder. Freely soluble in chloroform and in ethyl acetate; slightly soluble in alcohol; insoluble in water.

**Meloxicam:** Pale yellow powder. Soluble in dimethylformamide; slightly soluble in acetone; very slightly soluble in methanol and in alcohol; practically insoluble in water.

**Melphalan:** Off-white to buff powder, having a faint odor. Melts at about 180°, with decomposition. Soluble in dilute mineral acids; slightly soluble in alcohol and in methanol; practically insoluble in water, in chloroform, and in ether.

**Memantine Hydrochloride:** White to off-white, colored powder. Slightly soluble in water.

**Menadione:** Bright yellow, crystalline, practically odorless powder. Is affected by sunlight. Soluble in vegetable oils; sparingly soluble in chloroform and in alcohol; practically insoluble in water.

**Menthol:** Colorless, hexagonal crystals, usually needle-like, or in fused masses, or crystalline powder. Has a pleasant, peppermint-like odor. Very soluble in alcohol, in chloroform, in ether, and in solvent hexane; freely soluble in glacial acetic acid, in mineral oil, and in fixed and volatile oils; slightly soluble in water. *NF category:* Flavors and fragrance.

**Meperidine Hydrochloride:** Fine, white, crystalline, odorless powder. The pH of a solution (1 in 20) is about 5. Very soluble in water; soluble in alcohol; sparingly soluble in ether.

**Mephobarbital:** White, odorless, crystalline powder, having a bitter taste. Its saturated solution is acid to litmus. Soluble in chloroform and in solutions of fixed alkali hydroxides and carbonates; slightly soluble in water, in alcohol, and in ether.

**Mepivacaine Hydrochloride:** White, odorless, crystalline solid. The pH of a solution (1 in 50) is about 4.5. Freely soluble in water and in methanol; very slightly soluble in chloroform; practically insoluble in ether.

**Meprobamate:** White powder, having a characteristic odor and a bitter taste. Freely soluble in acetone and in alcohol; slightly soluble in water; practically insoluble or insoluble in ether.

**Mercaptopurine:** Yellow, odorless or practically odorless, crystalline powder. Melts at a temperature exceeding 308°, with decomposition. Soluble in hot alcohol and in dilute alkali solutions; slightly soluble in 2 N sulfuric acid; insoluble in water, in acetone, and in ether.

**Ammoniated Mercury:** White, pulverulent pieces or white, amorphous powder. Is odorless, and is stable in air, but darkens on exposure to light. Readily soluble in warm hydrochloric, nitric, and acetic acids; insoluble in water, and in alcohol.

**Meropenem:** Colorless to white or light yellow crystals or crystalline powder. Soluble in dimethylformamide and in 5% dibasic potassium phosphate solution; sparingly soluble in water and in 5% monobasic potassium phosphate solution; practically insoluble in alcohol, in acetone, in methylene chloride, and in ether.

**Mesalamine:** Light tan to pink colored, needle-shaped crystals. Color may darken on exposure to air. Is odorless or may have a slight characteristic odor. Soluble in dilute hydrochloric acid and in dilute alkali hydroxides; slightly soluble in water; very slightly soluble in methanol, in dehydrated alcohol, and in acetone; practically insoluble in *n*-butyl alcohol, in chloroform, in ether, in ethyl acetate, in *n*-hexane, in methylene chloride, and in *n*-propyl alcohol.

**Mesna:** White or slightly yellow crystalline powder; hygroscopic. Freely soluble in water; slightly soluble in alcohol; practically insoluble in cyclohexane.

**Mestranol:** White to creamy white, odorless, crystalline powder. Freely soluble in chloroform; soluble in dioxane; sparingly soluble in dehydrated alcohol; slightly soluble in methanol; insoluble in water.

**Metaproterenol Sulfate:** White to off-white, crystalline powder. Freely soluble in water.

**Metaxalone:** White to almost-white, crystalline powder. Freely soluble in chloroform; soluble in methanol and in alcohol; practically insoluble in ether and in water.

**Metformin Hydrochloride:** White, crystalline powder. Freely soluble in water; slightly soluble in alcohol; practically insoluble in acetone and in methylene chloride.

**Methacholine Chloride:** Colorless or white crystals, or white, crystalline powder. Is odorless or has a slight odor, and is very hygroscopic. Its solutions are neutral to litmus. Very soluble in water; freely soluble in alcohol and in chloroform.

**Methacrylic Acid and Ethyl Acrylate Copolymer Dispersion:** Milky-white liquid of low viscosity. It is miscible with water in any proportion; the milky-white appearance is retained. A clear or slightly opalescent, viscous solution is obtained on mixing one part with five parts of acetone, alcohol, or isopropyl alcohol; the polymer substance is first precipitated, but then dissolves in the excess organic solvent. A clear or slightly opalescent, viscous solution is obtained on mixing one part with two parts of 1 N sodium hydroxide. *NF category:* Coating agent; film-forming agent; diluent; wet binder.

**Methacrylic Acid and Ethyl Acrylate Copolymer:** White powder having a faint, characteristic odor. Soluble to freely soluble in methanol, in alcohol, in isopropyl alcohol, and in acetone, each of which contains not less than 3% of water; soluble in diluted alkali, in simulated intestinal fluid TS, and in buffer solutions of pH 7 and above; insoluble in water, in diluted acids, in simulated gastric fluid TS, and in buffer solutions of up to pH 5. The solubility between pH 5.5 and pH 7 depends on the content of methacrylic acid units in the copolymer. *NF category:* Coating agent; film-forming agent.

**Partially-Neutralized Methacrylic Acid and Ethyl Acrylate Copolymer:** White or almost white, free-flowing powder. Freely soluble in alcohol, in methanol, and in a 40 g/L solution of sodium hydroxide; soluble in solutions at pH values above pH 5.5 under salt formation; practically insoluble in ethyl acetate and in acidic aqueous solutions. *NF category:* Coating agent; film-forming agent.

**Methacrylic Acid and Methyl Methacrylate Copolymer:** White powder having a faint, characteristic odor. Soluble to freely soluble in methanol, in alcohol, in isopropyl alcohol, and in acetone, each of which contains not less than 3% of water; soluble in diluted alkali, in simulated intestinal fluid TS, and in buffer solutions of pH 7 and above; insoluble in water, in diluted acids, in simulated gastric fluid TS, and in buffer solutions of up to pH 5. The solubility between pH 5.5 and pH 7 depends on the content of methacrylic acid units in the copolymer. *NF category:* Coating agent; film-forming agent.

**Methacycline Hydrochloride:** Yellow to dark yellow, crystalline powder. Soluble in water.

**Methadone Hydrochloride:** Colorless crystals or white, crystalline, odorless powder. Freely soluble in alcohol and in chloroform; soluble in water; practically insoluble in ether and in glycerin.

**Methadone Hydrochloride Oral Concentrate:** Clear to slightly hazy, syrupy liquid.

**Methamphetamine Hydrochloride:** White crystals or white, crystalline powder. Is odorless or practically so. Its solutions have a pH of about 6. Freely soluble in water, in alcohol, and in chloroform; very slightly soluble in absolute ether.

**Methazolamide:** White or faintly yellow, crystalline powder having a slight odor. Melts at about 213°. Soluble in dimethylformamide; slightly soluble in acetone; very slightly soluble in water and in alcohol.

**Methenamine:** Colorless, lustrous crystals or white, crystalline powder. Is practically odorless. When brought into contact with fire, it readily ignites, burning with a smokeless flame. It sublimes at about 260°, without melting. Its solutions

are alkaline to litmus. Freely soluble in water; soluble in alcohol and in chloroform.

**Methenamine Mandelate:** White, crystalline powder. Has a sour taste and is practically odorless. Its solutions have a pH of about 4. Melts at about 127°, with decomposition. Very soluble in water; soluble in alcohol and in chloroform; slightly soluble in ether.

**Methimazole:** White to pale buff, crystalline powder, having a faint, characteristic odor. Its solutions are practically neutral to litmus. Freely soluble in water, in alcohol, and in chloroform; slightly soluble in ether.

**Methionine:** White crystals, having a characteristic odor and taste. Soluble in water, in warm dilute alcohol, and in dilute mineral acids; insoluble in ether, in absolute alcohol, in benzene, and in acetone (L-form). *NF category:* Flavors and fragrance; pH modifier (acidifying agent/alkalizing agent/buffering agent); antioxidant.

**Methocarbamol:** White powder, odorless, or having a slight characteristic odor. Melts at about 94°, or, if previously ground to a fine powder, melts at about 90°. Soluble in alcohol only with heating; sparingly soluble in water and in chloroform; insoluble in benzene and in *n*-hexane.

**Methohexital:** White to faintly yellowish-white, crystalline, odorless powder. Slightly soluble in alcohol, in chloroform, and in dilute alkalies; very slightly soluble in water.

**Methohexital Sodium for Injection:** White to off-white, hygroscopic powder. Is essentially odorless.

**Methotrexate:** Orange-brown, or yellow, crystalline powder. Freely soluble in dilute solutions of alkali hydroxides and carbonates; slightly soluble in 6 N hydrochloric acid; practically insoluble in water, in alcohol, in chloroform, and in ether.

**Methotrimeprazine:** Fine, white, practically odorless, crystalline powder. Melts at about 126°. Freely soluble in chloroform, in ether, and in boiling alcohol; sparingly soluble in methanol and in alcohol at 25°; practically insoluble in water.

**Methoxsalen:** White to cream-colored, fluffy, needle-like crystals. Is odorless. Freely soluble in chloroform; soluble in boiling alcohol, in acetone, in acetic acid, in propylene glycol, and in benzene; sparingly soluble in boiling water and in ether; practically insoluble in water.

**Methoxsalen Topical Solution:** Clear, colorless liquid.

**Methoxyflurane:** Clear, practically colorless, mobile liquid, having a characteristic odor. Boils at about 105°. Miscible with alcohol, with acetone, with chloroform, with ether, and with fixed oils.

**Methsuximide:** White to grayish white, crystalline powder. Is odorless, or has not more than a slight odor. Very soluble in chloroform; freely soluble in alcohol and in ether; slightly soluble in hot water.

**Methyclothiazide:** White or practically white, crystalline powder. Is odorless, or has a slight odor. Freely soluble in acetone and in pyridine; sparingly soluble in methanol; slightly soluble in alcohol; very slightly soluble in water, in chloroform, and in benzene.

**Methyl Acrylate, Methyl Methacrylate and Methacrylic Acid (7:3:1) Copolymer 280000 Dispersion:** Milky-white liquid of low viscosity. It is miscible with water in any proportion; the milky-white appearance is retained. A clear or slightly opalescent, viscous solution is obtained on mixing one part of the dispersion with five parts of acetone, ethanol or isopropyl alcohol; the polymer substance is first precipitated, but then dissolves in the excess organic solvent. A clear or slightly opalescent solution is obtained on mixing one part of the dispersion with two parts of 1 N sodium hydroxide. *NF category*: Coating agent; diluent; film-forming agent; wet binder.

**Methyl Alcohol:** Clear, colorless liquid, having a characteristic odor. Is flammable. Miscible with water, with alcohol, with ether, with benzene, and with most other organic solvents. *NF category:* Solvent.

**Methyl Benzylidene Camphor:** A white, fine crystalline powder. Very soluble in chloroform; freely soluble in alcohol; practically insoluble in water.

**Methyl Isobutyl Ketone:** Transparent, colorless, mobile, volatile liquid, having a faint ketonic and camphoraceous odor. Slightly soluble in water. Miscible with alcohol, with ether, and with benzene. *NF category:* Alcohol denaturant; solvent.

**Methyl Salicylate:** Colorless, yellowish, or reddish liquid, having the characteristic odor and taste of wintergreen. It boils between 219° and 224°, with some decomposition. Soluble in alcohol and in glacial acetic acid; slightly soluble in water. *NF category:* Flavors and fragrance.

**Methylbenzethonium Chloride:** White, hygroscopic crystals, having a mild odor. Its solutions are neutral or slightly alkaline to litmus. Very soluble in water, in alcohol, and in ether; practically insoluble in chloroform.

**Methylcellulose:** White, fibrous powder or granules. Its aqueous suspensions are neutral to litmus. It swells in water and produces a clear to opalescent, viscous, colloidal suspension. Soluble in glacial acetic acid and in a mixture of equal volumes of alcohol and chloroform; insoluble in alcohol, in ether, and in chloroform. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; wet binder; emulsifying agent; film-forming agent; disintegrant.

**Methyldopa:** White to yellowish-white, odorless, fine powder, which may contain friable lumps. Very soluble in 3 N hydrochloric acid; sparingly soluble in water; slightly soluble in alcohol; practically insoluble in ether.

**Methylene Blue:** Dark green or blue crystals or crystalline powder having a bronze-like luster. Is odorless or practically so, and is stable in air. Its solutions in water and in alcohol are deep blue in color. Slightly soluble in water and in alcohol. *NF category:* Free radical scavenger.

**Methylene Chloride:** Clear, colorless, mobile liquid, having an odor resembling that of chloroform. Miscible with alcohol, with ether, and with fixed and volatile oils. *NF category:* Solvent.

**Methylergonovine Maleate:** White to pinkish-tan, microcrystalline powder. Is odorless. Slightly soluble in water and in alcohol; very slightly soluble in chloroform and in ether.

**Methylnaltrexone Bromide:** White to almost-white crystalline powder. Freely soluble in dimethylsulfoxide; soluble in dimethylformamide and in water; slightly soluble in methanol; very slightly soluble in ethanol; practically insoluble in toluene.

**Methylparaben:** White, crystalline powder or colorless crystals. Freely soluble in alcohol and in methanol; slightly soluble in water. *NF category:* Antimicrobial preservative.

**Methylparaben Sodium:** White, hygroscopic powder. Freely soluble in water; sparingly soluble in alcohol; insoluble in fixed oils. *NF category:* Antimicrobial preservative.

**Methylphenidate Hydrochloride:** White, odorless, fine, crystalline powder. Its solutions are acid to litmus. Freely soluble in water and in methanol; soluble in alcohol; slightly soluble in chloroform and in acetone.

**Methylprednisolone:** White to practically white, odorless, crystalline powder. Melts at about 240°, with some decomposition (see *Melting Range or Temperature* ⟨741⟩). Sparingly soluble in alcohol, in dioxane, and in methanol; slightly soluble in acetone and in chloroform; very slightly soluble in ether; practically insoluble in water.

**Methylprednisolone Acetate:** White or practically white, odorless, crystalline powder. Melts at about 225°, with some decomposition (see *Melting Range or Temperature* ⟨741⟩).

Official

https://nhathuocngocanh.com/

Soluble in dioxane; sparingly soluble in acetone, in alcohol, in chloroform, and in methanol; slightly soluble in ether; practically insoluble in water.

**Methylprednisolone Hemisuccinate:** White or nearly white, odorless or nearly odorless, hygroscopic solid. Freely soluble in alcohol; soluble in acetone; very slightly soluble in water.

**Methylprednisolone Sodium Succinate:** White or nearly white, odorless, hygroscopic, amorphous solid. Very soluble in water and in alcohol; very slightly soluble in acetone; insoluble in chloroform.

**Methylpyrrolidone:** A clear, colorless to very slightly yellow liquid. Miscible with water and with most organic solvents including alcohol, ketones, and aromatic and chlorinated hydrocarbons. Boiling point: about 202°. Refractive index: about 1.469. *NF category:* Solvent.

**Methylsulfonylmethane:** White powder or flake crystal. Melts at about 109°. Freely soluble in water, in methanol, in alcohol, and in acetone; sparingly soluble in ether.

**Methyltestosterone:** White or creamy white crystals or crystalline powder. Is odorless and is stable in air, but is slightly hygroscopic. Is affected by light. Soluble in alcohol, in methanol, in ether, and in other organic solvents; sparingly soluble in vegetable oils; practically insoluble in water.

**Methysergide Maleate:** White to yellowish-white or reddish-white, crystalline powder. Is odorless or has not more than a slight odor. Slightly soluble in water and in alcohol; very slightly soluble in chloroform; practically insoluble in ether.

**Metoclopramide Hydrochloride:** White or practically white, crystalline, odorless or practically odorless powder. Very soluble in water; freely soluble in alcohol; sparingly soluble in chloroform; practically insoluble in ether.

**Metoprolol Succinate:** White to off-white powder. Freely soluble in water; soluble in methanol; sparingly soluble in alcohol; slightly soluble in isopropyl alcohol.

**Metoprolol Tartrate:** White, crystalline powder. Very soluble in water; freely soluble in methylene chloride, in chloroform, and in alcohol; slightly soluble in acetone; insoluble in ether.

**Metronidazole:** White to pale yellow, odorless crystals or crystalline powder. Is stable in air, but darkens on exposure to light. Soluble in dilute hydrochloric acid (1 in 2); sparingly soluble in water and in alcohol; slightly soluble in ether and in chloroform.

**Metronidazole Benzoate:** White to slightly yellow, crystalline powder. Freely soluble in methylene chloride; soluble in acetone; slightly soluble in alcohol; very slightly soluble in ethyl ether; practically insoluble in water.

**Metyrapone:** White to light amber, fine, crystalline powder, having a characteristic odor. Darkens on exposure to light. Soluble in methanol and in chloroform; sparingly soluble in water. It forms water-soluble salts with acids.

**Mexiletine Hydrochloride:** White powder. Freely soluble in dehydrated alcohol and in water; slightly soluble in acetonitrile; practically insoluble in ether. Optically inactive (1 in 20 solution in water).

**Mibolerone:** White to off-white powder. Slightly soluble in chloroform, in dioxane, and in methylene chloride; practically insoluble in water (0.0454 mg per mL at 37°).

**Micafungin Sodium:** White to almost white amorphous powder. Freely soluble in water, in isotonic sodium chloride, in *N,N*-dimethylformamide, and in dimethyl sulfoxide; slightly soluble in methyl alcohol; practically insoluble in acetonitrile, in alcohol, in acetone, in diethyl ether, and in *n*-hexane.

**Miconazole:** White to pale cream powder. Melts in the range of 78° to 88°. May exhibit polymorphism. Freely soluble in alcohol, in methanol, in isopropyl alcohol, in acetone, in propylene glycol, in chloroform, and in dimethylformamide; soluble in ether; insoluble in water.

**Miconazole Nitrate:** White or practically white, crystalline powder, having not more than a slight odor. Melts in the range of 178° to 183°, with decomposition. Freely soluble in dimethyl sulfoxide; soluble in dimethylformamide; sparingly soluble in methanol; slightly soluble in alcohol, in chloroform, and in propylene glycol; very slightly soluble in water and in isopropyl alcohol; insoluble in ether.

**Midazolam:** White or yellowish powder. The hydrochloride salt of midazolam is soluble in aqueous solutions. Insoluble in water.

**Midodrine Hydrochloride:** White crystalline powder. Soluble in water; sparingly soluble in methanol.

**Milrinone:** White to tan, crystalline solid. Is hygroscopic. Freely soluble in dimethyl sulfoxide; very slightly soluble in methanol; practically insoluble in water and in chloroform.

**Mineral Oil:** Colorless, transparent, oily liquid, free or practically free from fluorescence. Is odorless and tasteless when cold, and develops not more than a faint odor of petroleum when heated. Soluble in volatile oils; insoluble in water and in alcohol. Miscible with most fixed oils but not with castor oil. *NF category:* Solvent; vehicle (oleaginous); emollient.

**Light Mineral Oil:** Colorless, transparent, oily liquid, free, or practically free, from fluorescence. Is odorless and tasteless when cold, and develops not more than a faint odor of petroleum when heated. Soluble in volatile oils; insoluble in water and in alcohol. Miscible with most fixed oils, but not with castor oil. *NF category:* Vehicle (oleaginous); lubricant; emollient; solvent.

**Minocycline Hydrochloride:** Yellow, crystalline powder. Soluble in solutions of alkali hydroxides and carbonates; sparingly soluble in water; slightly soluble in alcohol; practically insoluble in chloroform and in ether.

**Minoxidil:** White to off-white, crystalline powder. Melts in the approximate range of between 248° and 268°, with decomposition. Soluble in alcohol and in propylene glycol; sparingly soluble in methanol; slightly soluble in water; practically insoluble in chloroform, in acetone, in ethyl acetate, and in hexane.

**Mirtazapine:** White to creamy white, crystalline powder. Freely soluble in methanol and in toluene; soluble in ethyl ether; sparingly soluble in *n*-hexane; practically insoluble in water.

**Misoprostol:** Clear, colorless or light yellow viscous liquid. Very slightly soluble in water.

**Mitomycin:** Blue-violet, crystalline powder. Soluble in acetone, in methanol, in butyl acetate, and in cyclohexanone; slightly soluble in water.

**Mitotane:** White, crystalline powder, having a slight, aromatic odor. Soluble in alcohol, in ether, in solvent hexane, and in fixed oils and fats; practically insoluble in water.

**Mitoxantrone Hydrochloride:** Dark blue powder. Sparingly soluble in water; slightly soluble in methanol; practically insoluble in acetone, in acetonitrile, and in chloroform.

**Modafinil:** White to off-white, crystalline powder. Sparingly soluble in methanol; slightly soluble in absolute alcohol; very slightly soluble in water.

**Moexipril Hydrochloride:** White to off-white powder. Soluble in water, in alcohol, and in methanol.

**Mometasone Furoate:** White to off-white powder. Melts at about 220°, with decomposition. Soluble in acetone and in methylene chloride.

**Monensin Sodium:** Off-white to tan, crystalline powder. Soluble in chloroform and in methanol; slightly soluble in water; practically insoluble in solvent hexane.

**Mono- and Di-glycerides:** Vary in consistency from yellow liquids, through ivory-colored plastics, to ivory white-colored solids (bead or flake forms). Soluble in alcohol, in ethyl acetate,

in chloroform, and in other chlorinated hydrocarbons; insoluble in water. *NF category:* Emulsifying agent.

**Monobenzone Ointment:** Dispersible with, but not soluble in, water.

**Monoethanolamine:** Clear, colorless, moderately viscous liquid, having a distinctly ammoniacal odor. Miscible with water, with acetone, with alcohol, with glycerin, and with chloroform. Immiscible with ether, with solvent hexane, and with fixed oils, although it dissolves many essential oils. *NF category:* Emulsifying agent; pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Monoglyceride Citrate:** Soft white to ivory-colored, waxy solid with a lard-like consistency and bland odor. Dispersible in most common fat solvents and in alcohol. Insoluble in water.

**Monosodium Glutamate:** White, practically odorless, free-flowing crystals or crystalline powder. Freely soluble in water; sparingly soluble in alcohol. May have either a slightly sweet or a slightly salty taste. *NF category:* Flavors and fragrance; pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Monothioglycerol:** Colorless or pale yellow, viscous liquid, having a slight sulfidic odor. Is hygroscopic. Freely soluble in water; insoluble in ether. Miscible with alcohol. *NF category:* Antioxidant; antimicrobial preservative.

**Montelukast Sodium:** White or almost white, hygroscopic powder. Freely soluble to very soluble in alcohol; freely soluble in water and in methylene chloride.

**Morantel Tartrate:** A white or pale yellow, crystalline powder. Very soluble in water and in alcohol; practically insoluble in ethyl acetate.

**Morphine Sulfate:** White, feathery, silky crystals, cubical masses of crystals, or white, crystalline powder. Is odorless, and when exposed to air it gradually loses water of hydration. Darkens on prolonged exposure to light. Freely soluble in hot water; soluble in water; slightly soluble in alcohol but more so in hot alcohol; insoluble in chloroform and in ether.

**Moxidectin:** White to pale yellow powder. Very soluble in alcohol; slightly soluble in hexane; practically insoluble in water.

**Moxifloxacin Hydrochloride:** Slightly yellow to yellow powder or crystals. Soluble in 0.1 N sodium hydroxide; sparingly soluble in water and in methanol; slightly soluble in 0.1 N hydrochloric acid, in dimethylformamide, and in alcohol; practically insoluble in methylene chloride, in acetone, in ethyl acetate, and in toluene; insoluble in *tert*-butyl methyl ether and *n*-heptane.

**Mupirocin:** White to off-white, crystalline solid. Freely soluble in acetone, in chloroform, in dehydrated alcohol, and in methanol; slightly soluble in ether; very slightly soluble in water.

**Mycophenolate Mofetil:** White or almost white, crystalline powder. Its melting range is between 94° and 98°. Freely soluble in acetone; soluble in methanol; sparingly soluble in dehydrated alcohol; slightly soluble in water.

**Mycophenolate Sodium:** White to off-white crystalline powder. Slightly soluble in water; practically insoluble in 0.1 N hydrochloric acid.

**Myristic Acid:** Hard, white or faintly yellow, somewhat glossy, crystalline solid or white or yellow-white powder. Soluble in alcohol, in chloroform, and in ether; practically insoluble in water. *NF category:* Antifoaming agent; emulsifying agent; lubricant.

**Nabumetone:** A white, or almost white, crystalline powder. Freely soluble in acetone; sparingly soluble in alcohol and in methanol; practically insoluble in water.

**Nadolol:** White to off-white, practically odorless, crystalline powder. Freely soluble in alcohol and in methanol; soluble in water at pH 2; slightly soluble in chloroform, in methylene chloride, in isopropyl alcohol, and in water (between pH 7 and pH 10); insoluble in acetone, in benzene, in ether, in hexane, and in trichloroethane.

**Nafcillin Sodium:** White to yellowish-white powder, having not more than a slight characteristic odor. Freely soluble in water and in chloroform; soluble in alcohol.

**Naloxone Hydrochloride:** White to slightly off-white powder. Its aqueous solution is acidic. Soluble in water, in dilute acids, and in strong alkali; slightly soluble in alcohol; practically insoluble in ether and in chloroform.

**Naloxone Hydrochloride Injection:** Clear, colorless liquid.

**Nandrolone Decanoate:** Fine, white to creamy white, crystalline powder. Is odorless, or may have a slight odor. Soluble in chloroform, in alcohol, in acetone, and in vegetable oils; practically insoluble in water.

**Naphazoline Hydrochloride:** White, crystalline powder. Freely soluble in water; soluble in alcohol.

**Naproxen:** White to off-white, practically odorless, crystalline powder. Soluble in chloroform, in dehydrated alcohol, and in alcohol; sparingly soluble in ether; practically insoluble in water.

**Naproxen Sodium:** White to creamy crystalline powder. Soluble in water and in methanol; sparingly soluble in alcohol; very slightly soluble in acetone; and practically insoluble in chloroform and in toluene. Melts at about 255°, with decomposition.

**Narasin:** White to off-white, crystalline powder. Melts at about 217°, with decomposition. Soluble in methanol and in water.

**Naratriptan Hydrochloride:** White to pale yellow solid. Soluble in water.

**Natamycin:** Off-white to cream-colored powder, which may contain up to 3 moles of water. Soluble in glacial acetic acid and in dimethylformamide; slightly soluble in methanol; practically insoluble in water.

**Nateglinide:** White powder. Freely soluble in methanol and in alcohol; soluble in ether; sparingly soluble in acetonitrile and in octanol; practically insoluble in water.

**Nefazodone Hydrochloride:** Nonhygroscopic, white powder. Freely soluble in chloroform; soluble in propylene glycol; slightly soluble in polyethylene glycol and in water.

**Neohesperidin Dihydrochalcone:** White or yellowish-white powder. Freely soluble in dimethyl sulfoxide; soluble in methanol; practically insoluble in water and in methylene chloride. *NF category:* Sweetening agent; flavors and fragrance.

**Neomycin Sulfate:** White to slightly yellow powder, or cryodesiccated solid. Is odorless or practically so and is hygroscopic. Its solutions are dextrorotatory. Freely soluble in water; very slightly soluble in alcohol; insoluble in acetone, in chloroform, and in ether.

**Nevirapine:** White to off-white, odorless to nearly odorless, crystalline powder. Slightly soluble in alcohol and in methanol; practically insoluble in water. Hydrous form also slightly soluble in propylene glycol.

**Niacin:** White crystals or crystalline powder. Is odorless, or has a slight odor. Melts at about 235°. Freely soluble in boiling water, in boiling alcohol, and in solutions of alkali hydroxides and carbonates; sparingly soluble in water; practically insoluble in ether.

**Niacinamide:** White, crystalline powder. Is odorless or practically so, and has a bitter taste. Its solutions are neutral to litmus. Freely soluble in water and in alcohol; soluble in glycerin.

**Nifedipine:** Yellow powder. Is affected by exposure to light. Freely soluble in acetone; practically insoluble in water.

**Nilotinib:** White to slightly yellowish or slightly greenish-yellowish solid. Decomposes prior to melting.

Slightly soluble in ethanol, in methanol, and in isopropanol; very slightly soluble in water.

**Nilutamide:** White or almost-white powder. Freely soluble in acetone and in ethyl acetate; soluble in methanol and in dichloromethane; sparingly soluble in absolute alcohol; very slightly soluble in water.

**Nimodipine:** Light yellow or yellow, crystalline powder, affected by light. Freely soluble in ethyl acetate; sparingly soluble in alcohol; practically insoluble in water. Exhibits polymorphism.

**Nitric Acid:** Highly corrosive fuming liquid, having a characteristic, highly irritating odor. Stains animal tissues yellow. Boils at about 120°. Specific gravity is about 1.41. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Nitrofurantoin:** Lemon-yellow, odorless crystals or fine powder. Has a bitter aftertaste. Soluble in dimethylformamide; very slightly soluble in water and in alcohol.

**Nitrofurazone:** Lemon yellow, odorless, crystalline powder. Darkens slowly on exposure to light. Melts at about 236°, with decomposition. Soluble in dimethylformamide; slightly soluble in propylene glycol and in polyethylene glycol mixtures; very slightly soluble in alcohol and in water; practically insoluble in chloroform and in ether.

**Nitrofurazone Ointment:** Yellow, opaque, and water-miscible, and has ointment-like consistency.

**Nitrogen:** Colorless, odorless, tasteless gas. Is nonflammable and does not support combustion. One L at 0° and at a pressure of 760 mm of mercury weighs about 1.251 g. One volume dissolves in about 65 volumes of water and in about 9 volumes of alcohol at 20° and at a pressure of 760 mm of mercury. *NF category:* Air displacement; propellant.

**Diluted Nitroglycerin:** When diluted with lactose, it is a white, odorless powder. When diluted with propylene glycol or alcohol, it is a clear, colorless, or pale yellow liquid. [NOTE—Undiluted nitroglycerin occurs as a white to pale yellow, thick, flammable, explosive liquid.] Undiluted nitroglycerin is soluble in methanol, in alcohol, in carbon disulfide, in acetone, in ethyl ether, in ethyl acetate, in glacial acetic acid, in benzene, in toluene, in nitrobenzene, in phenol, in chloroform, and in methylene chloride; slightly soluble in water.

**Nitromersol:** Brownish yellow to yellow granules or brownish yellow to yellow powder. Is odorless and tasteless and is affected by light. Soluble in solutions of alkalies and of ammonia by opening of the anhydride ring and the formation of a salt; very slightly soluble in water, in alcohol, in acetone, and in ether.

**Nitromersol Topical Solution:** Clear, reddish-orange solution. Is affected by light.

**Nitrous Oxide:** Colorless gas, without appreciable odor or taste. One L at 0° and at a pressure of 760 mm of mercury weighs about 1.97 g. One volume dissolves in about 1.4 volumes of water at 20° and at a pressure of 760 mm of mercury. Freely soluble in alcohol; soluble in ether and in oils. *NF category:* Propellant.

**Nizatidine:** Off-white to buff crystalline solid. Freely soluble in chloroform; soluble in methanol; sparingly soluble in water.

**Nonoxynol 9:** Clear, colorless to light yellow, viscous liquid. Soluble in water, in alcohol, and in corn oil. *NF category:* Wetting and/or solubilizing agent.

**Norepinephrine Bitartrate:** White or faintly gray, odorless, crystalline powder. Slowly darkens on exposure to air and light. Its solutions are acid to litmus, having a pH of about 3.5. Freely soluble in water; slightly soluble in alcohol; practically insoluble in chloroform and in ether. Melts between 98° and 104°, without previous drying of the specimen, the melt being turbid.

**Norepinephrine Bitartrate Injection:** Colorless or practically colorless liquid, gradually turning dark on exposure to air and light.

**Norethindrone:** White to creamy white, odorless, crystalline powder. Is stable in air. Soluble in chloroform and in dioxane; sparingly soluble in alcohol; slightly soluble in ether; practically insoluble in water.

**Norethindrone Acetate:** White to creamy white, odorless, crystalline powder. Very soluble in chloroform; freely soluble in dioxane; soluble in ether and in alcohol; practically insoluble in water.

**Norflurane:** Non-flammable hydrofluorocarbon (HFC) and haloalkane refrigerant used as a propellant in metered dose inhalers. Clear and colorless liquefied gas under pressure.

**Norgestimate:** White to pale yellow powder. Very to freely soluble in methylene chloride; sparingly soluble in acetonitrile; insoluble in water.

**Norgestrel:** White or practically white, practically odorless, crystalline powder. Freely soluble in chloroform; sparingly soluble in alcohol; insoluble in water.

**Norelgestromin:** White to off-white powder. Freely soluble in acetone, in ethanol, in methanol, and in dimethylformamide; sparingly soluble in methylene chloride and in iso-propanol; slightly soluble in acetonitrile; practically insoluble in water.

**Nortriptyline Hydrochloride:** White to off-white powder, having a slight, characteristic odor. Its solution (1 in 100) has a pH of about 5. Soluble in water and in chloroform; sparingly soluble in methanol; practically insoluble in ether, in benzene, and in most other organic solvents.

**Noscapine:** Fine, white or practically white, crystalline powder. Freely soluble in chloroform; soluble in acetone; slightly soluble in alcohol and in ether; practically insoluble in water.

**Novobiocin Sodium:** White or yellowish-white, odorless, hygroscopic, crystalline powder. Freely soluble in water, in alcohol, in methanol, in glycerin, and in propylene glycol; slightly soluble in butyl acetate; practically insoluble in acetone, in chloroform, and in ether.

**Nystatin:** Yellow to light tan powder. Is hygroscopic, and is affected by long exposure to light, heat, and air. Freely soluble in dimethylformamide and in dimethyl sulfoxide; very slightly soluble in methanol; practically insoluble or insoluble in water, in alcohol, in *n*-propyl alcohol, in *n*-butyl alcohol, in chloroform, and in ether.

**Octoxynol 9:** Clear, pale yellow, viscous liquid, having a faint odor and a bitter taste. Soluble in benzene and in toluene; practically insoluble in solvent hexane. Miscible with water, with alcohol, and with acetone. *NF category:* Wetting and/or solubilizing agent.

**Octyldodecanol:** Clear water-white, free-flowing liquid. Soluble in alcohol and in ether; insoluble in water. *NF category:* Vehicle (oleaginous); emollient; emulsifying agent.

**Octyl Methoxycinnamate:** Pale yellow oil. Insoluble in water.

**Ofloxacin:** Pale yellowish-white to light yellowish-white crystals or crystalline powder. Sparingly soluble in chloroform; slightly soluble in alcohol, in methanol, and in water.

Hydrophilic Ointment:*NF category:* Ointment base.

White Ointment:*NF category:* Ointment base.

Yellow Ointment:*NF category:* Ointment base.

**Olanzapine:** A yellow crystalline solid. Soluble in *n*-propanol; sparingly soluble in acetonitrile; slightly soluble in methanol and in dehydrated alcohol; practically insoluble in water.

**Oleic Acid:** Colorless to pale yellow, oily liquid when freshly prepared, but on exposure to air it gradually absorbs oxygen and darkens. Has a characteristic, lard-like odor and taste. When strongly heated in air, it is decomposed with the

production of acrid vapors. Practically insoluble in water. Miscible with alcohol, with chloroform, with ether, with benzene, and with fixed and volatile oils. *NF category:* Emulsifying agent.

**Oleovitamin A and D:** Yellow to red, oily liquid, practically odorless or having a fish-like odor, and having no rancid odor or taste. Is a clear liquid at temperatures exceeding 65°, and may crystallize on cooling. Is unstable in air and in light. Very soluble in ether and in chloroform; soluble in dehydrated alcohol and in vegetable oils; insoluble in water and in glycerin.

**Oleovitamin A and D Capsules:** The oil contained in Oleovitamin A and D Capsules is a yellow to red, oily liquid, practically odorless or having a fish-like odor, and having no rancid odor or taste. Is a clear liquid at temperatures exceeding 65°, and may crystallize on cooling. Is unstable in air and in light.

**Oleoyl Polyoxylglycerides:** Amber, oily liquids. May develop deposit after prolonged storage at 20°. Freely soluble in methylene chloride; practically insoluble but dispersible in water. *NF category:* Ointment base; solvent; emulsifying agent; wetting and/or solubilizing agent.

**Oleyl Alcohol:** Clear, colorless to light yellow, oily liquid. Has a faint characteristic odor and a bland taste. Soluble in alcohol, in ether, in isopropyl alcohol, and in light mineral oil; insoluble in water. *NF category:* Emollient; emulsifying agent.

**Oleyl Oleate:** Clear, colorless to light yellow liquid. Has a faint characteristic odor. Slightly soluble in alcohol. Miscible with chloroform and with ether. *NF category:* Emollient; emulsifying agent.

**Olive Oil:** Pale yellow, or light greenish-yellow, oily liquid, having a slight, characteristic odor and taste, with a faintly acrid aftertaste. Slightly soluble in alcohol. Miscible with ether, with chloroform, and with carbon disulfide. *Specific Gravity* ⟨841⟩: Between 0.910 and 0.915. *NF category:* Methacrylic Acid and Vehicle (oleaginous).

**Olmesartan Medoxomil:** White to off-white crystalline powder. Sparingly soluble in methanol; practically insoluble in water.

**Olopatadine Hydrochloride:** White crystalline powder. Very soluble in formic acid; sparingly soluble in water; very slightly soluble in dehydrated alcohol.

**Omeprazole:** White to off-white powder. Soluble in dichloromethane; sparingly soluble in methanol and in alcohol; very slightly soluble in water.

**Omeprazole Magnesium:** White to off-white powder. Sparingly soluble in methanol; slightly soluble in alcohol; very slightly soluble in water and in dichloromethane.

**Ondansetron:** White to off-white powder. Very soluble in acid solutions; sparingly soluble in water.

**Ondansetron Hydrochloride:** White to off-white powder. Soluble in methanol; sparingly soluble in water and in alcohol; slightly soluble in isopropyl alcohol and in dichloromethane; very slightly soluble in acetone, in chloroform, and in ethyl acetate.

**Opium:** Has a very characteristic odor and a very bitter taste.

**Powdered Opium:** Light brown or moderately yellowish-brown powder.

**Orbifloxacin:** White to pale yellow crystals or crystalline powder. Odorless. Soluble in acetic acid; very slightly soluble in methanol, in water, and in chloroform; practically insoluble in ethanol and in diethyl ether.

**Orlistat:** White to off-white fine powder or fine powder with lumps. Freely soluble in chloroform; very soluble in methanol and in alcohol; practically insoluble in water.

**Orphenadrine Citrate:** White, practically odorless, crystalline powder, having a bitter taste. Sparingly soluble in water; slightly soluble in alcohol; insoluble in chloroform, in benzene, and in ether.

**Oseltamivir Phosphate:** White to off-white powder. Freely soluble in water; soluble in methanol, in dimethyl sulfoxide, and in propylene glycol; sparingly soluble in dimethylformamide; slightly soluble in alcohol; very slightly soluble in isopropyl alcohol and in polyethylene glycol 400; practically insoluble in acetonitrile, in acetone, in dichloromethane, and in *n*-hexane.

**Oxacillin Sodium:** Fine, white, crystalline powder, odorless or having a slight odor. Freely soluble in water, in methanol, and in dimethyl sulfoxide; slightly soluble in absolute alcohol, in chloroform, in pyridine, and in methyl acetate; insoluble in ethyl acetate, in ether, in benzene, and in ethylene chloride.

**Oxacillin Sodium for Injection:** Fine, white, crystalline powder, odorless or having a slight odor. Freely soluble in water, in methanol, and in dimethyl sulfoxide; slightly soluble in absolute alcohol, in chloroform, in pyridine, and in methyl acetate; insoluble in ethyl acetate, in ether, in benzene, and in ethylene chloride.

**Oxaliplatin:** White to off-white crystalline powder. Slightly soluble in water; very slightly soluble in methanol; practically insoluble in alcohol.

**Oxandrolone:** White, odorless, crystalline powder. Is stable in air, but darkens on exposure to light. Melts at about 225°. Freely soluble in chloroform; sparingly soluble in alcohol and in acetone; practically insoluble in water.

**Oxaprozin:** White to yellowish-white, crystalline powder.

**Oxazepam:** Creamy white to pale yellow powder. Is practically odorless. Slightly soluble in alcohol and in chloroform; very slightly soluble in ether; practically insoluble in water.

**Oxcarbazepine:** Light orange to creamish white or off-white powder. Soluble in acetic acid; sparingly soluble in chloroform; practically insoluble in water.

**Oxfendazole:** White or almost white powder. Slightly soluble in alcohol and in methylene chloride; practically insoluble in water.

**Oxprenolol Hydrochloride:** White, crystalline powder. Freely soluble in alcohol, in chloroform, and in water; sparingly soluble in acetone; practically insoluble in ether.

**Oxtriphylline:** White, crystalline powder, having an amine-like odor. A solution (1 in 100) has a pH of about 10.3. Freely soluble in water and in alcohol; very slightly soluble in chloroform.

**Oxybenzone:** Pale yellow powder. Freely soluble in alcohol and in toluene; practically insoluble in water.

**Oxybutynin Chloride:** White, crystalline, practically odorless powder. Very soluble in methanol and in chloroform; freely soluble in water and in alcohol; soluble in acetone; slightly soluble in ether; very slightly soluble in hexane.

**Oxycodone Hydrochloride:** White to off-white, hygroscopic crystals or powder. Is odorless. Soluble in water; slightly soluble in alcohol.

**Oxygen:** Colorless, odorless, tasteless gas, which supports combustion more energetically than does air. One L at 0° and at a pressure of 760 mm of mercury weighs about 1.429 g. One volume dissolves in about 32 volumes of water and in about 7 volumes of alcohol at 20° and at a pressure of 760 mm of mercury.

**Oxymetazoline Hydrochloride:** White to practically white, fine crystalline powder. Is hygroscopic. Melts at about 300°, with decomposition. Soluble in water and in alcohol; practically insoluble in benzene, in chloroform, and in ether.

**Oxymetholone:** White to creamy white, crystalline powder. Is odorless, and is stable in air. Freely soluble in chloroform; soluble in dioxane; sparingly soluble in alcohol; slightly soluble in ether; practically insoluble in water.

Official

https://pharmacopeia.cn/v29240/

**Oxymorphone Hydrochloride:** White or slightly off-white, odorless powder. Darkens on exposure to light. Its aqueous solutions are slightly acidic. Freely soluble in water; sparingly soluble in alcohol and in ether.

**Oxyquinoline Sulfate:** Yellow powder. Melts at about 185°. Very soluble in water; freely soluble in methanol; slightly soluble in alcohol; practically insoluble in acetone and in ether. *NF category:* Chelating and/or complexing agent.

**Oxytetracycline:** Pale yellow to tan, odorless, crystalline powder. Is stable in air, but exposure to strong sunlight causes it to darken. It loses potency in solutions of pH below 2, and is rapidly destroyed by alkali hydroxide solutions. Freely soluble in 3 N hydrochloric acid and in alkaline solutions; sparingly soluble in alcohol; very slightly soluble in water.

**Oxytetracycline Hydrochloride:** Yellow, odorless, crystalline powder, having a bitter taste. Is hygroscopic. Decomposes at a temperature exceeding 180°, and exposure to strong sunlight or to temperatures exceeding 90° in moist air causes it to darken. Its potency is diminished in solutions having a pH below 2, and is rapidly destroyed by alkali hydroxide solutions. Freely soluble in water, but crystals of oxytetracycline base separate as a result of partial hydrolysis of the hydrochloride; sparingly soluble in alcohol and in methanol, and even less soluble in dehydrated alcohol; insoluble in chloroform and in ether.

**Paclitaxel:** White to off-white powder. Soluble in alcohol; insoluble in water.

**Padimate O:** A light yellow, mobile liquid having a faint, aromatic odor. Soluble in alcohol, in isopropyl alcohol, and in mineral oil; practically insoluble in water, in glycerin, and in propylene glycol.

**Paliperidone:** White to yellow powder. Sparingly soluble in 0.1 N hydrochloric acid and in methylene chloride; slightly soluble in *N,N*-dimethylformamide and in tetrahydrofuran; practically insoluble in water, in 0.1 N sodium hydroxide, and in hexane.

**Palm Oil:** White to yellowish, fatty solid to semisolid. Insoluble in water. *NF category:* Coating agent; emulsifying agent.

**Hydrogenated Palm Oil:** White to yellowish, fatty solid to semi-solid. Freely soluble in ether; very slightly soluble in alcohol; practically insoluble in water. *NF category:* Coating agent; lubricant; wet binder.

**Palm Kernel Oil:** White to yellowish, fatty solid. Insoluble in water. *NF category:* Coating agent; emulsifying agent; suppository base.

**Palmitic Acid:** Hard, white or faintly yellow, somewhat glossy crystalline solid, or white or yellowish-white powder. It has a slight characteristic odor and taste. Soluble in alcohol, in ether, and in chloroform; practically insoluble in water. *NF category:* Antifoaming agent; emulsifying agent; lubricant.

**Palonosetron Hydrochloride:** White to off-white, crystalline powder. Freely soluble in water; soluble in propylene glycol; slightly soluble in ethanol; very slightly soluble to slightly soluble in isopropyl alcohol.

**Pamidronate Disodium:** White, crystalline powder. Soluble in water and in 2 N sodium hydroxide; sparingly soluble in 0.1 N hydrochloric acid and in 0.1 N acetic acid; practically insoluble in organic solvents.

**Pancreatin:** Cream-colored, amorphous powder, having a faint, characteristic, but not offensive odor. It hydrolyzes fats to glycerol and fatty acids, changes protein into proteoses and derived substances, and converts starch into dextrins and sugars. Its greatest activities are in neutral or faintly alkaline media; more than traces of mineral acids or large amounts of alkali hydroxides make it inert. An excess of alkali carbonate also inhibits its action.

**Pancrelipase:** Cream-colored, amorphous powder, having a faint, characteristic, but not offensive odor. Pancrelipase hydrolyzes fats to glycerol and fatty acids, changes protein into proteoses and derived substances, and converts starch into dextrins and sugars. Its greatest activities are in neutral or faintly alkaline media; more than traces of mineral acids or large amounts of alkali hydroxides make it inert. An excess of alkali carbonate also inhibits its action.

**Pancrelipase Capsules:** The contents of Capsules conform to the *Description* under *Pancrelipase*, except that the odor may vary with the flavoring agent used.

**Pancuronium Bromide:** White, yellowish-white, or slightly pink, crystalline powder. Is hygroscopic. Freely soluble in water, in methylene chloride, and in alcohol.

**Panthenol:** White to creamy white, crystalline powder having a slight, characteristic odor. Freely soluble in water, in alcohol, and in propylene glycol; soluble in chloroform and in ether; slightly soluble in glycerin.

**Pantoprazole Sodium:** White to off-white powder. Freely soluble in water, in methanol, and in dehydrated alcohol; practically insoluble in hexane and in dichloromethane.

**Papain:** White to light tan, amorphous powder. Soluble in water, the solution being colorless to light yellow and more or less opalescent; practically insoluble in alcohol, in chloroform, and in ether.

**Papaverine Hydrochloride:** White crystals or white, crystalline powder. Is odorless, and has a slightly bitter taste. Is optically inactive. Its solutions are acid to litmus. Melts at about 220°, with decomposition. Soluble in water and in chloroform; slightly soluble in alcohol; practically insoluble in ether.

**Parachlorophenol:** White or pink crystals having a characteristic phenolic odor. When undiluted, it whitens and cauterizes the skin and mucous membranes. Melts at about 42°. Very soluble in alcohol, in glycerin, in chloroform, in ether, and in fixed and volatile oils; soluble in petrolatum; sparingly soluble in water and in liquid petrolatum.

**Paraffin:** Colorless or white, more or less translucent mass showing a crystalline structure. Is odorless and tasteless, and is slightly greasy to the touch. Freely soluble in chloroform, in ether, in volatile oils, and in most warm fixed oils; slightly soluble in dehydrated alcohol; insoluble in water and in alcohol. *NF category:* Stiffening agent; ointment base.

**Synthetic Paraffin:** Very hard, white, practically tasteless and odorless wax. Contains mostly long-chain, unbranched, saturated hydrocarbons, with a small amount of branched hydrocarbons. Is represented by the formula $C_nH_{2n2}$, in which *n* may range from 20 to about 100. The average molecular weight may range from 400 to 1400. Slightly soluble in aromatic and normal paraffinic solvents; very slightly soluble in aliphatic, oxygenated, and halogenated hydrocarbon solvents; insoluble in water. *NF category:* Stiffening agent.

**Paraldehyde:** Colorless, transparent liquid. Has a strong, characteristic but not unpleasant or pungent odor, and a disagreeable taste. Specific gravity is about 0.99. Soluble in water, but less soluble in boiling water. Miscible with alcohol, with chloroform, with ether, and with volatile oils.

**Paricalcitol:** White to almost white powder. Soluble in alcohol; insoluble in water.

**Paromomycin Sulfate:** Creamy white to light yellow powder. Is odorless or practically odorless, and is very hygroscopic. Very soluble in water; insoluble in alcohol, in chloroform, and in ether.

**Paroxetine Hydrochloride:** White to off-white solid. Soluble in methanol and in alcohol; slightly soluble in water.

**Peanut Oil:** Colorless or pale yellow, oily liquid with a bland taste. May have a characteristic, nutty odor. Very slightly soluble in alcohol. Miscible with ether, with chloroform, and with carbon disulfide. *Specific Gravity* ⟨841⟩: Between 0.912 and 0.920. *Refractive Index* ⟨831⟩: Between 1.462 and 1.464 at 40°. *NF category:* Solvent; vehicle (oleaginous).

**Pectin:** Coarse or fine powder, yellowish-white in color, almost odorless, and having a mucilaginous taste. Soluble in 20 parts of water, forming a viscous, opalescent, colloidal solution that flows readily and is acid to litmus; practically insoluble in alcohol or in diluted alcohol and in other organic solvents. Pectin dissolves in water more readily if first moistened with alcohol, glycerin, or simple syrup, or if first mixed with 3 or more parts of sucrose. *NF category:* Suspending and/or viscosity-increasing agent; emulsifying agent; film-forming agent.

**Pemetrexed Disodium:** White or almost white powder. Freely soluble in water; very slightly soluble in dehydrated alcohol; practically insoluble in methylene chloride.

**Penicillamine:** White or practically white, crystalline powder, having a slight, characteristic odor. Freely soluble in water; slightly soluble in alcohol; insoluble in chloroform and in ether.

**Penicillin G Benzathine:** White, odorless, crystalline powder. Sparingly soluble in alcohol; very slightly soluble in water.

**Penicillin G Potassium:** Colorless or white crystals, or white, crystalline powder. Is odorless or practically so, and is moderately hygroscopic. Its solutions are dextrorotatory. Its solutions retain substantially full potency for several days at temperatures below 15°, but are rapidly inactivated by acids, by alkali hydroxides, by glycerin, and by oxidizing agents. Very soluble in water, in saline TS, and in dextrose solutions; sparingly soluble in alcohol.

**Penicillin G Procaine:** White crystals or white, very fine, microcrystalline powder. Is odorless or practically odorless, and is relatively stable in air. Its solutions are dextrorotatory. Is rapidly inactivated by acids, by alkali hydroxides, and by oxidizing agents. Soluble in alcohol and in chloroform; slightly soluble in water.

**Penicillin G Sodium:** Colorless or white crystals or white to slightly yellow, crystalline powder. Is odorless or practically odorless, and is moderately hygroscopic. Its solutions are dextrorotatory. Is relatively stable in air, but is inactivated by prolonged heating at about 100°, especially in the presence of moisture. Its solutions lose potency fairly rapidly at room temperature, but retain substantially full potency for several days at temperatures below 15°. Its solutions are rapidly inactivated by acids, by alkali hydroxides, by oxidizing agents, and by penicillinase.

**Penicillin V:** White, odorless, crystalline powder. Freely soluble in alcohol and in acetone; very slightly soluble in water; insoluble in fixed oils.

**Penicillin V Potassium:** White, odorless, crystalline powder. Very soluble in water; slightly soluble in alcohol; insoluble in acetone.

**Pentamidine Isethionate:** White or almost white powder or colorless crystals, hygroscopic. Freely soluble in water; sparingly soluble in alcohol; practically insoluble in methylene chloride.

**Pentazocine:** White or very pale, tan-colored powder. Freely soluble in chloroform; soluble in alcohol, in acetone, and in ether; sparingly soluble in benzene and in ethyl acetate; practically insoluble in water.

**Pentazocine Hydrochloride:** White, crystalline powder. It exhibits polymorphism, one form melting at about 254° and the other at about 218°. Freely soluble in chloroform; soluble in alcohol; sparingly soluble in water; very slightly soluble in acetone and in ether; practically insoluble in benzene.

**Pentetic Acid:** White, odorless or almost odorless powder. Melts with foaming and degradation at 220°. *NF category:* Chelating and/or complexing agent; antimicrobial preservative; sequestering agent.

**Pentobarbital:** White to practically white, fine, practically odorless powder. May occur in a polymorphic form that melts at about 116°. This form gradually reverts to the more stable higher-melting form upon being heated at about 110°. Very soluble in alcohol, in methanol, in ether, in chloroform, and in acetone; soluble in benzene; very slightly soluble in water and in carbon tetrachloride.

**Pentobarbital Sodium:** White, crystalline granules or white powder. Is odorless or has a slight characteristic odor, and has a slightly bitter taste. Its solutions decompose on standing, heat accelerating the decomposition. Very soluble in water; freely soluble in alcohol; practically insoluble in ether.

**Pentoxifylline:** White to almost white crystalline powder. Freely soluble in chloroform and in methanol; soluble in water; sparingly soluble in alcohol; slightly soluble in ether.

**Peppermint:** Has an aromatic, characteristic odor and a pungent taste, and produces a cooling sensation in the mouth. *NF category:* Flavors and fragrance.

**Peppermint Oil:** Colorless or pale yellow liquid, having a strong, penetrating, characteristic odor and a pungent taste, followed by a sensation of cold when air is drawn into the mouth. *NF category:* Flavors and fragrance.

**Peppermint Spirit:** A clear, colorless liquid with a peppermint fragrance. Freely soluble in methanol and in diethyl ether; soluble in water. *NF category:* Flavors and fragrance.

**Peppermint Water:** *NF category:* Vehicle (flavored and/or sweetened).

**Perflubron:** Clear, colorless, practically odorless liquid.

**Pergolide Mesylate:** White to off-white powder. Sparingly soluble in methanol; slightly soluble in water, in dehydrated alcohol, and in chloroform; very slightly soluble in acetone; practically insoluble in ether.

**Perindopril Erbumine:** White or off-white, crystalline powder; freely soluble in water and in alcohol; sparingly soluble in methylene chloride.

**Perphenazine:** White to creamy white, odorless powder. Freely soluble in alcohol and in chloroform; soluble in acetone; practically insoluble in water.

**Petrolatum:** Unctuous yellowish to light amber mass, having not more than a slight fluorescence even after being melted. Is transparent in thin layers. Is free or practically free from odor and taste. Freely soluble in benzene, in carbon disulfide, in chloroform, and in turpentine oil; soluble in ether, in solvent hexane, and in most fixed and volatile oils; practically insoluble in cold and hot alcohol and in cold dehydrated alcohol; insoluble in water. *NF category:* Ointment base; emollient.

**Hydrophilic Petrolatum:** *NF category:* Ointment base.

**White Petrolatum:** White or faintly yellowish, unctuous mass, transparent in thin layers even after cooling to 0°. Freely soluble in benzene, in carbon disulfide, and in chloroform; soluble in ether, in solvent hexane, and in most fixed and volatile oils; slightly soluble in cold or hot alcohol, and in cold dehydrated alcohol; insoluble in water. *NF category:* Ointment base.

**Phenazopyridine Hydrochloride:** Light or dark red to dark violet, crystalline powder. Is odorless, or has a slight odor. Melts at about 235°, with decomposition. Slightly soluble in water, in alcohol, and in chloroform.

**Phendimetrazine Tartrate:** White, odorless, crystalline powder. Freely soluble in water; sparingly soluble in warm alcohol; insoluble in chloroform, in acetone, in ether, and in benzene. Phendimetrazine base is extracted by organic solvents from alkaline solution.

**Phenelzine Sulfate:** White to yellowish white powder, having a characteristic odor. Freely soluble in water; practically insoluble in alcohol, in chloroform, and in ether.

**Pheniramine Maleate:** White, crystalline powder having a faint amine-like odor. Soluble in water and in alcohol.

Official

https://pharmacopeia.cn/v29240/

**Phenobarbital:** White, odorless, glistening, small crystals, or white, crystalline powder, which may exhibit polymorphism. Is stable in air. Its saturated solution has a pH of about 5. Soluble in alcohol, in ether, and in solutions of fixed alkali hydroxides and carbonates; sparingly soluble in chloroform; very slightly soluble in water.

**Phenobarbital Sodium:** Flaky crystals, or white, crystalline granules, or white powder. Is odorless, has a bitter taste, and is hygroscopic. Its solutions are alkaline to phenolphthalein TS, and decompose on standing. Very soluble in water; soluble in alcohol; practically insoluble in ether and in chloroform.

**Phenol:** Colorless to light pink, interlaced or separate, needle-shaped crystals, or white to light pink, crystalline mass. Has a characteristic odor. Is liquefied by warming and by the addition of 10% of water. Boils at about 182°, and its vapor is flammable. Gradually darkens on exposure to light and air. Very soluble in alcohol, in glycerin, in chloroform, in ether, and in fixed and volatile oils; soluble in water; sparingly soluble in mineral oil. *NF category:* Antimicrobial preservative.

**Liquefied Phenol:** Colorless to pink liquid, which may develop a red tint upon exposure to air or light. Has a characteristic, somewhat aromatic odor. It whitens and cauterizes the skin and mucous membranes. Specific gravity is about 1.065. Miscible with alcohol, with ether, and with glycerin. A mixture of equal volumes of Liquefied Phenol and glycerin is miscible with water.

**Camphorated Phenol Topical Gel:** Clear, colorless, oily gel.

**Phenolsulfonphthalein:** A bright-red to dark-red, crystalline powder. Slightly soluble in alcohol; very slightly soluble in water.

**Phenoxyethanol:** A colorless, slightly viscous liquid. Slightly soluble in water, in peanut oil, and in olive oil. Miscible with acetone, with alcohol, and with glycerol. *NF category:* Antimicrobial preservative.

**Phentermine Hydrochloride:** White, odorless, hygroscopic, crystalline powder. Soluble in water and in the lower alcohols; slightly soluble in chloroform; insoluble in ether.

**Phentolamine Mesylate:** White or off-white, odorless, crystalline powder. Its solutions are acid to litmus, having a pH of about 5, and slowly deteriorate. Melts at about 178°. Freely soluble in water and in alcohol; slightly soluble in chloroform.

**Phenylalanine:** White, odorless crystals, having a slightly bitter taste. Sparingly soluble in water; very slightly soluble in methanol, in alcohol, and in dilute mineral acids.

**Phenylbenzimidazole Sulfonic Acid:** White to ivory-colored, odorless powder. Soluble in alcohol; practically insoluble in oily solvents and in water. Its salts are freely soluble in water.

**Phenylbutazone:** White to off-white, odorless, crystalline powder. Freely soluble in acetone and in ether; soluble in alcohol; very slightly soluble in water.

**Phenylephrine Bitartrate:** White or almost white powder or colorless crystals. Freely soluble in water.

**Phenylephrine Hydrochloride:** White or practically white, odorless crystals, having a bitter taste. Freely soluble in water and in alcohol.

**Phenylephrine Hydrochloride Nasal Solution:** Clear, colorless or slightly yellow, odorless liquid. Is neutral or acid to litmus.

**Phenylephrine Hydrochloride Ophthalmic Solution:** Clear, colorless or slightly yellow liquid, depending on the concentration.

**Phenylethyl Alcohol:** Colorless liquid, having a rose-like odor and a sharp, burning taste. Very soluble in alcohol, in fixed oils, in glycerin, and in propylene glycol; sparingly soluble in water; slightly soluble in mineral oil. *NF category:* Antimicrobial preservative.

**Phenylmercuric Acetate:** White to creamy white, crystalline powder, or small white prisms or leaflets. Is odorless. Soluble in alcohol and in acetone; slightly soluble in water. *NF category:* Antimicrobial preservative.

**Phenylmercuric Nitrate:** White, crystalline powder. Is affected by light. Its saturated solution is acid to litmus. Slightly soluble in alcohol and in glycerin; very slightly soluble in water. It is more soluble in the presence of either nitric acid or alkali hydroxides. *NF category:* Antimicrobial preservative.

**Phenylpropanolamine Hydrochloride:** White, crystalline powder, having a slight aromatic odor. Is affected by light. Freely soluble in water and in alcohol; insoluble in ether.

**Phenyltoloxamine Citrate:** White, crystalline powder. Very soluble in boiling water; slightly soluble in cold water and in alcohol; practically insoluble in cold acetone, in ethyl ether, and in toluene.

**Phenytoin:** White, odorless powder. Melts at about 295°. Soluble in hot alcohol; slightly soluble in cold alcohol, in chloroform, and in ether; practically insoluble in water.

**Phenytoin Sodium:** White, odorless powder. Is somewhat hygroscopic and on exposure to air gradually absorbs carbon dioxide. Freely soluble in water, the solution usually being somewhat turbid due to partial hydrolysis and absorption of carbon dioxide; soluble in alcohol; practically insoluble in ether and in chloroform.

**Phosphoric Acid:** Colorless, odorless liquid of syrupy consistency. Specific gravity is about 1.71. Miscible with water and with alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Diluted Phosphoric Acid:** Clear, colorless, odorless liquid. Specific gravity is about 1.057. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Physostigmine Salicylate:** White, shining, odorless crystals or white powder. Acquires a red tint when exposed to heat, light, air, or contact with traces of metals for long periods. Melts at about 184°. Freely soluble in chloroform; soluble in alcohol; sparingly soluble in water; slightly soluble in ether.

**Phytonadione:** Clear, yellow to amber, very viscous, odorless or practically odorless liquid, having a specific gravity of about 0.967. Is stable in air, but decomposes on exposure to sunlight. Soluble in dehydrated alcohol, in benzene, in chloroform, in ether, and in vegetable oils; slightly soluble in alcohol; insoluble in water.

**Pilocarpine:** A viscous, oily liquid, or crystals melting at about 34°. Exceedingly hygroscopic. Soluble in water, in alcohol, and in chloroform; sparingly soluble in ether and in benzene; practically insoluble in petroleum ether.

**Pilocarpine Hydrochloride:** Colorless, translucent, odorless, faintly bitter crystals. Is hygroscopic and is affected by light. Its solutions are acid to litmus. Very soluble in water; freely soluble in alcohol; slightly soluble in chloroform; insoluble in ether.

**Pilocarpine Nitrate:** Shining, white crystals. Is stable in air but is affected by light. Its solutions are acid to litmus. Freely soluble in water; sparingly soluble in alcohol; insoluble in chloroform and in ether.

**Pimozide:** White, crystalline powder. Freely soluble in chloroform; slightly soluble in ether and in alcohol; insoluble in water.

**Pindolol:** White to off-white, crystalline powder, having a faint odor. Slightly soluble in methanol; very slightly soluble in chloroform; practically insoluble in water.

**Pioglitazone Hydrochloride:** White crystals or crystalline powder. Soluble in dimethylformamide; slightly soluble in dehydrated alcohol; very slightly soluble in acetone and in acetonitrile; practically insoluble in water; insoluble in ether.

**Piperacillin:** White to off-white, crystalline powder. Very soluble in methanol; slightly soluble in isopropyl alcohol; very

slightly soluble in ethyl acetate and practically insoluble to very slightly soluble in water.

**Piperacillin Sodium:** White to off-white solid. Freely soluble in water and in alcohol.

**Piperazine:** White to slightly off-white lumps or flakes, having an ammoniacal odor. Soluble in water and in alcohol; insoluble in ether.

**Piperazine Citrate:** White, crystalline powder, having not more than a slight odor. Its solution (1 in 10) has a pH of about 5. Soluble in water; insoluble in alcohol and in ether.

**Piperazine Dihydrochloride:** White crystalline powder. Soluble in water.

**Piperazine Phosphate:** White crystalline powder. Sparingly soluble in water; practically insoluble in alcohol.

**Piroxicam:** Off-white to light tan or light yellow, odorless powder. Forms a monohydrate that is yellow. Slightly soluble in alcohol and in aqueous alkaline solutions; very slightly soluble in water, in dilute acids, and in most organic solvents.

**Plantago Seed:** All varieties are practically odorless and have a bland, mucilaginous taste.

**Podophyllum:** Has a slight odor and a disagreeably bitter and acrid taste.

**Podophyllum Resin:** Amorphous powder, varying in color from light brown to greenish yellow, turning darker when subjected to a temperature exceeding 25° or when exposed to light. Has a slight, peculiar, faintly bitter taste. Its alcohol solution is acid to moistened litmus paper. Soluble in alcohol with a slight opalescence; partially soluble in ether and in chloroform.

**Polacrilin Potassium:** White to off-white, free-flowing powder. Has a faint odor or is odorless. Insoluble in water and in most liquids. *NF category:* Disintegrant.

**Polidocanol:** White, waxy solid in appearance and texture at 15°–20°. Polidocanol is hygroscopic. Soluble in water and in alcohol; practically insoluble in light petroleum.

**Poloxalene:** Colorless or pale yellow liquid. Soluble in water, in chloroform, and in ethylene dichloride.

**Poloxamer:** *NF category:* Wetting and/or solubilizing agent; emulsifying agent; lubricant.

**Poloxamer 124:** Colorless liquid, having a mild odor. When solidified, it melts at about 16°. Freely soluble in water, in alcohol, in isopropyl alcohol, in propylene glycol, and in xylene.

**Poloxamer 188:** White, prilled or cast solid. Is odorless, or has a very mild odor. Melts at about 52°. Freely soluble in water and in alcohol.

**Poloxamer 237:** White, prilled or cast solid. Is odorless, or has a very mild odor. Melts at about 49°. Freely soluble in water and in alcohol; sparingly soluble in isopropyl alcohol and in xylene.

**Poloxamer 338:** White, prilled or cast solid. Is odorless, or has a very mild odor. Melts at about 57°. Freely soluble in water and in alcohol; sparingly soluble in propylene glycol.

**Poloxamer 407:** White, prilled or cast solid. Is odorless, or has a very mild odor. Melts at about 56°. Freely soluble in water, in alcohol, and in isopropyl alcohol.

**Polycarbophil:** White to creamy white granules, having a characteristic, ester-like odor. Swells in water to a range of volumes, depending primarily on the pH. Insoluble in water, in dilute acids, in dilute alkalies, and in common organic solvents. *NF category:* Emulsifying agent; suspending and/or viscosity-increasing agent; wet binder.

**Hydrogenated Polydecene:** Clear, colorless, odorless, tasteless liquid. Very slightly soluble in water. *NF category:* Emollient; ointment base; solvent; vehicle (oleaginous).

**Polydextrose:** Off-white to light tan-colored solid. Very soluble in water; soluble in alcohol; slightly soluble in glycerin and in propylene glycol. *NF category:* Bulking agent; humectant; coating agent; suspending and/or viscosity-increasing agent; diluent.

**Hydrogenated Polydextrose:** Off-white to light tan-colored solid. Very soluble in water; soluble in alcohol; slightly soluble in glycerin and in propylene glycol. *NF category:* Bulking agent; coating agent; humectant; suspending and/or viscosity-increasing agent; wet binder.

**Polyethylene Glycol:** Polyethylene Glycol is usually designated by a number that corresponds approximately to its average molecular weight. As the average molecular weight increases, the water solubility, vapor pressure, hygroscopicity, and solubility in organic solvents decrease, while congealing temperature, specific gravity, flash point, and viscosity increase. Liquid grades occur as clear to slightly hazy, colorless or practically colorless, slightly hygroscopic, viscous liquids, having a slight, characteristic odor, and a specific gravity at 25° of about 1.12. Solid grades occur as practically odorless and tasteless, white, waxy, plastic material having a consistency similar to beeswax, or as creamy white flakes, beads, or powders. The accompanying table states the approximate congealing temperatures that are characteristic of commonly available grades. Liquid grades are miscible with water; solid grades are freely soluble in water; and all are soluble in acetone, in alcohol, in chloroform, in ethylene glycol monoethyl ether, in ethyl acetate, and in toluene; all are insoluble in ether and in hexane. *NF category:* Coating agent; plasticizer; solvent; suppository base; lubricant; film-forming agent; ointment base; diluent.

| Nominal Molecular Weight Polyethylene Glycol | Approximate Congealing Temperature (°) |
|---|---|
| 300 | –11 |
| 400 | 6 |
| 600 | 20 |
| 900 | 34 |
| 1000 | 38 |
| 1450 | 44 |
| 4500 | 58 |
| 8000 | 60 |

**Polyethylene Glycol 3350:** White granular, powder, or flake. Approximate congealing temperature: 56°. Freely soluble in water; soluble in acetone, in alcohol, in chloroform, in ethylene glycol monoethyl ether, in ethyl acetate, and in toluene; insoluble in ether and in hexane. *NF category:* Coating agent; diluent; film-forming agent; lubricant; ointment base; plasticizer; solvent; suppository base.

**Polyethylene Glycol Monomethyl Ether:** Polyethylene Glycol Monomethyl Ether is usually designated by a number that corresponds approximately to its average molecular weight. As the average molecular weight increases, the water solubility, vapor pressure, hygroscopicity, and solubility in organic solvents decrease, while congealing temperature, specific gravity, flash point, and viscosity increase. Liquid grades occur as clear to slightly hazy, colorless or practically colorless, slightly hygroscopic, viscous liquids, having a slight, characteristic odor, and a specific gravity at 25° of about 1.09–1.10. Solid grades occur as practically odorless and tasteless, white, waxy, plastic material having a consistency similar to beeswax, or as creamy white flakes, beads, or powders. The accompanying table states the approximate congealing temperatures that are characteristic of commonly available grades. Liquid grades are miscible with water; solid grades are freely soluble in water; and all are soluble in acetone, in alcohol, in chloroform, in ethylene glycol monoethyl ether, in

**Polyethylene Oxide:** Polyethylene oxide resins are high molecular weight polymers having the common structure:

$$(–O–CH_2CH_2–)_n$$

in which *n*, the degree of polymerization, varies from about 2000 to over 100,000. Polyethylene oxide, being a polyether, strongly hydrogen, bonds with water. It is nonionic and undergoes salting-out effects associated with neutral molecules in solutions of high dielectric media. Salting-out effects manifest themselves in depressing the upper temperature limit of solubility, and in reducing the viscosity of both dilute and concentrated solutions of the polymers. All molecular weight grades are powdered or granular solids. They are soluble in water but, because of the high solution viscosities obtained (see *table*), solutions over 1% in water may be difficult to prepare. The water solubility, hygroscopicity, solubility in organic solvents, and melting point do not vary in the specified molecular weight range. At room temperature polyethylene oxide is miscible with water in all proportions. At concentrations of about 20% polymer in water, the solutions are nontacky, reversible, elastic gels. At higher concentrations, the solutions are tough, elastic materials with the water acting as a plasticizer. Polyethylene oxide is also freely soluble in acetonitrile, in ethylene dichloride, in trichloroethylene, and in methylene chloride. Heating may be required to obtain solutions in many other organic solvents. It is insoluble in aliphatic hydrocarbons, in ethylene glycol, in diethylene glycol, and in glycerol. *NF category:* Suspending and/or viscosity-increasing agent; wet binder; coating agent; release-modifying agent.

| Approximate Molecular Weight | Typical Solution Viscosity (cps), 25° | |
|---|---|---|
| | 5% Solution | 1% Solution |
| 100,000 | 40 | |
| 200,000 | 100 | |
| 300,000 | 800 | |
| 400,000 | 3000 | |
| 600,000 | 6000 | |
| 900,000 | 15,000 | |
| 4,000,000 | | 3500 |
| 5,000,000 | | 5500 |

**Polyethylene 50 Stearate:** *NF category:* Emulsifying and/or solubilizing agent.

**Polyglyceryl 3 Diisostearate:** Viscous liquid. Soluble in alcohol, in methylene chloride, in mineral oil, and in vegetable oils; insoluble in water. *NF category:* Emulsifying agent; ointment base.

**Polyglyceryl Dioleate:** Viscous liquid. Soluble in methylene chloride, in mineral oil, and in vegetable oils; sparingly soluble in alcohol; insoluble in water. *NF category:* Emulsifying agent.

**Polyisobutylene:** Low molecular-weight grades are soft and gummy; high molecular-weight grades are tough and elastic. All grades are light in color, odorless, and tasteless. Soluble in diisobutylene, in toluene, and in chloroform; insoluble in water. *NF category:* Adhesive.

**Polymyxin B Sulfate:** White to buff-colored powder. Is odorless or has a faint odor. Freely soluble in water; slightly soluble in alcohol.

**Polyoxyl Lauryl Ether:** A material with 3–5 oxyethylene units per molecule is a colorless liquid. Soluble or dispersible in alcohol; practically insoluble in water and in hexane. A material with 9–23 oxyethylene units per molecule is a white, waxy mass. Soluble or dispersible in water; soluble in alcohol; practically insoluble in hexane. *NF category:* Emulsifying agent; wetting and/or solubilizing agent.

**Polyoxyl Oleate:** A slightly yellowish, viscous liquid. Dispersible in water and in oils. Soluble in alcohol and in isopropyl alcohol. Miscible with fatty oils and with waxes. Its refractive index is about 1.466.

**Polyoxyl 10 Oleyl Ether:** White, soft semisolid, or pale yellow liquid, having a bland odor. Soluble in water and in alcohol. Dispersible in mineral oil and in propylene glycol, with possible separation on standing. *NF category:* Emulsifying agent; lubricant; wetting and/or solubilizing agent.

**Polyoxyl 15 Hydroxystearate:** Yellowish to white waxy mass. Very soluble in water; soluble in alcohol and in 2-propanol; insoluble in mineral oil. It solidifies at 25°. *NF category:* Wetting and/or solubilizing agent; vehicle (oleaginous); lubricant; emulsifying agent.

**Polyoxyl 20 Cetostearyl Ether:** Cream-colored, waxy, unctuous mass, melting, when heated, to a clear brownish-yellow liquid. Soluble in water, in alcohol, and in acetone; insoluble in solvent hexane. *NF category:* Wetting and/or solubilizing agent; emulsifying agent; lubricant.

**Polyoxyl 35 Castor Oil:** Yellow, oily liquid, having a faint, characteristic odor and a somewhat bitter taste. Very soluble in water, producing a practically odorless and colorless solution; soluble in alcohol and in ethyl acetate; insoluble in mineral oils. *NF category:* Wetting and/or solubilizing agent; emulsifying agent; lubricant.

**Polyoxyl 40 Hydrogenated Castor Oil:** White to yellowish paste or pasty liquid, having a faint odor and a slight taste. Very soluble in water, producing a practically tasteless, odorless, and colorless solution; soluble in alcohol and in ethyl acetate; insoluble in mineral oils. *NF category:* Wetting and/or solubilizing agent; emulsifying agent; lubricant.

**Polyoxyl Stearate:** White or slightly yellowish waxy mass. Soluble in alcohol and in isopropyl alcohol. Polyoxyl stearate corresponding to a product with 6–8 units of ethylene oxide per molecule is soluble in fatty oils and in waxes; practically insoluble in water. Polyoxyl stearate corresponding to a product with 20–100 units of ethylene oxide per molecule is soluble in water; practically insoluble in fatty oils and in waxes. *NF category:* Emulsifying agent; wetting and/or solubilizing agent.

**Polyoxyl Stearyl Ether:** A white to yellowish-white, waxy, unctuous mass, pellets, microbeads, or flakes. Polyoxyl Stearyl Ether with 2 oxyethylene units per molecule is soluble in alcohol, with heating, and in methylene chloride; practically insoluble in water. Polyoxyl Stearyl Ether with 10 oxyethylene units per molecule is soluble in water and in alcohol. Polyoxyl

Official

https://mhathaway.com/

Stearyl Ether with 20 oxethylene units per molecule is soluble in water, in alcohol, and in methylene chloride. After melting, it solidifies at about 45°. *NF category:* Emulsifying agent; wetting and/or solubilizing agent.

**Polypropylene Glycol 11 Stearyl Ether:** Colorless or pale yellow, clear or slightly turbid liquid. Soluble in ethanol (96%), in mineral oils, and in 2-propanol; practically insoluble in water, in propylene glycol, and in glycerol. Relative density: about 0.94 at 25°. Refractive index: about 1.448 at 25°. *NF category:* Emollient; solvent; vehicle.

**Polysorbate 20:** Lemon to amber liquid having a faint characteristic odor. Soluble in water, in alcohol, in ethyl acetate, in methanol, and in dioxane; insoluble in mineral oil. *NF category:* Wetting and/or solubilizing agent; emulsifying agent; lubricant; suspending and/or viscosity-increasing agent.

**Polysorbate 40:** Yellow liquid having a faint, characteristic odor. Soluble in water and in alcohol; insoluble in mineral oil and in vegetable oils. *NF category:* Wetting and/or solubilizing agent; emulsifying agent; lubricant; suspending and/or viscosity-increasing agent.

**Polysorbate 60:** Lemon- to orange-colored, oily liquid or semi-gel having a faint, characteristic odor. Soluble in water, in ethyl acetate, and in toluene; insoluble in mineral oil and in vegetable oils. *NF category:* Emulsifying agent; lubricant; suspending and/or viscosity-increasing agent; wetting and/or solubilizing agent.

**Polysorbate 80:** Lemon- to amber-colored, oily liquid having a faint, characteristic odor and a warm, somewhat bitter taste. Very soluble in water, producing an odorless and practically colorless solution; soluble in alcohol and in ethyl acetate; insoluble in mineral oil. *NF category:* Wetting and/or solubilizing agent; emulsifying agent; lubricant; suspending and/or viscosity-increasing agent.

**Polyvinyl Acetate:** White or off-white powder or colorless granules or beads. Freely soluble in ethyl acetate; soluble in alcohol, in acetone, and in chloroform; practically insoluble in water. It is hygroscopic and swells in water. *NF category:* Coating agent; desiccant; wet binder; film-forming agent.

**Polyvinyl Acetate Dispersion:** Opaque, white or off-white, slightly viscous liquid. Miscible with water and with ethanol. It is sensitive to spoilage by microbial contaminants. *NF category:* Coating agent; film-forming agent; release-modifying agent.

**Polyvinyl Acetate Phthalate:** Free-flowing white powder. May have a slight odor of acetic acid. Soluble in methanol and in alcohol; insoluble in water, in methylene chloride, and in chloroform. *NF category:* Coating agent; film-forming agent.

**Polyvinyl Alcohol:** White to cream-colored granules, or white to cream-colored powder. Is odorless. Freely soluble in water at room temperature. Solution may be effected more rapidly at somewhat higher temperatures. *NF category:* Suspending and/or viscosity-increasing agent; coating agent; film-forming agent; polymers for ophthalmic use.

**Sulfurated Potash:** Irregular, liver-brown pieces when freshly made, changing to a greenish yellow. Has an odor of hydrogen sulfide and a bitter, acrid, and alkaline taste, and decomposes on exposure to air. A solution (1 in 10) is light brown in color and is alkaline to litmus. Freely soluble in water, usually leaving a slight residue. Alcohol dissolves only the sulfides.

**Potassium Acetate:** Colorless, monoclinic crystals or white, crystalline powder having a saline and slightly alkaline taste. Is odorless, or has a faint acetous odor. Deliquesces on exposure to moist air. Very soluble in water; freely soluble in alcohol.

**Potassium Alginate:** White to yellow, fibrous or granular powder. Dissolves in water to form a viscous, colloidal solution; insoluble in alcohol and in hydroalcoholic solutions in which the alcohol content is greater than 30% by weight; insoluble in chloroform, in ether, and in acids having a pH lower than about 3. *NF category:* Emulsifying agent; suspending and/or viscosity-increasing agent.

**Potassium Benzoate:** White, odorless, or practically odorless, granular or crystalline powder. Is stable in air. Freely soluble in water; soluble in 90% alcohol; sparingly soluble in alcohol. *NF category:* Antimicrobial preservative; lubricant.

**Potassium Bicarbonate:** Colorless, transparent, monoclinic prisms or as a white, granular powder. Is odorless, and is stable in air. Its solutions are neutral or alkaline to phenolphthalein TS. Freely soluble in water; practically insoluble in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Potassium Bitartrate:** Colorless or slightly opaque crystals, or white, crystalline powder. A saturated solution is acid to litmus. Soluble in boiling water; slightly soluble in water; very slightly soluble in alcohol.

**Potassium Bromide:** White, crystalline powder or colorless, cubical crystals. Freely soluble in water and in glycerol; slightly soluble in alcohol.

**Potassium Chloride:** Colorless, elongated, prismatic, or cubical crystals, or white, granular powder. Is odorless, has a saline taste, and is stable in air. Its solutions are neutral to litmus. Freely soluble in water; insoluble in alcohol. *NF category:* Tonicity agent.

**Potassium Citrate:** Transparent crystals or white, granular powder. Is odorless, has a cooling, saline taste, and is deliquescent when exposed to moist air. Freely soluble in water; very slightly soluble in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent); chelating and/or complexing agent.

**Potassium Gluconate:** White to yellowish-white, crystalline powder or granules. Is odorless, has a slightly bitter taste, and is stable in air. Its solutions are slightly alkaline to litmus. Freely soluble in water; practically insoluble in dehydrated alcohol, in ether, in benzene, and in chloroform.

**Potassium Hydroxide:** White or practically white, fused masses, or small pellets, or flakes, or sticks, or other forms. Is hard and brittle and shows a crystalline fracture. Exposed to air, it rapidly absorbs carbon dioxide and moisture, and deliquesces. Very soluble in boiling alcohol; freely soluble in water, in alcohol, and in glycerin. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Potassium Iodide:** Hexahedral crystals, either transparent and colorless or somewhat opaque and white, or a white, granular powder. Is slightly hygroscopic. Its solutions are neutral or alkaline to litmus. Very soluble in water and even more soluble in boiling water; freely soluble in glycerin; soluble in alcohol.

**Potassium Iodide Oral Solution:** Clear, colorless, odorless liquid, having a characteristic, strongly salty taste. Is neutral or alkaline to litmus. Specific gravity is about 1.70.

**Potassium Metabisulfite:** White or colorless, free-flowing crystals, crystalline powder, or granules, usually having an odor of sulfur dioxide. Gradually oxidizes in air to the sulfate. Its solutions are acid to litmus. Soluble in water; insoluble in alcohol. *NF category:* Antioxidant; antimicrobial preservative.

**Potassium Metaphosphate:** White, odorless powder. Soluble in dilute solutions of sodium salts; insoluble in water. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Potassium Nitrate:** White, crystalline powder or colorless crystals. Very soluble in boiling water; freely soluble in water; soluble in glycerin; practically insoluble in alcohol.

**Potassium Permanganate:** Dark purple crystals, almost opaque by transmitted light and of a blue metallic luster by reflected light. Its color is sometimes modified by a dark

Preview

https://pharmacopeia.cn/

bronze-like appearance. Is stable in air. Freely soluble in boiling water; soluble in water.

**Dibasic Potassium Phosphate:** Colorless or white, somewhat hygroscopic, granular powder. The pH of a solution (1 in 20) is about 8.5 to 9.6. Freely soluble in water; very slightly soluble in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Monobasic Potassium Phosphate:** Colorless crystals or white, granular or crystalline powder. Is odorless, and is stable in air. The pH of a solution (1 in 100) is about 4.5. Freely soluble in water; practically insoluble in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Potassium Sodium Tartrate:** Colorless crystals or white, crystalline powder, having a cooling, saline taste. As it effloresces slightly in warm, dry air, the crystals are often coated with a white powder. Freely soluble in water; practically insoluble in alcohol.

**Potassium Sorbate:** White crystals or powder, having a characteristic odor. Melts at about 270°, with decomposition. Freely soluble in water; soluble in alcohol. *NF category:* Antimicrobial preservative.

**Povidone:** White to slightly creamy white powder. Is hygroscopic. Freely soluble in water, in methanol, and in alcohol; slightly soluble in acetone; practically insoluble in ether. *NF category:* Suspending and/or viscosity-increasing agent; wet binder; polymers for ophthalmic use.

**Povidone-Iodine:** Yellowish-brown to reddish-brown, amorphous powder, having a slight, characteristic odor. Its solution is acid to litmus. Soluble in water and in alcohol; practically insoluble in chloroform, in carbon tetrachloride, in ether, in solvent hexane, and in acetone.

**Povidone-Iodine Topical Aerosol Solution:** The liquid obtained from Povidone-Iodine Topical Aerosol Solution is transparent, having a reddish brown color.

**Pralidoxime Chloride:** White to pale-yellow, crystalline powder. Is odorless and is stable in air. Freely soluble in water.

**Pramipexole Dihydrochloride:** White to almost white crystalline powder. Freely soluble in water; soluble in methanol; slightly soluble in alcohol; practically insoluble in methylene chloride.

**Pramoxine Hydrochloride:** White to practically white, crystalline powder, having a numbing taste. May have a slight aromatic odor. The pH of a solution (1 in 100) is about 4.5. Freely soluble in water and in alcohol; soluble in chloroform; very slightly soluble in ether.

**Prasugrel Hydrochloride:** White to almost-white powder. Soluble in water; slightly soluble in acetonitrile; practically insoluble in ethyl acetate.

**Pravastatin Sodium:** White to yellowish white, hygroscopic powder. Freely soluble in water and in methanol; soluble in dehydrated alcohol; practically insoluble in acetonitrile and in chloroform.

**Praziquantel:** White or practically white, crystalline powder; odorless or having a faint characteristic odor. Freely soluble in alcohol and in chloroform; very slightly soluble in water.

**Prazosin Hydrochloride:** White to tan powder. Slightly soluble in water, in methanol, in dimethylformamide, and in dimethylacetamide; very slightly soluble in alcohol; practically insoluble in chloroform and in acetone.

**Prednicarbate:** White to almost white, crystalline powder. Freely soluble in acetone and in alcohol; sparingly soluble in propylene glycol; practically insoluble in water.

**Prednisolone:** White to practically white, odorless, crystalline powder. Melts at about 235°, with some decomposition (see *Melting Range or Temperature* ⟨741⟩). Soluble in methanol and in dioxane; sparingly soluble in acetone and in alcohol; slightly soluble in chloroform; very slightly soluble in water.

**Prednisolone Acetate:** White to practically white, odorless, crystalline powder. Melts at about 235°, with some decomposition (see *Melting Range or Temperature* ⟨741⟩). Slightly soluble in acetone, in alcohol, and in chloroform; practically insoluble in water.

**Prednisolone Hemisuccinate:** Fine, creamy white powder with friable lumps; practically odorless. Melts at about 205°, with decomposition. Freely soluble in alcohol; soluble in acetone; very slightly soluble in water.

**Prednisolone Sodium Phosphate:** White or slightly yellow, friable granules or powder. Is odorless or has a slight odor. Is slightly hygroscopic. Freely soluble in water; soluble in methanol; slightly soluble in alcohol and in chloroform; very slightly soluble in acetone and in dioxane.

**Prednisolone Sodium Succinate for Injection:** Creamy white powder with friable lumps, having a slight odor.

**Prednisolone Tebutate:** White to slightly yellow, free-flowing powder, which may show some soft lumps. Is odorless or has not more than a moderate, characteristic odor. Is hygroscopic. Freely soluble in chloroform and in dioxane; soluble in acetone; sparingly soluble in alcohol and in methanol; very slightly soluble in water.

**Prednisone:** White to practically white, odorless, crystalline powder. Melts at about 230°, with some decomposition (see *Melting Range or Temperature* ⟨741⟩). Slightly soluble in alcohol, in chloroform, in dioxane, and in methanol; very slightly soluble in water.

**Pregabalin:** White to off-white, crystalline solid. Freely soluble in water and in both basic and acidic aqueous solutions.

**Prilocaine:** White or almost white powder or crystal aggregates. Very soluble in alcohol and in acetone; slightly soluble in water.

**Prilocaine Hydrochloride:** White, odorless, crystalline powder, having a bitter taste. Freely soluble in water and in alcohol; slightly soluble in chloroform; very slightly soluble in acetone; practically insoluble in ether.

**Primaquine Phosphate:** Orange-red, crystalline powder. Is odorless and has a bitter taste. Its solutions are acid to litmus. Melts at about 200°. Soluble in water; insoluble in chloroform and in ether.

**Primidone:** White, crystalline powder. Is odorless and has a slightly bitter taste. Slightly soluble in alcohol; very slightly soluble in water and in most organic solvents.

**Probenecid:** White or practically white, fine, crystalline powder. Is practically odorless. Soluble in dilute alkali, in chloroform, in alcohol, and in acetone; practically insoluble in water and in dilute acids.

**Procainamide Hydrochloride:** White to tan, crystalline powder. Is odorless. Its solution (1 in 10) has a pH between 5 and 6.5. Very soluble in water; soluble in alcohol; slightly soluble in chloroform; very slightly soluble in benzene and in ether.

**Procainamide Hydrochloride Injection:** Colorless, or having not more than a slight yellow color.

**Procaine Hydrochloride:** Small, white crystals or white, crystalline powder. Is odorless. Exhibits local anesthetic properties when placed on the tongue. Freely soluble in water; soluble in alcohol; slightly soluble in chloroform; practically insoluble in ether.

**Procaine Hydrochloride Injection:** Clear, colorless liquid.

**Prochlorperazine:** Clear, pale yellow, viscous liquid. Is sensitive to light. Freely soluble in alcohol, in chloroform, and in ether; very slightly soluble in water.

**Prochlorperazine Edisylate:** White to very light yellow, odorless, crystalline powder. Its solutions are acid to litmus.

Official

Freely soluble in water; very slightly soluble in alcohol; insoluble in ether and in chloroform.

**Prochlorperazine Maleate:** White or pale yellow, practically odorless, crystalline powder. Its saturated solution is acid to litmus. Slightly soluble in warm chloroform; practically insoluble in water and in alcohol.

**Procyclidine Hydrochloride:** White, crystalline powder, having a moderate, characteristic odor. Melts at about 225°, with decomposition. Soluble in water and in alcohol; insoluble in ether and in acetone.

**Progesterone:** White or creamy white, odorless, crystalline powder. Is stable in air. Soluble in alcohol, in acetone, and in dioxane; sparingly soluble in vegetable oils; practically insoluble in water.

**Proguanil Hydrochloride:** White, crystalline powder. Sparingly soluble in alcohol; slightly soluble in water; practically insoluble in methylene chloride.

**Proline:** White, odorless crystals, having a slightly sweet taste. Freely soluble in water and in absolute alcohol; insoluble in ether, in butanol, and in isopropanol.

**Promazine Hydrochloride:** White to slightly yellow, practically odorless, crystalline powder. It oxidizes upon prolonged exposure to air and acquires a blue or pink color. Freely soluble in water and in chloroform.

**Promethazine Hydrochloride:** White to faint yellow, practically odorless, crystalline powder. Slowly oxidizes, and acquires a blue color, on prolonged exposure to air. Freely soluble in water, in hot dehydrated alcohol, and in chloroform; practically insoluble in ether, in acetone, and in ethyl acetate.

**Propafenone Hydrochloride:** White powder. Soluble in methanol and in hot water; slightly soluble in alcohol and in chloroform; very slightly soluble in acetone; insoluble in diethyl ether and in toluene.

**Propane:** Colorless, flammable gas (boiling temperature is about −42°). One hundred volumes of water dissolves 6.5 volumes at 17.8° and 753 mm pressure; 100 volumes of anhydrous alcohol dissolves 790 volumes at 16.6° and 754 mm pressure; 100 volumes of ether dissolves 926 volumes at 16.6° and 757 mm pressure; 100 volumes of chloroform dissolves 1299 volumes at 21.6° and 757 mm pressure. Vapor pressure at 21° is about 10290 mm of mercury (108 psig). *NF category:* Propellant.

**Propanediol:** Clear, colorless, hygroscopic liquid. *Specific Gravity* ⟨841⟩, *Method I*: 1.040–1.065. Soluble in water, in alcohol, in methyl alcohol, in isopropyl alcohol, in butyl alcohol, in acetone, in propylene glycol, and miscible with many polar solvents. *NF category:* Humectant; solvent; wetting and/or solubilizing agent.

**Propantheline Bromide:** White or practically white crystals. Is odorless and has a bitter taste. Melts at about 160°, with decomposition. Very soluble in water, in alcohol, and in chloroform; practically insoluble in ether and in benzene.

**Proparacaine Hydrochloride:** White to off-white, or faintly buff-colored, odorless, crystalline powder. Its solutions are neutral to litmus. Soluble in water, in warm alcohol, and in methanol; insoluble in ether and in benzene.

**Proparacaine Hydrochloride Ophthalmic Solution:** Colorless or faint yellow solution.

**Propionic Acid:** Oily liquid having a slight pungent, rancid odor. Miscible with water and with alcohol and various other organic solvents. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent); antimicrobial preservative; antioxidant.

**Propofol:** Clear, colorless to slightly yellowish liquid. Very soluble in methanol and in ethanol; slightly soluble in cyclohexane and in isopropyl alcohol; very slightly soluble in water.

**Propranolol Hydrochloride:** White to off-white, crystalline powder. Is odorless and has a bitter taste. Melts at about 164°. Soluble in water and in alcohol; slightly soluble in chloroform; practically insoluble in ether.

**Propyl Gallate:** White, crystalline powder having a very slight, characteristic odor. Freely soluble in alcohol; slightly soluble in water. *NF category:* Antioxidant.

**Propylene Glycol:** Clear, colorless, viscous liquid having a slight, characteristic taste. Is practically odorless. Absorbs moisture when exposed to moist air. Miscible with water, with acetone, and with chloroform. Soluble in ether and will dissolve many essential oils, but is immiscible with fixed oils. *NF category:* Humectant; plasticizer; solvent; antimicrobial preservative.

**Propylene Glycol Alginate:** White to yellowish fibrous or granular powder. Practically odorless and tasteless. Soluble in water, in solutions of dilute organic acids, and, depending on the degree of esterification, in hydroalcoholic mixture containing up to 60% by weight of alcohol to form stable, viscous colloidal solutions at a pH of 3. *NF category:* Suspending and/or viscosity-increasing agent; emulsifying agent.

**Propylene Glycol Diacetate:** Clear, colorless liquid having a mild, fruity odor. Soluble in water. *NF category*: Emulsifying agent; solvent.

**Propylene Glycol Dicaprylate/Dicaprate:** Clear, colorless or slightly yellow oily liquid at 20°. Soluble in fatty oils and in light petroleum; slightly soluble in dehydrated alcohol; practically insoluble in water. *NF category:* Emulsifying agent; vehicle.

**Propylene Glycol Dilaurate:** Clear, oily liquid at 20°. Colorless or slightly yellow. Very soluble in alcohol, in methanol, and in methylene chloride; practically insoluble in water. *NF category:* Emollient; emulsifying agent.

**Propylene Glycol Monocaprylate:** Clear, colorless, or slightly yellow, oily liquid at 20°. Very soluble in alcohol, in chloroform, and in methylene chloride; practically insoluble in water. *NF category:* Vehicle; emulsifying agent; diluent.

**Propylene Glycol Mono and Dicaprylate:** Clear, colorless, or slightly yellow, oily liquid at 20°. Very soluble in alcohol, in chloroform, and in methylene chloride; practically insoluble in water. *NF category*: Vehicle (solid carrier); emulsifying agent; diluent.

**Propylene Glycol Monolaurate:** Clear, oily liquid at 20°. Colorless or slightly yellow. Very soluble in alcohol, in methanol, and in methylene chloride; practically insoluble in water. *NF category:* Emollient; emulsifying agent.

**Propylene Glycol Monostearate:** White, wax-like solid or as white, wax-like beads or flakes. Has a slight, agreeable, fatty odor and taste. Soluble in organic solvents such as alcohol, mineral or fixed oils, benzene, ether, and acetone; insoluble in water, but may be dispersed in hot water with the aid of a small amount of soap or other suitable surface-active agent. *NF category:* Emulsifying agent.

**Propylhexedrine:** Clear, colorless liquid, having a characteristic, amine-like odor. Volatilizes slowly at room temperature. Absorbs carbon dioxide from the air, and its solutions are alkaline to litmus. Boils at about 205°. Very slightly soluble in water. Miscible with alcohol, with chloroform, and with ether.

**Propylparaben:** Small, colorless crystals or white powder. Freely soluble in alcohol and in ether; slightly soluble in boiling water; very slightly soluble in water. *NF category:* Antimicrobial preservative.

**Propylparaben Sodium:** White powder. Is odorless and hygroscopic. Freely soluble in water; sparingly soluble in alcohol; insoluble in fixed oils. *NF category:* Antimicrobial preservative.

**Propylthiouracil:** White, powdery, crystalline substance. Is starch-like in appearance and to the touch, and has a bitter taste. Soluble in ammonium hydroxide and in alkali

hydroxides; sparingly soluble in alcohol; slightly soluble in water, in chloroform, and in ether.

**Protamine Sulfate Injection:** Colorless solution, which may have the odor of a preservative.

**Protriptyline Hydrochloride:** White to yellowish powder. Is odorless, or has not more than a slight odor. Melts at about 168°. Freely soluble in water, in alcohol, and in chloroform; practically insoluble in ether.

**Pseudoephedrine Hydrochloride:** Fine, white to off-white crystals or powder, having a faint characteristic odor. Very soluble in water; freely soluble in alcohol; slightly soluble in chloroform.

**Pseudoephedrine Sulfate:** White crystals or crystalline powder. Is odorless. Freely soluble in alcohol.

**Pullulan:** White powder. Freely soluble in water; practically insoluble in dehydrated alcohol. *NF category:* Coating agent; plasticizer; polymer membrane; sequestering agent; suspending and/or viscosity-increasing agent; wetting and/or solubilizing agent; bulking agent; diluent; disintegrant; wet binder; capsule shell; film-forming agent.

**Pumice:** Very light, hard, rough, porous, grayish masses or gritty, grayish powder. Is odorless and tasteless, and is stable in air. Practically insoluble in water; is not attacked by acids.

**Pyrantel Pamoate:** Yellow to tan solid. Soluble in dimethyl sulfoxide; slightly soluble in dimethylformamide; practically insoluble in water and in methanol.

**Pyrazinamide:** White to practically white, odorless or practically odorless, crystalline powder. Sparingly soluble in water; slightly soluble in alcohol, in ether, and in chloroform.

**Pyrethrum Extract:** Pale yellow liquid having a bland, flowery odor. Soluble in mineral oil and in most organic solvents; insoluble in water. *Pyrethrins I* denotes the group containing pyrethrin 1, cinerin 1, and jasmolin 1; *Pyrethrins II* denotes the group containing pyrethrin 2, cinerin 2, and jasmolin 2.

**Pyridostigmine Bromide:** White or practically white, crystalline powder, having an agreeable, characteristic odor. Is hygroscopic. Freely soluble in water, in alcohol, and in chloroform; slightly soluble in solvent hexane; practically insoluble in ether.

**Pyridoxine Hydrochloride:** White to practically white crystals or crystalline powder. Is stable in air, and is slowly affected by sunlight. Its solutions have a pH of about 3. Freely soluble in water; slightly soluble in alcohol; insoluble in ether.

**Pyrilamine Maleate:** White, crystalline powder, usually having a faint odor. Its solutions are acid to litmus. Very soluble in water; freely soluble in alcohol and in chloroform; slightly soluble in ether and in benzene.

**Pyrimethamine:** White, odorless, crystalline powder. Slightly soluble in acetone, in alcohol, and in chloroform; practically insoluble in water.

**Quazepam:** Off-white to yellowish powder.

**Quetiapine Fumarate:** White to off-white crystalline powder. Soluble in 0.1 N hydrochloric acid; slightly soluble in water, in alcohol, and in methanol.

**Quinapril Hydrochloride:** White to off-white powder, with a pink cast at times. Freely soluble in aqueous solvents.

**Quinidine Gluconate:** White powder. Is odorless and has a very bitter taste. Freely soluble in water; slightly soluble in alcohol.

**Quinidine Sulfate:** Fine, needle-like, white crystals, frequently cohering in masses, or fine, white powder. Is odorless, and darkens on exposure to light. Its solutions are neutral or alkaline to litmus. Soluble in alcohol; sparingly soluble in chloroform; slightly soluble in water; insoluble in ether.

**Quinine Sulfate:** White, fine, needle-like crystals, usually lusterless, making a light and readily compressible mass. Is odorless. It darkens on exposure to light. Its saturated solution is neutral or alkaline to litmus. Freely soluble in alcohol at 80°, and in a mixture of 2 volumes of chloroform and 1 volume of dehydrated alcohol; sparingly soluble in water at 100°; slightly soluble in water, in alcohol, and in chloroform; very slightly soluble in ether.

**Racemethionine:** Almost white, crystalline powder or small flakes. Sparingly soluble in water; very slightly soluble in alcohol. It dissolves in dilute acids and in dilute solutions of alkali hydroxides. It melts at about 270°. *NF category:* Antioxidant; pH modifier (acidifying agent/alkalizing agent/buffering agent); flavors and fragrance.

**Racepinephrine:** White to nearly white, crystalline, odorless powder, gradually darkening on exposure to light and air. With acids, it forms salts that are readily soluble in water, and the base may be recovered by the addition of ammonium hydroxide. Very slightly soluble in water and in alcohol; insoluble in ether, in chloroform, and in fixed and volatile oils.

**Racepinephrine Hydrochloride:** Fine, white, odorless powder. Darkens on exposure to light and air. Its solutions are acid to litmus. Melts at about 157°. Freely soluble in water; sparingly soluble in alcohol.

**Raloxifene Hydrochloride:** Almost white to pale yellow powder. Freely soluble in dimethylsulfoxide; slightly soluble to sparingly soluble in methanol; practically insoluble to very slightly soluble in water; practically insoluble in ether and in ethyl acetate.

**Raltegravir Potassium:** White to off-white powder. Soluble in water; slightly soluble in methanol; very slightly soluble in acetonitrile and in ethanol; insoluble in isopropyl alcohol.

**Ramipril:** White to almost white crystalline powder. Freely soluble in methanol; sparingly soluble in water.

**Ranitidine Hydrochloride:** White to pale yellow, crystalline, practically odorless powder. Is sensitive to light and moisture. Melts at about 140°, with decomposition. Very soluble in water; sparingly soluble in alcohol.

**Regorafenib:** White to pink or brownish powder. Sparingly soluble in acetone; slightly soluble in acetonitrile, in methanol, in ethanol, and in ethyl acetate; practically insoluble in water and in heptane.

**Fully Hydrogenated Rapeseed Oil:** White, waxy solid. Insoluble in water and in alcohol. *NF category:* Coating agent; stiffening agent.

**Superglycerinated Fully Hydrogenated Rapeseed Oil:** White solid. Insoluble in water and in alcohol. *NF category:* Coating agent; emulsifying agent; stiffening agent.

**Purified Rayon:** White, lustrous or dull, fine, soft, filamentous fibers, appearing under the microscope as round, oval, or slightly flattened translucent rods, straight or crimped, striate and with serrate cross-sectional edges. Is practically odorless and practically tasteless. Very soluble in ammoniated cupric oxide TS and in dilute sulfuric acid (3 in 5); insoluble in ordinary solvents.

**Repaglinide:** White to off-white solid. Melts at about 132° to 136°. Soluble in methanol.

**Reserpine:** White or pale buff to slightly yellowish, odorless, crystalline powder. Darkens slowly on exposure to light, but more rapidly when in solution. Freely soluble in acetic acid and in chloroform; slightly soluble in benzene; very slightly soluble in alcohol and in ether; insoluble in water.

**Resorcinol:** White, or practically white, needle-shaped crystals or powder. Has a faint, characteristic odor and a sweetish, followed by a bitter, taste. Acquires a pink tint on exposure to light and air. Its solution (1 in 20) is neutral or acid to litmus. Freely soluble in water, in alcohol, in glycerin, and in ether; slightly soluble in chloroform.

**Ribavirin:** White, crystalline powder. Freely soluble in water; slightly soluble in dehydrated alcohol.

**Riboflavin:** Yellow to orange-yellow, crystalline powder having a slight odor. Melts at about 280°. Its saturated solution is neutral to litmus. When dry, it is not appreciably affected by diffused light, but when in solution, light induces quite rapid deterioration, especially in the presence of alkalies. Soluble in dilute solutions of alkalies; very slightly soluble in water, in alcohol, and in isotonic sodium chloride solution; insoluble in ether and in chloroform.

**Riboflavin 5′-Phosphate Sodium:** Fine, orange-yellow, crystalline powder, having a slight odor. Sparingly soluble in water. When dry, it is not affected by diffused light, but when in solution, light induces deterioration rapidly. Is hygroscopic.

**Rifabutin:** Amorphous red-violet powder. Soluble in chloroform and in methanol; sparingly soluble in alcohol; very slightly soluble in water.

**Rifampin:** Red-brown, crystalline powder. Freely soluble in chloroform; soluble in ethyl acetate and in methanol; very slightly soluble in water.

**Riluzole:** White to slightly yellow powder or crystalline powder. Freely soluble in acetonitrile, in alcohol, and in methylene chloride; slightly soluble in hexane; very slightly soluble in water.

**Rimexolone:** White to off-white powder. Freely soluble in chloroform; sparingly soluble in methanol.

**Riociguat:** White or yellowish powder. Very slightly soluble in anhydrous ethanol; practically insoluble in water and in heptane.

**Risedronate Sodium:** White to off-white powder. Soluble in water and in aqueous solutions; insoluble in common organic solvents.

**Risperidone:** White or almost white powder. Soluble in methylene chloride; sparingly soluble in alcohol; practically insoluble in water.

**Ritonavir:** White to light tan powder. Freely soluble in methanol and in methylene chloride; very slightly soluble in acetonitrile; practically insoluble in water.

**Rivaroxaban:** White to yellow powder. Slightly soluble in organic solvents (e.g., acetone, polyethylene glycol 400); practically insoluble in water and in aqueous media.

**Rivastigmine Tartrate:** White to off-white powder. Very soluble in water and in methanol; very slightly soluble in ethyl acetate.

**Rizatriptan Benzoate:** White to almost white crystalline powder. Soluble in water; sparingly soluble in alcohol; slightly soluble in methylene chloride.

**Rocuronium Bromide:** Almost white or pale yellow. Slightly hygroscopic powder. Freely soluble in water and in dehydrated alcohol.

**Roflumilast:** White to off-white powder. Freely soluble in acetone; sparingly soluble in ethanol; practically insoluble in water and in hexane.

**Ropinirole Hydrochloride:** Pale cream to yellow powder. Soluble in water.

**Ropivacaine:** White to off-white powder. Freely soluble in methylene chloride; soluble in ethanol; practically insoluble in water.

**Ropivacaine Hydrochloride:** White, crystalline powder. Soluble in water.

**Rose Oil:** Colorless or yellow liquid, having the characteristic odor and taste of rose. At 25° is a viscous liquid. Upon gradual cooling, changes to a translucent, crystalline mass, easily liquefied by warming. *NF category:* Flavors and fragrance.

**Rose Water Ointment:** *NF category:* Ointment base.

**Stronger Rose Water:** Practically colorless and clear, having the pleasant odor and taste of fresh rose blossoms. Is free from empyreuma, mustiness, and fungal growths. *NF category:* Flavors and fragrance.

**Rosiglitazone Maleate:** White to off-white solid. Sparingly soluble in alcohol; slightly soluble in methylene chloride; practically insoluble to very slightly soluble in water.

**Rosuvastatin Calcium:** A white to off-white, amorphous, hydrophilic powder. Soluble in dimethyl formamide, in dimethyl sulfoxide, in acetone, and in acetonitrile; sparingly soluble in methanol; sparingly soluble to slightly soluble in water; slightly soluble in ethanol.

**Rotigotine:** White or light-brownish powder. Soluble in anhydrous alcohol; very slightly soluble in heptane; practically insoluble in water.

**Rufinamide:** White, crystalline neutral powder. Slightly soluble in tetrahydrofuran and in methanol; very slightly soluble in alcohol and in acetonitrile; practically insoluble in water.

**Saccharin:** White crystals or white, crystalline powder. Is odorless or has a faint, aromatic odor. In dilute solution, it is intensely sweet. Its solutions are acid to litmus. Soluble in boiling water; sparingly soluble in alcohol; slightly soluble in water, in chloroform, and in ether. Is readily dissolved by dilute solutions of ammonia, by solutions of alkali hydroxides, and by solutions of alkali carbonates with the evolution of carbon dioxide. *NF category:* Sweetening agent.

**Saccharin Calcium:** White crystals or white, crystalline powder. Is odorless, or has a faint, aromatic odor, and has an intensely sweet taste even in dilute solutions. Its dilute solution is about 300 times as sweet as sucrose. Freely soluble in water. *NF category:* Sweetening agent.

**Saccharin Sodium:** White crystals or white, crystalline powder. Is odorless, or has a faint, aromatic odor, and has an intensely sweet taste even in dilute solutions. Its dilute solution is about 300 times as sweet as sucrose. When in powdered form, it usually contains about one-third the theoretical amount of water of hydration as a result of efflorescence. Freely soluble in water; sparingly soluble in alcohol. *NF category:* Sweetening agent.

**Saccharin Sodium Oral Solution:** Clear, colorless, odorless liquid, having a sweet taste.

**Safflower Oil:** Light yellow oil. Thickens and becomes rancid on prolonged exposure to air. Insoluble in water. Miscible with ether and with chloroform. *NF category:* Vehicle (oleaginous); emollient; solvent.

**Salicylamide:** White, practically odorless, crystalline powder. Freely soluble in ether and in solutions of alkalies; soluble in alcohol and in propylene glycol; slightly soluble in water and in chloroform.

**Salicylic Acid:** White crystals, usually in fine needles, or fluffy, white, crystalline powder. Has a sweetish, followed by an acrid, taste and is stable in air. The synthetic form is white and odorless. When prepared from natural methyl salicylate, it may have a slightly yellow or pink tint, and a faint, mint-like odor. Freely soluble in alcohol and in ether; soluble in boiling water; sparingly soluble in chloroform; slightly soluble in water and in benzene.

**Salmeterol Xinafoate:** White to off-white powder. Soluble in methanol; slightly soluble in alcohol, in isopropanol, and in chloroform; practically insoluble in water (pH 8), and in saline solution (0.9% w/w).

**Scopolamine Hydrobromide:** Colorless or white crystals or white, granular powder. Melts at about 197°, with decomposition. Is odorless, and slightly efflorescent in dry air. Freely soluble in water; soluble in alcohol; slightly soluble in chloroform; insoluble in ether.

**Secobarbital:** White, amorphous or crystalline, odorless powder, having a slightly bitter taste. Its saturated solution has a pH of about 5.6. Freely soluble in alcohol, in ether, and in solutions of fixed alkali hydroxides and carbonates; soluble in chloroform; very slightly soluble in water.

Official

https://nhathuocngocanh.com/

**Secobarbital Sodium:** White powder. Is odorless, has a bitter taste, and is hygroscopic. Its solutions decompose on standing, heat accelerating the decomposition. Very soluble in water; soluble in alcohol; practically insoluble in ether.

**Selegiline Hydrochloride:** White, odorless, crystalline powder. Freely soluble in water, in chloroform, and in methanol.

**Selenium Sulfide:** Reddish-brown to bright orange powder, having not more than a faint odor. Practically insoluble in water and in organic solvents.

**Sennosides:** Brownish powder.

**Serine:** White, odorless crystals, having a sweet taste. Soluble in water; practically insoluble in absolute alcohol and in ether.

**Sertraline Hydrochloride:** White or off-white crystalline powder. Sparingly soluble or slightly soluble in absolute alcohol; slightly soluble in water and in isopropanol; and slightly or very slightly soluble in acetone.

**Sesame Oil:** Pale yellow, oily liquid. Is practically odorless, and has a bland taste. Slightly soluble in alcohol. Miscible with ether, with chloroform, with solvent hexane, and with carbon disulfide. *NF category:* Solvent, vehicle (oleaginous).

**Sevoflurane:** Clear, colorless, volatile, nonflammable liquid. Slightly soluble in water. Miscible with alcohol, with chloroform, and with ether.

**Shellac:** *Orange Shellac*—Thin, hard, brittle, transparent, pale lemon-yellow to brownish orange flakes, having little or no odor; *Bleached Shellac*—Opaque, amorphous cream to yellow granules or coarse powder, having little or no odor. Soluble (very slowly) in alcohol, 85% to 95% (w/w), in ether, 13% to 15%, in benzene, 10% to 20%, in petroleum ether, 2% to 6%; soluble in aqueous solutions of ethanolamines, alkalies, and borax; sparingly soluble in oil of turpentine; insoluble in water. *NF category:* Coating agent; film-forming agent; release-modifying agent.

**Sildenafil Citrate:** White or almost white slightly hygroscopic crystalline powder. Slightly soluble in water and in methanol; practically insoluble in hexane.

**Dental-Type Silica:** Fine, white, hygroscopic, odorless, amorphous powder, in which the diameter of the average particles ranges between 0.5 and 40 µm. Soluble in hot solutions of alkali hydroxides; insoluble in water, in alcohol, and in acid (except hydrofluoric acid). *NF category:* Glidant and/or anticaking agent; suspending and/or viscosity-increasing agent.

**Hydrophobic Colloidal Silica:** Light, fine, white or almost white, amorphous powder, not wettable by water. Dissolves slowly in hot solutions of alkali hydroxides. Practically insoluble in water and in mineral acids, except hydrofluoric acid. *NF category:* Glidant and/or anticaking agent; suspending and/or viscosity-increasing agent.

**Purified Siliceous Earth:** Very fine, white, light gray, or pale buff mixture of amorphous powder and lesser amounts of crystalline polymorphs, including quartz and cristobalite. Is gritty, readily absorbs moisture, and retains about four times its weight of water without becoming fluid. Insoluble in water, in acids, and in dilute solutions of the alkali hydroxides. *NF category:* Filtering aid; sorbent.

**Silicon Dioxide:** Fine, white, hygroscopic, odorless, amorphous powder, in which the diameter of the average particles ranges between 2 and 10 µm. Soluble in hot solutions of alkali hydroxides; insoluble in water, in alcohol, and in other organic solvents. *NF category:* Desiccant; suspending and/or viscosity-increasing agent.

**Colloidal Silicon Dioxide:** Light, white, nongritty powder of extremely fine particle size (about 15 nm). Soluble in hot solutions of alkali hydroxides; insoluble in water and in acid (except hydrofluoric). *NF category:* Glidant and/or anticaking agent; suspending and/or viscosity-increasing agent; disintegrant.

**Silver Nitrate:** Colorless or white crystals. The pH of its solutions is about 5.5. On exposure to light in the presence of organic matter, it becomes gray or grayish black. Very soluble in water and even more so in boiling water; freely soluble in boiling alcohol; sparingly soluble in alcohol; slightly soluble in ether.

**Toughened Silver Nitrate:** White, crystalline masses generally molded as pencils or cones. It breaks with a fibrous fracture. Its solutions are neutral to litmus. It becomes gray or grayish black upon exposure to light. Soluble in water to the extent of its nitrate content (there is always a residue of silver chloride); partially soluble in alcohol; slightly soluble in ether.

**Simethicone:** Translucent, gray, viscous fluid. The liquid phase is soluble in chloroform, in ether, and in benzene, but silicon dioxide remains as a residue in these solvents. Insoluble in water and in alcohol. *NF category:* Antifoaming agent; water-repelling agent; diluent.

**Simvastatin:** White to off-white powder. Freely soluble in chloroform, in methanol, and in alcohol; sparingly soluble in propylene glycol; very slightly soluble in hexane; practically insoluble in water.

**Sitagliptin Phosphate:** White or almost white powder. Soluble in water; very slightly soluble in anhydrous ethanol; practically insoluble in heptane.

**Soda Lime:** White or grayish-white granules. May have a color if an indicator has been added. *NF category:* Sorbent, carbon dioxide.

**Sodium Acetate:** Colorless, transparent crystals, or white, granular crystalline powder, or white flakes. Is odorless or has a faint acetous odor, and has a slightly bitter, saline taste. Is efflorescent in warm, dry air. Very soluble in water; soluble in alcohol. *NF category:* Flavors and fragrance; pH modifier (acidifying agent/alkalizing agent/buffering agent); antimicrobial preservative; transfer ligand.

**Sodium Alginate:** Practically odorless and tasteless, coarse or fine powder, yellowish white in color. Soluble in water, forming a viscous, colloidal solution; insoluble in alcohol and in hydroalcoholic solutions in which the alcohol content is greater than about 30% by weight, in chloroform, in ether, and in acids when the pH of the resulting solution becomes lower than about 3. *NF category:* Suspending and/or viscosity-increasing agent; film-forming agent; release-modifying agent; disintegrant; wet binder.

**Sodium Ascorbate:** White or very faintly yellow crystals or crystalline powder. Is odorless or practically odorless. Is relatively stable in air. On exposure to light it gradually darkens. Freely soluble in water; very slightly soluble in alcohol; insoluble in chloroform and in ether. *NF category:* Antioxidant.

**Sodium Benzoate:** White, odorless or practically odorless, granular or crystalline powder. Is stable in air. Freely soluble in water; soluble in 90% alcohol; sparingly soluble in alcohol. *NF category:* Antimicrobial preservative; lubricant.

**Sodium Bicarbonate:** White, crystalline powder. Is stable in dry air, but slowly decomposes in moist air. Its solutions, when freshly prepared with cold water, without shaking, are alkaline to litmus. The alkalinity increases as the solutions stand, as they are agitated, or as they are heated. Soluble in water; insoluble in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Sodium Borate:** Colorless, transparent crystals or white, crystalline powder. Is odorless. Its solutions are alkaline to phenolphthalein TS. As it effloresces in warm, dry air, the crystals are often coated with white powder. Freely soluble in boiling water and in glycerin; soluble in water; insoluble in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent); antimicrobial preservative; emulsifying agent.

**Sodium Bromide:** White, crystalline powder or colorless, cubical crystals. Freely soluble in water; soluble in alcohol.

**Sodium Butyrate:** Clear, colorless, hygroscopic powder. Soluble in water and in methanol. Melting range is about 250° to 253°.

**Sodium Caprylate:** A white, crystalline powder. Very soluble or freely soluble in water; freely soluble in acetic acid; sparingly soluble in alcohol; practically insoluble in acetone.

**Sodium Carbonate:** Colorless crystals, or white, crystalline powder or granules. Is stable in air under ordinary conditions. When exposed to dry air above 50°, the hydrous salt effloresces and, at 100°, becomes anhydrous. Very soluble in boiling water; freely soluble in water. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Sodium Cetostearyl Sulfate:** A white or pale yellow, amorphous or crystalline powder. Soluble in hot water giving an opalescent solution; slightly soluble in alcohol; practically insoluble in cold water. *NF category:* Emulsifying agent.

**Sodium Chloride:** Colorless, cubic crystals or white crystalline powder. Has a saline taste. Freely soluble in water; soluble in glycerin; slightly soluble in alcohol. *NF category:* Tonicity agent; diluent.

**Sodium Chloride Inhalation Solution:** Clear, colorless solution.

**Bacteriostatic Sodium Chloride Injection:** Clear, colorless solution, odorless or having the odor of the bacteriostatic substance. *NF category:* Vehicle (sterile).

**Sodium Chloride Irrigation:** Clear, colorless solution.

**Sodium Citrate:** Colorless crystals, or white, crystalline powder. Hydrous form very soluble in boiling water; freely soluble in water; insoluble in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent); sequestering agent; transfer ligand.

**Sodium Citrate and Citric Acid Oral Solution:** Clear solution having the color of any added preservative or flavoring agents.

**Sodium Dehydroacetate:** White or practically white, odorless powder, having a slight characteristic taste. Freely soluble in water, in propylene glycol, and in glycerin. *NF category:* Antimicrobial preservative.

**Sodium Fluoride:** White, odorless powder. Soluble in water; insoluble in alcohol.

**Sodium Formaldehyde Sulfoxylate:** White crystals or hard, white masses, having the characteristic odor of garlic. Freely soluble in water; slightly soluble in alcohol, in ether, in chloroform, and in benzene. *NF category:* Antioxidant.

**Sodium Hydroxide:** White, or practically white, fused masses, in small pellets, in flakes, or sticks, and in other forms. Is hard and brittle and shows a crystalline fracture. Exposed to the air, it rapidly absorbs carbon dioxide and moisture. Freely soluble in water and in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Sodium Hypochlorite Solution:** Clear, pale greenish-yellow liquid, having the odor of chlorine. Is affected by light.

**Sodium Iodide:** Colorless, odorless crystals, or white, crystalline powder. Is deliquescent in moist air, and develops a brown tint upon decomposition. Very soluble in water; freely soluble in alcohol and in glycerin.

**Sodium Lactate Solution:** Clear, colorless or practically colorless, slightly viscous liquid, odorless or having a slight, not unpleasant odor. Miscible with water. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent); antimicrobial preservative; humectant; flavors and fragrance.

**Sodium Lauroyl Sarcosinate:** White or almost white powder. Freely soluble in water, giving a clear or slightly hazy solution; sparingly soluble in alcohol. *NF category*: Emulsifying agent; surfactant; wetting and/or solubilizing agent.

**Sodium Lauryl Sulfate:** Small, white or light yellow crystals having a slight, characteristic odor. Freely soluble in water, forming an opalescent solution. *NF category:* Emulsifying agent; lubricant; wetting and/or solubilizing agent.

**Sodium Metabisulfite:** White crystals or white to yellowish, crystalline powder, having the odor of sulfur dioxide. Freely soluble in water and in glycerin; slightly soluble in alcohol. *NF category:* Antioxidant; antimicrobial preservative.

**Sodium Monofluorophosphate:** White to slightly gray, odorless powder. Freely soluble in water.

**Sodium Nitrite:** White to slightly yellow, granular powder, or white or practically white, opaque, fused masses or sticks. Has a mild, saline taste and is deliquescent in air. Its solutions are alkaline to litmus. Freely soluble in water; sparingly soluble in alcohol.

**Sodium Nitrite Injection:** Clear, colorless liquid.

**Sodium Nitroprusside:** Reddish-brown, practically odorless, crystals or powder. Freely soluble in water; slightly soluble in alcohol; very slightly soluble in chloroform; insoluble in benzene.

**Dibasic Sodium Phosphate (*dried*):** White powder that readily absorbs moisture. Freely soluble in water; insoluble in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent); chelating and/or complexing agent.

**Dibasic Sodium Phosphate (*heptahydrate*):** Colorless or white, granular or caked salt. Effloresces in warm, dry air. Its solutions are alkaline to phenolphthalein TS, a 0.1 M solution having a pH of about 9. Freely soluble in water; very slightly soluble in alcohol. *NF category:* Buffering agent.

**Monobasic Sodium Phosphate:** Colorless crystals or white, crystalline powder. Is odorless and is slightly deliquescent. Its solutions are acid to litmus and effervesce with sodium carbonate. Freely soluble in water; practically insoluble in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent); chelating and/or complexing agent.

**Tribasic Sodium Phosphate:** The formula for a crystalline material is approximately $4(Na_3PO_4 \cdot 12H_2O)NaOH$. It occurs as white, odorless crystals or granules or as a crystalline powder. Freely soluble in water; insoluble in alcohol. The pH of a 1 in 100 solution is between 11.5 and 12.0.

**Sodium Picosulfate:** White or almost white crystalline powder. Freely soluble in water; slightly soluble in alcohol.

**Sodium Polystyrene Sulfonate:** Golden brown, fine powder. Is odorless and has a characteristic taste. Insoluble in water.

**Sodium Propionate:** Colorless, transparent crystals or granular, crystalline powder. Is odorless, or has a faint acetic-butyric odor and is deliquescent in moist air. Very soluble in water; soluble in alcohol. *NF category:* Antimicrobial preservative.

**Sodium Salicylate:** Amorphous or microcrystalline powder or scales. Is colorless, or has not more than a faint, pink tinge. Is odorless, or has a faint, characteristic odor, and is affected by light. A freshly made solution (1 in 10) is neutral or acid to litmus. Very soluble in boiling water and in boiling alcohol; freely (and slowly) soluble in water and in glycerin; slowly soluble in alcohol.

**Sodium Starch Glycolate:** White, tasteless, odorless, relatively free-flowing powder; available in several different viscosity grades. A 2% (w/v) dispersion in cold water settles, on standing, in the form of a highly hydrated layer. *NF category:* Disintegrant.

**Sodium Stearate:** Fine, white powder, soapy to the touch, usually having a slight, tallow-like odor. Is affected by light. Its solutions are alkaline to phenolphthalein TS. Slowly soluble in cold water and in cold alcohol; readily soluble in hot water and

in hot alcohol. *NF category:* Emulsifying agent; glidant and/or anticaking agent; stiffening agent; lubricant.

**Sodium Stearyl Fumarate:** Fine, white powder. Slightly soluble in methanol; practically insoluble in water. *NF category:* Lubricant.

**Sodium Succinate:** White crystals or white powder. Freely soluble in water. *NF category:* Flavors and fragrance; pH modifier.

**Sodium Sulfate:** Large, colorless, odorless, transparent crystals, or a granular powder. Effloresces rapidly in air, liquefies in its water of hydration at about 33°, and loses all of its water of hydration at about 100°. Freely soluble in water; soluble in glycerin; insoluble in alcohol.

**Sodium Sulfite:** Colorless crystals. Freely soluble in water; very slightly soluble in alcohol. *NF category:* Antioxidant; antimicrobial preservative.

**Sodium Tartrate:** Transparent, colorless, odorless crystals. Freely soluble in water; insoluble in alcohol. *NF category:* Sequestering agent; transfer ligand.

**Sodium Thiosulfate:** Large, colorless crystals or coarse, crystalline powder. Is deliquescent in moist air and effloresces in dry air at temperatures exceeding 33°. Its solutions are neutral or faintly alkaline to litmus. Very soluble in water; insoluble in alcohol. *NF category:* Antioxidant.

**Solifenacin Succinate:** White to pale, yellowish-white crystal or crystalline powder. Freely soluble in water and in methanol.

**Sorafenib Tosylate:** White or slightly yellowish or brownish powder. Soluble in PEG 400; slightly soluble in ethanol; practically insoluble in aqueous media and in heptane.

**Sorbic Acid:** Free-flowing, white, crystalline powder, having a characteristic odor. Soluble in alcohol and in ether; slightly soluble in water. *NF category:* Antimicrobial preservative.

**Sorbitan Monolaurate:** Yellow to amber-colored, oily liquid, having a bland, characteristic odor. Soluble in mineral oil; slightly soluble in cottonseed oil and in ethyl acetate; insoluble in water. *NF category:* Emulsifying agent; lubricant; suspending and/or viscosity-increasing agent; wetting and/or solubilizing agent.

**Sorbitan Monooleate:** Viscous, yellow to amber-colored, oily liquid, having a bland, characteristic odor. Insoluble in water and in propylene glycol. Miscible with mineral and vegetable oils. *NF category:* Emulsifying agent; lubricant; suspending and/or viscosity-increasing agent; wetting and/or solubilizing agent.

**Sorbitan Monopalmitate:** Cream-colored, waxy solid having a faint fatty odor. Soluble in warm absolute alcohol; soluble, with haze, in warm peanut oil and in warm mineral oil; insoluble in water. *NF category:* Emulsifying agent; lubricant; suspending and/or viscosity-increasing agent; wetting and/or solubilizing agent.

**Sorbitan Monostearate:** Cream-colored to tan, hard, waxy solid, having a bland odor and taste. Soluble, with haze, above 50° in mineral oil and in ethyl acetate; insoluble in cold water and in acetone. Dispersible in warm water. *NF category:* Emulsifying agent; lubricant; suspending and/or viscosity-increasing agent; wetting and/or solubilizing agent.

**Sorbitan Sesquioleate:** Viscous, yellow to amber-colored, oily liquid. Soluble in alcohol, in isopropyl alcohol, in cottonseed oil, and in mineral oil; insoluble in water and in propylene glycol. *NF category:* Emulsifying agent; lubricant; suspending and/or viscosity-increasing agent; wetting and/or solubilizing agent.

**Sorbitan Trioleate:** Yellow to amber-colored, oily liquid. Soluble in methyl alcohol, in alcohol, in isopropyl alcohol, in corn oil, in cottonseed oil, and in mineral oil; insoluble in water, in ethylene glycol, and in propylene glycol. *NF category:* Emulsifying agent; lubricant; suspending and/or viscosity-increasing agent; wetting and/or solubilizing agent.

**Sorbitol:** D-Sorbitol occurs as white granules, powder, or crystalline masses. Is odorless, and has a sweet taste with a cold sensation. Very soluble in water; sparingly soluble in alcohol; and practically insoluble in ethyl ether. Is hygroscopic. *NF category:* Humectant; sweetening agent; diluent; plasticizer.

**Sorbitol Solution:** Clear, colorless, syrupy liquid. Is odorless and has a sweet taste. It sometimes separates into crystalline masses. Miscible with water, with alcohol, with glycerin, and with propylene glycol. Is neutral to litmus. *NF category:* Sweetening agent; vehicle (flavored and/or sweetened).

**Sorbitol Sorbitan Solution:** A clear, colorless to pale yellow, syrupy liquid. Is odorless and has a sweet taste. Insoluble in mineral oil and in vegetable oil. Miscible with water, with alcohol, with glycerin, and with propylene glycol. *NF category:* Humectant; plasticizer.

**Sotalol Hydrochloride:** White, crystalline powder. It is hydrophilic. Soluble in water, in propylene glycol, and in ethanol; slightly soluble in chloroform.

**Soybean Oil:** Clear, pale yellow, oily liquid having a characteristic odor and taste. Insoluble in water. Miscible with ether and with chloroform. *Specific Gravity* ⟨841⟩: between 0.916 and 0.922. *Refractive Index* ⟨831⟩: between 1.465 and 1.475. *NF category:* Vehicle (oleaginous); solvent.

**Hydrogenated Soybean Oil:** A white mass or powder that melts to a clear, pale yellow liquid when heated. Freely soluble in methylene chloride, in hexane after heating, and in toluene; very slightly soluble in alcohol; practically insoluble in water. *NF category:* Emollient.

**Spectinomycin Hydrochloride:** White to pale-buff crystalline powder. Freely soluble in water; practically insoluble in alcohol, in chloroform, and in ether.

**Spironolactone:** Light cream-colored to light tan, crystalline powder. Has a faint to mild mercaptan-like odor; is stable in air. Freely soluble in benzene and in chloroform; soluble in ethyl acetate and in alcohol; slightly soluble in methanol and in fixed oils; practically insoluble in water.

**Squalane:** Colorless, practically odorless transparent oil. Slightly soluble in acetone; very slightly soluble in absolute alcohol; insoluble in water. Miscible with ether and with chloroform. *NF category:* Ointment base; vehicle (oleaginous).

**Stannous Chloride:** White, crystalline powder or colorless crystals, efflorescent in air. Freely soluble in water (the solution becomes cloudy after standing or on dilution) and in alcohol. Dissolves in dilute hydrochloric acid. *NF category:* Emulsifying agent; antioxidant; reducing agent.

**Stannous Fluoride:** White, crystalline powder, having a bitter, salty taste. Melts at about 213°. Freely soluble in water; practically insoluble in alcohol, in ether, and in chloroform. *NF category:* Reducing agent.

**Stanozolol:** Odorless, crystalline powder, occurring in two forms: as needles, melting at about 155°, and as prisms, melting at about 235°. Soluble in dimethylformamide; sparingly soluble in alcohol and in chloroform; slightly soluble in ethyl acetate and in acetone; very slightly soluble in benzene; insoluble in water.

**Star Anise Oil:** Clear, colorless to light yellow in the liquid state having a powerful and characteristic licorice–like scent. Congeals between 15° and 19°. Miscible with alcohol. *NF category*: Flavors and fragrance.

**Corn Starch:** Irregular, angular, white masses (which may be bleached) or fine powder. Is odorless, and has a slight, characteristic taste. Insoluble in cold water and in alcohol. *NF category:* Diluent; disintegrant; wet binder; suspending and/or viscosity-increasing agent.

**Hydroxypropyl Corn Starch:** White or slightly yellowish powder. Practically insoluble in cold water and in alcohol. *NF*

*category:* Diluent; disintegrant; wet binder; emulsifying agent; suspending and/or viscosity-increasing agent.

**Pregelatinized Hydroxypropyl Corn Starch:** White or slightly yellowish powder. It swells in water and produces a clear or translucent, viscous, colloidal mixture. *NF category:* Suspending and/or viscosity-increasing agent; diluent; disintegrant; wet binder; emulsifying agent.

**Pea Starch:** White or almost white, very fine powder. Practically insoluble in cold water and in alcohol. *NF category:* Suspending and/or viscosity-increasing agent; diluent; disintegrant; wet binder.

**Hydroxypropyl Pea Starch:** White or slightly yellowish powder. Practically insoluble in cold water and in alcohol. *NF category:* Suspending and/or viscosity-increasing agent; diluent; disintegrant; wet binder; emulsifying agent.

**Pregelatinized Hydroxypropyl Pea Starch:** White or slightly yellowish powder. It swells in water and produces a clear or translucent, viscous, colloidal mixture. *NF category:* Suspending and/or viscosity-increasing agent; wet binder; diluent; disintegrant.

**Potato Starch:** Irregular, angular, white masses (which may be bleached) or fine powder. Is odorless, and has a slight, characteristic taste. Insoluble in cold water and in alcohol. *NF category:* Suspending and/or viscosity-increasing agent; diluent; disintegrant; wet binder.

**Hydroxypropyl Potato Starch:** White or slightly yellowish powder. Practically insoluble in cold water and in alcohol. *NF category:* Suspending and/or viscosity-increasing agent; diluent; disintegrant; wet binder; emulsifying agent.

**Pregelatinized Hydroxypropyl Potato Starch:** White or slightly yellowish powder. It swells in water and produces a clear or translucent, viscous, colloidal mixture. *NF category:* Suspending and/or viscosity-increasing agent; wet binder; diluent; disintegrant.

**Pregelatinized Starch:** Moderately coarse to fine, white to off-white powder. Is odorless and has a slight, characteristic taste. Slightly soluble to soluble in cold water; insoluble in alcohol. *NF category:* Wet binder; diluent; disintegrant; release-modifying agent.

**Pregelatinized Modified Starch:** Moderately coarse to fine, white to off-white powder. Is odorless and has a slight, characteristic taste. Soluble to slightly soluble in cold water; insoluble in alcohol. *NF category:* Coating agent; diluent; disintegrant; wet binder; release-modifying agent.

**Tapioca Starch:** Irregular, angular, white to pale yellow masses (which may be bleached) or fine powder. Insoluble in cold water and in alcohol. *NF category:* Suspending and/or viscosity-increasing agent; diluent; disintegrant; wet binder.

**Wheat Starch:** Irregular, angular, white masses (which may be bleached) or fine powder. Is odorless and has a slight, characteristic taste. Insoluble in cold water and in alcohol. *NF category:* Suspending and/or viscosity-increasing agent; diluent; disintegrant; wet binder.

**Hydrogenated Starch Hydrolysate:** Concentrated, aqueous solution or spray-dried or dried powder. Very soluble in water; insoluble in alcohol. *NF category:* Sweetening agent; humectant; diluent; wet binder.

**Stavudine:** White to off-white, crystalline powder. Soluble in water, in dimethylacetamide, and in dimethyl sulfoxide; sparingly soluble in methanol, in alcohol, and in acetonitrile; slightly soluble in dichloromethane; insoluble in hexane.

**Stearic Acid:** Hard, white or faintly yellowish, somewhat glossy and crystalline solid, or white or yellowish-white powder. Its odor and taste are slight, suggesting tallow. Freely soluble in chloroform and in ether; soluble in alcohol; practically insoluble in water. *NF category:* Emulsifying agent; lubricant.

**Purified Stearic Acid:** Hard, white or faintly yellowish, somewhat glossy and crystalline solid, or white or yellowish-white powder. Its odor and taste are slight, suggesting tallow. Freely soluble in chloroform and in ether; soluble in alcohol; practically insoluble in water. *NF category:* Lubricant.

**Stearoyl Polyoxylglycerides:** Pale yellow, waxy solids. Dispersible in warm water and in warm paraffin. Freely soluble in methylene chloride; soluble in warm methanol. *NF category:* Ointment base; solvent; emulsifying agent; wetting and/or solubilizing agent.

**Stearyl Alcohol:** Unctuous, white flakes or granules. Has a faint, characteristic odor and a bland, mild taste. Soluble in alcohol and in ether; insoluble in water. *NF category:* Stiffening agent.

**Storax:** Semiliquid, grayish to grayish-brown, sticky, opaque mass depositing on standing a heavy dark brown layer (Levant Storax); or semisolid, sometimes a solid mass, softened by gently warming (American Storax). Is transparent in thin layers, has a characteristic odor and taste, and is more dense than water. Soluble, usually incompletely, in an equal weight of warm alcohol, in acetone, in carbon disulfide, and in ether, some insoluble residue usually remaining; insoluble in water.

**Streptomycin Sulfate:** White or practically white powder. Is odorless or has not more than a faint odor. Is hygroscopic, but is stable in air and on exposure to light. Its solutions are acid to practically neutral to litmus. Freely soluble in water; very slightly soluble in alcohol; practically insoluble in chloroform.

**Succinic Acid:** White, odorless crystals. Freely soluble in boiling water; soluble in water, in alcohol, and in glycerin. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Succinylcholine Chloride:** White, odorless, crystalline powder. Its solutions have a pH of about 4. The dihydrate form melts at about 160°; the anhydrous form melts at about 190°, and is hygroscopic. Freely soluble in water; slightly soluble in alcohol and in chloroform; practically insoluble in ether.

**Sucralfate:** White or almost-white amorphous powder. Soluble in a dilute solution of mineral acids or alkali hydroxides; practically insoluble in water, in alcohol, and in methylene chloride.

**Sucralose:** White to off-white, crystalline powder. Freely soluble in water, in methanol, and in alcohol; slightly soluble in ethyl acetate. *NF category:* Sweetening agent.

**Sucrose:** White, crystalline powder or lustrous, dry, colorless or white crystals. Very soluble in water; slightly soluble in alcohol; practically insoluble in dehydrated alcohol. *NF category:* Coating agent; sweetening agent; diluent; suspending and/or viscosity-increasing agent; wet binder.

**Sucrose Diacetate Hexaisobutyrate:** Colorless or pale yellow, clear or slightly turbid liquid. Freely soluble in acetone, in ethanol, in ethyl lactate, in benzyl alcohol, in triacetin, and in medium-chain triglycerides; soluble in ethyl acetate; very slightly soluble in water. *NF category:* Wet binder; plasticizer; ointment base; diluent.

**Sucrose Palmitate:** White or almost white, unctuous powder. Sparingly soluble in ethanol (96%); very slightly soluble in water. *NF category:* Suspending and/or viscosity-increasing agent; emulsifying agent.

**Sucrose Octaacetate:** White, practically odorless powder, having an intensely bitter taste. Is hygroscopic. Very soluble in methanol and in chloroform; soluble in alcohol and in ether; very slightly soluble in water. *NF category:* Alcohol denaturant.

**Sucrose Stearate:** White or almost white, unctuous powder. Sparingly soluble in ethanol (96%); very slightly soluble in water. *NF category:* Emulsifying agent; lubricant.

**Sufentanil Citrate:** White powder. Freely soluble in methanol; soluble in water; sparingly soluble in acetone, in alcohol, and in chloroform. Melts between 133° and 140°.

**Compressible Sugar:** Practically white, crystalline, odorless powder, having a sweet taste. Is stable in air. The sucrose portion of Compressible Sugar is very soluble in water. *NF category:* Sweetening agent; diluent.

**Confectioner's Sugar:** Fine, white, odorless powder, having a sweet taste. Is stable in air. The sucrose portion of Confectioner's Sugar is soluble in cold water. Confectioner's Sugar is freely soluble in boiling water. *NF category:* Sweetening agent; diluent; coating agent.

**Sugar Spheres:** Hard, brittle, free-flowing, spherical masses ranging generally in size from 10- to 60-mesh. Usually white, but may be colored. Solubility in water varies according to the sugar-to-starch ratio. *NF category:* Vehicle (solid carrier); diluent.

**Sulbactam Sodium:** White to off-white, crystalline powder. Freely soluble in water and in dilute acid; sparingly soluble in acetone, in ethyl acetate, and in chloroform.

**Sulconazole Nitrate:** White to off-white, crystalline powder. Melts at about 130°, with decomposition. Freely soluble in pyridine; sparingly soluble in methanol; slightly soluble in alcohol, in chloroform, in acetone, and in methylene chloride; very slightly soluble in water, in toluene, and in dioxane.

**Sulfacetamide Sodium:** White, crystalline powder. Is odorless and has a bitter taste. Freely soluble in water; sparingly soluble in alcohol; practically insoluble in chloroform and in ether.

**Sulfadiazine:** White or slightly yellow powder. Is odorless or nearly odorless and is stable in air, but slowly darkens on exposure to light. Freely soluble in dilute mineral acids, in solutions of potassium and sodium hydroxides, and in ammonia TS; sparingly soluble in alcohol and in acetone; slightly soluble in human serum at 37°; practically insoluble in water.

**Silver Sulfadiazine:** White to creamy-white, crystalline powder, odorless to having a slight odor. Is stable in air, but turns yellow on exposure to light. Freely soluble in 30% ammonium solution; slightly soluble in acetone; practically insoluble in alcohol, in chloroform, and in ether. Decomposes in moderately strong mineral acids.

**Sulfadiazine Sodium:** White powder. On prolonged exposure to humid air it absorbs carbon dioxide with the liberation of sulfadiazine and becomes incompletely soluble in water. Its solutions are alkaline to phenolphthalein. Is affected by light. Freely soluble in water; slightly soluble in alcohol.

**Sulfadimethoxine:** Practically white, crystalline powder. Soluble in 2 N sodium hydroxide; sparingly soluble in 2 N hydrochloric acid; slightly soluble in alcohol, in ether, in chloroform, and in hexane; practically insoluble in water.

**Sulfamethazine:** White to yellowish-white powder, which may darken on exposure to light. Has a slightly bitter taste and is practically odorless. Soluble in acetone; slightly soluble in alcohol; very slightly soluble in water and in ether.

**Sulfamethizole:** White crystals or powder, having a slightly bitter taste. Is practically odorless, and has no odor of hydrogen sulfide. Freely soluble in solutions of ammonium, potassium, and sodium hydroxides; soluble in dilute mineral acids and in acetone; sparingly soluble in alcohol; very slightly soluble in water, in chloroform, and in ether; practically insoluble in benzene.

**Sulfamethoxazole:** White to off-white, practically odorless, crystalline powder. Freely soluble in acetone and in dilute solutions of sodium hydroxide; sparingly soluble in alcohol; practically insoluble in water, in ether, and in chloroform.

**Sulfapyridine:** White or faintly yellowish-white crystals, granules, or powder. Is odorless or practically odorless, and is stable in air, but slowly darkens on exposure to light. Freely soluble in dilute mineral acids and in solutions of potassium and sodium hydroxides; sparingly soluble in acetone; slightly soluble in alcohol; very slightly soluble in water.

**Sulfasalazine:** Bright yellow or brownish-yellow, odorless, fine powder. Melts at about 255°, with decomposition. Soluble in aqueous solutions of alkali hydroxides; very slightly soluble in alcohol; practically insoluble in water, in ether, in chloroform, and in benzene.

**Sulfathiazole:** Fine, white or faintly yellowish-white, practically odorless powder. Soluble in acetone, in dilute mineral acids, in solutions of alkali hydroxides, and in 6 N ammonium hydroxide; slightly soluble in alcohol; very slightly soluble in water.

**Sulfisoxazole:** White to slightly yellowish, odorless, crystalline powder. Soluble in boiling alcohol and in 3 N hydrochloric acid; very slightly soluble in water.

**Sulfisoxazole Acetyl:** White or slightly yellow, crystalline powder. Sparingly soluble in chloroform; slightly soluble in alcohol; practically insoluble in water.

**Precipitated Sulfur:** Very fine, pale yellow, amorphous or microcrystalline powder. Is odorless and tasteless. Very soluble in carbon disulfide; slightly soluble in olive oil; very slightly soluble in alcohol; practically insoluble in water.

**Sublimed Sulfur:** Fine, yellow, crystalline powder, having a faint odor and taste. Sparingly soluble in olive oil; practically insoluble in water and in alcohol.

**Sulfur Dioxide:** Colorless, nonflammable gas, possessing a strong, suffocating odor characteristic of burning sulfur. Under pressure, it condenses readily to a colorless liquid that boils at –10° and has a density of approximately 1.5. At 20° and at standard pressure, approximately 36 volumes dissolve in 1 volume of water and approximately 114 volumes dissolve in 1 volume of alcohol. Soluble also in ether and in chloroform. *NF category:* Antioxidant; antimicrobial preservative.

**Sulfuric Acid:** Clear, colorless, oily liquid. Miscible with water and with alcohol with the generation of much heat. Is very caustic and corrosive. Specific gravity is about 1.84. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Sulindac:** Yellow, crystalline powder, which is odorless or practically so. Slightly soluble in methanol, in alcohol, in acetone, and in chloroform; very slightly soluble in isopropanol and in ethyl acetate; practically insoluble in hexane and in water.

**Sulisobenzone:** Light tan powder, with a melting point of about 145°. Freely soluble in methanol, in alcohol, and in water; sparingly soluble in ethyl acetate.

**Sumatriptan:** White to pale yellow powder. Very slightly soluble in water.

**Sumatriptan Succinate:** White or almost white powder. Freely soluble in water; sparingly soluble in methanol; practically insoluble in methylene chloride.

**Sunflower Oil:** Clear, light yellow liquid. It is miscible with petroleum at a boiling point of 40°–60°. Practically insoluble in water and in alcohol. *Refractive Index* ⟨831⟩: 1.472–1.474 at 25°. *Specific Gravity* ⟨841⟩: 0.914–0.924 at 20°. *NF category*: Coating agent; emollient; solvent; diluent; vehicle (oleaginous).

**Syrup:** *NF category:* Sweetening agent; wet binder; vehicle.

**Tacrolimus:** White crystals or white crystalline powder. Very soluble in methanol; freely soluble in *N,N*-dimethylformamide, and in alcohol; practically insoluble in water.

**Tadalafil:** White or almost white powder. Freely soluble in dimethyl sulfoxide; slightly soluble in methylene chloride; practically insoluble in water.

**Tagatose:** White or almost white crystals, having a sweet taste. Very soluble in water; very slightly soluble in alcohol. *NF category:* Sweetening agent; humectant.

Official Text

**Talc:** Very fine, white or grayish-white, crystalline powder. Is unctuous, adheres readily to the skin, and is free from grittiness. *NF category:* Glidant and/or anticaking agent; lubricant; diluent.

**Tamoxifen Citrate:** White, fine, crystalline powder. Soluble in methanol; very slightly soluble in water, in acetone, in chloroform, and in alcohol. Melts at about 142°, with decomposition.

**Tamsulosin Hydrochloride:** White or almost white crystalline powder. Melts with decomposition at approximately 230°. Freely soluble in formic acid; sparingly soluble in methanol; slightly soluble in water and in dehydrated alcohol; practically insoluble in ether.

**Tannic Acid:** Amorphous powder, glistening scales, or spongy masses, varying in color from yellowish-white to light brown. Is odorless or has a faint, characteristic odor, and has a strongly astringent taste. Very soluble in water, in acetone, and in alcohol; freely soluble in diluted alcohol; slightly soluble in dehydrated alcohol; practically insoluble in benzene, in chloroform, in ether, and in solvent hexane; 1 g dissolves in about 1 mL of warm glycerin.

**Tartaric Acid:** Colorless or translucent crystals or white, fine to granular, crystalline powder. Is odorless, has an acid taste, and is stable in air. Very soluble in water; freely soluble in alcohol. *NF category:* pH modifier (acidifying agent/alkalizing agent/buffering agent); flavors and fragrance; sequestering agent.

**Taurine:** White crystals or crystalline powder. Soluble in water.

**Tazobactam:** White to pale yellow, nonhygroscopic, crystalline powder. Soluble in dimethylformamide; slightly soluble in water, in methanol, in acetone, and in alcohol; very slightly soluble in ethyl acetate, in ethyl ether, and in chloroform; insoluble in hexane.

**Technetium Tc 99m Aggregated Albumin Injection:** Milky suspension, from which particles settle upon standing.

**Technetium Tc 99m Pentetate Injection:** Clear, colorless solution.

**Sodium Pertechnetate Tc 99m Injection:** Clear, colorless solution.

**Technetium Tc 99m (Pyro- and trimeta-) Phosphates Injection:** Clear solution.

**Technetium Tc 99m Sulfur Colloid Injection:** Colloidal dispersion. Slightly opalescent, colorless to light tan liquid.

**Telmisartan:** White or slightly yellowish, crystalline powder. Sparingly soluble in methylene chloride; slightly soluble in methanol; practically insoluble in water. It dissolves in 1 M sodium hydroxide.

**Temazepam:** White or nearly white, crystalline powder. Sparingly soluble in alcohol; very slightly soluble in water. Melts between 157° and 163°, within a 3° range.

**Temozolomide:** White to light pink/light tan powder. Soluble in dimethyl sulfoxide; sparingly soluble in water; practically insoluble in toluene.

**Teniposide:** White to off-white, crystalline powder. Very soluble in acetone and in dimethylformamide; slightly soluble in methanol; insoluble in water and in ether.

**Terazosin Hydrochloride:** White to pale yellow, crystalline powder. Freely soluble in isotonic saline solution; soluble in methanol and in water; slightly soluble in alcohol and in 0.1 N hydrochloric acid; very slightly soluble in chloroform; practically insoluble in acetone and in hexanes.

**Terbinafine Hydrochloride:** White or off-white powder. Freely soluble in dehydrated alcohol and in methanol; slightly soluble in acetone; very slightly or slightly soluble in water.

**Terbutaline Sulfate:** White to gray-white, crystalline powder. Is odorless or has a faint odor of acetic acid. Soluble in water and in 0.1 N hydrochloric acid; slightly soluble in methanol; insoluble in chloroform.

**Terconazole:** White to off-white powder. Freely soluble in methylene chloride; soluble in acetone; sparingly soluble in alcohol; practically insoluble in water. It exhibits polymorphism.

**Terpin Hydrate:** Colorless, lustrous crystals or white powder. Has a slight odor, and effloresces in dry air. A hot solution (1 in 100) is neutral to litmus. When dried in vacuum at 60° for 2 hours, it melts at about 103°. Very soluble in boiling alcohol; soluble in alcohol; sparingly soluble in boiling water; slightly soluble in water, in chloroform, and in ether.

**Testosterone:** White or slightly creamy white crystals or crystalline powder. Is odorless, and is stable in air. Freely soluble in dehydrated alcohol and in chloroform; soluble in dioxane and in vegetable oils; slightly soluble in ether; practically insoluble in water.

**Testosterone Cypionate:** White or creamy white, crystalline powder. Is odorless or has a slight odor, and is stable in air. Freely soluble in alcohol, in chloroform, in dioxane, and in ether; soluble in vegetable oils; insoluble in water.

**Testosterone Enanthate:** White or creamy white, crystalline powder. Is odorless or has a faint odor characteristic of heptanoic acid. Very soluble in ether; soluble in vegetable oils; insoluble in water.

**Testosterone Propionate:** White or creamy white crystals or crystalline powder. Is odorless and is stable in air. Freely soluble in alcohol, in dioxane, in ether, and in other organic solvents; soluble in vegetable oils; insoluble in water.

**Tetracaine:** White or light yellow, waxy solid. Soluble in alcohol, in ether, in benzene, and in chloroform; very slightly soluble in water.

**Tetracaine Hydrochloride:** Fine, white, crystalline, odorless powder. Has a slightly bitter taste followed by a sense of numbness. Its solutions are neutral to litmus. Melts at about 148°, or may occur in either of two other polymorphic modifications that melt at about 134° and 139°, respectively. Mixtures of the forms may melt within the range of 134° to 147°. Is hygroscopic. Very soluble in water; soluble in alcohol; insoluble in ether and in benzene.

**Tetracycline:** Yellow, odorless, crystalline powder. Is stable in air, but exposure to strong sunlight causes it to darken. It loses potency in solutions of pH below 2, and is rapidly destroyed by alkali hydroxide solutions. Freely soluble in dilute acid and in alkali hydroxide solutions; sparingly soluble in alcohol; very slightly soluble in water; practically insoluble in chloroform and in ether.

**Tetracycline Hydrochloride:** Yellow, odorless, crystalline powder. Is moderately hygroscopic. Is stable in air, but exposure to strong sunlight in moist air causes it to darken. It loses potency in solution at a pH below 2, and is rapidly destroyed by alkali hydroxide solutions. Soluble in water and in solutions of alkali hydroxides and carbonates; slightly soluble in alcohol; practically insoluble in chloroform and in ether.

**Tetrahydrozoline Hydrochloride:** White, odorless solid. Melts at about 256°, with decomposition. Freely soluble in water and in alcohol; very slightly soluble in chloroform; practically insoluble in ether.

**Thalidomide:** White to off-white powder. Very soluble in dimethyl sulfoxide; sparingly soluble in ethanol and in water.

**Theophylline:** White, odorless, crystalline powder, having a bitter taste. Is stable in air. Freely soluble in solutions of alkali hydroxides and in ammonia; sparingly soluble in alcohol, in chloroform, and in ether; slightly soluble in water, but more soluble in hot water.

**Theophylline Sodium Glycinate:** White, crystalline powder having a slight ammoniacal odor and a bitter taste. Freely soluble in water; very slightly soluble in alcohol; practically insoluble in chloroform.

**Thiabendazole:** White to practically white, odorless or practically odorless powder. Slightly soluble in acetone and in alcohol; very slightly soluble in chloroform and in ether; practically insoluble in water.

**Thiamine Hydrochloride:** White crystals or crystalline powder, usually having a slight, characteristic odor. When exposed to air, the anhydrous product rapidly absorbs about 4% of water. Melts at about 248°, with some decomposition. Freely soluble in water; soluble in glycerin; slightly soluble in alcohol; insoluble in ether and in benzene.

**Thiamine Mononitrate:** White crystals or crystalline powder, usually having a slight, characteristic odor. Sparingly soluble in water; slightly soluble in alcohol; very slightly soluble in chloroform.

**Thimerosal:** Light cream-colored, crystalline powder, having a slight characteristic odor. Is affected by light. The pH of a solution (1 in 100) is about 6.7. Freely soluble in water; soluble in alcohol; practically insoluble in ether. *NF category:* Antimicrobial preservative.

**Thimerosal Topical Solution:** Clear liquid, having a slight characteristic odor. Is affected by light.

**Thimerosal Tincture:** Transparent, mobile liquid, having the characteristic odor of alcohol and acetone. Is affected by light.

**Thioguanine:** Pale yellow, odorless or practically odorless, crystalline powder. Freely soluble in dilute solutions of alkali hydroxides; insoluble in water, in alcohol, and in chloroform.

**Thiopental Sodium:** White to off-white, crystalline powder, or yellowish-white to pale greenish-yellow, hygroscopic powder. May have a disagreeable odor. Its solutions are alkaline to litmus. Its solutions decompose on standing, and on boiling precipitation occurs. Soluble in water and in alcohol; insoluble in benzene, in absolute ether, and in solvent hexane.

**Thiopental Sodium for Injection:** White to off-white, crystalline powder, or yellowish-white to pale greenish-yellow, hygroscopic powder. May have a disagreeable odor. Its solutions are alkaline to litmus. Its solutions decompose on standing, and on boiling precipitation occurs.

**Thioridazine:** White to slightly yellow, crystalline or micronized powder, odorless or having a faint odor. Very soluble in chloroform; freely soluble in dehydrated alcohol and in ether; practically insoluble in water.

**Thioridazine Hydrochloride:** White to slightly yellow, granular powder, having a faint odor and a very bitter taste. Freely soluble in water, in methanol, and in chloroform; insoluble in ether.

**Thiostrepton:** White to off-white, crystalline solid. Soluble in glacial acetic acid, in chloroform, in dimethylformamide, in dimethyl sulfoxide, in dioxane, and in pyridine; practically insoluble in water, in the lower alcohols, in nonpolar organic solvents, and in dilute aqueous acids or alkali.

**Thiotepa:** Fine, white, crystalline flakes, having a faint odor. Freely soluble in water, in alcohol, in chloroform, and in ether.

**Thiotepa for Injection:** White powder.

**Thiothixene:** White to tan, practically odorless crystals. Is affected by light. Very soluble in chloroform; slightly soluble in methanol and in acetone; practically insoluble in water.

**Threonine:** White, odorless crystals, having a slightly sweet taste. Freely soluble in water; insoluble in absolute alcohol, in ether, and in chloroform.

**Thymol:** Colorless, often large, crystals, or white, crystalline powder, having an aromatic, thyme-like odor and a pungent taste. Is affected by light. Its alcohol solution is neutral to litmus. Freely soluble in alcohol, in chloroform, in ether, and in olive oil; soluble in glacial acetic acid and in fixed and volatile oils; very slightly soluble in water. *NF category:* Antimicrobial preservative; flavors and fragrance; antioxidant.

**Thyroid:** Yellowish to buff-colored, amorphous powder, having a slight, characteristic, meat-like odor and a saline taste.

**Tiagabine Hydrochloride:** White to off-white powder. Freely soluble in methanol and in alcohol; soluble in isopropanol; very slightly soluble in chloroform; sparingly soluble in water; practically insoluble in *n*-heptane.

**Tiamulin:** A sticky, translucent yellowish mass, slightly hygroscopic. Very soluble in dichloromethane; freely soluble in dehydrated alcohol; practically insoluble in water.

**Ticagrelor:** White or off-white to pale pink powder. Freely soluble in methanol; soluble in ethanol; practically insoluble in water.

**Ticarcillin Disodium:** White to pale yellow powder, or white to pale yellow solid. Freely soluble in water.

**Tigecycline:** Orange powder. Freely soluble in water; soluble in 1-octanol; slightly soluble in methanol, in ethanol, and in isopropyl alcohol.

**Tiletamine Hydrochloride:** White to off-white, crystalline powder. Freely soluble in water and in 0.1 N hydrochloric acid; soluble in methanol; slightly soluble in chloroform; practically insoluble in ether.

**Tilmicosin:** White to off-white, amorphous solid. Slightly soluble in water and in *n*-hexane.

**Timolol Maleate:** White to practically white, odorless or practically odorless powder. Soluble in water, in alcohol, and in methanol; sparingly soluble in chloroform and in propylene glycol; insoluble in ether and in cyclohexane.

**Tinidazole:** Almost white or pale yellow, crystalline powder. Soluble in acetone and in methylene chloride; sparingly soluble in methanol; practically insoluble in water.

**Tiotropium Bromide:** White to yellowish-white powder or crystals. Soluble to sparingly soluble in methanol and in water.

**Titanium Dioxide:** White, odorless, tasteless powder. Its 1 in 10 suspension in water is neutral to litmus. Insoluble in water, in hydrochloric acid, in nitric acid, and in 2 N sulfuric acid. Dissolves in hydrofluoric acid and in hot sulfuric acid. Is rendered soluble by fusion with potassium bisulfate or with alkali carbonates or hydroxides. *NF category:* Coating agent.

**Tizanidine Hydrochloride:** Almost white to slightly yellow, crystalline powder. Slightly soluble in water and in methanol.

**Tobramycin:** White to off-white, hygroscopic powder. Freely soluble in water; very slightly soluble in alcohol; practically insoluble in chloroform and in ether.

**Tobramycin Sulfate Injection:** Clear, colorless solution.

**Tocopherol:** Clear, colorless to yellow, yellowish-brown, or greenish-yellow, viscous oil. Is odorless. Soluble in oils, in fats, in acetone, in alcohol, in chloroform, in ether, and in alcohol; insoluble in water. *NF category:* Antioxidant.

**Tocopherols Excipient:** Brownish-red to red, clear, viscous oil, having a mild, characteristic odor and taste. May show a slight separation of waxlike constituents in microcrystalline form. Oxidizes and darkens slowly in air and on exposure to light, particularly in alkaline media. Soluble in alcohol; insoluble in water. Miscible with acetone, with chloroform, with ether, and with vegetable oils. *NF category:* Antioxidant.

**Tolazamide:** White to off-white, crystalline powder, odorless or having a slight odor. Melts with decomposition in the approximate range of 161° to 173°. Freely soluble in chloroform; soluble in acetone; slightly soluble in alcohol; very slightly soluble in water.

**Tolazoline Hydrochloride:** White to off-white, crystalline powder. Its solutions are slightly acid to litmus. Freely soluble in water and in alcohol.

**Tolbutamide:** White, or practically white, crystalline powder. Is slightly bitter and practically odorless. Soluble in alcohol and in chloroform; practically insoluble in water.

**Tolcapone:** Yellow, fine powder or fine powder with lumps. Freely soluble in acetone and in tetrahydrofuran; soluble in methanol and in ethyl acetate; sparingly soluble in chloroform and in dichloromethane; insoluble in water and in *n*-hexane.

**Tolmetin Sodium:** Light yellow to light orange, crystalline powder. Freely soluble in water and in methanol; slightly soluble in alcohol; very slightly soluble in chloroform.

**Tolnaftate:** White to creamy white, fine powder, having a slight odor. Freely soluble in acetone and in chloroform; sparingly soluble in ether; slightly soluble in alcohol; practically insoluble in water.

**Tolterodine Tartrate:** White or almost white, crystalline powder. Sparingly soluble in water; slightly soluble in anhydrous ethanol; practically insoluble in heptane.

**Tolu Balsam:** Brown or yellowish-brown, plastic solid, transparent in thin layers and brittle when old, dried, or exposed to cold temperatures. Has a pleasant, aromatic odor resembling that of vanilla, and a mild, aromatic taste. Soluble in alcohol, in chloroform, and in ether, sometimes with slight residue or turbidity; practically insoluble in water and in solvent hexane. *NF category:* Flavors and perfumes.

**Topiramate:** White to off-white powder. Freely soluble in dichloromethane.

**Torsemide:** White to off-white, crystalline powder. Slightly soluble in 0.1 N sodium hydroxide, in 0.1 N hydrochloric acid, in alcohol, and in methanol; very slightly soluble in acetone and in chloroform; practically insoluble in water and in ether.

**Tragacanth:** Is odorless, and has an insipid, mucilaginous taste. *NF category:* Suspending and/or viscosity-increasing agent.

**Tramadol Hydrochloride:** White, crystalline powder. Freely soluble in water and in methanol; very slightly soluble in acetone.

**Trandalopril:** White or almost white powder. Freely soluble in methylene chloride; sparingly soluble in absolute alcohol; practically insoluble in water.

**Tranexamic Acid:** White, crystalline powder. Freely soluble in water and in glacial acetic acid; practically insoluble in acetone and in alcohol.

**Tranylcypromine Sulfate:** White or almost white crystalline powder. Freely soluble in water; very slightly soluble in alcohol and in ether; practically insoluble in chloroform.

**Travoprost:** Clear, colorless, viscous oil. Insoluble in water.

**Trazodone Hydrochloride:** White to off-white, crystalline powder. Sparingly soluble in chloroform and in water. Melts between 231° and 234° when the melting point determination is carried out in an evacuated capillary tube; otherwise melts with decomposition over a broad range below 230°.

**Trehalose:** White, odorless, nonhygroscopic crystalline powder. Soluble in water, solubility increases with temperature; practically insoluble in dehydrated alcohol. Trehalose is typically used in the dihydrate form. *NF category:* Bulking agent; sweetening agent; diluent; disintegrant; wet binder; vehicle.

**Tretinoin:** Yellow to light-orange, crystalline powder. Slightly soluble in alcohol, in chloroform, and in methanol; insoluble in water.

**Triacetin:** Colorless, somewhat oily liquid having a slight, fatty odor and a bitter taste. Soluble in water; slightly soluble in carbon disulfide. Miscible with alcohol, with ether, and with chloroform. *NF category:* Plasticizer; humectant; solvent.

**Triamcinolone:** White or practically white, odorless, crystalline powder. Slightly soluble in alcohol and in methanol; very slightly soluble in water, in chloroform, and in ether.

**Triamcinolone Acetonide:** White to cream-colored, crystalline powder, having not more than a slight odor. Sparingly soluble in dehydrated alcohol, in chloroform, and in methanol; practically insoluble in water.

**Triamcinolone Diacetate:** Fine, white to off-white, crystalline powder, having not more than a slight odor. Soluble in chloroform; sparingly soluble in alcohol and in methanol; slightly soluble in ether; practically insoluble in water.

**Triamcinolone Hexacetonide:** White to cream-colored powder. Soluble in chloroform; slightly soluble in methanol; practically insoluble in water.

**Triamterene:** Yellow, odorless, crystalline powder. Soluble in formic acid; sparingly soluble in methoxyethanol; very slightly soluble in acetic acid, in alcohol, and in dilute mineral acids; practically insoluble in water, in benzene, in chloroform, in ether, and in dilute alkali hydroxides.

**Triazolam:** White to off-white, practically odorless, crystalline powder. Soluble in chloroform; slightly soluble in alcohol; practically insoluble in ether and in water.

**Tributyl Citrate:** Clear, practically colorless, oily liquid. Freely soluble in alcohol, in isopropyl alcohol, in acetone, and in toluene; insoluble in water. *NF category:* Plasticizer.

**Trichlorfon:** White crystalline powder. Very soluble in methylene chloride; freely soluble in acetone, in alcohol, in benzene, in chloroform, in ether, and in water; very slightly soluble in hexane and in pentane. Decomposed by alkali. Melts at about 78° with decomposition.

**Trichlormethiazide:** White or practically white, crystalline powder. Is odorless, or has a slight characteristic odor. Melts at about 274°, with decomposition. Freely soluble in acetone; soluble in methanol; sparingly soluble in alcohol; very slightly soluble in water, in ether, and in chloroform.

**Trichloromonofluoromethane:** Clear, colorless gas, having a faint, ethereal odor. Its vapor pressure at 25° is about 796 mm of mercury (1 psig). *NF category:* Propellant.

**Triclabendazole:** White to off-white crystalline powder. Soluble in acetone; sparingly soluble in ethanol; practically insoluble in water.

**Triclocarban:** White powder. Freely soluble in ethanol, in acetone, and in polyethylene glycol; slightly soluble in acetonitrile and in propylene glycol; insoluble in water.

**Triclosan:** Fine, whitish, crystalline powder. Melts at about 57°. Soluble in methanol, in alcohol, and in acetone; slightly soluble in hexane; practically insoluble in water.

**Trientine Hydrochloride:** White to pale yellow, crystalline powder, hygroscopic. Freely soluble in water; soluble in methanol; slightly soluble in alcohol; insoluble in chloroform and in ether.

**Triethyl Citrate:** Practically colorless, oily liquid. Soluble in water. Miscible with alcohol and with ether. *NF category:* Plasticizer; solvent.

**Trifluoperazine Hydrochloride:** White to pale yellow, crystalline powder. Is practically odorless, and has a bitter taste. Melts at about 242°, with decomposition. Freely soluble in water; soluble in alcohol; sparingly soluble in chloroform; insoluble in ether and in benzene.

**Triflupromazine:** Viscous, light amber-colored, oily liquid, which crystallizes on prolonged standing into large, irregular crystals. Practically insoluble in water.

**Triflupromazine Hydrochloride:** White to pale tan, crystalline powder, having a slight, characteristic odor. Melts between 170° and 178°. Soluble in water, in alcohol, and in acetone; insoluble in ether.

**Trifluridine:** Odorless, white powder appearing under the microscope as rodlike crystals; melts at 175°, with sublimation.

**Medium-Chain Triglycerides:** Colorless or slightly yellowish, oily liquid. Practically insoluble in water. Miscible with alcohol, with methylene chloride, with hexane, and with fatty oils. The refractive index is 1.440–1.452 at 20° (see

*Refractive Index* ⟨831⟩). *NF category:* Emulsifying agent; solvent; suspending and/or viscosity-increasing agent.

**Trihexyphenidyl Hydrochloride:** White or slightly off-white, crystalline powder, having not more than a very faint odor. Melts at about 250°. Soluble in alcohol and in chloroform; slightly soluble in water.

**Trimeprazine Tartrate:** White to off-white, odorless, crystalline powder. Freely soluble in water and in chloroform; soluble in alcohol; very slightly soluble in ether and in benzene.

**Trimethobenzamide Hydrochloride:** White, crystalline powder having a slight phenolic odor. Soluble in water and in warm alcohol; insoluble in ether and in benzene.

**Trimethoprim:** White to cream-colored, odorless crystals, or crystalline powder. Soluble in benzyl alcohol; sparingly soluble in chloroform and in methanol; slightly soluble in alcohol and in acetone; very slightly soluble in water; practically insoluble in ether and in carbon tetrachloride.

**Trimethoprim Sulfate:** White to off-white, crystalline powder. Soluble in water, in alcohol, in dilute mineral acids, and in fixed alkalies.

**Trimipramine Maleate:** White to almost white crystalline powder. Slightly soluble in water and in alcohol.

**Tripelennamine Hydrochloride:** White, crystalline powder. Slowly darkens on exposure to light. Its solutions are practically neutral to litmus. Freely soluble in water, in alcohol, and in chloroform; slightly soluble in acetone; insoluble in benzene, in ether, and in ethyl acetate.

**Triprolidine Hydrochloride:** White, crystalline powder, having no more than a slight, but unpleasant, odor. Its solutions are alkaline to litmus, and it melts at about 115°. Soluble in water, in alcohol, and in chloroform; insoluble in ether.

**Trolamine:** Colorless to pale yellow, viscous, hygroscopic liquid having a slight, ammoniacal odor. Soluble in chloroform. Miscible with water and with alcohol. *NF category:* Emulsifying agent; pH modifier (acidifying agent/alkalizing agent/buffering agent).

**Tromethamine:** White, crystalline powder, having a slight, characteristic odor. Freely soluble in water.

**Tropicamide:** White or practically white, crystalline powder, odorless or having not more than a slight odor. Freely soluble in chloroform and in solutions of strong acids; slightly soluble in water.

**Trospium Chloride:** Colorless or white to slightly yellow crystalline powder. Very soluble in water; freely soluble in methanol.

**Crystallized Trypsin:** White to yellowish white, odorless, crystalline or amorphous powder.

**Tryptophan:** White to slightly yellowish-white crystals or crystalline powder, having a slightly bitter taste. Soluble in hot alcohol and in dilute hydrochloric acid.

**Tylosin:** White to buff-colored powder. Freely soluble in methanol; soluble in alcohol, in amyl acetate, in chloroform, and in dilute mineral acids; slightly soluble in water.

**Tylosin Tartrate:** Almost white or slightly yellow, hygroscopic powder. Freely soluble in water and in dichloromethane; slightly soluble in alcohol. It dissolves in dilute solutions of mineral acids.

**Tyloxapol:** Viscous, amber liquid, having a slight, aromatic odor. May exhibit a slight turbidity. Slowly but freely miscible with water. Soluble in glacial acetic acid, in benzene, in toluene, in carbon tetrachloride, in chloroform, and in carbon disulfide. *NF category:* Wetting and/or solubilizing agent.

**Tyrosine:** White, odorless, tasteless crystals or crystalline powder. Very slightly soluble in water; insoluble in alcohol and in ether.

**Ubidecarenone:** Yellow to orange, crystalline powder. Melts at about 48°. Soluble in ether; very slightly soluble in dehydrated alcohol; practically insoluble in water.

**Undecylenic Acid:** Clear, colorless to pale yellow liquid having a characteristic odor. Practically insoluble in water. Miscible with alcohol, with chloroform, with ether, with benzene, and with fixed and volatile oils.

**Urea:** Colorless to white, prismatic crystals, or white, crystalline powder, or small white pellets. Is practically odorless, but may gradually develop a slight odor of ammonia upon long standing. Its solutions are neutral to litmus. Freely soluble in water and in boiling alcohol; practically insoluble in chloroform and in ether.

**Urea C 13:** See *Urea*.

**Ursodiol:** White or almost white, crystalline powder. Freely soluble in alcohol and in glacial acetic acid; sparingly soluble in chloroform; slightly soluble in ether; practically insoluble in water.

**Valacyclovir Hydrochloride:** White to off-white powder. Soluble in water; insoluble in dichloromethane.

**Powdered Valerian Extract:** Brown, hygroscopic, powdery or easily pulverizable mass. Soluble in water to form a slightly cloudy solution; sparingly soluble in 70 percent alcohol; practically insoluble in alcohol.

**Valganciclovir Hydrochloride:** White to off-white powder. Very slightly soluble in alcohol; practically insoluble in 2-propanol, in hexane, in acetone, and in ethyl acetate.

**Valine:** White, odorless, tasteless crystals. Soluble in water; practically insoluble in ether, in alcohol, and in acetone.

**Valproic Acid:** Colorless to pale yellow, slightly viscous, clear liquid, having a characteristic odor. Refractive index: about 1.423 at 20°. Freely soluble in 1 N sodium hydroxide, in methanol, in alcohol, in acetone, in chloroform, in benzene, in ether, and in *n*-heptane; slightly soluble in water and in 0.1 N hydrochloric acid.

**Valrubicin:** Orange to orange-red, crystalline powder. Soluble in methylene chloride, in dehydrated alcohol, in methanol, and in acetone; very slightly soluble in water, in hexane, and in petroleum ether.

**Valsartan:** White or almost white, hygroscopic powder. Freely soluble in anhydrous ethanol; sparingly soluble in methylene chloride; practically insoluble in water.

**Vancomycin Hydrochloride:** White, almost white, or tan to brown, free-flowing powder, odorless, and having a bitter taste. Freely soluble in water; insoluble in ether and in chloroform.

**Vanillin:** Fine, white to slightly yellow crystals, usually needle-like, having an odor and taste suggestive of vanilla. Is affected by light. Its solutions are acid to litmus. Freely soluble in alcohol, in chloroform, in ether, and in solutions of the fixed alkali hydroxides; soluble in glycerin and in hot water; slightly soluble in water. *NF category:* Flavors and fragrance.

**Vardenafil Hydrochloride:** White or slightly brown or yellow powder. Freely soluble in anhydrous alcohol; slightly soluble in water; practically insoluble in heptane.

**Vasopressin Injection:** Clear, colorless or practically colorless liquid, having a faint, characteristic odor.

**Vecuronium Bromide:** White or creamy white crystals, or a crystalline powder. Sparingly soluble in alcohol; slightly soluble in water and in acetone.

**Hydrogenated Vegetable Oil:** Type I Hydrogenated Vegetable Oil—Fine, white powder, beads, or small flakes. Type II Hydrogenated Vegetable Oil—Plastic (semi-solid) or flakes having a softer consistency than Type I. Soluble in hot isopropyl alcohol, in hexane, and in chloroform; insoluble in water. *NF category:* Hydrogenated Vegetable Oil—Wet binder; Type I Hydrogenated Vegetable Oil—Lubricant; Type II Hydrogenated Vegetable Oil—Ointment base.

**Venlafaxine Hydrochloride:** Off-white to white crystalline powder. Soluble in methanol and in water.

**Verapamil Hydrochloride:** White or practically white, crystalline powder. Is practically odorless and has a bitter taste.

Freely soluble in chloroform; soluble in water; sparingly soluble in alcohol; practically insoluble in ether.

**Vigabatrin:** White or almost white powder. Freely soluble in water; slightly soluble in methanol; very slightly soluble in alcohol and in chloroform; practically insoluble in methylene chloride; insoluble in hexane and in toluene.

**Vinblastine Sulfate:** White or slightly yellow, odorless, amorphous or crystalline powder. Is hygroscopic. Freely soluble in water.

**Vincristine Sulfate:** White to slightly yellow, odorless, amorphous or crystalline powder. Is hygroscopic. Freely soluble in water; soluble in methanol; slightly soluble in alcohol.

**Vincristine Sulfate for Injection:** Yellowish-white solid, having the characteristic appearance of products prepared by freeze-drying.

**Vinorelbine Tartrate:** White to yellow or light brown, amorphous powder. Freely soluble in water.

**Vitamin A:** In liquid form, a light-yellow to red oil that may solidify upon refrigeration. In solid form, has the appearance of any diluent that has been added. May be practically odorless or may have a mild fishy odor, but has no rancid odor or taste. Is unstable to air and light. In liquid form, very soluble in chloroform and in ether; soluble in absolute alcohol and in vegetable oils; insoluble in water and in glycerin. In solid form, may be dispersible in water.

**Vitamin E:** Practically odorless and tasteless. The alpha tocopherols and alpha tocopheryl acetates occur as clear, yellow, or greenish yellow, viscous oils. *d*-Alpha tocopheryl acetate may solidify in the cold. Alpha tocopheryl acid succinate occurs as a white powder; the *d*-isomer melts at about 75°, and the *dl*-form melts at about 70°. The alpha tocopherols are unstable to air and light, particularly when in alkaline media. The esters are stable to air and light, but are unstable to alkali; the acid succinate is also unstable when held molten. Alpha tocopheryl acid succinate is very soluble in chloroform; soluble in alcohol, in ether, in acetone, and in vegetable oils; slightly soluble in alkaline solutions; insoluble in water. The other forms of Vitamin E are insoluble in water; soluble in alcohol; miscible with ether, with acetone, with vegetable oils, and with chloroform. *NF category:* Antioxidant; plasticizer.

**Vitamin E Preparation:** The liquid forms are clear, yellow to brownish red, viscous oils. The solid forms are white to tan-white granular powders. The liquid forms are soluble in alcohol; insoluble in water. Miscible with ether, with acetone, with vegetable oils, and with chloroform. The solid forms disperse in water to give cloudy suspensions.

**Voriconazole:** White to almost white powder. Freely soluble in acetone and in methylene chloride; very slightly soluble in water.

**Warfarin Sodium:** White, odorless, amorphous or crystalline powder, having a slightly bitter taste. Is discolored by light. Very soluble in water; freely soluble in alcohol; very slightly soluble in chloroform and in ether.

**Water for Injection:** Clear, colorless, odorless liquid. *NF category:* Solvent; pharmaceutical water.

**Bacteriostatic Water for Injection:** Clear, colorless liquid, odorless or having the odor of the antimicrobial substance. *NF category:* Vehicle (sterile); pharmaceutical water.

**Sterile Water for Inhalation:** Clear, colorless solution.

**Sterile Water for Injection:** Clear, colorless, odorless liquid. *NF category:* Solvent; pharmaceutical water.

**Sterile Water for Irrigation:** Clear, colorless, odorless liquid. *NF category:* Solvent; pharmaceutical water.

**Purified Water:** Clear, colorless, odorless liquid. *NF category:* Solvent; pharmaceutical water.

**Carnauba Wax:** Light brown to pale yellow, moderately coarse powder or flakes, possessing a characteristic bland odor, and free from rancidity. Specific gravity is about 0.99. Freely soluble in warm benzene; soluble in warm chloroform and in warm toluene; slightly soluble in boiling alcohol; insoluble in water. *NF category:* Coating agent.

**Emulsifying Wax:** Creamy white, wax-like solid, having a mild, characteristic odor. Freely soluble in ether, in chloroform, in most hydrocarbon solvents, and in aerosol propellants; soluble in alcohol; insoluble in water. *NF category:* Emulsifying agent; wetting and/or solubilizing agent; stiffening agent.

**Microcrystalline Wax:** White or cream-colored, odorless, waxy solid. Soluble in chloroform, in ether, in volatile oils, and in most warm fixed oils; sparingly soluble in dehydrated alcohol; insoluble in water. *NF category:* Coating agent; stiffening agent.

**White Wax:** Yellowish-white solid, somewhat translucent in thin layers. Has a faint, characteristic odor, and is free from rancidity. Specific gravity is about 0.95. Sparingly soluble in cold alcohol; insoluble in water. Boiling alcohol dissolves the cerotic acid and a portion of the myricin, which are constituents of White Wax. Completely soluble in chloroform, in ether, and in fixed and volatile oils. Partly soluble in cold benzene and in cold carbon disulfide; completely soluble in these liquids at about 30°. *NF category:* Stiffening agent.

**Yellow Wax:** Solid varying in color from yellow to grayish brown. Has an agreeable, honey-like odor. Is somewhat brittle when cold, and presents a dull, granular, noncrystalline fracture when broken. It becomes pliable from the heat of the hand. Specific gravity is about 0.95. Sparingly soluble in cold alcohol; insoluble in water. Boiling alcohol dissolves the cerotic acid and a portion of the myricin, that are constituents of Yellow Wax. Soluble in chloroform, in ether, in fixed oils, and in volatile oils; sparingly soluble in cold benzene and in cold carbon disulfide; soluble in these liquids at about 30°. *NF category:* Stiffening agent.

**Wheat Bran:** Light tan powder having a characteristic aroma. Practically insoluble in cold water and in alcohol. Available in a variety of particle sizes depending upon the degree of milling to which it is subjected. Color and flavor development variable, depending on the extent to which it is heat-stabilized.

**Xanthan Gum:** Cream-colored powder. Its solutions in water are neutral to litmus. Soluble in hot or cold water. *NF category:* Suspending and/or viscosity-increasing agent; film-forming agent; polymers for ophthalmic use; release-modifying agent.

**Xylazine:** Colorless to white crystals. Sparingly soluble in dilute acid, in acetone, and in chloroform; insoluble in dilute alkali.

**Xylazine Hydrochloride:** Colorless to white crystals. Sparingly soluble in dilute acid, in acetone, and in methanol; insoluble in dilute alkali.

**Xylitol:** White crystals or crystalline powder. It has a sweet taste and produces a cooling sensation in the mouth. One g dissolves in about 0.65 mL of water. Sparingly soluble in alcohol. Crystalline xylitol has a melting range between 92° and 96°. *NF category:* Coating agent; emollient; humectant; sweetening agent; diluent.

**Xylometazoline Hydrochloride:** White to off-white, odorless, crystalline powder. Melts above 300°, with decomposition. Freely soluble in alcohol; soluble in water; sparingly soluble in chloroform; practically insoluble in benzene and in ether.

**Xylose:** Colorless needles or white, crystalline powder. Is odorless, and has a slightly sweet taste. Very soluble in water; slightly soluble in alcohol.

**Yohimbine Hydrochloride:** White to yellow powder. Melts at about 295°, with decomposition. Soluble in boiling water; slightly soluble in water and in alcohol.

Official

https://nlathdocs.usp.org/

**Zaleplon:** White to off-white powder. Sparingly soluble in alcohol; slightly soluble in propylene glycol; practically insoluble in water.

**Zanamivir:** White, crystalline powder. Sparingly soluble in water; insoluble in acetone, in acetonitrile, in alcohol, and in isopropyl alcohol.

**Zein:** White to yellow powder. Soluble in aqueous alcohols, in glycols, in ethylene glycol ethyl ether, in furfuryl alcohol, in tetrahydrofurfuryl alcohol, in aqueous alkaline solutions of pH 11.5 or greater, and in acetone-water mixtures between the limits of 60% and 80% of acetone by volume; insoluble in water, in acetone, and in all anhydrous alcohols except methanol. *NF category:* Coating agent; wet binder.

**Zidovudine:** White to yellowish powder. Melts at about 124°. Exhibits polymorphism. Soluble in alcohol; sparingly soluble in water.

**Zileuton:** White to off-white powder.

**Zinc Acetate:** White crystals or granules, having a slight acetous odor and an astringent taste. Is slightly efflorescent. Freely soluble in water and in boiling alcohol; slightly soluble in alcohol. *NF category:* Emollient.

**Zinc Chloride:** White or practically white, odorless, crystalline powder, or white or practically white crystalline granules. May also be in porcelain-like masses or molded into cylinders. Is very deliquescent. A solution (1 in 10) is acid to litmus. Very soluble in water; freely soluble in alcohol and in glycerin. Its solution in water or in alcohol is usually slightly turbid, but the turbidity disappears when a small quantity of hydrochloric acid is added.

**Zinc Gluconate:** White or practically white powder or granules. Soluble in water; very slightly soluble in alcohol.

**Zinc Oxide:** Very fine, odorless, amorphous, white or yellowish white powder, free from gritty particles. It gradually absorbs carbon dioxide from air. Soluble in dilute acids; insoluble in water and in alcohol. *NF category:* Antimicrobial preservative; coating agent.

**Zinc Stearate:** Fine, white, bulky powder, free from grittiness. Has a faint, characteristic odor. Is neutral to moistened litmus paper. Insoluble in water, in alcohol, and in ether. *NF category:* Lubricant.

**Zinc Sulfate:** Colorless, transparent prisms, or small needles. May occur as a white, granular, crystalline powder. Is odorless and is efflorescent in dry air. Its solutions are acid to litmus. Very soluble in water (heptahydrate); freely soluble in water (monohydrate) and in glycerin (heptahydrate); practically insoluble in alcohol (monohydrate); insoluble in alcohol (heptahydrate).

**Zinc Undecylenate:** Fine, white powder. Practically insoluble in water and in alcohol.

**Ziprasidone Hydrochloride (anhydrous):** White to slightly pink powder. Soluble in anhydrous formic acid; insoluble in *n*-hexane.

**Ziprasidone Hydrochloride (monohydrate):** White to slightly pink powder. Slightly soluble in methanol and in methylene chloride; practically insoluble in water.

**Zolazepam Hydrochloride:** White to off-white, crystalline powder. Freely soluble in water and in 0.1 N hydrochloric acid; soluble in methanol; slightly soluble in chloroform; practically insoluble in ether.

**Zolmitriptan:** White to off-white, crystalline powder. Freely soluble to soluble in methanol; soluble in water; sparingly soluble in dichloromethane; practically insoluble in toluene.

**Zolpidem Tartrate:** White to off-white powder, hygroscopic. Sparingly soluble in methanol; slightly soluble in water; practically insoluble in methylene chloride.

**Zonisamide:** White to off-white powder. Freely soluble in dimethylformamide; soluble in methanol.

# General Information

The chapters in this section are information, and aside from excerpts given herein from Federal Acts and regulations that may be applicable, they contain no standards, tests, assays, nor other mandatory specifications, with respect to any Pharmacopeial articles. The excerpts from pertinent Federal Acts and regulations included in this section are placed here inasmuch as they are not of Pharmacopeial authorship. Revisions of the federal requirements that affect these excerpts will be included in *USP Supplements* as promptly as practical. The official requirements for Pharmacopeial articles are set forth in the *General Notices,* the individual monographs, and the *General Tests and Assays* chapters of this *Pharmacopeia.*

# GENERAL NOTICES AND REQUIREMENTS

The *General Notices and Requirements* section (the *General Notices*) presents the basic assumptions, definitions, and default conditions for the interpretation and application of the *United States Pharmacopeia* (*USP*) and the *National Formulary* (*NF*).

Requirements stated in these *General Notices* apply to all articles recognized in the *USP* and *NF* (the "compendia") and to all general chapters unless specifically stated otherwise.

# 1. TITLE AND REVISION

The full title of this joint compendium is *The Pharmacopeia of the United States of America* and the *National Formulary* (*USP–NF*). Although *USP* and *NF* are published together and share these *General Notices*, they are separate compendia. Where the terms "*USP*", "*NF*", or "*USP–NF*" are used without further qualification, they refer to the currently official standard.

New and revised content is added to the *USP–NF* periodically (see section *2.10 Official Text*). Routine revisions are published three times a year, on the following dates, corresponding with three "issues":

*USP–NF* 2021 Issue 1: Published November 1, 2020
*USP–NF* 2021 Issue 2: Published February 1, 2021
*USP–NF* 2021 Issue 3: Published June 1, 2021

"Issues" represent dates on which new and revised content is added to the *USP–NF*. The *USP–NF* is in continuous revision, with standards having official dates that correspond to their specific revision histories.

*Change to read:*

# 2. OFFICIAL STATUS AND LEGAL RECOGNITION

### 2.10. Official Text

*Official text* of the *USP* and *NF* is published online at https://online.uspnf.com.

Routine revisions are published in the *USP–NF* and become official on the date indicated, usually six months after publication.

Accelerated Revisions, published periodically in the *USP–NF*, are designed to make revisions official more quickly than through the routine process for publishing standards in the *USP–NF*. Accelerated Revisions may also be published on the *Official Text* section of USP's website (www.uspnf.com/official-text). Accelerated Revisions supersede previously published content and become official on the date indicated.

*Interim Revision Announcements* are Accelerated Revisions to *USP* and *NF* that contain revisions and their official dates.

*Revision Bulletins* are Accelerated Revisions to official text or postponements that require expedited publication. They generally are official immediately unless otherwise specified in the *Revision Bulletin*.

*Errata* are Accelerated Revisions representing corrections to items erroneously published.

Periodically, a non-official volume of associated revisions and additions to the *USP–NF* is published in print or other media. This volume is intended to serve as a historical reference document and is not considered official text.

### 2.20. Official Articles

An *official article* is an article that is recognized in *USP* or *NF*. An article is deemed to be recognized and included in a compendium when a monograph for the article is published in the compendium and an official date is generally or specifically assigned to the monograph.

The title specified in a monograph is the *official title* for such article. Other names considered to be synonyms of the *official titles* may not be used as substitutes for *official titles*. ▲For a biologic product licensed under the Public Health Service Act, the *official title* shall be the title specified in the relevant monograph plus any prefix and/or suffix designated by the FDA unless otherwise specified in the applicable monograph.▲ (USP 1-Dec-2022) For drug products that incorporate a sensor to detect that the product has been administered, the *official title* shall be the title specified in the relevant drug product monograph plus the words "with sensor".

*Official articles* include both *official substances* and *official products*. An *official substance* is a drug substance, excipient, dietary ingredient, other ingredient, or component of a finished device for which the monograph title includes no indication of the nature of the finished form.

An *official product* is a drug product, dietary supplement, compounded preparation, or finished device for which a monograph is provided.

### 2.30. Legal Recognition

The *USP* and *NF* are recognized in the laws and regulations of many countries throughout the world. Regulatory authorities may enforce the standards presented in the *USP* and *NF*, but because recognition of the *USP* and *NF* may vary by country, users should understand applicable laws and regulations. In the United States under the Federal Food, Drug, and Cosmetic Act (FDCA), both *USP* and *NF* are recognized as official compendia. A drug with a name recognized in *USP–NF* must comply with compendial identity standards or be deemed adulterated, misbranded, or both. See, e.g., FDCA § 501(b) and 502(e)(3)(b); also U.S. Food and Drug Administration (FDA) regulations, 21 CFR § 299.5(a&b). To avoid being deemed adulterated, such drugs must also comply with compendial standards for strength, quality, and purity, unless labeled to show all respects in which the drug differs. See, e.g., FDCA § 501(b) and 21 CFR § 299.5(c). In addition, to avoid being deemed misbranded, drugs recognized in *USP–NF* must also be packaged and labeled in compliance with compendial standards. See FDCA § 502(g).

A dietary supplement represented as conforming to specifications in *USP* will be deemed a misbranded food if it fails to so conform. See FDCA § 403(s)(2)(D).

Enforcement of *USP* standards is the responsibility of FDA and other government authorities in the U.S. and elsewhere. USP has no role in enforcement.

# 3. CONFORMANCE TO STANDARDS

Official

### 3.10. Applicability of Standards

Standards for an article recognized in the compendia (*USP–NF*) are expressed in the article's monograph, applicable general chapters, and *General Notices*. The identity, strength, quality, and purity of an article are determined by the official tests, procedures, and acceptance criteria, and other requirements incorporated in the monograph, in applicable general chapters, or in the *General Notices*.

In a monograph, requirements for official articles are indicated in two ways: (1) for certain monographs, after the official title, the primarily informational portions of the text appear first, followed by the text comprising requirements, the latter section of the monograph being introduced by a double arrow symbol »; and (2) for monographs more recently redesigned, requirements appear in the official title and in any text beginning with the section titled "Definition". In either format, information that appears: (1) after the title but before the double arrow symbol; (2) after the title but before the section titled "Definition"; or (3) in or after the section titled "Auxiliary Information" is provided for informational purposes. See *Preface* for information related to updates to Chemical Information.

Where conformance to any specifications represented by Chemical Information is critical to establishing identity, purity, potency, or another quality attribute of an official article, the monograph will include such specifications in the text that states requirements.

"Applicable general chapters" means general chapters numbered below 1000 or above 2000 that are made applicable to an article through reference in *General Notices*, a monograph, or another applicable general chapter numbered below 1000. Where the requirements of a monograph differ from the requirements specified in these *General Notices* or an applicable general chapter, the monograph requirements apply and supersede the requirements of the *General Notices* or applicable general chapters, whether or not the monograph explicitly states the difference.

General chapters numbered 1000 to 1999 are for informational purposes only. They contain no mandatory tests, assays, or other requirements applicable to any official article, regardless of citation in a general chapter numbered below 1000, a monograph, or these *General Notices*. General chapters numbered above 2000 apply only to articles that are intended for use as dietary ingredients and dietary supplements. General chapter citations in *NF* monographs refer to *USP* general chapters.

Early adoption of revised standards in advance of the official date is allowed by USP unless specified otherwise at the time of publication. Where revised standards for an existing article have been published as final approved "official text" (as approved in section *2.10 Official Text*) but have not yet reached the official date (6 months after publication, unless otherwise specified; see "official date", section *2.20 Official Articles*), compliance with the revised standard shall not preclude a finding or indication of conformance with

@2024 USPC

compendial standards, unless USP specifies otherwise by prohibiting early adoption in a particular standard.

The standards in the relevant monograph, general chapter(s), and *General Notices* apply at all times in the life of the article from production to expiration. It is also noted that the manufacturer's specifications, and manufacturing practices (e.g., Quality by Design, Process Analytical Technology, and Real Time Release Testing initiatives), generally are followed to ensure that the article will comply with compendial standards until its expiration date, when stored as directed. Every compendial article in commerce shall be so constituted that when examined in accordance with these assays and test procedures, it meets all applicable pharmacopeial requirements (*General Notices*, monographs, and general chapters). Thus, any official article is expected to meet the compendial standards if tested, and any official article actually tested as directed in the relevant monograph must meet such standards to demonstrate compliance.

Some tests, such as those for *Dissolution* and *Uniformity of Dosage Units*, require multiple dosage units in conjunction with a decision scheme. These tests, albeit using a number of dosage units, are in fact one determination. These procedures should not be confused with statistical sampling plans. The similarity to statistical procedures may seem to suggest an intent to make inference to some larger group of units, but in all cases, statements about whether the compendial standard is met apply only to the units tested. Repeats, replicates, statistical rejection of outliers, or extrapolations of results to larger populations, as well as the necessity and appropriate frequency of batch testing, are neither specified nor proscribed by the compendia; such decisions are based on the objectives of the testing. Frequency of testing and sampling are left to the preferences or direction of those performing compliance testing, and other users of *USP–NF*, including manufacturers, buyers, or regulatory authorities.

Official products are prepared according to recognized principles of good manufacturing practice and from ingredients that meet *USP* or *NF* standards, where standards for such ingredients exist (for dietary supplements, see section *3.10.20 Applicability of Standards to Medical Devices, Dietary Supplements, and Their Components and Ingredients*).

Official substances are prepared according to recognized principles of good manufacturing practice and from ingredients complying with specifications designed to ensure that the resultant substances meet the requirements of the compendial monographs.

**3.10.10. Applicability of Standards to Drug Products, Drug Substances, and Excipients**

The applicable *USP* or *NF* standard applies to any article marketed in the United States that (1) is recognized in the compendium and (2) is intended or labeled for use as a drug or as an ingredient in a drug. Such articles (drug products, drug substances, and excipients) include both human drugs (whether dispensed by prescription, "over the counter", or otherwise), as well as animal drugs. The applicable standard applies to such articles whether or not the added designation "USP" or "NF" is used. The standards apply equally to articles bearing the official titles or names derived by transposition of the definitive words of official titles or transposition in the order of the names of two or more drug substances in official titles, or where there is use of synonyms with the intent or effect of suggesting a significant degree of identity with the official title or name.

**3.10.20. Applicability of Standards to Medical Devices, Dietary Supplements, and Their Components and Ingredients**

An article recognized in *USP* or *NF* shall comply with the compendial standards if the article is a medical device, component intended for a medical device, dietary supplement, dietary ingredient, or other ingredient that is intended for incorporation into a dietary supplement, and is labeled as conforming to the *USP* or *NF*.

Generally, dietary supplements are prepared from ingredients that meet *USP*, *NF*, or *Food Chemicals Codex* standards. Where such standards do not exist, substances may be used in dietary supplements if they have been shown to be of acceptable food grade quality using other suitable procedures.

**3.10.30. Applicability of Standards to the Practice of Compounding**

*USP* compounding practice standards, *Pharmaceutical Compounding—Nonsterile Preparations* ⟨795⟩ and *Pharmaceutical Compounding—Sterile Preparations* ⟨797⟩, as appropriate, apply to compounding practice or activity regardless of whether a monograph exists for the compounded preparation or these chapters are referenced in such a monograph. In the United States, ⟨795⟩ and ⟨797⟩ are not applicable to drugs compounded by entities registered with FDA as outsourcing facilities as defined by FDCA § 503B, because such facilities are required to comply with FDA's current good manufacturing practice requirements. Compounded preparations, including drug products compounded by outsourcing facilities, may also be subject to applicable monographs; see section *2.20 Official Articles* and section *4.10 Monographs*.

**3.10.40. Applicability of Global Health Monographs**

Global Health Monographs (GHM) do not apply to products marketed in the United States. Monographs in this section of the *USP–NF* are not considered "applicable" *USP–NF* monographs for use in pharmacy compounding in the United States under the Federal Food, Drug, and Cosmetic Act. GHMs are provided for possible use outside of the United States, at the discretion of individual government authorities.

Applicability of a GHM, in whole or in part, along with the applicability of associated *General Notices* and general chapter requirements, in whole or in part, is at the discretion of individual government authorities.

Where a product purports to comply with the requirements of an official GHM, it is recommended that the product label or labeling clearly specify conformance to a GHM, e.g., "USP-GHM" or "USP–GH". The designations, "USP–NF", "USP", and "NF" should be used only to indicate conformance to USP or NF monographs outside of GHMs (see section *3.20 Indicating Conformance*).

The designation "USP–GHM" or "USP–GH" on the label may not and does not constitute an endorsement by USP and does not represent assurance by USP that the article is known to comply with the relevant standards. USP may seek legal redress if an article purports to be or is represented as an official GHM article and such claim is determined by USP not to be made in good faith.

Enforcement of GHM requirements is the responsibility of government authorities outside of the U.S. USP has no role in enforcement.

## 3.20. Indicating Conformance

A drug product, drug substance, or excipient may use the designation "USP" or "NF" in conjunction with its official title or elsewhere on the label only when (1) a monograph is provided in the specified compendium and (2) the article complies with the identity prescribed in the specified compendium.

When a drug product, drug substance, compounded preparation, or excipient differs from the relevant *USP* or *NF* standard of strength, quality, or purity, as determined by the application of the tests, procedures, and acceptance criteria set forth in the relevant compendium, its difference shall be plainly stated on its label.

Official

https://nhathuocngocanh.com/

When a drug product, drug substance, compounded preparation, or excipient fails to comply with the identity prescribed in *USP* or *NF* or contains an added substance that interferes with the prescribed tests and procedures, the article shall be designated by a name that is clearly distinguishing and differentiating from any name recognized in *USP* or *NF*.

A medical device, dietary supplement, or ingredient or component of a medical device or dietary supplement may use the designation "USP" or "NF" in conjunction with its official title or elsewhere on the label only when (1) a monograph is provided in the specified compendium and (2) the article complies with the monograph standards and other applicable standards in that compendium.

The designation "USP" or "NF" on the label may not and does not constitute an endorsement by USP and does not represent assurance by USP that the article is known to comply with the relevant standards. USP may seek legal redress if an article purports to be or is represented as an official article in one of USP's compendia and such claim is determined by USP not to be made in good faith.

The designation "USP–NF" may be used on the label of an article provided that the label also bears a statement such as "Meets *NF* standards as published by USP", indicating the particular compendium to which the article purports to apply.

When the letters "USP", "NF", or "USP–NF" are used on the label of an article to indicate compliance with compendial standards, the letters shall appear in conjunction with the official title of the article. The letters are not to be enclosed in any symbol such as a circle, square, etc., and shall appear in capital letters.

If a dietary supplement does not comply with all applicable compendial requirements but contains one or more dietary ingredients or other ingredients that are recognized in *USP* or *NF*, the individual ingredient(s) may be designated as complying with *USP* or *NF* standards or being of *USP* or *NF* quality provided that the designation is limited to the individual ingredient(s) and does not suggest that the dietary supplement complies with *USP* standards.

# 4. MONOGRAPHS AND GENERAL CHAPTERS

Official

## 4.10. Monographs

Monographs set forth the article's name, definition, specification, and other requirements related to packaging, storage, and labeling. The specification consists of tests, procedures, and acceptance criteria that help ensure the identity, strength, quality, and purity of the article. For general requirements relating to specific monograph sections, see section *5. Monograph Components*.

Because monographs may not provide standards for all relevant characteristics, some official substances may conform to the *USP* or *NF* standard but differ with regard to nonstandardized properties that are relevant to their use in specific preparations. To assure substitutability in such instances, users may wish to ascertain functional equivalence or determine such characteristics before use.

### 4.10.10. Applicability of Test Procedures

A single monograph may include more than one test, procedure, and/or acceptance criterion for the same attribute. Unless otherwise specified in the monograph, all tests are requirements. In some cases, monograph instructions allow the selection of tests that reflect attributes of different manufacturers' articles, such as different polymorphic forms, impurities, hydrates, and dissolution. Monograph instructions indicate the tests, procedures, and/or acceptance criteria to be used and the required labeling.

The order in which the tests are listed in the monograph is based on the order in which they are approved by the relevant Expert Committee for inclusion in the monograph. Test 1 is not necessarily the test for the innovator or for the reference product. Depending on monograph instructions, a labeling statement is not typically required if Test 1 is used.

### 4.10.20. Acceptance Criteria

The acceptance criteria allow for analytical error, for unavoidable variations in manufacturing and compounding, and for deterioration to an extent considered acceptable under practical conditions. The existence of compendial acceptance criteria does not constitute a basis for a claim that an official substance that more nearly approaches 100% purity "exceeds" compendial quality. Similarly, the fact that an article has been prepared to tighter criteria than those specified in the monograph does not constitute a basis for a claim that the article "exceeds" the compendial requirements.

An official product shall be formulated with the intent to provide 100% of the quantity of each ingredient declared on the label. Where the minimum amount of a substance present in a dietary supplement is required by law to be higher than the lower acceptance criterion allowed for in the monograph, the upper acceptance criterion contained in the monograph may be increased by a corresponding amount.

The acceptance criteria specified in individual monographs and in the general chapters for compounded preparations are based on such attributes of quality as might be expected to characterize an article compounded from suitable bulk drug substances and ingredients, using the procedures provided or recognized principles of good compounding practice, as described in these compendia.

## 4.20. General Chapters

Each general chapter is assigned a number that appears in angle brackets adjacent to the chapter name (e.g., *Chromatography* ⟨621⟩). General chapters may contain the following:

- Descriptions of tests and procedures for application through individual monographs,
- Descriptions and specifications of conditions and practices for pharmaceutical compounding,
- General information for the interpretation of the compendial requirements,

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:34:47 AM(EST)
Printed by: USP NF

DOI: https://doi.org/10.31003/USPNF_M99989_09_01
@2024 USPC

- Descriptions of general pharmaceutical storage, dispensing, and packaging practices, or
- General guidance to manufacturers of official substances or official products.

When a general chapter is referenced in a monograph, acceptance criteria may be presented after a colon.

Some chapters may serve as introductory overviews of a test or of analytical techniques. They may reference other general chapters that contain techniques, details of the procedures, and, at times, acceptance criteria.

# 5. MONOGRAPH COMPONENTS

Official

### 5.10. Molecular Formula

The use of the molecular formula for the official substance(s) named in defining the required strength of a compendial article is intended to designate the chemical entity or entities, as given in the complete chemical name of the article, having absolute (100%) purity.

### 5.20. Added Substances

Added substances are presumed to be unsuitable for inclusion in an official article and therefore prohibited, if their presence impairs the bioavailability, therapeutic efficacy, or safety of the official article; or they interfere with the assays and tests prescribed for determining compliance with the compendial standards (see section *3.20 Indicating Conformance*).

The air in a container of an official article may, where appropriate, be evacuated or be replaced by carbon dioxide, helium, argon, or nitrogen, or by a mixture of these gases. The use of such gas need not be declared in the labeling.

**5.20.10. Added Substances in Official Substances**

Official substances may contain only the specific added substances that are permitted by the individual monograph. Such added substances shall not exceed the quantity required for providing their intended effect. Where such addition is permitted, the label shall indicate the name(s) and amount(s) of any added substance(s).

**5.20.20. Added Substances (Excipients and Ingredients) in Official Products**

Suitable substances and excipients such as antimicrobial agents, pharmaceutical bases, carriers, coatings, flavors, preservatives, stabilizers, and vehicles may be added to an official product to enhance its stability, usefulness, or elegance, or to facilitate its preparation, unless otherwise specified in the individual monograph.

Added substances and excipients employed solely to impart color may be incorporated into official products other than those intended for parenteral or ophthalmic use, in accordance with the regulations pertaining to the use of colors issued by the FDA, provided such added substances or excipients are otherwise appropriate in all respects. (See also *Injections and Implanted Drugs Products* ⟨1⟩*, Product Quality Tests Common to Parenteral Dosage Forms, Specific Tests, Vehicles and added substances, Added substances*.)

The proportions of the substances constituting the base in ointment and suppository products and preparations may be varied to maintain a suitable consistency under different climatic conditions, provided that the concentrations of drug substances are not varied and provided that the bioavailability, therapeutic efficacy, and safety of the preparation are not impaired.

***5.20.20.1. In Compounded Preparations***

Compounded preparations for which a complete composition is given shall contain only the ingredients named in the formulas unless specifically exempted herein or in the individual monograph. Deviation from the specified processes or methods of compounding, although not from the ingredients or proportions thereof, may occur provided that the finished preparation conforms to the relevant standards and to preparations produced by following the specified process.

Where a monograph for a compounded preparation calls for an ingredient in an amount expressed on the dried basis, the ingredient need not be dried before use if due allowance is made for the water or other volatile substances present in the quantity taken.

Specially denatured alcohol formulas are available for use in accordance with federal statutes and regulations of the Internal Revenue Service. A suitable formula of specially denatured alcohol may be substituted for Alcohol in the manufacture of official preparations intended for internal or topical use, provided that the denaturant is volatile and does not remain in the finished product. A preparation that is intended for topical application to the skin may contain specially denatured alcohol, provided that the denaturant is either a usual ingredient in the preparation or a permissible added substance; in either case the denaturant shall be identified on the label of the topical preparation. Where a process is given in the individual monograph, any preparation compounded using denatured alcohol shall be identical to that prepared by the monograph process.

***5.20.20.2. In Dietary Supplements***

Additional ingredients may be added to dietary supplement products provided that the additional ingredients (1) comply with applicable regulatory requirements, and (2) do not interfere with the assays and tests prescribed for determining compliance with compendial standards.

### 5.30. Description and Solubility

Only where a quantitative solubility test is given in a monograph and is designated as such is it a test for purity.

A monograph may include information regarding the article's description. Information about an article's "description and solubility" also is provided in the reference table *Description and Relative Solubility of USP and NF Articles*. The reference table merely denotes the properties of articles

https://pharmacopeia.com/
Printed on: Fri Jan 05 2024 06:34:47 AM(EST)
Printed by: USP NF
Do Not Distribute
Status: Currently Official on 05-Jan-2024
Official Date: Official as of 01-Dec-2022
DOI Ref: p2ufa
DocId: GUID-6E790F63-0496-4C20-AF21-E7C283E3343E_9_en-US
Document Type: FRONT MATTER
DOI: https://doi.org/10.31003/USPNF_M99989_09_01
@2024 USPC

that comply with monograph standards. The reference table is intended primarily for those who use, prepare, and dispense drugs and/or related articles. Although the information provided in monographs and the information in the reference table may indirectly assist in the preliminary evaluation of an article, it is not intended to serve as a standard or test for purity.

The approximate solubility of a compendial substance is indicated by one of the following descriptive terms:

| Descriptive Term | Parts of Solvent Required for 1 Part of Solute |
|---|---|
| Very soluble | Less than 1 |
| Freely soluble | From 1 to 10 |
| Soluble | From 10 to 30 |
| Sparingly soluble | From 30 to 100 |
| Slightly soluble | From 100 to 1,000 |
| Very slightly soluble | From 1,000 to 10,000 |
| Practically insoluble, or Insoluble | Greater than or equal to 10,000 |

## 5.40. Identification

A compendial test titled *Identification* is provided as an aid in verifying the identity of articles as they are purported to be, e.g., those taken from labeled containers, and to establish whether it is the article named in *USP–NF*. The *Identification* test for a particular article may consist of one or more procedures. When a compendial *Identification* test is undertaken, all requirements of all specified procedures in the test must be met to satisfy the requirements of the test. Failure of an article to meet all the requirements of a prescribed *Identification* test (i.e., failure to meet the requirements of all of the specified procedures that are components of that test) indicates that the article is mislabeled and/or adulterated.

## 5.50. Assay

Assay tests for compounded preparations are not intended for evaluating a compounded preparation before dispensing, but instead are intended to serve as the official test in the event of a question or dispute regarding the preparation's conformance to official standards.

### 5.50.10. Units of Potency (Biological)

For substances that cannot be completely characterized by chemical or physical means or that need confirmation of functionality or tertiary structure, it may be necessary to express quantities of biological activity in units of biological potency, each defined by an authoritative, designated reference standard. In cases where international reference materials have been discontinued, international units of potency may be defined in terms of molecular mass, such as in the cases of vitamins A, D, and E.

Where available, World Health Organization (WHO) international biological standards define the International Units (IU). *USP* monographs refer to the units assigned by USP Reference Standards either directly as International Units (IU) or as "USP Units". For some biological products, units of potency are value assigned against a corresponding U.S. Standard established by FDA, whether or not International Units or USP Units have been defined (see *Biologics* ⟨1041⟩). Note that product-related labeling, e.g., on containers, need not use the full phrase "USP [product name] Units" that appears in many *USP* monograph labeling sections. The term "USP Units" can be used on product labeling consistent with USP compendial requirements, provided it is clear from the context that the potency is stated in terms of USP [product name] Units. In such circumstances it should be clear that "USP Units" and "USP [product name] Units" share the same meaning.

## 5.60. Impurities and Foreign Substances

Tests for the presence of impurities and foreign substances are provided to limit such substances to amounts that are unobjectionable under conditions in which the article is customarily employed (see also *Impurities in Drug Substances and Drug Products* ⟨1086⟩).

Nonmonograph tests and acceptance criteria suitable for detecting and controlling impurities that may result from a change in the processing methods or that may be introduced from external sources should be employed in addition to the tests provided in the individual monograph, where the presence of the impurity is inconsistent with applicable good manufacturing practices or good pharmaceutical practices.

### 5.60.10. Other Impurities in *USP* and *NF* Articles

If a *USP* or *NF* monograph includes an assay or organic impurity test based on chromatography, other than a test for residual solvents, and that monograph procedure does not detect an impurity present in the substance, the amount and identity of the impurity, where both are known, shall be stated in the labeling (certificate of analysis) of the official substance, under the heading *Other Impurity(ies)*.

The presence of any unlabeled other impurity in an official substance is a variance from the standard if the content is 0.1% or greater. The sum of all *Other Impurities* combined with the monograph-detected impurities may not exceed 2.0% (see *Ordinary Impurities* ⟨466⟩), unless otherwise stated in the monograph.

The following categories of drug substances are excluded from *Other Impurities* requirements:

- Fermentation products and semi-synthetics derived therefrom,
- Radiopharmaceuticals,
- Biologics,
- Biotechnology-derived products,
- Peptides,
- Herbals, and
- Crude products of animal or plant origin.

Any substance known to be toxic shall not be listed under *Other Impurities*.

### 5.60.20. Residual Solvents in *USP* and *NF* Articles

All *USP* and *NF* articles are subject to relevant control of residual solvents, even when no test is specified in the individual monograph. If solvents are used during production, they must be of suitable quality. In addition, the toxicity and residual level of each solvent shall be taken into consideration, and the solvents limited according to the principles defined and the requirements specified in *Residual Solvents* ⟨467⟩, using the general methods presented therein or other suitable methods.

### 5.60.30. Elemental Impurities in USP Drug Products and Dietary Supplements

Elemental impurities in official drug products are controlled according to the principles defined and requirements specified in *Elemental Impurities—Limits* ⟨232⟩. Elemental contaminants in official dietary supplements are controlled according to the principles defined and requirements specified in *Elemental Contaminants in Dietary Supplements* ⟨2232⟩.

## 5.70. Performance Tests

Where content uniformity determinations have been made using the same analytical methodology specified in the *Assay*, with appropriate allowances made for differences in sample

Official

https://nhathuoc.org.vn/

preparation, the average of all of the individual content uniformity determinations may be used as the *Assay* value.

### 5.80. USP Reference Standards

USP Reference Standards are authentic specimens that have been approved as suitable for use in *USP* or *NF* tests and assays (see *USP Reference Standards* ⟨11⟩). Where *USP* or *NF* tests or assays call for the use of a USP Reference Standard, only those results obtained using the specified USP Reference Standard are conclusive. Where a procedure calls for the use of a compendial article rather than for a USP Reference Standard as a material standard of reference, a substance meeting all of the compendial monograph requirements for that article shall be used. If any new *USP* or *NF* standard requires the use of a new USP Reference Standard that is not yet available, that portion of the standard containing the requirement shall not be official until the specified USP reference material is available.

Announcements of the availability of new USP Reference Standards and announcements of tests or procedures that are held in abeyance pending availability of required USP Reference Standards are also available on the "Official Text" tab of USP's website (www.uspnf.com). Unless otherwise directed in the procedure in the individual monograph or in a general chapter, USP Reference Standards are to be used in accordance with the instructions on the label of the Reference Standard.

# 6. TESTING PRACTICES AND PROCEDURES

Official

### 6.10. Safe Laboratory Practices

In performing compendial procedures, safe laboratory practices shall be followed, including precautionary measures, protective equipment, and work practices consistent with the chemicals and procedures used. Before undertaking any procedure described in the compendia, the analyst should be aware of the hazards associated with the chemicals and the techniques and means of protecting against them. These compendia are not designed to describe such hazards or protective measures.

### 6.20. Automated Procedures

Automated and manual procedures employing the same basic chemistry are considered equivalent provided the automated system is properly qualified as being suitable to execute the compendial manual method and the analytical procedure is verified under the new equipment conditions.

### 6.30. Alternative and Harmonized Methods and Procedures

An alternative method or procedure is defined as any method or procedure other than the compendial method or procedure for the article in question. The alternative method or procedure must be fully validated (see *Validation of Compendial Procedures* ⟨1225⟩) and must produce comparable results to the compendial method or procedure within allowable limits established on a case-by-case basis. Alternative methods or procedures can be developed for any one of a number of reasons not limited to simplification of sample preparation, enhanced precision and accuracy, improved (shortened) run time, or being better suited to automation than the compendial method or procedure. Only those results obtained by the methods and procedures given in the compendia are conclusive.

For evaluation as a potential replacement or addition to the standard, alternative methods and procedures should be submitted to USP (see section *4.10 Monographs*).

Certain general chapters contain a statement that the text in question is harmonized with the corresponding text of the *European Pharmacopoeia* and/or the *Japanese Pharmacopoeia* and that these texts are interchangeable. Therefore, if a substance or preparation is found to comply with a requirement using an interchangeable method or procedure from one of these pharmacopeias, it should comply with the requirements of the *USP–NF*. When a difference appears, or in the event of dispute, only the result obtained by the method and/or procedure given in the *USP–NF* is conclusive.

### 6.40. Dried, Anhydrous, Ignited, or Solvent-Free Basis

All calculations in the compendia assume an "as-is" basis unless otherwise specified.

Test procedures may be performed on the undried or unignited substance and the results calculated on the dried, anhydrous, or ignited basis, provided a test for *Loss on Drying*, or *Water Determination*, or *Loss on Ignition*, respectively, is given in the monograph. Where the presence of moisture or other volatile material may interfere with the procedure, previous drying of the substance is specified in the individual monograph and is obligatory.

The term "solvent-free" signifies that the calculation shall be corrected for the presence of known solvents as determined using the methods described in ⟨467⟩ unless a test for limit of organic solvents is provided in the monograph.

The term "previously dried" without qualification signifies that the substance shall be dried as directed under *Loss on Drying* ⟨731⟩ or *Water Determination* ⟨921⟩ (gravimetric determination).

Where drying in vacuum over a desiccant is directed, a vacuum desiccator, a vacuum drying pistol, or other suitable vacuum drying apparatus shall be used.

#### 6.40.10. Ignite to Constant Weight

"Ignite to constant weight" means that ignition shall be continued at 800 ± 25°, unless otherwise indicated, until two consecutive weighings, the second of which is taken after an additional period appropriate to the nature and quantity of the residue, do not differ by more than 0.50 mg per g of substance taken.

#### 6.40.20. Dried to Constant Weight

"Dried to constant weight" means that drying shall be continued until two consecutive weighings, the second of which is taken after an additional drying period appropriate to

https://pharmacopeia.cn/

Document Type: FRONT MATTER
DOI: https://doi.org/10.31003/USPNF_M99989_09_01
@2024 USPC

the nature and quantity of the residue, do not differ by more than 0.50 mg per g of substance taken.

## 6.50. Preparation of Solutions

### 6.50.10. Filtration

Where a procedure gives direction to "filter" without further qualification, the liquid shall be passed through suitable filter paper or equivalent device until the filtrate is clear. Due to the possibility of filter effects, the initial volumes of a filtrate may be discarded.

### 6.50.20. Solutions

Unless otherwise specified, all solutions shall be prepared with Purified Water. Solutions for quantitative measures shall be prepared using accurately weighed or accurately measured analytes (see section *8.20 About*).

An expression such as "(1 in 10)" means that 1 part *by volume* of a liquid shall be diluted with, or 1 part *by weight* of a solid shall be dissolved in, a sufficient quantity of the diluent or solvent to make the volume of the finished solution 10 parts *by volume*. For example, a 1 in 10 solution is prepared by diluting 1 mL of a liquid or dissolving 1 g of a solid in sufficient solvent to make 10 mL of the solution. An expression such as "(20:5:2)" means that the respective numbers of parts, by volume, of the designated liquids shall be mixed, unless otherwise indicated.

#### *6.50.20.1. Adjustments to Solutions*

When a specified concentration is called for in a procedure, a solution of other normality or molarity may be used, provided that allowance is made for the difference in concentration and that the change does not increase the error of measurement.

Proportionately larger or smaller quantities than the specified weights and volumes of assay or test substances and Reference Standards may be taken, provided the measurement is made with at least equivalent accuracy.

Unless otherwise indicated, analyte concentrations shall be prepared to within ten percent (10%) of the indicated value. In the case in which a procedure is adapted to the working range of an instrument, solution concentrations may differ from the indicated value by more than ten percent (10%), with appropriate changes in associated calculations. Any changes shall fall within the validated range of the instrument.

When adjustment of pH is indicated with either an acid or base and the concentration is not indicated, appropriate concentrations of that acid or base may be used.

#### *6.50.20.2. Test Solutions*

Information on Test Solutions (TS) is provided in the *Test Solutions* portion of the *Reagents, Indicators, and Solutions* section of the *USP–NF*. Use of an alternative Test Solution or a change in the Test Solution used may require validation.

#### *6.50.20.3. Indicator Solutions*

Where a procedure specifies the use of an indicator TS, approximately 0.2 mL, or 3 drops, of the solution shall be added unless otherwise directed.

## 6.60. Units Necessary to Complete a Test

Unless otherwise specified, a sufficient number of units to ensure a suitable analytical result shall be taken.

### 6.60.10. Tablets

Where the procedure of a Tablet monograph directs to weigh and finely powder not fewer than a given number of Tablets, a counted number of Tablets shall be weighed and reduced to a powder. The portion of the powdered Tablets taken shall be representative of the whole Tablets and shall, in turn, be weighed accurately.

### 6.60.20. Capsules

Where the procedure of a Capsule monograph gives direction to remove, as completely as possible, the contents of not fewer than a given number of the Capsules, a counted number of Capsules shall be carefully opened and the contents quantitatively removed, combined, mixed, and weighed accurately. The portion of mixed Capsules contents taken shall be representative of the contents of the Capsules and shall, in turn, be weighed accurately.

## 6.70. Reagents

The proper conduct of the compendial procedures and the reliability of the results depend, in part, upon the quality of the reagents used in the performance of the procedures. Unless otherwise specified, reagents conforming to the specifications set forth in the current edition of *Reagent Chemicals* published by the American Chemical Society (ACS) shall be used. Where such ACS reagent specifications are not available or where the required purity differs, compendial specifications for reagents of acceptable quality are provided (see the *Reagents, Indicators, and Solutions* section of the *USP–NF*). Reagents not covered by any of these specifications should be of a grade suitable to the proper performance of the method of assay or test involved.

Listing of these reagents, including the indicators and solutions employed as reagents, in no way implies that they have therapeutic utility; furthermore, any reference to *USP* or *NF* in their labeling shall include also the term "reagent" or "reagent grade". USP may supply reagents if they otherwise may not be generally commercially available.

## 6.80. Equipment

Unless otherwise specified, a specification for a definite size or type of container or apparatus in a procedure is given solely as a recommendation. Other dimensions or types may be used if they are suitable for the intended use.

### 6.80.10. Apparatus for Measurement

Where volumetric flasks or other exact measuring, weighing, or sorting devices are specified, this or other equipment of at least equivalent accuracy shall be employed.

#### *6.80.10.1. Pipet/Pipette*

Where a pipet/pipette is specified, a suitable buret may be substituted. Where a "to contain" pipet/pipette is specified, a suitable volumetric flask may be substituted.

#### *6.80.10.2. Light Protection*

Where low-actinic or light-resistant containers are specified, either containers specially treated to protect contents from light or clear containers that have been rendered opaque by application of a suitable coating or wrapping may be used.

### 6.80.20. Instrumental Apparatus

An instrument may be substituted for the specified instrument if the substitute uses the same fundamental principles of operation and is of equivalent or greater sensitivity and accuracy. These characteristics shall be qualified as appropriate. Where a particular brand or source of a material, instrument, or piece of equipment, or the name and address of a manufacturer or distributor, is mentioned (ordinarily in a footnote), this identification is furnished solely for informational purposes as a matter of convenience, without implication of approval, endorsement, or certification.

#### *6.80.20.1. Chromatographic Tubes and Columns*

The term "diameter" refers to internal diameter (ID).

#### *6.80.20.2. Tubing*

The term "diameter" refers to outside diameter (OD).

@2024 USPC

***6.80.20.3. Steam Bath***

Where use of a steam bath is directed, use actively flowing steam or another regulated heat source controlled at an equivalent temperature.

***6.80.20.4. Water Bath***

A water bath requires vigorously boiling water unless otherwise specified.

**6.80.30. Temperature Reading Devices**

Temperature reading devices suitable for pharmacopeial tests conform to specifications that are traceable to a National Institute of Standards and Technology (NIST) standard or equivalent. Temperature reading devices may be of the liquid-in-glass type or an analog or digital temperature indicator type, such as a resistance temperature device, thermistor, or thermocouple. Standardization of thermometers is performed on an established testing frequency with a temperature standard traceable to NIST. For example, refer to the current issue of American Society of Testing and Materials (ASTM) standards E1 for liquid-in-glass thermometers.

# 7. TEST RESULTS

## 7.10. Interpretation of Requirements

Analytical results observed in the laboratory (or calculated from experimental measurements) are compared with stated acceptance criteria to determine whether the article conforms to compendial requirements.

The reportable value, which often is a summary value for several individual determinations, is compared with the acceptance criteria. The reportable value is the end result of a completed measurement procedure, as documented.

Where acceptance criteria are expressed numerically herein through specification of an upper and/or lower limit, permitted values include the specified values themselves, but no values outside the limit(s). Acceptance criteria are considered significant to the last digit shown.

**7.10.5. Nominal Concentrations in Equations**

Where a "nominal concentration" is specified, calculate the concentration based on the label claim. In assay procedures, water correction is typically stated in the Definition and on the label of the USP Reference Standard. For other procedures, correction for assayed content, potency, or both is made prior to using the concentration in the equation provided in the monograph.

**7.10.10. Equivalence Statements in Titrimetric Procedures**

The directions for titrimetric procedures conclude with a statement of the weight of the analyte that is equivalent to each mL of the standardized titrant. In such an equivalence statement, the number of significant figures in the concentration of the titrant should be understood to correspond to the number of significant figures in the weight of the analyte. Corrections to calculations based on the blank determination are to be made for all titrimetric assays where appropriate (see *Titrimetry* ⟨541⟩).

## 7.20. Rounding Rules

The observed or calculated values shall be rounded off to the number of decimal places that is in agreement with the limit expression. Numbers should not be rounded until the final calculations for the reportable value have been completed. Intermediate calculations (e.g., slope for linearity) may be rounded for reporting purposes, but the original (not rounded) value should be used for any additional required calculations. Acceptance criteria are fixed numbers and are not rounded.

When rounding is required, consider only one digit in the decimal place to the right of the last place in the limit expression. If this digit is smaller than 5, it is eliminated and the preceding digit is unchanged. If this digit is equal to or greater than 5, it is eliminated and the preceding digit is increased by 1.

**Illustration of Rounding Numerical Values for Comparison with Requirements**

| Compendial Requirement | Unrounded Value | Rounded Result | Conforms |
|---|---|---|---|
| Assay limit ≥98.0% | 97.96% | 98.0% | Yes |
| | 97.92% | 97.9% | No |
| | 97.95% | 98.0% | Yes |
| Assay limit ≤101.5% | 101.55% | 101.6% | No |
| | 101.46% | 101.5% | Yes |
| | 101.45% | 101.5% | Yes |
| Limit test ≤0.02% | 0.025% | 0.03% | No |
| | 0.015% | 0.02% | Yes |

# 8. TERMS AND DEFINITIONS

### 8.10. Abbreviations

- RS refers to a USP Reference Standard.
- CS refers to a Colorimetric Solution.
- TS refers to a Test Solution.
- VS refers to a Volumetric Solution that is standardized in accordance with directions given in the individual monograph or in the *Reagents, Indicators, and Solutions* section of *USP–NF*.

### 8.20. About

"About" indicates a quantity within 10%.

If the measurement is stated to be "accurately measured" or "accurately weighed", follow the statements in *Volumetric Apparatus* ⟨31⟩ and *Balances* ⟨41⟩, respectively.

### 8.30. Alcohol Content

Percentages of alcohol, such as those under the heading *Alcohol Content*, refer to percentage by volume of $C_2H_5OH$ at 15.56°. Where a formula, test, or assay calls for alcohol, ethyl alcohol, or ethanol, the *USP* monograph article Alcohol shall be used. Where reference is made to "$C_2H_5OH$", absolute (100%) ethanol is intended. Where a procedure calls for dehydrated alcohol, alcohol absolute, or anhydrous alcohol, the *USP* monograph article Dehydrated Alcohol shall be used.

### 8.40. Atomic Weights

Atomic weights used in computing molecular weights and the factors in the assays and elsewhere are those established by the IUPAC Commission on Isotopic Abundances and Atomic Weights.

### 8.50. Blank Determinations

Where it is directed that "any necessary correction" be made by a blank determination, the determination shall be conducted using the same quantities of the same reagents treated in the same manner as the solution or mixture containing the portion of the substance under assay or test, but with the substance itself omitted.

### 8.60. Concomitantly

"Concomitantly" denotes that the determinations or measurements are to be performed in immediate succession.

### 8.70. Desiccator

The instruction "in a desiccator" indicates use of a tightly closed container of suitable size and design that maintains an atmosphere of low moisture content by means of a suitable desiccant such as anhydrous calcium chloride, magnesium perchlorate, phosphorus pentoxide, or silica gel. See also section *8.220 Vacuum Desiccator*.

### 8.80. Logarithms

Logarithms are to the base 10.

### 8.90. Microbial Strain

A microbial strain cited and identified by its American Type Culture Collection (ATCC) catalog number shall be used directly or, if subcultured, shall be used not more than five passages removed from the original strain.

### 8.100. Negligible

"Negligible" indicates a quantity not exceeding 0.50 mg.

### 8.110. NLT/NMT

"NLT" means "not less than". "NMT" means "not more than."

### 8.120. Odor

"Odorless", "practically odorless", "a faint characteristic odor", and variations thereof indicate evaluation of a suitable quantity of freshly opened material after exposure to the air for 15 minutes. An odor designation is descriptive only and should not be regarded as a standard of purity for a particular lot of an article.

### 8.130. Percent

"Percent" used without qualification means:

- For mixtures of solids and semisolids, percent weight in weight;
- For solutions or suspensions of solids in liquids, percent weight in volume;
- For solutions of liquids in liquids, percent volume in volume;
- For solutions of gases in liquids, percent weight in volume.

For example, a 1 percent solution is prepared by dissolving 1 g of a solid or semisolid, or 1 mL of a liquid, in sufficient solvent to make 100 mL of the solution.

### 8.140. Percentage Concentrations

Percentage concentrations are expressed as follows:

- *Percent Weight in Weight* (w/w) is defined as the number of g of a solute in 100 g of solution.
- *Percent Weight in Volume* (w/v) is defined as the number of g of a solute in 100 mL of solution.
- *Percent Volume in Volume* (v/v) is defined as the number of mL of a solute in 100 mL of solution.

### 8.150. Pressure

Pressure is determined by use of a suitable manometer or barometer calibrated in terms of the pressure exerted by a column of mercury of the stated height.

### 8.160. Reaction Time

Reaction time is 5 minutes unless otherwise specified.

### 8.170. Specific Gravity

Specific gravity is the weight of a substance in air at 25° divided by the weight of an equal volume of water at the same temperature.

### 8.180. Temperatures

Temperatures are expressed in centigrade (Celsius) degrees, and all measurements are made at 25° unless otherwise indicated. Where moderate heat is specified, any temperature not higher than 45° (113° F) is indicated.

### 8.190. Time

Unless otherwise specified, rounding rules, as described in section *7.20 Rounding Rules*, apply to any time specified.

### 8.200. Transfer

"Transfer" indicates a quantitative manipulation.

### 8.210. Vacuum

"Vacuum" denotes exposure to a pressure of less than 20 mm of mercury (2.67 kPas), unless otherwise indicated.

### 8.220. Vacuum Desiccator

"Vacuum desiccator" indicates a desiccator that maintains a low-moisture atmosphere at a reduced pressure of not more than 20 mm of mercury (2.67 kPas) or at the pressure designated in the individual monograph.

### 8.230. Water

#### 8.230.10. Water as an Ingredient in an Official Product

As an ingredient in an official product, water meets the requirements of the appropriate water monograph in *USP* or *NF*.

#### 8.230.20. Water in the Manufacture of Official Substances

When used in the manufacture of official substances, water shall meet the requirements for drinking water as set forth in the U.S. Environmental Protection Agency National Primary Drinking Water Regulations or in the drinking water regulations of the European Union or of Japan, or in the World Health Organization's Guidelines for Drinking Water Quality. Additional specifications may be required in monographs.

#### 8.230.30. Water in a Compendial Procedure

When water is called for in a compendial procedure, the *USP* monograph article Purified Water shall be used unless otherwise specified. Definitions for other types of water are provided in *Reagents, Indicators, and Solutions* and in *Water for Pharmaceutical Purposes* ⟨1231⟩.

### 8.240. Weights and Measures

In general, weights and measures are expressed in the International System of Units (SI) as established and revised by the *Conférence générale des poids et mesures*. For compendial purposes, the term "weight" is considered to be synonymous with "mass".

Molality is designated by the symbol *m* preceded by a number that represents the number of moles of the designated solute contained in 1 kilogram of the designated solvent.

Molarity is designated by the symbol M preceded by a number that represents the number of moles of the designated solute contained in an amount of the designated solvent that is sufficient to prepare 1 liter of solution.

Normality is designated by the symbol N preceded by a number that represents the number of equivalents of the designated solute contained in an amount of the designated solvent that is sufficient to prepare 1 liter of solution.

The symbol for degrees (°) without a qualifying unit of measure represents degrees Celsius.

Chart of Symbols and Prefixes commonly employed for SI metric units and other units:

| | Units | Symbol | Notes |
|---|---|---|---|
| **Length** | | | |
| | meter | m | |
| | centimeter | cm | |
| | millimeter | mm | |
| | micrometer | µm | Previously referred to as a micron |
| | nanometer | nm | Previously the symbol mµ (for millimicron) was used |
| | Ångström | Å | Equal to 0.1 nm |
| **Mass** | | | |
| | kilogram | kg | |
| | gram | g | |
| | milligram | mg | |
| | microgram | µg | The symbol µg is used in the *USP* and *NF* to represent micrograms, but micrograms may be represented as "mcg" for labeling and prescribing purposes. The term "gamma", symbolized by γ, frequently is used to represent micrograms in biochemical literature. |
| | nanogram | ng | |
| | picogram | pg | |
| | dalton | Da | Also referred to as the unified atomic mass unit and is equal to 1/12 times the mass of the free carbon 12 atom. |
| | kilodalton | kDa | |
| **Time** | | | |
| | second | s | |
| | minute | min | |
| | hour | h | |
| **Volume** | | | |
| | liter | L | 1 L is equal to 1000 $cm^3$ (cubic centimeters) |
| | deciliter | dL | |
| | milliliter | mL | 1 mL is equal to 1 $cm^3$, sometimes referred to as cc |
| | microliter | µL | |
| **Temperature** | | | |
| | Celsius | °C | |
| **Amount of Substance** | | | |
| | mole | mol | Historically referred to as gram-molecular weight or gram-atomic weight |
| | millimole | mmol | |

| | Units | Symbol | Notes |
|---|---|---|---|
| | micromole | µmol | |
| | femtomole | fmol | |
| | equivalent | Eq | Also referred to as gram-equivalent weight. It is used in the calculation of substance concentration in units of normality. This unit is no longer preferred for use in analytical chemistry or metrology. |
| | milli equivalent | mEq | |
| | osmole | Osmol | Osmotic pressure of a solution, related to substance concentration. |
| | milliosmole | mOsmol | |
| **Pressure** | | | |
| | pascal | Pa | |
| | kilopascal | kPa | |
| | pounds per square inch | psi | |
| | millimeter of mercury | mmHg | Equal to 133.322 Pa |
| **Electrical units** | | | |
| | ampere | A | |
| | volt | V | |
| | millivolt | mV | |
| | hertz | Hz | Unit of frequency |
| | kilohertz | kHz | |
| | megahertz | MHz | |
| | electron volt | eV | |
| | kilo-electron volt | keV | |
| | mega-electron volt | MeV | |

| | Units | Symbol | Notes |
|---|---|---|---|
| **Radiation** | | | |
| | becquerel | Bq | SI unit of activity for radionuclides |
| | kilobecquerel | kBq | |
| | megabecquerel | MBq | |
| | gigabecquerel | GBq | |
| | curie | Ci | Non-SI unit of activity for radionuclides |
| | millicurie | mCi | |
| | microcurie | µCi | |
| | nanocurie | nCi | |
| **Other** | | | |
| | acceleration due to gravity | g | Used to express rate of centrifugation |
| | revolutions per minute | rpm | Used to express rate of centrifugation |

**Selected SI Prefixes**

| Name | Symbol | Factor |
|---|---|---|
| giga | G | $10^{9}$ |
| mega | M | $10^{6}$ |
| kilo | k | $10^{3}$ |
| deci | d | $10^{-1}$ |
| centi | c | $10^{-2}$ |
| milli | m | $10^{-3}$ |
| micro | µ | $10^{-6}$ |
| nano | n | $10^{-9}$ |
| pico | p | $10^{-12}$ |
| femto | f | $10^{-15}$ |

Official

# 9. PRESCRIBING AND DISPENSING

### 9.10. Use of Metric Units

Prescriptions for compendial articles shall be written to state the quantity and/or strength desired in metric units unless otherwise indicated in the individual monograph [see also section *5.50.10 Units of Potency (Biological)* above]. If an amount is prescribed by any other system of measurement, only an amount that is the metric equivalent of the prescribed amount shall be dispensed. Abbreviations for the terms "Units" or "International Units" shall not be used for labeling or prescribing purposes. Apothecary unit designations on labels and labeling shall not be used.

### 9.20. Changes in Volume

In the dispensing of prescription medications, slight changes in volume owing to variations in room temperatures may be disregarded.

# 10. PRESERVATION, PACKAGING, STORAGE, AND LABELING

### 10.10. Packaging and Storage

All articles in *USP* or *NF* are subject to the packaging and storage requirements specified in *Packaging and Storage Requirements* ⟨*659*⟩, unless different requirements are provided in an individual monograph.

### 10.20. Labeling

All articles in *USP* or *NF* are subject to the labeling requirements specified in *Labeling* ⟨*7*⟩, unless different requirements are provided in an individual monograph.

# Chapter Guide: Microbiology Products

To return to the Chapter Charts main list, *click here*.

Nonsterile Products

Microbial Enumeration

- ⟨61⟩ *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests*
- ⟨610⟩ *Alternative Microbiological Sampling Methods for Nonsterile Inhaled and Nasal Products*
- ⟨1111⟩ *Microbiological Examination of Nonsterile Products: Acceptance Criteria for Pharmaceutical Preparations and Substances for Pharmaceutical Use*
- ⟨2021⟩ *Microbial Enumeration Tests—Nutritional and Dietary Supplements*
- ⟨2023⟩ *Microbiological Attributes for Nonsterile Nutritional and Dietary Supplements*

Absence of Objectionable Microorganisms

- ⟨60⟩ *Microbiological Examination of Nonsterile Products: Tests for Burkholderia Cepacia Complex*
- ⟨62⟩ *Microbiological Examination of Nonsterile Products: Tests for Specified Microorganisms*
- ⟨63⟩ *Mycoplasma Tests*
- ⟨610⟩ *Alternative Microbiological Sampling Methods for Nonsterile Inhaled and Nasal Products*
- ⟨1111⟩ *Microbiological Examination of Nonsterile Products: Acceptance Criteria for Pharmaceutical Preparations and Substances for Pharmaceutical Use*
- ⟨1113⟩ *Microbial Characterization, Identification, and Strain Typing*
- ⟨1115⟩ *Bioburden Control of Nonsterile Drug Substances and Products*
- ⟨2022⟩ *Microbiological Procedures for Absence of Specified Microorganisms—Nutritional and Dietary Supplements*

Sterile Products[1]

Sterility Tests

- ⟨71⟩ *Sterility Tests*
- ⟨1071⟩ *Rapid Microbial Tests for Release of Sterile Short-Life Products: A Risk-Based Approach*
- ⟨1113⟩ *Microbial Characterization, Identification, and Strain Typing*
- ⟨1208⟩ *Sterility Testing—Validation of Isolator Systems*

Endotoxins/Pyrogens

- ⟨1085⟩ *Guidelines on Endotoxins Test*

Mycoplasma

- ⟨63⟩ *Mycoplasma Tests*
- ⟨1113⟩ *Microbial Characterization, Identification, and Strain Typing*
- ⟨1229.17⟩ *Mycoplasma Sterilization*

Aseptic Processing

- ⟨1113⟩ *Microbial Characterization, Identification, and Strain Typing*
- ⟨1116⟩ *Microbiological Control and Monitoring of Aseptic Processing Environments*
- ⟨1208⟩ *Sterility Testing—Validation of Isolator Systems*
- ⟨1211⟩ *Sterility Assurance*
- ⟨1228⟩ *Depyrogenation*
- ⟨1228.1⟩ *Dry Heat Depyrogenation*
- ⟨1228.3⟩ *Depyrogenation by Filtration*
- ⟨1228.4⟩ *Depyrogenation by Rinsing*
- ⟨1228.5⟩ *Endotoxin Indicators for Depyrogenation*
- ⟨1229⟩ *Sterilization of Compendial Articles*
- ⟨1229.3⟩ *Monitoring of Bioburden*
- ⟨1229.4⟩ *Sterilizing Filtration of Liquids*
- ⟨1229.12⟩ *New Sterilization Methods*
- ⟨1229.14⟩ *Sterilization Cycle Development*
- ⟨1229.17⟩ *Mycoplasma Sterilization*
- ⟨1229.18⟩ *Viral Clearance Methods*

Filtration

- ⟨1211⟩ *Sterility Assurance*
- ⟨1228⟩ *Depyrogenation*
- ⟨1228.3⟩ *Depyrogenation by Filtration*
- ⟨1228.4⟩ *Depyrogenation by Rinsing*
- ⟨1228.5⟩ *Endotoxin Indicators for Depyrogenation*
- ⟨1229⟩ *Sterilization of Compendial Articles*

Assembly[2]

Assembly

- ⟨1116⟩ *Microbiological Control and Monitoring of Aseptic Processing Environments*
- ⟨1207⟩ *Package Integrity Evaluation—Sterile Products*
- ⟨1207.1⟩ *Package Integrity Testing in the Product Life Cycle—Test Method Selection and Validation*
- ⟨1207.2⟩ *Package Integrity Leak Test Technologies*
- ⟨1207.3⟩ *Package Seal Quality Test Technologies*
- ⟨1228⟩ *Depyrogenation*
- ⟨1228.1⟩ *Dry Heat Depyrogenation*
- ⟨1228.5⟩ *Endotoxin Indicators for Depyrogenation*
- ⟨1229⟩ *Sterilization of Compendial Articles*
- ⟨1229.6⟩ *Liquid-Phase Sterilization*
- ⟨1229.11⟩ *Vapor Phase Sterilization*
- ⟨1229.15⟩ *Sterilizing Filtration of Gases*

Other

- ⟨151⟩ *Pyrogen Test*
- ⟨1072⟩ *Disinfectants and Antiseptics*
- ⟨1112⟩ *Application of Water Activity Determination to Nonsterile Pharmaceutical Products*
- ⟨1116⟩ *Microbiological Control and Monitoring of Aseptic Processing Environments*
- ⟨1117⟩ *Microbiological Best Laboratory Practices*
- ⟨1223⟩ *Validation of Alternative Microbiological Methods*

Terminal Sterilization

Terminal Sterilization

- ⟨56⟩ *Methods for Determination of Resistance of Microorganisms to Sterilization Processes*
- ⟨1222⟩ *Terminally Sterilized Pharmaceutical Products—Parametric Release*
- ⟨1228⟩ *Depyrogenation*
- ⟨1228.1⟩ *Dry Heat Depyrogenation*
- ⟨1228.4⟩ *Depyrogenation by Rinsing*
- ⟨1228.5⟩ *Endotoxin Indicators for Depyrogenation*
- ⟨1229⟩ *Sterilization of Compendial Articles*
- ⟨1229.12⟩ *New Sterilization Methods*
- ⟨1229.13⟩ *Sterilization-in-Place*
- ⟨1229.14⟩ *Sterilization Cycle Development*
- ⟨1229.17⟩ *Mycoplasma Sterilization*
- ⟨1229.18⟩ *Viral Clearance Methods*

Moist Heat

- ⟨55⟩ *Biological Indicators—Resistance Performance Tests*
- ⟨56⟩ *Methods for Determination of Resistance of Microorganisms to Sterilization Processes*
- ⟨1211⟩ *Sterility Assurance*
- ⟨1228⟩ *Depyrogenation*
- ⟨1229⟩ *Sterilization of Compendial Articles*
- ⟨1229.1⟩ *Steam Sterilization by Direct Contact*
- ⟨1229.2⟩ *Moist Heat Sterilization of Aqueous Liquids*
- ⟨1229.3⟩ *Monitoring of Bioburden*
- ⟨1229.5⟩ *Biological Indicators for Sterilization*
- ⟨1229.9⟩ *Physicochemical Integrators and Indicators for Sterilization*
- ⟨1229.13⟩ *Sterilization-in-Place*
- ⟨1229.14⟩ *Sterilization Cycle Development*

Dry Heat

- ⟨55⟩ *Biological Indicators—Resistance Performance Tests*
- ⟨1211⟩ *Sterility Assurance*
- ⟨1228⟩ *Depyrogenation*
- ⟨1228.1⟩ *Dry Heat Depyrogenation*

# Mission and Preface

This section provides background information on the United States Pharmacopeial Convention (USP), as well as general information about the *United States Pharmacopeia* and the *National Formulary (USP–NF)*. Whether a document is official or not official is not linked to when a specific publication becomes official, but is based on the individual document. USP publishes the *USP–NF* on a set schedule, and each individual document is associated with its indicated official date. Learn more about USP's document-centric official dates on our website (www.uspnf.com/new-uspnf-online-faqs/end-user#irg1).

## MISSION STATEMENT

*USP–NF* is published in continuing pursuit of the mission of USP: *To improve global health through public standards and related programs that help ensure the quality, safety, and benefit of medicines and foods.*

## HISTORY

USP has a rich history, dating back to 1820, when 11 physicians met in the Senate Chamber of the U.S. Capitol building to establish a pharmacopeia for the United States. Learn more about USP's history and major milestones on the USP website (https://www.usp.org/about/usp-timeline).

## CONTENT OF *USP–NF*

*USP–NF* contains official substance (ingredient) and product monographs for official articles recognized in *USP–NF* (see *General Notices 2.20 Official Articles*). *USP–NF* also includes monographs for compounded preparations. With few exceptions, such as articles covered by *Global Health* monographs, the intent is that all articles for which monographs are provided in *USP–NF* are legally marketed in the United States or are contained in legally marketed articles. *Global Health* monographs are provided for articles that are not approved or legally marketed in the United States, but that have been approved by a stringent regulatory authority [as defined by the World Health Organization (WHO)] and are used for essential purposes in other parts of the world (see *General Notices 3.10.40 Applicability of Global Health Monographs*).

A *USP–NF* monograph for an official substance, product, or preparation may consist of various components, including the article's name; definition; packaging, storage, and other requirements; and a specification. General chapters provide frequently cited procedures, sometimes with acceptance criteria, in order to compile into one location repetitive information that is applicable to many monographs. See *General Notices 3.10 Applicability of Standards* for more information about standards contained in *USP–NF* monographs and general chapters.

The *USP Admissions List* section of the *USP–NF* indicates those new and revised monographs and general chapters as well as any omissions that published on a specific delivery date.

**Revisions to *USP–NF*—**

*USP–NF* is continuously revised by an exceptional process of public involvement and substantial interaction between USP and its stakeholders, both domestically and internationally. Revisions are presented in the *USP–NF* three times per year in November, February, and June. *Accelerated Revisions* [including *Errata, Interim Revision Announcements* (*IRA*s), and *Revision Bulletins*] are published periodically and with greater frequency.

***Regular Revisions***—USP's regular revision process calls for publication of a proposed revision in the *Pharmacopeial Forum (PF)* for a 90-day notice and comment period and, after the revision is approved by the relevant USP Expert Committee, publication in the *USP–NF*.

***Accelerated Revisions***—The *Accelerated Revision* process is used to make revisions to *USP–NF* official more quickly than through USP's *Regular Revision* process. Learn more about accelerated revisions and the criteria for and implementation thereof on the USP website (http://www.uspnf.com/official-text).

### Modification of Compendial References—

USP and its Expert Committees periodically deem it necessary to modify general chapter titles or similar text that may be referenced in other standards throughout the *USP–NF*. When this occurs, USP staff undertake a rigorous process for identifying and updating such references. These updates may occur through a regular revision, or, in cases in which an update appears to present no significant change in the affected standard, through a direct update of the reference in that standard without providing an opportunity for notice and comment. In all cases, USP will publish on its website a notice indicating the source change, any resulting references, and whether those references will be updated through a regular revision or a direct update.

### Updating Chemical Information—

Updates to the *Chemical Information* section at the beginning of monographs occur on an ongoing basis. Chemical names and molecular weights may also be reviewed and updated when a monograph undergoes revision to match the *United States Adopted Names* (*USAN*) or the original source of chemical information. Chemical structures are updated on a continuous basis.

Chemical names typically reflect the naming conventions at the time of the monograph development or revision. If the nomenclature rules of CAS or IUPAC are significantly changed, the chemical names can be revised or added to implement those rules. Molecular weights are derived from the chemical formula and are based on the table of atomic weights as published by the IUPAC. When the IUPAC recommended values are changed to reflect the isotopic composition of normal terrestrial material, it is understood that the changes in molecular weights will be made in due course.

Graphical representation of the chemical compound structures is intended as a visual aid to help establish chemical identity and is understood to represent one of many possible ways to depict the molecule. Addition of a graphical representation or changes in such representation, that result in the same chemical information, e.g., a flipped chiral molecule or adding a molecule structure, may be introduced outside of the revision process. It is also understood that in the case of tautomerism, the molecule depicted may be one of the tautomers, but it is intended to represent all isomers in equilibrium. Stereogenic centers depicted with plain bonds imply mixtures of pertinent stereomers—enantiomer, diastereomers, epimers (anomers), etc. (see *General Notices 3.10 Applicability of Standards*).

### Shading and Symbols—

Shading is used to identify text that has been modified, added, or deleted since it was last published. Symbols identify the beginning and end of each revision or nonharmonized text. The following table summarizes the types of symbols and the associated subscripts used in USP publications:

| Revision Type | Revision Symbol and Text |
|---|---|
| In Process Regular Revision | ▲▲(USP 1-May-2023) |
| | ▲▲(NF 1-May-2023) |
| | ▲▲(GH 1-May-2023) |
| Interim Revision Announcement | ▲▲(IRA 1-Jul-2023) |
| Revision Bulletin | ▲▲(RB 1-Jul-2023) |
| Harmonization | ◆◆ |
| Errata | ▲▲(ERR 1-Jul-2023) |
| Chapter References | ▲▲(CN 1-Jul-2023) |
| | ▲▲(Official 1-Jul-2023) |
| Pending | ▲▲(TBD) |

### *Commentary*—

For revisions that are published for public review and comment in *PF*, the proposal may advance to official status or be republished in *PF* for further notice and comment. If comments are received, they are considered and incorporated as appropriate by the Expert Committee(s). In cases where proposals advance to official status without republication in *PF*, a summary of comments received and the appropriate Expert Committee's responses are published in the *Commentary* section of the USP website at the time the revision is published (see Rules and Procedures of the 2020-2025 Council of Experts, Section 9.05 Publication in the Pharmacopeial Forum).

The *Commentary* is not part of the official text and is not intended to be enforceable by regulatory authorities. Rather, it explains the basis of the Expert Committee's response to public comments. If there is a difference between the contents of the *Commentary* and the official text, the official text prevails. In case of a dispute or question of interpretation, the language of the official text, alone and independent of the *Commentary*, shall prevail.

### *USP-NF* Presentations—

See *General Notices 2.10 Official Text* for more information about *USP–NF* product formats. The *USP-NF* is available online. *USP43–NF38 (published November 1, 2019)* was the last publication made available in print or on a flash drive.

### *USP–NF Translations*—

Translations of the *USP–NF* are available in Spanish, Russian, and Chinese. The Spanish translation is current; other translations are based on previous revisions of the *USP–NF*.

### *USP Reference Standards*—

The use of USP Reference Standards promotes uniform quality of drugs and supports reliability and consistency by those performing compliance testing and other users of *USP–NF*, including manufacturers, buyers, and regulatory authorities. USP Reference Standards are referenced in specific procedures in both monographs and general chapters. USP advances this material via careful characterization studies and collaborative testing, followed by review and approval of the compendial use of the reference material by Expert Committees of the Council of Experts. This program benefits from the widespread voluntary contribution of suitable materials and test data from pharmaceutical manufacturers. The *USP Catalog*, which lists the collection of USP Reference Standards, and more information about use and storage, can

Official

https://pharmacopeia.cn/v29240/

be accessed on USP's website (https://www.usp.org/reference-standards/reference-standards-catalog).

# USP GOVERNING, STANDARDS-SETTING, AND ADVISORY BODIES

USP's governing, standards-setting, and advisory bodies include the USP Convention, the Board of Trustees, the Council of Experts and its Expert Committees, Expert Panels, Subcommittees, Joint Standard-Setting Subcommittees, and staff. Additional volunteer bodies include Stakeholder Forums and Project Teams, which offer stakeholders the opportunity to contribute, through advice and recommendations, to the advancement of USP's standards and processes. Learn about the composition and work of the USP Convention, Board of Trustees, Expert Committees, and Expert Panels on the USP website (https://www.usp.org/about/convention-membership). Learn more about Stakeholder Forums and Project Teams on the USP website (https://www.usp.org/get-involved/provide-input/stakeholder-forums). A listing of all current Voting Delegates of the USP Convention and members and Government Liaisons to the Council of Experts and its Expert Committees can be found on the USP website (https://www.usp.org/about/convention-membership, https://www.usp.org/about/volunteer-experts/expert-committees).

**Working with the Food and Drug Administration—**

USP works with the Secretary of the Department of Health and Human Services, and the principal agency in the Department for this work is the Food and Drug Administration (FDA). USP works in many ways with the agency, but the primary interaction is through the Government Liaison Program. The Government Liaison Program allows representatives of FDA and other government agencies to participate in Expert Committee, Expert Panel, and Subcommittee and related meetings, enabling interactions between government staff and Expert volunteer bodies. Staff in the FDA Centers who are responsible for review of compendial activities provide specific links and opportunities for exchange of comments. The Office of Policy for Pharmaceutical Quality in the Center for Drug Evaluation and Research provides a primary compendial point of contact between FDA and USP.

Official

# RULES AND PROCEDURES

**Governing Documents—**

*USP–NF* standards are recognized widely because they are authoritative and science-based and are established by a transparent and credible process. See the *Articles of Incorporation* section in this publication; the Bylaws (https://www.usp.org/about/convention-membership/bylaws), and the *Rules and Procedures of the Council of Experts* (https://www.usp.org/about/leadership/policies-rules). Collectively, these documents serve USP volunteers and staff as the governing principles for USP's standards-setting activities.

# LEGAL RECOGNITION

**Recognition of *USP–NF*—**

*USP–NF* is recognized by law and custom in many countries throughout the world. In the United States, the Federal Food, Drug, and Cosmetic Act (FD&C Act) defines the term "official compendium" as the official *USP*, the official *NF*, the official *Homeopathic Pharmacopeia of the United States,* or any supplement to them. *USP–NF* standards play a role in the

https://pharmacopeia.cn/

adulteration and misbranding provisions of the FD&C Act, which apply as well to biologics, a subset of drugs, under the Public Health Service Act (see *General Notices 2.30 Legal Recognition*).

FDA requires that names for articles that are not official must be clearly distinguished and differentiated from any name recognized in an official compendium. Drugs with a name recognized in *USP–NF* also will be considered misbranded unless they meet compendial standards for packaging and labeling (see *General Notices 3.10.10 Applicability of Standards to Drug Products, Drug Substances, and Excipients* for more information).

**Drugs—**

USP's goal is to have substance and drug product monographs in *USP–NF* for FDA-approved drugs in the United States, including chemical and biologic medicines, and their ingredients. USP also provides monographs in *USP–NF* for legally marketed therapeutic products not approved by FDA, e.g., pre-1938 drugs, over-the-counter (OTC) drugs marketed under FDA's OTC Monograph system, dietary supplements, and compounded preparations. The *Global Health* section of *USP–NF* contains monographs for articles that are not approved or legally marketed in the United States, but that have been approved by a stringent regulatory authority (as defined by WHO) and are used for essential purposes in other parts of the world. Conformance with a *USP–NF* monograph, if applicable, is required at all times in the life of an article from production to expiration.

**Biologics—**

In the United States, biologics are considered to be a subset of drugs, whether they were approved by FDA under the FD&C Act [and received a new drug application (NDA)] or under the Public Health Service Act [PHS Act, where they receive a biologics license application (BLA)]. As of March 23, 2020, applications for biological products approved under the FD&C Act are deemed to be licenses for the biological products under the PHS Act. All PHS Act biologics are subject to the applicable drug regulatory requirements of the FD&C Act, which means they are required to comply with the adulteration and misbranding provisions of the FD&C Act, including *USP–NF* compendial requirements, to the extent that such requirements apply to a particular biologic product. This is equally so for biologics approved under the long-standing PHS Act "351(a)" pathway, as well as the new "351(k)" pathway for biosimilars added by the 2010 healthcare reform legislation (Biologics Price Competition and Innovation Act, Title VII, Subtitle A of the Patient Protection and Affordable Care Act, Public Law 111-148).

**Dietary Supplements—**

The Dietary Supplement Health and Education Act of 1994 amendments to the FD&C Act provide that a dietary supplement may be deemed a misbranded food if it is covered by the specifications of an official compendium (e.g., *USP–NF*), is represented as conforming to the specifications of an official compendium, and fails to so conform. This contrasts with pharmaceutical products, wherein conformance to applicable compendial standards is mandatory, whether or not the product claims to conform.

**Compounding—**

USP provides general chapters and monographs for compounded preparations, as well as monographs for bulk substances used in compounding. USP standards are recognized in various provisions of the FD&C Act and such provisions do not differentiate between manufactured and compounded medicines. Moreover, the FD&C Act and the 2013 Drug Quality and Security Act specifically reference USP standards for compounding. Learn more about compounding on the USP website (https://www.usp.org/compounding).

**Medical Devices—**

Section 201(h) of the FD&C Act defines a device as an instrument, apparatus, similar article, or component thereof recognized in *USP–NF*. Section 502(e) of the FD&C Act defines the established name of a device in the absence of an FDA designation of the official name as the official title in an official compendium. Despite these statutory provisions, there is no comparable recognition of USP's role in establishing compendial standards for medical devices as exists for drugs and biologics. Under authority granted by the Food and Drug Administration Modernization Act of 1997, the Center for Devices and Radiological Health recognizes national and international standards, including some *USP* tests and assays, for medical devices.

**Nomenclature—**

For information on the nomenclature development process, the Nomenclature and Labeling Expert Committee, and USP's work with United States Adopted Names (USAN), see the USP website (https://www.usp.org/expert-committees/nomenclature-and-labeling-expert-committee-work-plan).

**Chemical Names and CAS Registry Numbers—**

Chemical subtitles given in the monographs are CA Index Names used by CAS, a division of the American Chemical Society. CAS Registry Number® and CAS RN® are registered trademarks of the American Chemical Society. They are provided only in monographs in which the titles specify substances that are definable chemical entities. The first subtitle is the inverted form of the systematic chemical name developed by CAS for the purpose of the Collective Index (CI). The second subtitle, given in uninverted form, is a preferred IUPAC name (PIN) sanctioned and used by the International Union of Pure and Applied Chemistry (IUPAC). Preferred IUPAC names also are used by the WHO. Occasionally a third subtitle is supplied for historical reasons or when the synonym uses an alternative, but equivalent, naming convention. Monographs with chemical subtitles also generally carry CAS registry numbers. These numbers function independently of nomenclature as invariant numerical designators of unique, unambiguous chemical substances in the CAS Registry℠, and thus are convenient and widely used.

# HARMONIZATION ACTIVITIES

USP participates in several collaborative activities with global pharmacopeias in both bilateral and multilateral settings. Examples of USP's current activities include the following.

**Pharmacopeial Discussion Group—**

USP harmonizes pharmacopeial excipient monographs and general chapters through the Pharmacopeial Discussion Group (PDG), which includes representatives from the European, Japanese, and United States pharmacopeias, and WHO (as an observer). According to the PDG definition, "a pharmacopeial general chapter or other pharmacopeial document is harmonized when a pharmaceutical substance or preparation tested by the harmonized procedure yields the same results, and the same accept/reject decision is reached." Information regarding PDG, including history, purpose, the PDG working procedure, and lists of monographs and general chapters that have completed stages 1–4 of the pharmacopeial harmonization process, resulting in an approved USP Stage 4 Harmonization text, is available on USP's website (https://www.usp.org/harmonized-standards).

**International Meeting of the World Pharmacopeias—**

USP works with WHO and global pharmacopeial partners in this WHO-led forum. Its initial focus was the strategy and establishment of Good Pharmacopoeial Practices (GPhP) as a set of guiding principles for the appropriate establishment of pharmacopeial standards. Following the completion of GPhP in 2016, the IMWP has primarily served as a venue for information and knowledge exchange across global pharmacopeias and recently served as a forum for rapid coordination of pharmacopeias to respond to public health emergencies, as was recently the case for the COVID-19 pandemic.

**Adopt Agreements—**

USP grants the rights to copy USP standards for use in other pharmacopeias through this formal mechanism.

**Bilateral Agreements—**

USP partners with pharmacopeias for the joint development of pharmacopeial standards using this informal process.

**USP Exchange Programs—**

USP regularly welcomes the exchange of scientific personnel through this program, with the goal of sharing scientific knowledge among global organizations involved in standards setting and the effective use of standards.

Official

# OTHER USP COMPENDIA

***USP Compounding Compendium—***

The *USP Compounding Compendium* is an online compendium that includes all compounding-related general chapters from the *USP–NF* as well as the supporting general chapters that are referenced in the compounding general chapters and in *USP–NF General Notices*. The purpose of the *USP Compounding Compendium* is to provide compounding practitioners with convenient access to associated general chapters.

***USP Herbal Medicines Compendium—***

The *USP Herbal Medicines Compendium (HMC)* is an online compendium that helps ensure the quality of the herbal ingredients used in herbal medicines. *HMC* monographs provide quality specifications—tests, procedures, and acceptance criteria—with validated analytical procedures and allied reference materials that aid in conformity assessment. *HMC* can help ingredient manufacturers, herbal product manufacturers, regulatory agencies, and other stakeholders to assess conformance of herbal medicinal ingredients with independent public standards and to control the quality of articles moving in international commerce. The *HMC* is available at https://hmc.usp.org.

***USP Dietary Supplements Compendium—***

The *Dietary Supplements Compendium* is an online compendium that combines *USP–NF* standards for dietary supplements, standards and information from the *Food Chemicals Codex*, regulatory and industry documents, and other tools and resources.

***Food Chemicals Codex—***

The *Food Chemicals Codex* (*FCC*) is an online compendium of internationally recognized monograph standards and tests for the purity and quality of food ingredients, e.g., preservatives, flavorings, colorings, and nutrients. *FCC* is

published every two years, with supplements every six months. Proposed revisions to *FCC* are available for public viewing and comment through the *FCC Forum*. The *FCC Forum* can be accessed free of charge at http://www.foodchemicalscodex.org.

# OTHER USP RESOURCES

***Chromatographic Columns—***

This comprehensive reference, previously titled *Chromatographic Reagents*, provides detailed information needed to conduct chromatographic procedures found in *USP–NF*. *Chromatographic Columns* lists the brand names of the column reagents cited in every proposal for new or revised gas- or liquid-chromatographic analytical procedures that have been published in *PF* since 1980. *Chromatographic Columns* also helps to track which column reagents were used to validate analytical procedures that have become official. The branded column reagents list is updated bimonthly and maintained on USP's website.

***USP Dictionary—***

The *USP Dictionary of USAN and International Drug Names* is an online resource containing the most up-to-date United States Adopted Names of drugs; official *USP–NF* names; nonproprietary, brand, and chemical names; graphic formulas; molecular formulas and weights; CAS registry numbers and code designations; drug manufacturers; and pharmacologic and therapeutic categories. The *Dictionary* helps to ensure the accuracy of the following: product labeling; reports, articles, and correspondence; FDA regulatory filings; and pharmaceutical package inserts. It is published annually. For more information about the *Dictionary* see the USP website (https://www.usp.org/products/usp-dictionary).

# NOTICE AND WARNING

*Concerning U.S. Patent, Trademark, Copyright, and Trade Secret Rights*—Substances, products, methods, tests, assays, or equipment referenced or described in the *USP–NF* may be associated with intellectual property rights, including but not limited to, registered trademarks, patents, copyright, and/or trade secrets. Nothing in the *USP–NF* should be construed as a representation as to such intellectual property rights. Furthermore, the inclusion in the *USP–NF* of a monograph, general chapter, or other reference addressing any substance, product, method, test, assay, or equipment with respect to which intellectual property rights may exist shall not be deemed, and is not intended as, a grant of, or authority to exercise, any right or privilege protected by such patent, trademark, copyright, and/or trade secret. All such rights and privileges are vested in their respective owners, and no other person may exercise the same without express permission, authority, or license secured from such owner. The inclusion in the *USP–NF* of a monograph, general chapter, or other reference addressing any substance, product, method, test, assay, or equipment is for informational purposes only and shall not be deemed, and is not intended as, marketing or support of, instructions to use or follow any substance, product, method, test, assay, or equipment that may be protected by such patent, trademark, copyright, and/or trade secret. Users of *USP–NF* are expressly advised that the risk of infringement of any patent, trademark, copyright, or trade secret rights is entirely the user's responsibility.

*Concerning Use of USP–NF Text*—Attention is called to the fact that *USP–NF* text is fully copyrighted. Authors and others wishing to use portions of the text should request permission to do so from the Legal Department of the USPC, legal@usp.org.

# Preface

This section contains monographs for articles which are not currently legally marketed in the United States, but which have been approved by a stringent regulatory authority as defined by the World Health Organization and are used for essential purposes in other parts of the world. Selection and prioritization of new entries to this section will be accomplished in close collaboration with stakeholders throughout the global health community. These monographs are not applicable to articles marketed for use in the United States.

# USP Admissions

## New Articles Appearing in *USP 2023, Issue 3*

### GENERAL CHAPTERS

⟨314⟩ Molecular Weight Determination for Copolymers Containing Alkyl Methacrylate or Alkyl Acrylate
⟨901⟩ Detection of Asbestos in Pharmaceutical Talc
⟨1079.3⟩ Monitoring Devices—Time, Temperature, and Humidity
⟨1504⟩ Quality Attributes of Starting Materials for the Chemical Synthesis of Therapeutic Peptides
⟨1567⟩ Pyrrolizidine Alkaloids as Contaminants
⟨1604⟩ Presentation of Aerodynamic Particle Size Distribution (ASPD) Measurement Data for Orally Inhaled Products
⟨1901⟩ Theory and Practice of Asbestos Detection in Pharmaceutical Talc

### REAGENTS, INDICATORS, AND SOLUTIONS

Gamma-Decalactone
Glycolide
DL-Lactide
Alpha Tocopherol

### USP MONOGRAPHS

Acetazolamide Extended-Release Capsules
Bivalirudin
Bivalirudin for Injection
Cisplatin Injection
Clobazam
Dapagliflozin Propanediol
Dimethyl Fumarate
Dimethyl Fumarate Delayed-Release Capsules
Gabapentin Compounded Cream

### DIETARY SUPPLEMENTS

Bromelain
Cranberry Fruit Juice Dry Extract
Cranberry Fruit Juice Dry Extract Capsules
Inositol Niacinate

# USP Annotated List

## General Notices, Monographs, General Chapters, Reagents, and Tables Affected by Changes Appearing in *USP 2023, Issue 3*

*Note—This list only contains In-Process Revision file types. In the lists below, if a section is new or if a subsection is added to or deleted from an existing section, it is labeled as such in parentheses after the section or subsection name. Items on this list that appear without the designation "new", "added", or "deleted" are items in which changes have been made to existing official text. The USP Admissions and Annotated lists are updated three times a year: Issue 1 (November), Issue 2 (February), and Issue 3 (June). These documents are static and will not be updated with the monthly revision postings. Although the Annotated List itself carries an official date, each Documentary Standard that is listed may have a different official date. Please open each standard to see its official date. For more questions on official statuses, please visit our Frequently Asked Questions (*https://www.usp.org/frequently-asked-questions/identifying-official-text*).*

### General Chapters

***Chemical Tests and Assays***

- ⟨314⟩ Molecular Weight Determination for Copolymers Containing Alkyl Methacrylate or Alkyl Acrylate (new)
- ⟨581⟩ Vitamin D Assay
  - ASSAY

***Physical Tests and Determinations***

- ⟨670⟩ Auxiliary Packaging Components
  - TITLE
  - PHARMACEUTICAL COIL
  - DESICCANT
  - ODOR ADSORBENT (added)
- ⟨831⟩ Refractive Index
- ⟨901⟩ Detection of Asbestos in Pharmaceutical Talc (new)

***General Information***

- ⟨1079⟩ Risks and Mitigation Strategies for the Storage and Transportation of Finished Drug Products
  - 4. RISK MITIGATION CATEGORIES AS QMS ELEMENTS
- ⟨1079.3⟩ Monitoring Devices—Time, Temperature, and Humidity (new)
- ⟨1094⟩ Capsules—Dissolution Testing and Related Quality Attributes
- ⟨1118⟩ Monitoring Devices—Time, Temperature, and Humidity (deleted)
- ⟨1504⟩ Quality Attributes of Starting Materials for the Chemical Synthesis of Therapeutic Peptides (new)
- ⟨1567⟩ Pyrrolizidine Alkaloids as Contaminants (new)
- ⟨1604⟩ Presentation of Aerodynamic Particle Size Distribution (APSD) Measurement Data for Orally Inhaled Products (new)
- ⟨1724⟩ Semisolid Drug Products—Performance Tests
- ⟨1901⟩ Theory and Practice of Asbestos Detection in Pharmaceutical Talc (new)
- ⟨1912⟩ Measurement of Yield Stress of Semisolids

### Reagents, Indicators, and Solutions

**Reagent Specifications**

- Bromelain
- Gamma-Decalactone (new)
- Glycolide (new)
- Guanine Hydrochloride
- DL-Lactide (new)
- Methylbenzothiazolone Hydrazone Hydrochloride
- Alpha Tocopherol (new)
- Water, Deaerated

### Reference Tables

**Description and Relative Solubility of USP and NF Articles**

- Candelilla Wax
- Cevimeline Hydrochloride (new)
- Clobazam (new)
- Dimethyl Fumarate (new)
- Guanfacine Hydrochloride (new)

**Excipients of USP and NF Articles**

- Candelilla Wax

## Monographs (*USP 2023, Issue 3*)

- Acetazolamide Extended-Release Capsules (new)
- Betamethasone Acetate
  - CHEMICAL INFORMATION
  - IDENTIFICATION
  - ASSAY
  - IMPURITIES
    - *Ordinary Impurities* (deleted) and *Organic Impurities* (added)
  - ADDITIONAL REQUIREMENTS
    - *USP Reference Standards*
- Bivalirudin (new)
- Bivalirudin for Injection (new)
- Calcium Pantothenate
  - ASSAY
  - IMPURITIES (added)
- Carbamazepine
  - CHEMICAL INFORMATION
  - IDENTIFICATION
    - *Spectroscopic Identification Tests, Infrared Spectroscopy, Test A*
  - ASSAY
  - IMPURITIES
    - *Organic Impurities*
  - ADDITIONAL REQUIREMENTS
    - *USP Reference Standards*
- Cefoperazone Sodium
  - CHEMICAL INFORMATION
  - ASSAY
  - SPECIFIC TESTS
    - *Sterility Tests* (deleted) and *Bacterial Endotoxins Test* (deleted)
  - ADDITIONAL REQUIREMENTS
    - *Labeling* (deleted)
- Cisplatin Injection (new)

Clobazam (new)
Cromolyn Sodium
- CHEMICAL INFORMATION
- IDENTIFICATION
  - *Spectroscopic Identification Tests, Infrared Spectroscopy, Test A*
- IMPURITIES
  - *Organic Impurities*

Cyanocobalamin
- IMPURITIES
  - *Related Compounds*

Dalteparin Sodium
- IDENTIFICATION
  - *Molecular Weight Distribution and Weight-Average Molecular Weight, Test B* and *Identification Tests—General, Sodium, Test D*
- IMPURITIES
  - *Limit of Nitrites*
- SPECIFIC TESTS
  - *Bacterial Endotoxins Test*
- ADDITIONAL REQUIREMENTS
  - *Labeling*

Dapagliflozin Propanediol (new)
Dimethyl Fumarate (new)
Dimethyl Fumarate Delayed-Release Capsules (new)
Sodium Fluoride F 18 Injection
- DEFINITION
- IDENTIFICATION
  - *Radiochemical Identity, Test B*
- ASSAY
- PURITY
  - *Radiochemical Purity*
- IMPURITIES
  - *Radionuclidic Impurities*
- SPECIFIC TESTS
  - *Sterility Tests*
- ADDITIONAL REQUIREMENTS
  - *Labeling*

Flurbiprofen
- CHEMICAL INFORMATION
- DEFINITION
- IDENTIFICATION
- ASSAY
- IMPURITIES
  - *Organic Impurities*
- ADDITIONAL REQUIREMENTS
  - *USP Reference Standards*

Flurbiprofen Tablets
- ASSAY
- PERFORMANCE TESTS
- IMPURITIES
- ADDITIONAL REQUIREMENTS

Gabapentin Compounded Cream (new)
Glucagon
- CHEMICAL INFORMATION
- DEFINITION
- IDENTIFICATION
- ASSAY
- PRODUCT-RELATED SUBSTANCES AND IMPURITIES
- PROCESS-RELATED IMPURITIES AND OTHER COMPONENTS (added)
- SPECIFIC TESTS
  - *Peptide Mapping* (added), *Mass Spectral Analysis* (added), *Microbial Enumeration Tests* (added), and *Water Determination, Method Ic*

Gramicidin
- IDENTIFICATION
- ASSAY
- IMPURITIES
  - *Organic Impurities* (added)
- SPECIFIC TESTS
  - *Composition* (added)

Isopropyl Alcohol
- ASSAY
- SPECIFIC TESTS
  - *Ultraviolet Absorption* (added)

Methylprednisolone
- CHEMICAL INFORMATION
- IDENTIFICATION
- ASSAY
- IMPURITIES
  - *Organic Impurities*
- SPECIFIC TESTS
  - *Optical Rotation, Specific Rotation*
- ADDITIONAL REQUIREMENTS

Morphine Sulfate
- CHEMICAL INFORMATION
- IDENTIFICATION
- ASSAY
- SPECIFIC TESTS
  - *Optical Rotation, Specific Rotation* and *Ammonium Salts* (deleted)

Nadolol
- CHEMICAL INFORMATION
- IDENTIFICATION
  - *Spectroscopic Identification Tests, Infrared Spectroscopy, Test A*
- ASSAY
- OTHER COMPONENTS
- IMPURITIES
  - *Organic Impurities*
- ADDITIONAL REQUIREMENTS
  - *USP Reference Standards*

Oxycodone Hydrochloride Tablets
- IDENTIFICATION
  - *Test B* (added)
- ASSAY
- PERFORMANCE TESTS
  - *Dissolution*
- IMPURITIES (added)
- ADDITIONAL REQUIREMENTS

Pantoprazole Sodium
- CHEMICAL INFORMATION
- IDENTIFICATION
  - *Identification Tests—General, Sodium, Test C*
- ASSAY
- IMPURITIES
- SPECIFIC TESTS
  - *Bacterial Endotoxins Test* (added)

Official

ADDITIONAL REQUIREMENTS
*Labeling* and *USP Reference Standards*
Spironolactone and Hydrochlorothiazide Tablets
IDENTIFICATION
*Test B* (added)
ASSAY
PERFORMANCE TESTS
IMPURITIES (added)
ADDITIONAL REQUIREMENTS
Sulbactam Sodium
CHEMICAL INFORMATION
IDENTIFICATION
IMPURITIES
SPECIFIC TESTS
*Bacterial Endotoxins Test* and *Sterility Tests*
ADDITIONAL REQUIREMENTS
*USP Reference Standards*
Talc
TITLE
DEFINITION
IDENTIFICATION
*Procedure, Test B* and *Procedure, Test C*
IMPURITIES
*Water-Soluble Substances*, *Limit of Calcium*, and *Test for Asbestos (Detection of Asbestos in Pharmaceutical Talc)*
SPECIFIC TESTS
*Microbial Enumeration Tests and Tests for Specified Microorganisms*
ADDITIONAL REQUIREMENTS
Terbutaline Sulfate
CHEMICAL INFORMATION
DEFINITION
IDENTIFICATION
*Spectroscopic Identification Tests, Infrared Spectroscopy, Test A* and *Identification Tests—General, Sulfate, Test C* (added)
ASSAY
IMPURITIES
*Organic Impurities*
SPECIFIC TESTS
*Acidity*
ADDITIONAL REQUIREMENTS
*USP Reference Standards*
Terbutaline Sulfate Injection
IDENTIFICATION
*Thin Layer Chromatography, Test A* (deleted) and *Test A* (added)
ASSAY
IMPURITIES (added)
SPECIFIC TESTS
*Bacterial Endotoxins Test* and *Sterility Tests* (added)
ADDITIONAL REQUIREMENTS
*USP Reference Standards*

## Monographs (Dietary Supplements)

Bromelain (new)
Cranberry Fruit Juice Dry Extract (new)
Cranberry Fruit Juice Dry Extract Capsules (new)
L-alpha-Glycerylphosphorylcholine
DEFINITION
ASSAY
SPECIFIC TESTS
*Optical Rotation, Specific Rotation* and *Water Determination, Method Ia*
Inositol Niacinate (new)

*Lacticaseibacillus rhamnosus*
TITLE
DEFINITION
IDENTIFICATION
*Nucleic Acid-Based Identification, Test B*
ADDITIONAL REQUIREMENTS
*Limosilactobacillus reuteri*
TITLE
DEFINITION
IDENTIFICATION
*Nucleic Acid-Based Identification, Test B*
ASSAY
ADDITIONAL REQUIREMENTS
Pummelo Peel
IDENTIFICATION
*HPTLC for Articles of Botanical Origin, Test A*
COMPOSITION
Pummelo Peel Flavonoids Dry Extract
DEFINITION
IDENTIFICATION
*HPTLC for Articles of Botanical Origin, Test A*
COMPOSITION
CONTAMINANTS
*Articles of Botanical Origin, Test for Aflatoxins* (deleted)
Pummelo Peel Powder
IDENTIFICATION
*HPTLC for Articles of Botanical Origin, Test A*
COMPOSITION

Identification

- ⟨198⟩ *Nuclear Magnetic Resonance Spectroscopy Identity Testing of Bacterial Polysaccharides Used in Vaccine Manufacture*
- ⟨621⟩ *Chromatography*
- ⟨736⟩ *Mass Spectrometry*
- ⟨761⟩ *Nuclear Magnetic Resonance Spectroscopy*
- ⟨1030⟩ *Biological Assay Chapters—Overview and Glossary*
- ⟨1032⟩ *Design and Development of Biological Assays*
- ⟨1033⟩ *Biological Assay Validation*
- ⟨1034⟩ *Analysis of Biological Assays*
- ⟨1052⟩ *Biotechnology Derived Articles—Amino Acid Analysis*
- ⟨1053⟩ *Capillary Electrophoresis*
- ⟨1054⟩ *Biotechnology Derived Articles—Isoelectric Focusing*
- ⟨1055⟩ *Biotechnology Derived Articles—Peptide Mapping*
- ⟨1056⟩ *Biotechnology Derived Articles—Polyacrylamide Gel Electrophoresis*
- ⟨1057⟩ *Biotechnology Derived Articles—Total Protein Assay*
- ⟨1102⟩ *Immunological Test Methods—General Considerations*
- ⟨1103⟩ *Immunological Test Methods—Enzyme-Linked Immunosorbent Assay (ELISA)*
- ⟨1104⟩ *Immunological Test Methods—Immunoblot Analysis*
- ⟨1126⟩ *Nucleic Acid-Based Techniques—Extraction, Detection, and Sequencing*
- ⟨1127⟩ *Nucleic Acid-Based Techniques—Amplification*
- ⟨1128⟩ *Nucleic Acid-Based Techniques—Microarray*
- ⟨1129⟩ *Nucleic Acid-Based Techniques—Genotyping*
- ⟨1234⟩ *Vaccines for Human Use—Polysaccharide and Glycoconjugate Vaccines*
- ⟨1235⟩ *Vaccines for Human Use—General Considerations*
- ⟨1238⟩ *Vaccines for Human Use—Bacterial Vaccines*
- ⟨1736⟩ *Applications of Mass Spectrometry*
- ⟨1761⟩ *Applications of Nuclear Magnetic Resonance Spectroscopy*
- ⟨1776⟩ *Image Analysis of Pharmaceutical Systems*

Characterization

- ⟨111⟩ *Design and Analysis of Biological Assays*
- ⟨432⟩ *Determination of Zeta Potential by Electrophoretic Light Scattering*
- ⟨507⟩ *Protein Determination Procedures*
- ⟨621⟩ *Chromatography*
- ⟨736⟩ *Mass Spectrometry*
- ⟨761⟩ *Nuclear Magnetic Resonance Spectroscopy*
- ⟨1030⟩ *Biological Assay Chapters—Overview and Glossary*
- ⟨1032⟩ *Design and Development of Biological Assays*
- ⟨1033⟩ *Biological Assay Validation*
- ⟨1034⟩ *Analysis of Biological Assays*
- ⟨1044⟩ *Cryopreservation of Cells*
- ⟨1052⟩ *Biotechnology Derived Articles—Amino Acid Analysis*
- ⟨1053⟩ *Capillary Electrophoresis*
- ⟨1054⟩ *Biotechnology Derived Articles—Isoelectric Focusing*
- ⟨1055⟩ *Biotechnology Derived Articles—Peptide Mapping*
- ⟨1056⟩ *Biotechnology Derived Articles—Polyacrylamide Gel Electrophoresis*
- ⟨1057⟩ *Biotechnology Derived Articles—Total Protein Assay*
- ⟨1084⟩ *Glycoprotein and Glycan Analysis—General Considerations*
- ⟨1102⟩ *Immunological Test Methods—General Considerations*
- ⟨1103⟩ *Immunological Test Methods—Enzyme-Linked Immunosorbent Assay (ELISA)*
- ⟨1104⟩ *Immunological Test Methods—Immunoblot Analysis*
- ⟨1105⟩ *Immunological Test Methods—Surface Plasmon Resonance*
- ⟨1126⟩ *Nucleic Acid-Based Techniques—Extraction, Detection, and Sequencing*
- ⟨1127⟩ *Nucleic Acid-Based Techniques—Amplification*
- ⟨1234⟩ *Vaccines for Human Use—Polysaccharide and Glycoconjugate Vaccines*
- ⟨1235⟩ *Vaccines for Human Use—General Considerations*
- ⟨1238⟩ *Vaccines for Human Use—Bacterial Vaccines*

Official

https://pharmacopeia.com/

- ⟨1430.1⟩ *Analytical Methodologies Based on Scattering Phenomena—Static Light Scattering*
- ⟨1430.2⟩ *Analytical Methodologies Based on Scattering Phenomena—Light Diffraction Measurements of Particle Size*
- ⟨1430.3⟩ *Analytical Methodologies Based on Scattering Phenomena—Dynamic Light Scattering*
- ⟨1430.4⟩ *Analytical Methodologies Based on Scattering Phenomena—Electrophoretic Light Scattering (Determination of Zeta Potential)*
- ⟨1430.5⟩ *Analytical Methodologies Based on Scattering Phenomena—Small Angle X-Ray Scattering and Small Angle Neutron Scattering*
- ⟨1430.6⟩ *Analytical Methodologies Based on Scattering Phenomena—Particle Counting via Light Scattering*
- ⟨1430.7⟩ *Analytical Methodologies Based on Scattering Phenomena—Nephelometry And Turbidimetry*
- ⟨1736⟩ *Applications of Mass Spectrometry*
- ⟨1761⟩ *Applications of Nuclear Magnetic Resonance Spectroscopy*
- ⟨1776⟩ *Image Analysis of Pharmaceutical Systems*

Equipment

- ⟨31⟩ *Volumetric Apparatus*
- ⟨41⟩ *Balances*
- ⟨1228.4⟩ *Depyrogenation by Rinsing*
- ⟨1229.13⟩ *Sterilization-in-Place*
- ⟨1229.15⟩ *Sterilizing Filtration of Gases*
- ⟨1229.16⟩ *Prion Inactivation*
- ⟨1251⟩ *Weighing on an Analytical Balance*

Misc. Tests

- ⟨1⟩ *Injections and Implanted Drug Products (Parenterals)—Product Quality Tests*
- ⟨660⟩ *Containers—Glass*
- ⟨661⟩ *Plastic Packaging Systems and Their Materials of Construction*
- ⟨661.1⟩ *Plastic Materials of Construction*
- ⟨661.2⟩ *Plastic Packaging Systems for Pharmaceutical Use*
- ⟨671⟩ *Containers—Performance Testing*
- ⟨697⟩ *Container Content for Injections*
- ⟨787⟩ *Subvisible Particulate Matter in Therapeutic Protein Injections*
- ⟨788⟩ *Particulate Matter in Injections*
- ⟨790⟩ *Visible Particulates in Injections*
- ⟨1660⟩ *Evaluation of the Inner Surface Durability of Glass Containers*
- ⟨1661⟩ *Evaluation of Plastic Packaging Systems for Pharmaceutical Use and Their Materials of Construction*
- ⟨1663⟩ *Assessment of Extractables Associated with Pharmaceutical Packaging/Delivery Systems*
- ⟨1664⟩ *Assessment of Drug Product Leachables Associated with Pharmaceutical Packaging/Delivery Systems*
- ⟨1776⟩ *Image Analysis of Pharmaceutical Systems*
- ⟨1787⟩ *Measurement of Subvisible Particulate Matter in Therapeutic Protein Injections*
- ⟨1788⟩ *Methods for the Determination of Subvisible Particulate Matter*
- ⟨1788.1⟩ *Light Obscuration Method for the Determination of Subvisible Particulate Matter*
- ⟨1788.2⟩ *Membrane Microscope Method for the Determination of Subvisible Particulate Matter*
- ⟨1788.3⟩ *Flow Imaging Method for the Determination of Subvisible Particulate Matter*

Description

- ⟨791⟩ *pH*
- ⟨1041⟩ *Biologics*

Safety

- ⟨11⟩ *USP Reference Standards*
- ⟨63⟩ *Mycoplasma Tests*
- ⟨71⟩ *Sterility Tests*
- ⟨85⟩ *Bacterial Endotoxins Test*
- ⟨88⟩ *Biological Reactivity Tests, In Vivo*
- ⟨90⟩ *Fetal Bovine Serum—Quality Attributes and Functionality Tests*
- ⟨151⟩ *Pyrogen Test*
- ⟨341⟩ *Antimicrobial Agents—Content*
- ⟨1024⟩ *Bovine Serum*
- ⟨1071⟩ *Rapid Microbial Tests for Release of Sterile Short-Life Products: A Risk-Based Approach*
- ⟨1085⟩ *Guidelines on Endotoxins Test*
- ⟨1113⟩ *Microbial Characterization, Identification, and Strain Typing*
- ⟨1121⟩ *Nomenclature*
